Abstract

Background: Environmental factors are increasingly being implicated as key influences on children's physical activity. Few studies have comprehensively examined children's perceptions of their environment, and there is a paucity of literature on acceptable and reliable scales for measuring these. This study aimed to develop and test the acceptability and reliability of a scale which examined a broad range of environmental perceptions among children.

Methods: Based on constructs from ecological models, a survey incorporating items on children's perceptions of the physical and social environment at home and in the neighbourhood was developed. This was administered on two occasions, nine days apart, to a sample of 39 children aged 11 years (54% boys), attending a metropolitan Australian elementary school. The acceptability of the survey was determined by the proportion of missing responses to each item. The test-retest reliability of individual items, scores and scales were determined using Kappa statistics and percent agreement for categorical variables, and intraclass correlation coefficients (ICC) for continuous variables.

Results: There were few missing responses to each question, with only 4% of all responses missing. Although some Kappa values were low, all categorical variables showed acceptable reliability when examined for percent agreement between test and retest (range 68%–100% agreement). Continuous variables all showed moderate to good ICC values (range 0.72–0.92).

Conclusion: Findings suggest this questionnaire is reliable and acceptable to children for assessing environmental perceptions relevant to physical activity among 11-year-old children.

Background

The physical and psychological health benefits of being physically active are well known [1]; however secular declines in children's physical activity are evident [2]. In order to develop effective strategies to arrest these declines, understanding factors that influence children's activity is important. Ecological models posit that there are multiple levels of influence on physical activity, including intrapersonal, social and physical environmental factors [3]. Intrapersonal factors have been widely investigated, and although measures are well conceptual-
ised and established, these factors appear only to explain part of the variance in children's activity [4].

The home and the local neighbourhood are two important settings for children's physical activity. Studies among adults have commonly defined the physical environment in terms of accessibility and availability of destinations and facilities, aesthetics, and safety [5]. Few studies have attempted to define, operationalise or measure these among children, and none have examined the psychometric properties of such measures. Children's social environment has typically been defined in terms of the proximal social influences (e.g. parental support), and measures are well established [6]. However, with few exceptions [7], almost no studies have assessed children's broader social environment (e.g. the local neighbourhood).

The aim of this study was to develop and test the reliability and acceptability of an instrument to assess a broad range of environmental perceptions that might predict physical activity among children, particularly the physical and social environments at home and in the neighbourhood.

**Participants and methods**

A convenience sample of Grade 5 and 6 children attending a metropolitan Melbourne elementary school participated (21 boys, 18 girls, aged 11.1 ± 0.7 years).

**Measures**

Children were asked to report their perceptions of the physical and social environments at home and in the neighbourhood. All items are shown in Table 1.

Items examining the size of the yard (1 item) and physical activity opportunities at home (16 items) were adapted from a published parent proxy-report survey examining children's leisure activities [8]. Responses were either dichotomous, or on a seven-point scale (later dichotomised), indicating whether the child did or did not have these items at home. A summed score indicating the number of opportunities for physical activity at home was created (range 0–16).

Ten items assessed the home social environment. Six items on family physical activity were adapted from a parent proxy-report survey [8]. Responses ranged from 'never' to 'daily', and were collapsed into no (never) or yes (all other options) response options. Four items on encouragement and support for activity were derived from previous study of psychosocial influences on children's physical activity [6]. Response options ranged from 'never' to 'daily', which were collapsed into yes/no categories. A scale evaluating the overall home social environment was generated by summing the positive (yes) responses to each of the 10 items (range 0–10), with a higher score indicating a more positive perceived home social environment.

Children's perceptions of the neighbourhood physical environment (access to destinations, aesthetic, and safety characteristics) were assessed with 29 items. Access (by active transport) to 15 neighbourhood destinations was assessed using items from a study examining Australian children's leisure activities [8]. Responses were on a seven-point scale with options ranging from never to daily as well as 'it's not within walking/cycling distance'. Based on this last option, responses were collapsed into two categories: 'can't access' and 'can access'. A score indicating the total number of neighbourhood destinations accessible by active transport was created by summing the positive responses to each item (range 0–15).

Fourteen items were used to assess children's perceptions of the neighbourhood aesthetic and safety characteristics, adapted from questions used in a study among adults [9]. Each response was dichotomised (‘yes’, or ‘no/don’t know’). Overall aesthetic and safety scales were developed by reverse coding negatively-worded items and summing the ‘yes’ responses. A higher score on these scales indicated more positive perceptions of neighbourhood aesthetics (range 0–5) and safety characteristics (range 0–9).

Questions assessing children's perceptions of the neighbourhood social environment were developed specifically for use in this study. Seven items (dichotomised to ‘yes’ or ‘no/don’t know’ response options) assessed children's perceptions of the social connections in their neighbourhood. An overall neighbourhood social environment scale was generated by summing the positive responses, with a higher score indicating more positive perceptions.

**Survey administration**

All questions were completed on two occasions (Times 1 and 2) up to nine days apart, during class time with researchers and the classroom teacher present.

**Statistical analyses**

The survey was assessed for acceptability by calculating the proportion of missing responses to each item. Intra-class correlations (ICC's) were used to examine similarities between responses for continuous variables [10], while the Kappa statistic (κ) and percent agreement between responses (the proportion of participants grouped within the same response category for test and retest), were used to determine the repeatability of the categorical variables. Adequate test-retest reliability was defined as ICC ≥ 0.75 for continuous variables [11], and the strength of agreement between responses to categori-

Think about the last month. How often did you do the following activities at home? (Have at home Y/N)
- Played with bats/racquets/golf clubs | .35 (.31, .45) | .03 | 82 | 2 |
- Played with balls | 1.0 (n/a) | .0001 | 100 | 2 |
- Rode my bike | .37 (.43, .63) | .003 | 92 | 1 |
- Went rollerblades | .58 (.20, .36) | .0001 | 81 | 2 |
- Rode my skateboard | .68 (.15, .31) | .001 | 84 | 1 |
- Jumped with my skipping rope | .45 (.22, .35) | .004 | 74 | 0 |
- Rode my scooter | .74 (.13, .29) | .0001 | 87 | 0 |
- Played with toys that I run around with (e.g. frisbees, water pistols) | .06 (.22, .23) | .59 | 68 | 2 |
- Played outside with my pet | 1.0 (n/a) | .0001 | 100 | 4 |

The social environment at home

Think about the last month. How often were the following people physically active with you? (Have at home Y/N)
- Whole family was active together | .30 (.27, .36) | .06 | 69 | 4 |
- Was active with Father | .23 (.33, .42) | .20 | 73 | 6 |
- Was active with Mother | .58 (.23, .43) | .0001 | 86 | 3 |
- Was active with grandparents | .65 (.21, .42) | .001 | 85 | 13 |
- Was active with siblings | .26 (.45, .59) | .15 | 87 | 8 |
- Was active with friends | .53 (.29, .51) | .002 | 89 | 4 |

Think about the last month. Did a friend or family member offer you encouragement or support to be physically active? (Have at home Y/N)
- Received offers to be physically active with a family member | .16 (.34, .39) | .32 | 74 | 4 |
- Received encouragement for physical activity from a family member | 1.0 (n/a) | .0001 | 100 | 5 |
- Received offers to be physically active with friends | .65 (.19, .37) | .0001 | 87 | 1 |
- Received encouragement for physical activity from friends | .42 (.23, .36) | .01 | 71 | 4 |

Which of the following statements are true about the area you live in?
(Have at home Y/N)

**Aesthetics – pleasing aesthetics**
- There are lots of nice houses 0.77 (-0.18, 0.42) 0.001 95 2
- It’s a nice and quiet place to live 0.54 (-0.28, 0.50) 0.001 89 2
- The houses have nice gardens 0.53 (-0.41, 0.59) 0.001 92 1

**Aesthetics – incivilities**
- There is lots of litter and rubbish -0.03 (-0.04, 0.04) 0.87 92 2

**Safety – general**
- It's easy to walk/cycle around 1.0 (n/a) 0.001 100 1
- It's a safe area to walk/cycle 0.53 (-0.34, 0.60) 0.001 92 1
- It's safe to walk/cycle to school 0.54 (-0.22, 0.38) 0.001 82 1

**Safety – traffic/road**
- The roads are safe 0.53 (-0.26, 0.46) 0.001 86 3
- Feel safe crossing the road 0.84 (-0.17, 0.43) 0.001 97 1
- There is heavy traffic 0.53 (-0.34, 0.59) 0.001 92 1

**Safety – personal**
- Worried about dogs roaming the streets 1.0 (n/a) 0.001 100 1
- Worried about strangers 0.53 (-0.34, 0.59) 0.001 92 1
- Worried about older kids hanging around -0.07 (-0.07, 0.06) 0.67 87 1

**The social environment in the neighbourhood**
Which of the following statements are true about the area you live in?
(Have at home Y/N)

- I have many friends in my area 0.79 (-0.14, 0.32) 0.001 92 1
- I have friends who live within a walking or cycling distance from my house 0.87 (-0.10, 0.26) 0.001 95 1
- I have children living next door or in street who I can play with 0.63 (-0.18, 0.35) 0.001 84 1
- I know many people in my area 0.62 (-0.21, 0.40) 0.001 87 1
- There are lots of children around to play with 0.38 (-0.23, 0.33) 0.01 68 1
- I know all of my neighbours quite well 0.58 (-0.18, 0.33) 0.001 79 2
- I know some of my neighbours quite well 0.42 (-0.28, 0.44) 0.001 81 1

* The total number of missing responses between test and retest from 39 participants.
Results
The survey appeared acceptable for children to complete, as they asked few questions, did not report any difficulties understanding the questions and only 11% of responses were missing (Table 1). The items with the most missing responses were those asking about physical activity with family members, particularly with grandparents (13/39 missing), suggesting these items may be difficult for children to complete (possibly reflecting the fact that some children may not have grandparents or siblings, or recall difficulties). On balance, the survey appears to be feasible and acceptable for children.

Results from test-retest reliability analyses are shown in Table 1. The home physical environment items (17 items) showed at least moderate reliability with the exception of two items (having a covered area outdoors and having active toys). All items showed at least fair agreement between test and retest. The physical activity opportunities at home score showed acceptable repeatability (ICC = 0.80, CI = 0.55–0.91). Of the 10 home social environment items, one (receiving offers for physical activity from family members) showed poor reliability according to $\kappa$ (0.16); however all items assessing the home social environment showed at least fair agreement (69% or better) from test to re-test. The home social environment scale also showed adequate test-retest reliability (ICC = 0.84, CI = 0.56–0.94) and good internal reliability (Cronbach’s $\alpha$ = 0.73).

The 29 neighbourhood physical environment items showed at least moderate reliability, with the exception of two access to destinations items (can access the post box and public transport), one aesthetic item (there is lots of litter and rubbish) and one safety item (worried about older kids hanging around), which showed poor $\kappa$ values. All items showed at least fair agreement (greater than 75%) between test and retest. The total number of accessible destinations in the neighbourhood score showed excellent test-retest reliability (ICC = 0.84, CI = 0.66–0.93) and the aesthetics and safety scales showed acceptable test-retest reliability (ICC = 0.72, CI = 0.45–0.86; ICC = 0.88, CI = 0.76–0.94 respectively). Internal reliability analyses showed that while the safety scale was acceptable (Cronbach’s $\alpha$ = 0.65), the aesthetics scale was not (Cronbach’s $\alpha$ = 0.43).

Of the seven items examining the neighbourhood social environment, only one showed less than moderate test-retest reliability (having lots of other children around to play with). All items showed at least fair agreement (68% or better) from test to retest. The neighbourhood social environment scale showed adequate test-retest reliability (ICC = 0.92, CI = 0.84–0.96) and good internal reliability (Cronbach’s $\alpha$ = 0.77).

Although several items showed poor to moderate test-retest reliability according to $\kappa$, all items in the questionnaire showed at least fair agreement (greater than 68%) between test and retest.

Conclusion
This study is the first to assess the test-retest reliability of a broad range of questions examining children’s perceptions of their physical and social environment at home and in the neighbourhood. The questions were mostly found to be acceptable and appropriate for this age group. Although several items did have poor $\kappa$ values, all items showed at least adequate agreement between test and retest. Further research may be required to design a questionnaire using language that may be more appropriate for children, to better define and operationalise the neighbourhood aesthetic environment for children, and to validate such measures of the environment. The results of this study provide some support for the use of these items when examining environmental determinants of physical activity among children.
