Abstract:	Background: Conducting research with dying persons can be controversial and challenging due to concerns for the vulnerability of the dying and the potential burden on those who participate with the possibility of little benefit. Aim: To conduct an integrative review to answer the question 'What are dying persons' perspectives or experiences of participating in research? Design: A structured integrative review of empirical literature was undertaken. Data Sources: CINAHL Complete, PsycINFO, Medline, Informit and Embase databases were searched for empirical literature published since inception of the databases until February 2017. Results: From 2369 references, 10 papers were included in the review. Six were qualitative studies and the remaining four were quantitative. Analysis revealed four themes: value of research, desire to help, expression of self and participation preferences. Dying persons value research participation, regarding their contribution as important, particularly if it provides an opportunity to help others. Participants perceived that the potential benefits of research can and should be measured in ways other than life

prolongation or cure. Willingness to participate is influenced by study type or feature and degree of inconvenience.

Conclusions: Understanding dying persons' perspectives of research participation will enhance future care of dying persons. It is essential that researchers do not exclude dying persons from clinically relevant research due to their prognosis, fear or burden or perceived vulnerability. The dying should be afforded the opportunity to participate in research with the knowledge it may contribute to science and understanding and improve the care and treatment of others.

PALLIATIVE MEDICINE AUTHOR SUBMISSION CHECKLIST

Please complete this checklist for all papers submitted. Please answer questions with yes, no (and give reasons) or not applicable. This checklist is a mandatory upload on submission, without it your paper will be returned without consideration.

Item	Explanation	Addressed? (Yes, No with reasons, Not applicable)
Article title	Have you followed our guidelines on writing a good title that will be found by search engines? (E.g. with methods in the title, use of common words for the issue addressed, no country names, and possibly indicating findings). If your study has an acronym is it included in the title?	Yes
Abstract	Have you followed our guidelines on writing your structured abstract? Please remember we have separate abstract structures for original research, reviews and case reports. There should be no abbreviations in the abstract, EXCEPT a study acronym which should be included if you have one. If a trial (or other design formally registered with a database) have you included your registration details?	Yes
Key statements	Have you included our key statements within the body of your paper (after abstract and before the main text is a good place!) and followed our guidelines for how these are to be written? There are three main headings required, and each may have 1-3 separate bullet points. Please use clear, succinct, single sentence separate bullet points rather than complex or multiple sentences.	Yes
Keywords	Have you given keywords for your study? We ask that these are current MeSH headings unless there is no suitable heading for use (please give explanation in cover letter).	Yes
International relevance	Have you contextualised your work for an international audience and explained how your work contributes to an international knowledge base?	Yes
Publishing guidelines	Have you submitted a checklist for a relevant publishing guideline as a supplementary file? These include CONSORT, PRISMA, COREQ checklists, but others may be more relevant for your type of manuscript. If no published checklist exists please create one as a table from the list of requirements in your chosen guideline. If your study design does not have a relevant publishing guideline please review closest	Yes

	matches and use the most appropriate with an explanation.	
Word count	Does your paper adhere to our word count for your article type? Please insert number of words in the box to the right. Remember that tables, figures, qualitative data extracts and references are not included in the word count.	Yes
Figures and tables and/or quotations	Have you adhered to our guidelines on the number of tables and figures for your article type? Data (e.g. quotations) for qualitative studies are not included in the word count, and we prefer that they are integrated into the text (e.g. not in a separate table).	Yes
Where appropriate have you included details (including reference number, date of registration and URL) of study registration on a database e.g. trials or review database. If your study has a published protocol, is this referenced within the paper?		N/A
Other study publications?	If there are other publications from this study are these referenced within the body of the paper? Please do not reference papers in preparation or submitted, but in-press publications are acceptable.	
Scales, measures or questionnaires	If your study primarily reports the development or testing of scales/measures or questionnaires have you included a copy of the instrument as a supplementary file?	N/A
Abbreviations	Have you removed all abbreviations from the text except for extremely well known, standard abbreviations, which should be spelt out in full first? We particularly discourage abbreviations for core concepts such as palliative or end of life care.	
Research ethics and governance approvals for research involving human subjects	Have you given full details of ethics/governance/data protection approvals with reference numbers, full name of the committee(s) giving approval and the date of approval? If such approvals are not required have you made it explicit within the paper why they were not required. Are details of consent procedures clear in the paper?	N/A
Date(s) of data collection	Have you given the dates of data collection for your study within the body of your text? If your data are over 5 years old you will need to articulate clearly why they are still relevant and important to current practice.	Yes

Structured discussion	Does your paper contain a structured discussion summarising the main findings, addressing strengths and limitations, articulating what this study adds, and presenting the implications for practice.	Yes
Case reports	If your study is a case report have you followed our clear structure for a case report, including highlighting what research is needed to address the issue raised? Have you made clear what consent was required or given for the publication of the case report? Have you provided evidence of such consent as a supplementary file to the editor?	N/A
Acknowledgements and declarations	Have you included a funding declaration according to the SAGE format? Are there acknowledgements to be made? Have you stated where data from the study are deposited and how they may be available to others? Have you conflicts of interest to declare?	
Supplementary data and materials	Is there any content which could be provided as supplementary data which would appear only in the online version of accepted papers? This could include large tables, full search strategies for reviews, additional data etc.	Yes, Table 3 could be included as a Supplementary file, rather than in the published paper
References	Are your references provided in SAGE Vancouver style?	Yes
Ownership of work.	Can you assert that you are submitting your original work, that you have the rights in the work, that you are submitting the work for first publication in the Journal and that it is not being considered for publication elsewhere and has not already been published elsewhere, and that you have obtained and can supply all necessary permissions for the reproduction of any copyright works not owned by you.	Yes

Title

Dying persons' perspectives on, or experiences of, participating in research: An integrative review

Running Head

Dying persons and research

Abstract

Background: Conducting research with dying persons can be controversial and challenging due to concerns for the vulnerability of the dying and the potential burden on those who participate with the possibility of little benefit.

Aim: To conduct an integrative review to answer the question 'What are dying persons' perspectives or experiences of participating in research?

Design: A structured integrative review of empirical literature was undertaken.

Data Sources: CINAHL Complete, PsycINFO, Medline, Informit and Embase databases were searched for empirical literature published since inception of the databases until February 2017.

Results: From 2369 references, 10 papers were included in the review. Six were qualitative studies and the remaining four were quantitative. Analysis revealed four themes: value of research, desire to help, expression of self and participation preferences. Dying persons value research participation, regarding their contribution as important, particularly if it provides an opportunity to help others. Participants perceived that the potential benefits of research can and should be measured in ways other than life prolongation or cure. Willingness to participate is influenced by study type or feature and degree of inconvenience.

Conclusions: Understanding dying persons' perspectives of research participation will enhance future care of dying persons. It is essential that researchers do not exclude dying persons from clinically relevant research due to their prognosis, fear or burden or perceived vulnerability. The

dying should be afforded the opportunity to participate in research with the knowledge it may contribute to science and understanding and improve the care and treatment of others.

Key Words: Ethics; Hospice Care; Palliative Care; Research Subjects; Research Participation; Terminally III

What is already known about the topic?

- Conducting research with dying persons can be controversial and challenging due to concerns for the vulnerability of dying persons and the potential burden that research might impose.
- Access to dying persons for research purposes is limited due to perceived gatekeeping by treating clinicians, managers and policy-makers

What this paper adds

- Dying persons value the opportunity to choose to participate in research, even when there is
 no hope of cure or life prolongation.
- Vulnerability should not be assumed in the dying person.
- Research participation can be beneficial to the dying person by providing an opportunity to help others, contribute to society, science and future patient care.

Implications for practice, theory or policy

- Dying persons should not be automatically excluded from research due to fear of harm or their perceived vulnerability.
- Dying persons can be invited to participate in research if the research has potential to contribute to science and understanding and inform future patient care.

Introduction

Conducting research with dying persons and/or in hospice or palliative care settings has been described as controversial and challenging ^{1, 2}, with the ethics of such research widely debated ³⁻⁷. There is concern about the actual or potential vulnerability of dying persons ^{5, 6, 8} and whether those nearing the end of life should be considered 'too vulnerable' to be involved in research ⁷. Yet there is evidence that research among vulnerable populations may not be harmful per se, and that there may also be direct benefit to participants ⁹. Nonetheless, perceived vulnerability of dying persons results in gatekeeping, where access to dying persons for the purposes of research is limited ^{6, 9-12}. Denying a person the opportunity to participate in research on the basis of an assumption of vulnerability however, is argued to be paternalistic ¹³.

Research participation may provide dying persons opportunities to share their story, reflect upon experiences and contribute to knowledge generation ¹¹. Recent research of cancer patients' participation in research has demonstrated their willingness to be approached about participation in clinical trials in the hope of improving their own treatment, helping others and contributing to scientific research. This evidence however, did not specifically relate to the perspectives of persons in the last stages of life ¹².

Reviews were published in 2010 and 2012, where the goal was to synthesis evidence related to patients' experiences of participation in research ^{1,13}. One focused on patients' willingness and participation in clinical trials ¹, and the other explored the views of patients (and others) on research participation when receiving end-of-life care ¹³. In both reviews patient participants were in various stages of their disease trajectory. This trajectory ranged from immediately after diagnosis, while receiving curative treatment, as well as approaching the end of life ^{1,13}. The end-of-life phase, also known as the terminal phase, can last days, weeks or months ¹⁴. This sensitive period, when people are approaching death, is when the question of conducting research to understand the experience is most controversial.

Aim

The aim of this integrative review was to answer the question: What are dying persons' perspectives or experiences of participating in research?

Design

A structured integrative review, following Whittemore and Knafl's ¹⁵ methodology, was undertaken. This approach was chosen because an integrative review is the broadest type of research review, allowing for the combination of diverse methodologies to enable a comprehensive understanding of problems or phenomena relevant to health care and policy ¹⁵. In contrast to a systematic review in which the randomised clinical trial and hierarchies of evidence are emphasised ¹⁶, an integrative review also allows for the combining of data from the theoretical as well as empirical literature ¹⁵.

Search methods

A search of Cumulative Index Nursing and Allied Health (CINAHL) Complete, PyscINFO, Medline, Informit and Embase databases was undertaken, using relevant search terms and common Boolean operators (Table 1), since inception of the databases till February, 2017. Inclusion and exclusion criteria were developed and agreed upon by members of the team (Table 2).

Search outcome

A staged screening process was undertaken involving the removal of duplicate references, screening of titles and abstracts, and subsequent full paper review. From the original 2369 references resulting from the search, 23 papers were retrieved for full review, and from these, 15 papers were discarded. The reference lists for the remaining eight papers were scanned for further relevant publications, and an additional two papers were identified that met the inclusion criteria. As a result, 10 papers were included in this integrative review (Figure 1).

Quality appraisal

There is no gold standard by which to appraise quality ¹⁵, but given that both qualitative and quantitative papers were included in this integrative review, a research critique framework produced by Caldwell et al. ¹⁷, which consists of 11 criteria suitable for assessing quality in both qualitative and quantitative papers, was chosen to evaluate the included papers. Caldwell et al's framework allows researchers to consider quality measures and the methodological strengths and weaknesses of qualitative and quantitative papers simultaneously ¹⁷. Using Caldwell et al's framework, the methodological quality of each included paper was independently assessed by two members of the research team (MB and LB) ¹⁷. Nine of the 10 papers scored 9/11 or higher against the quality criteria and the remaining paper scored 8/11 (Table 3). Whilst quality scores can be used as a criteria for exclusion, in this case, an a priori decision was made not to exclude papers on this basis, but instead to use the quality assessments to describe the quality of the literature in this area.

Data abstraction and synthesis

The purpose of this stage of the review was to reduce the data from each of the included papers and identify common threads. Data from each paper were extracted to create individual evidence tables, detailing key features including author/s, year of publication, country, study design, purpose/aim, setting and sample, data collection methods/measures and findings ¹⁵. This approach enabled succinct organisation of data and ease of comparison between papers. The evidence tables were then used to facilitate constant comparative analysis to identify patterns, commonalities and differences ¹⁵. The process enables the evidence from diverse methodologies to be synthesised to produce a comprehensive portrayal of the topic of concern, and an integrated summation of the phenomenon presented in narrative form ¹⁵.

Results

The papers included in this integrative review spanned studies conducted in five countries, and in each of the included papers, participants were identified as having a limited life-expectancy, end-stage disease or receiving palliative or hospice care. Participants included those receiving inpatient care, outpatient care, or those previously involved in a palliative medicine clinical trial. (Table 4).

From the analysis, four themes emerged, (i) The Value of Research, (ii) Desire to Help, (iii) Expression of Self and (iv) Participation Preferences.

The Value of Research

Acknowledging that research and the pursuit of new knowledge was an essential part of the workings of a health institution ¹⁸, participants responded positively (85%) when asked about researchers and their ability to be honest about research participation ¹⁹. Understanding that their own care was likely informed by research evidence ¹⁸, participants affirmed that it was indeed ethical for dying patients to participate in research, and in fact, it was unethical not to include dying patients ²⁰. Research participation was considered preferable to relying on doctors guessing how to treat terminally ill patients ¹⁸. Participants suggested there was a 'freedom' in being near death, with nothing to lose by voicing their opinion or saying precisely what they wished ¹⁸, underpinning their decision to participate. For others, participation in research was contingent on there being no possibility of it delaying their death since for them, life prolongation was seen as a hazard, not a benefit ¹⁸.

Desire to help

Desire to help was a dominant theme found in every study included in this integrative review.

Participants spoke of the desire to help others, themselves and to aid research or researchers.

Desire to help others

Participants understood it was the knowledge gained from research that guided their treatment, and they wanted others to have the same benefit ¹⁸. In three studies, the desire to help others who may be in a similar position in the future was an important factor in patients' decisions to take part in research ²¹⁻²³. In relation to patients with Motor Neurone Disease (MND), Bellamy and colleagues ²¹ reported that patients made a conscious decision to take part in any research related to MND because they wanted to contribute in ways that raised awareness and knowledge about the disease, in the hope of saving others from going through the same experience ²¹.

The desire to help others was also reflected in Head and Faul's ¹⁹ survey findings, where 76% of patients suggested they would likely participate if the research would benefit others with the same illness in the future. Likewise, White et al.²⁴ reported that 82% of patients in their study were interested in participating in a trial that was unlikely to help them, but might help others in the future. Some patients said that when they had little time left to live, it was important they used that time to do something of enduring value ¹⁸, and one of the perceived benefits of research participation was to feel good about helping others ²⁵.

Desire to help self

Despite their terminal diagnosis, participants maintained a desire to help themselves in ways other than cure. Research participation offered an opportunity to benefit personally ¹⁹ and was listed as one of the top three reasons for research participation ²². For some patients, research participation had the potential to make them feel better ²⁵ and was considered a valuable experience for self ²³. Others suggested participation offered the opportunity to think about issues they had not necessarily considered or discussed ²⁶.

The desire to achieve symptom control rather than cure was identified in two studies ^{22, 24}. Other potential personal benefits identified by participants included the opportunity to obtain a referral for emotional distress ²⁶ and the belief they would be followed more closely by the clinician team, or perhaps receive better care as a result of participating ^{19, 25}. Others suggested that participation

might be enjoyable ²², and in a study seeking feedback on various possible research studies, 84% of respondents were interested in a trial of pain medication, 81% expressed interest in a trial of a special mattress, and 79% were interested in a trial of aromatherapy ²⁴, all therapies that participants perceived to have potential to be beneficial.

Desire to contribute to research or help researchers

The desire to contribute to, or advance research was identified as important in several of the included studies. Participants suggested that the importance of research ²², a desire to help the researcher ²⁷ and contribute to scientific knowledge ^{19, 27} and medical literature ²³ influenced research participation. The opportunity to enrich the lives of future patients ²³ through research was an important motivation for participation.

Expression of self

Participation in research was considered a positive experience because it offered an opportunity to feel engaged and validated and to express gratitude.

Feeling validated and engaged

The opportunity to participate in research was valued by participants as a way of feeling engaged with the world as a person beyond their illness ²¹. Others reported that research participation had made them feel special, offered a way to restore the balance of power and to be seen as an equal human being and was linked to living ²¹. Research participation was also seen as a way to think about and reflect on their own lives ²³, offering the opportunity to participate in meaningful activity other than being the person living with a life-limiting illness ²¹ or the dying person ¹⁸. Similar sentiments were expressed by survey participants, with 'sense of purpose' and 'meaning to life' identified as benefits of research participation ²⁵. Others reported feeling a sense of contribution and appreciated the opportunity for social interaction that came with research participation ²⁶. In another study, patients welcomed the opportunity to talk with an interested outsider and make

sense of their experiences ²⁷. This was particularly important for those who reported being unable to talk with others such as their treating team, family or clergy ²⁶.

Expressing Gratitude

Participation also offered an opportunity for participants to have their say, give back to the services that they perceived had been supportive of them during the course of their illness ²¹, express their gratitude ²⁷ and say thank you for the care they received ²¹. Some saw it as their duty to give something back; and that an interview, for example, was the least they could do ²⁷. 'Because the staff have been good to me' was one of the most frequently stated reasons for participation in research ²².

Participation preferences

Participants in the included studies also provided insights into their preferences for participation. In relation to research recruitment, participants expressed a preference to be approached about research participation by staff familiar to them, with whom relationships had already been established ^{18, 25}, rather than an independent investigator ²⁵. This approach was preferable as they could avoid the need to explain their situation or problems to a new person, and addressed the concern that an independent researcher may not be able to cope with the issues of dying ¹⁸.

Participants also expressed their preferences for types of studies they would participate in. In

relation to clinical trials, even when the clinical trial was unlikely to help them, participants in the study by White et al. ²⁴ remained consistently positive about participation, if the trial was likely to help others in the future (82%), might help symptoms but not help the cancer (88%), when the clinical trial is quick and easy (94%), or when the doctors were very keen for the patient to participate (84%). In relation to placebo-controlled randomised trials however, Terry et al. ¹⁸ found that participants reported concerns based on the assumption that those in the placebo arm of a trial

would suffer worse outcomes or receive no active treatment. Hence, active comparator trials were more acceptable to patients ¹⁸.

Willingness to participate according to the level of burden associated with studies was explored in two studies. Willingness to participate reduced with increasing burden, where burden was related to invasiveness of treatment and level of commitment. Ross and Cornbleet ²² measured willingness of participants to participate in three hypothetical studies. Factors that would reduce willingness to participate included a dislike of blood tests, uncertainty about the drug, lack of appeal for the proposed therapy, the burden of record keeping, that the study would upset them, and that they didn't have the associated condition or a need to talk ²². Willingness to participate was also explored by White et al. ²⁴ in relation to the level of study invasiveness. The majority of participants were interested in less invasive studies such as pain education research, trialling a special mattress or aromatherapy. As the degree of uncertainty or invasiveness increased, willingness to participate decreased. For example, more than half of respondents stated they were not interested in trialling a new oral 'pain killer' of unknown benefit, and even less were interested in trialling an injection, epidural or spinal stimulator designed to reduce pain ²⁴.

Participants' willingness to tolerate inconvenience daily, weekly and monthly was also measured by White et al. ²⁴. Approximately one third of participants were willing to tolerate extra hospital visits, answer questions or complete a questionnaire, have extra blood tests or scans or take extra tablets, once a week. Participants were less willing to tolerate daily interventions, and more than one third reported that they would not be willing over any timeframe to have extra injections as part of a trial

Discussion

In the past, researchers have avoided research with vulnerable populations such as dying persons, because of the prevailing perception that it would be too burdensome or perhaps even unethical ^{9,}

28. The dominant ethical principle associated with the question of research involving dying persons is

respect ²⁹. Respect in this context is about protecting the life, health, privacy, and dignity of the human subject of research ³⁰ and recognising that each human being has value, autonomy, and the capacity to make decisions for him or herself ²⁹. With this in mind, researchers and clinicians should work to ensure dying persons are afforded the same level of respect and autonomy as others, including the opportunity to participate in research. To deny dying persons this opportunity on the basis of their life-limiting illness denies their right to autonomy. Evidence from this review demonstrates that dying persons not only value the opportunity to participate in research but regard their contribution as important to themselves and others.

The evidence in this review also challenges assumptions related to recruitment. A common requirement of institutional review boards is that recruitment is undertaken via an independent third party to avoid potential coercion ⁸. However, consistent with previous research ^{25, 31}, this review suggests that dying persons may prefer to be approached about research by a member of their treating team with whom a relationship is already established. A way forward is for institutional review boards to allow recruitment by members of the patient's treating team, where other measures, such as a silent opt-out process, in which potential participants can decline through inaction is in place ³².

Whilst not the focus of this review, of note is the inherent sampling bias of studies included in this review. By the very nature of research regarding participation preferences, the perspectives of dying persons who chose not to participate, are not included in this review. Where information about reasons for declining to participate are provided, the reasons vary, suggesting at the very least, that dying persons do maintain autonomy in decision-making when it comes to research participation, and can and do refuse to participate in research for reasons other than just their terminal illness.

How benefit is defined is also an important consideration in research involving dying persons.

Institutional review boards are mandated to ensure that there is a reasonable likelihood that the populations in which the research is carried out stand to benefit from the results of the research ³⁰.

Hence, when dying persons are considered, any research that does not seek to improve their condition or benefit the person in some way may be considered unethical. This review has shown that benefit can and should be measured in ways other than life prolongation or cure. Altruism, and the desire to be of help were dominant themes to emerge from this review, and similarly reflected in other research involving patient cohorts with significant illness ^{9, 10, 13}. Making a contribution to society, helping others and advancing research should also be considered benefits from research for the individual participant ^{4, 9, 12, 33}.

The need for a concerted approach to expand evidence to underpin palliative and end-of-life care is well documented ³⁴. The benefits of enhancing healthcare through research are obvious, yet in palliative and end-of-life care, the reluctance and perceived difficulty of conducting research has meant that care provided to dying persons may be less likely to be based on research evidence ⁹. Although research with dying persons may be seen as more challenging, researchers can work to overcome these challenges in order to ensure that care provided to dying persons is underpinned by research evidence ⁹.

Strengths and Limitations

A key strength of this review was the focus on research conducted with dying persons, specifically identified in the included manuscripts as either dying, terminal, terminally ill, having a short prognosis or receiving end-stage palliative care. This is an important distinction from other systematic reviews, where patients with cancer and other life-limiting diagnoses were included, but where death was not imminent and the focus of care was cure.

The integrative review design enabled research evidence derived from diverse methodologies to be synthesised, providing a comprehensive understanding of dying persons' perspectives on, or experiences of, participating in research. This is critically important because assumptions made by clinicians and treating teams have historically limited access to dying persons for the purposes of

research but this review provides evidence that gatekeeping may not necessarily be in the best interests of the dying person.

There are several limitations to this review. The database search retrieved numerous research publications about studies reporting on patients' perceptions and/or experience of research participation, except the participant populations were not specifically described as dying. Rather, many included patients receiving curative and palliative care, where the findings are not separated. Hence, even though these papers may have had findings relevant to this review, they were excluded. As stated earlier, the findings of this review represent the views of those who participated in the ten included studies, and the perspectives of those who declined participation is not as well understood.

Conclusion

Previous reviews have explored clinical trial participation by dying persons, others have included participants with a life-limiting diagnosis, at various stages of their disease trajectory including immediately after diagnosis. This integrative review is the first to synthesise evidence related to dying persons' perspectives on or experiences of participating in research. Given the expectation that care is evidence-based, understanding dying persons' perspectives of research participation will enhance the future care of dying persons, if it is conducted with sensitivity and respect. Therefore it is essential that researchers do not exclude dying persons from clinically relevant research, as a result of their prognosis, fear of burden or perceived vulnerability.

Rather, dying persons should be afforded the same opportunities as those seeking active treatment to participate in and contribute to research, where appropriate, with the knowledge that even if the research cannot result in an improvement to their condition, benefit may be measured in other ways, including contributing to the body of research evidence that informs the care of others.

Researchers should be encouraged to undertake research involving those nearing the end of life if the intended research has the potential to contribute to science and understanding and inform future patient care.
