Materials and methods: We performed 2 mg/hg I.P. glucose tolerance test in SOD 1 knock out (KO) mice ($n = 11$) and wild type (WT) mice ($n = 10$). To determine whether the glucose intolerance resulted from insulin resistance, whole body insulin sensitivity was measured with a 2 h euglycemic hyperinsulinemic (18 mU/kg/min) with tritiated glucose ($n = 6$ per group). We determined also insulin secretion during a hyperglycemic clamp ($+350$ mg/dl) for 90 minutes.

Results: The body weight in KO mice was lower compared with the WT (20.3 ± 4.2 vs. 24.8 ± 2.7 g; $p < 0.05$). Fasting plasma glucose and insulin concentrations were similar in both groups. Ablation of SOD1 resulted in glucose intolerance during an intraperitoneal (2mg/hg) glucose tolerance test (AUC = 28853 ± 5831 in WT vs. 36235 ± 5065 in KO mice; $p = 0.05$). No differences in peripheral (muscle) and hepatic insulin sensitivity were observed between WT and KO mice during 2h euglycemic hyperinsulinemic clamp. During the hyperglycemic clamp, first phase (0–10 min) insulin secretion was significantly reduced in KO mice (plasma insulin AUC = 7566 ± 2146 in WT vs. 4324 ± 410 mU/ml/min in KO; $p < 0.05$, $n = 3$ per group). Second phase (10–90 min) insulin secretion tended to be reduced in KO mice (16238.82 ± 3900.18 in KO vs. 20468.53 ± 8805.628 in WT; $p = \text{NS}$).

Conclusion: In summary increased oxidative stress due to SOD 1 ablation leads to glucose intolerance due to impaired beta cell insulin secretion without change in muscle or hepatic sensitivity to insulin. Oxidative stress in beta cells could be involved in the defective first phase insulin secretion observed in the early stages of T2DM.

Mitochondrial reactive oxygen species generation in obese non-diabetic and T2DM subjects

M. Abdul-Ghani, R. Jani, A. Chaves, M. Molina, D. Tripathy, R. DeFronzo
University of Texas Health Science Center at San Antonio, San Antonio, United States

Background and aims: Increased oxidative stress has long been implicated in the pathogenesis of type 2 diabetes mellitus (T2DM) and its complications. However, no previous study has directly measured the rate of reactive oxygen species (ROS) production in insulin resistant individuals. Since insulin resistance in skeletal muscle is a central feature in T2DM, the aim of this study was to quantitate directly mitochondrial ROS production in skeletal muscle of obese, insulin resistant, normal glucose tolerant (NGT), and T2DM subjects and compared the result with those in lean healthy NGT individuals.

Materials and methods: Ten lean healthy NGT subjects (BMI = 26.0 ± 0.9 , age = 40 ± 2), 10 obese NGT subjects (BMI = 37.3 ± 2.5 , age = 40 ± 3) and 9 T2DM drug naïve subjects (BMI = 38.8 ± 2.4 , age = 43 ± 3) were studied with insulin clamp and vastus lateralis muscle biopsy. Mitochondrial ATP synthesis rate and ROS production were measured *ex vivo* in isolated muscle mitochondria with chemiluminescence and fluorescent techniques, respectively.

Results: Compared to lean NGT subjects, both obese and T2DM subjects had a reduced rate of ATP synthesis (58 ± 4 vs 39 ± 4 and 44 ± 5 nmole/mg protein.min with glutamate [$p < 0.01$], and 62 ± 9 vs 39 ± 4 and 42 ± 6 nmole/mg

protein.min with succinate, respectively [$P<0.05$] with ANOVA). However, the rate of ROS production with complex I and complex II substrates was decreased in obese vs lean subjects, (85 ± 21 vs 247 ± 58 pmole/mg protein.min with glutamate [$p<0.002$]) and 31 ± 7 vs 80 ± 23 with succinate [$p<0.05$]). In contrast, in T2DM, ROS production from glutamate (247 ± 58) and succinate (85 ± 21) was similar to lean controls. ROS production in non-diabetic (lean and obese) subjects, with both substrates, strongly correlated with the rate of mitochondrial ATP production ($r=0.71$, $p<0.0009$ for glutamate and $r=0.83$, $p<0.0001$ for succinate) and with total glucose disposal measured with the euglycemic hyperinsulinemic clamp ($r=0.74$, $p<0.0004$ for glutamate and $r=0.51$, $p<0.02$ for succinate). The ATP/ROS ratio was 470, 498 and 233 with glutamate and 1611, 1623 and 703 with succinate in lean, obese and T2DM subjects, respectively ($P<0.02$ for glutamate and $P<0.05$ with succinate with ANOVA).

Conclusion: (i) mitochondrial ATP production rate is reduced in both obese insulin resistant and T2DM subjects compared to lean NGT individuals; (ii) the decrease in ROS production in obese NGT subjects and “normal” ROS production in T2DM compared to lean NGT subjects argue against a significant role for excessive mitochondrial ROS production in the pathogenesis of insulin resistance in human skeletal muscle.

Increased skeletal muscle phosphodiester contents of patients with type 2 diabetes mellitus relate to insulin resistance and impaired mitochondrial function

J.M. Szendroedi¹, A.I. Schmid², M. Chmelik², P. Nowotny³, M. Wolzt³, M. Roden¹

¹1st Medical Department, Hanusch Hospital, Karl-Landsteiner Institute for Endocrinology and Metabolism, ²Medical University of Vienna, MR centre of excellence, Vienna, ³University of Vienna, Department of Internal Medicine 3, Vienna, Austria

Background and aims: The membrane composition of skeletal muscle has been related to insulin action. Possible mechanisms suggested include changed membrane fluidity, which could affect insulin receptor activation, release of different second messenger molecules influencing cellular processes, and altered cellular energy expenditure influencing lipid stores. However, the factors determining muscle phosphodiester concentrations are yet unclear.

Materials and methods: Glucose metabolism, ectopic lipid deposition in muscle (IMCL) and mitochondrial function were measured in 10 overweight type-2 diabetic patients (T2DM: age: 59 ± 6 a, BMI: 27 ± 3 kg/m²), 10 sex-/age-/body mass-matched elderly (CONo: 57 ± 6 a, 26 ± 3 kg/m²) and 11 younger controls (CONy: 27 ± 2 a, 23 ± 2 kg/m²). Phosphodiester content (PDE), ATP synthetic flux (fATP) and IMCL were assessed with ³¹P/H magnetic resonance spectroscopy, insulin sensitivity was determined via hyperinsulinemic-euglycemic clamp tests (M-value).

Results: PDE was ~31% lower in CONy than in overweight CONo and T2DM (T2DM: 2.8 ± 0.2 , CONo: 2.5 ± 0.2 , CONy: 1.8 ± 0.1 mmol/l, $P=0.002$) despite comparable muscle lipid contents. M was lower in diabetic patients (~35% vs. CONo, ~56% vs. CONy; $P<0.05$). T2DM had ~37% lower fATP than CONy (8.6 ± 2 vs. 11.8 ± 3 $\mu\text{mol}\cdot\text{g}^{-1}\cdot\text{min}^{-1}$; $P<0.05$, CONo (10.4 ± 3). PDE related negatively to M ($r=-0.620$, $P<0.001$) and fATP ($r=-0.371$, $P<0.05$), and positively to age ($r=0.610$, $P<0.001$) and BMI ($r=0.672$, $P<0.001$) but did not relate to IMCL. HbA1c ($r=0.672$, $P<0.001$) and fasting plasma glucose ($r=0.614$, $P<0.001$) related positively to PDE over the entire study group and also within the group of T2DM patients.

Conclusion: PDE content of skeletal muscle strongly relates to insulin resistance, impairment of mitochondrial function and parameters of metabolic control, is increased in elderly and obese and does not depend on intramyocellular lipid contents.

Impaired macroautophagy as a cause of insulin resistance and mitochondrial dysfunction associated with aging

H. Jung¹, S. Kim², N. Cho², J. Kim², M.-K. Lee², K.-W. Kim², H.-K. Lee³, M.-S. Lee²

¹Samsung Medical Center, ²Seoul National University Hospital, Seoul, Republic of Korea

Background and aims: Macroautophagy is a cellular process whereby cellular organelles including mitochondria are degraded. Macroautophagy has been reported to decline with aging, which may lead to decreased mitochondrial function. In the present study, we studied the role of macroautophagy in age-associated insulin resistance and mitochondrial dysfunction.

Materials and methods: Glucose tolerance test and insulin tolerance test were performed in young and old C57BL/6 mice. Insulin signaling *in vivo* was examined in the skeletal muscle and liver tissues by immunoblotting. Resting O₂ consumption and mitochondrial complex activities were measured. Steady-state macroautophagy level was assessed by LC3 immunoblotting and electron microscopy. The relationship between macroautophagy, mitochondrial complex activity and insulin resistance was investigated using differentiated L6 myotubes.

Results: Old mice (> 18 months) showed glucose intolerance, hyperinsulinemia and increased HOMA index, suggesting insulin resistance. Insulin signaling, e.g., IRS1 and AKT phosphorylation after insulin administration *in vivo* was impaired in old mice. Mitochondrial complex I and II/III activities of muscle and liver tissues were decreased, potentially explaining insulin resistance in aged mice. Resting O₂ consumption was also lower in old mice (Fig.1). Electron microscopy and LC3 immunoblotting showed that macroautophagy was impaired in old mice (Fig.2). The inhibition of macroautophagy in L6 myotubes induced mitochondrial dysfunction and impaired insulin signaling (Fig.3).

Conclusion: Mitochondrial complex activities and macroautophagy were decreased in the skeletal muscle and liver tissues of insulin-resistant old mice. As inhibition of macroautophagy *in vitro* induced mitochondrial dysfunction and impaired insulin signaling, decline of macroautophagy may be one of the important causes of age-associated mitochondrial dysfunction and insulin resistance.

A new type of insulin sensitiser, BGP-15 regulates mitochondrial function

A. Kolonics¹, A. Cselenyak², E. Kiss³, P.N. Literati⁴, K. Tory¹¹Molecular pharmacology, N-Gene Research Laboratories, ²Human Physiology and Clinical Experimental Research, Semmelweis University, ³Immunology, Eotvos Lorand University, ⁴Molecular pharmacology, N-Gene Research Laboratories, Budapest, Hungary

Background and aims: The insulin-sensitizing property of BGP-15 (R,S-O-(3-piperidino-2-hydroxy-1-propyl)-nicotinic-acid-amidoxime) has been demonstrated in diabetic animal models and in insulin-resistant patients by hyperinsulinemic euglycemic clamp method (Diabetes 55 Suppl. 1. A483, 2006). JUN kinase mediated inhibition of insulin signaling is a common pathogenic mechanism in insulin resistance associated with obesity, inflammation and mitochondrial dysfunction. Inhibition of JUN kinase activation by the stimulation of stress protein (HSP72) expression has been demonstrated as a novel insulin sensitizing mechanism of BGP-15 (PNAS 105: 1739, 2008). We aimed to study the cellular mechanisms of insulin sensitizing effect of BGP-15 in insulin sensitive cell culture.

Materials and methods: The effect of BGP-15 was evaluated in insulin responsive human keratinocyte cell line (HaCaT) in hyperglycaemic condition. Glucose transport was measured by 2-deoxy-D-glucose uptake (2-DOG). Insulin signaling was characterized by phosphorylation level of IRS-1 (Tyr989) and Akt (Ser473). Laser Confocal Microscopy was applied for localization of actin, PIP-2 and BGP-15-Biotine conjugate. The effects of a 5-day BGP-15 treatment were examined by measuring mitochondrial mass and insulin signaling in soleus of diabetic Gotoh-Kakizaki (GK) rats.

Results: Hyperglycaemia reduced insulin induced 2-DOG uptake and IRS-1 and Akt phosphorylation. BGP-15 treatment (30', 24h) significantly stimulated 2-DOG uptake but in contrast to insulin it resulted in marginal increase in IRS-1 and Akt phosphorylation in hyperglycaemic HaCaT cells. BGP-15 induced waves of PIP-2 formation and actin polymerization in 1 hour. Temporary elevation of mitochondrial 3-nitro-tyrosine level and phosphorylation of AMPK were also observed. 3-nitro-tyrosine derived partly from increased nitric oxide production. It was accompanied by increased cytosolic appearance of constitutive nitric oxide synthase and HSP72. A 3-day BGP-15 treatment restored insulin induced phosphorylation of IRS-1 and improved mitochondrial mass in hyperglycaemic HaCaT cells. A 5-day BGP-15 treatment resulted in improved insulin sensitivity, insulin signaling and increased mitochondrial mass in soleus of Goto-Kakizaki diabetic rats. Biotine-BGP-15/Streptavidine-FITC staining on fixed cells revealed the accumulation of the conjugated drug in mitochondria. Precipitation study with Biotine-BGP-15/CaptAvidin agarose exposed mitochondrial Complex I (75 kDa subunit) binding.

Figure 3.

Supported by: Nano/Bio Science Program Grant and 21C Frontier Functional Proteomics Project

Conclusion: These observations suggest that BGP-15 regulates mitochondrial function through nitric oxide production and binding to Complex I. BGP-15 induced cytoskeletal rearrangement and rapid chaperone release may be a secondary consequence. These changes may contribute to improved insulin sensitivity.

Mt2a is involved in TNF α induced insulin resistance

S. Dubois¹, T. Connor², N. Konstantopoulos², C. Swinton², K. Walder²

¹Faculty of Medicine Lyon Sud, Inserm870/INRA1235, Oullins, France,

²Metabolic Research Unit, Deakin University, Geelong, Australia

Background and aims: The Adipose Tissue is now recognised as an endocrine/paracrine organ which can influence whole body metabolism not only through the release of non-esterified free fatty acids but also via many adipokines such as Tumor Necrosis Factor α (TNF α). TNF α is a proinflammatory cytokine that has been implicated as a contributing cause of insulin resistance—eg reduced proteins levels of GLUT4 and several insulin signaling proteins; but although the effects of TNF α are well known, the mechanisms by which TNF α induces insulin resistance are not well understood. Our goal was to investigate potential new targets of TNF α . One of them could be the Metallothionein 2a (Mt2a) which is part of the heavy metal-binding proteins family and has been shown to be regulated by cytokines such as TNF α . Mt2a polymorphisms have been recently described and associated to type 2 diabetes and its complications. On the other hand, in type 2 diabetic patients, key factors regulating mitochondrial metabolism and biogenesis are reduced, notably the Complex I of the Electron Transport Chain (ETC). Our aim was to investigate the hypothesis that Mt2a and/or Complex I might be involved in TNF α induced insulin resistance.

Materials and methods: We used 3T3-L1 as an in vitro model of adipocytes in which insulin resistance (impaired insulin action) was induced by treating mature adipocytes with TNF α (10ng/ml, 72h). In order to further explore the potential role of Mt2a or Complex I in insulin resistance; we treated 3T3-L1 mature adipocytes with Mt2a protein (500ng, 24h) or the Complex I inhibitor (Rotenone, 200 nM, 24h). Following treatments, insulin sensitivity was determined by 2-deoxyglucose uptake and RNA and proteins were extracted. Real-Time PCR of specific target genes was performed.

Results: Preliminary results show that insulin-stimulated glucose uptake was inhibited by 55% ($p < 0.0001$ compared to vehicle, $n = 5$) and by 53% ($p < 0.001$ compared to vehicle, $n = 5$) when 3T3-L1 adipocytes were treated with TNF α or Mt2a, respectively. Results of gene expression analysis show that Mt2a and Complex I (NduFa9) mRNA levels were significantly increase ($p < 0.001$, $n = 3$) and decrease ($p = 0.01$, $n = 3$), respectively following TNF α treatment. Key proteins involved in insulin signaling pathway such as AKT gene expression was unchanged with Mt2a treatment, but significantly decrease with Rotenone treatment ($p < 0.01$, $n = 3$). Similarly, opposite results between treatments were observed for Protein Tyrosine Phosphatase 1B (PTP1B) gene expression that was increase with Mt2a treatment ($p < 0.01$, $n = 3$) and unchanged with Rotenone treatment.

Conclusion: We conclude that Mt2a and ETC/Complex I might be involved in TNF α induced insulin resistance via an up/down regulation of several and different insulin signaling key proteins. These results raise the concept of considering metallothioneins proteins and notably Mt2a or Complex I (NduFa9) as potential therapeutic targets for type 2 diabetes. Future directions involved to measure insulin signaling specific genes protein level following Mt2a or Rotenone treatment.

PS 045 Vascular effects of insulin

625

High fat feeding induced loss of insulin-mediated vascular sensitivity in muscle

S. Rattigan, P. St-Pierre, A.J. Genders, L. Keith, M.A. Vincent, S.M. Richards

Menzies Research Institute, University of Tasmania, Hobart, Australia

Background and aims: It has been widely reported that skeletal muscle glucose uptake is blunted in rats fed a high fat diet. We have demonstrated that Obese Zucker rats (a genetic model of obesity and insulin-resistance), have impaired insulin-mediated muscle microvascular recruitment, even at high doses of insulin (20mU.min⁻¹.kg⁻¹). The effect high fat feeding has on insulin's effect to increase total blood flow and microvascular recruitment is unknown. Thus the aim of this study was to determine the effect of high fat feeding on the haemodynamic actions of insulin.

Materials and methods: Hooded Wistar rats were placed on a high fat diet (60% of calorie intake derived from fat) for 4 weeks or a normal chow diet. All rats were fasted overnight prior to euglycaemic hyperinsulinaemic clamps performed at two doses of insulin (3mU.min⁻¹.kg⁻¹ x 2h and 10mU.min⁻¹.kg⁻¹ x 2h). The jugular veins and the carotid artery were cannulated for intravenous infusions, arterial blood sampling and monitoring of arterial blood pressure. Femoral blood flow (FBF) was monitored by a probe positioned around the femoral artery. Microvascular recruitment was determined by the metabolism of infused 1-methyl xanthine.

Results: Compared to rats fed a normal diet (NF), high-fat fed animals (HFF) showed an increase in total body mass (NF= 232.50 \pm 1.71g vs HFF= 248.21 \pm 2.60g, $p < 0.01$) and in epididymal adipose tissue mass (NF= 1376 \pm 66mg vs HFF= 2755 \pm 146mg $p < 0.01$). High fat feeding induced a state of insulin resistance as seen by an increase in fasting blood glucose (NF= 2.82 \pm 0.06mM vs HFF= 3.52 \pm 0.09mM, $p < 0.05$) and plasma insulin (NF= 73 \pm 11pmol/L vs HFF= 147 \pm 12pmol/L, $p < 0.05$). High fat feeding had no effect on blood pressure or heart rate. Whole body insulin sensitivity reflected by the glucose infusion rate during the clamps was significantly lower in HFF compared to NF. The loss of insulin sensitivity was greater at 3mU.min⁻¹.kg⁻¹ (Δ -70%) compared to 10mU.min⁻¹.kg⁻¹ (Δ -20%). In HFF there was no change in FBF at 3mU.min⁻¹.kg⁻¹ insulin (Δ +12%, NS) but a significant increase with 10mU.min⁻¹.kg⁻¹ insulin (Δ +67%, $p < 0.01$), although this was blunted compared to the increase observed in the NF animal (Δ +142%, NF vs HFF $p = 0.11$). HFF animals had impaired insulin-mediated microvascular recruitment but the effect was greater at the lower dose of insulin (3mU.min⁻¹.kg⁻¹ NF= Δ +48% vs HFF= Δ +15%, 10mU.min⁻¹.kg⁻¹ NF= Δ +42% vs HFF= Δ +29%). Preliminary results examining the effect of muscle contraction using field stimulation indicated that at low intensity contraction, HFF also decreased the microvascular responses to contraction.

Conclusion: We conclude that high fat feeding causes marked impairment in microvascular responses in skeletal muscle, and is likely to increase the metabolic impact of high fat feeding and cause greater whole body insulin resistance by limiting the delivery of hormones and nutrients to muscle. However, in contrast to the complete lack of vascular responsiveness of the Zucker obese rat to insulin, the HFF rat showed a reduced sensitivity of both microvascular recruitment and muscle glucose uptake to insulin. This situation is akin to the inhibition of insulin-mediated microvascular recruitment by tumour necrosis factor- α , which can be overcome at higher doses of insulin.

Insulin increases matrix metalloproteinase-2 synthesis, secretion and activity in aortic vascular smooth muscle cells through the PI3-K pathway: effect reduced by insulin resistance

G. Doronzo, M. Viretto, I. Russo, P. Del Mese, L. Mattiello, G. Anfossi, M. Trovati

Department of Clinical and Biological Sciences, Diabetes Unit, San Luigi Gonzaga Hospital, Orbassano-Turin, Italy

Background and aims: Matrix metalloproteinases (MMPs) are zinc-dependent endopeptidases secreted as pro-enzymes, activated after specific cleavage and inhibited by specific tissue inhibitors (TIMPs). They degrade extracellular matrix and play a role in physiological and pathological angiogenesis, in the

vascular smooth muscle cell (VSMC) migration from media to intima occurring in the formation of atherosclerotic plaques, in plaque instabilization via fibrous cup rupture and in the pathogenesis of aortic aneurysms. It has been described that insulin exerts pro-atherogenic effects via the MAPK-pathway and anti-atherogenic effects via the PI3-K pathway, which is less activated by insulin in the insulin-resistant states. Aim of the study is to clarify whether insulin influences in VSMC synthesis and activation of MMP-2, which is constitutively produced in these cells, and whether this putative effect is modified by the presence of insulin resistance.

Materials and methods: The study has been carried out in VSMC obtained as primary culture in our laboratory from aortas of insulin sensitive lean Zucker rats (fa/+) and insulin resistant obese Zucker rats (fa/fa), by measuring the influence of a 24-hour incubation with 2 nM insulin on MMP-2 protein synthesis and secretion (western immunoblotting) (n=6), on TIMP-2 synthesis (western immunoblotting) (n=6) and on MMP-2 activity (gelatin zymography) (n=6), in the absence and in the presence of a 1-hour pre-incubation with the specific PI3-K inhibitor LY294002 (50 μ M) (n=4). Results obtained after densitometric assays are expressed as mean \pm SEM.

Results: In aortic VSMC from lean Zucker rats, insulin 2nM: i) increased MMP-2 synthesis, secretion and activity (p=0.002–0.0001) by a PI3-K-dependent mechanism blunted by LY294002; ii) did not modify TIMP-2 synthesis. In aortic VSMC from obese Zucker rats, insulin increased synthesis, secretion and activity of MMP-2 (p=0.05–0.004), but at an extent significantly lower than in VSMC from lean Zucker rats. In particular: i) synthesis of MMP-2 was 216.53 \pm 31.06% of baseline in lean vs 127.8 \pm 11.51% in obese Zucker rats (p=0.002); ii) secretion of MMP-2 was 166 \pm 11.62% of baseline in lean vs 109.4 \pm 2.82% in obese Zucker rats (p=0.0001); iii) activity of MMP-2 was 271.8 \pm 40.6% of baseline in lean vs 123.8 \pm 10.6% in obese Zucker rats (p=0.013).

Conclusion: We observed that insulin increases MMP-2 synthesis, secretion and activity in aortic VSMC from lean, insulin-sensitive Zucker rats with a mechanism mediated by the PI3-K pathway and that this effect is attenuated in VSMC from obese, insulin resistant Zucker rats. MMPs are involved both in reparative vascular processes and in vascular damage: thus, an increase of their production and activity is not “good” or “bad” per se, but depends on the different settings. However, if we consider the role of MMPs in plaque formation and instabilization, our data support the conclusion that insulin exerts a pro-atherogenic effect via the signalling pathway usually considered anti-atherogenic, and that this pro-atherogenic insulin action is impaired in a classical animal model of insulin resistance. Thus, vascular insulin actions mediated by the PI3-K pathway are not necessarily “good”, and their impairment in the insulin-resistant states is not necessarily “bad”.

Insulin-mediated capillary recruitment in muscle is sensitive to intra-cerebroventricular NOS inhibitor

M.G. Clark, E.A. Bradley, K. Willson, D. Choi-Lundberg, S.M. Richards, S. Rattigan
Menzies Research Institute, University of Tasmania, Hobart, Australia

Background and aims: We have previously reported that insulin acts *in vivo* to increase capillary recruitment in hindlimb muscle of rats to enhance delivery and thus increase glucose uptake. In normally responsive rats these events are NO-dependent such that systemic administration of nitric oxide synthase (NOS) inhibitor increases blood pressure, blocks systemic insulin-mediated capillary recruitment and glucose uptake in muscle. In addition, others have reported that intra-cerebroventricular (ICV) administration of NOS inhibitor to conscious rats raises blood pressure, increases plasma glucose levels and reduces whole body glucose disposal during insulin clamp. Accordingly, the present study was conducted to test whether there was a NO-dependent pathway in the central nervous system involved in insulin-mediated muscle capillary recruitment and glucose uptake.

Materials and methods: Anaesthetized rats underwent standard surgery for a hyperinsulinaemic euglycaemic clamp and then were placed in a Kopf stereotactic apparatus for insertion of an ICV cannula into the lateral ventricle. Animals were allowed to stabilize for 60 min and then underwent an insulin clamp (10mU.min⁻¹.kg⁻¹) for 70 min while still under anaesthesia. L-NMMA (167 μ g/ μ l in CSF) was infused ICV at 0.5 μ l/min for two periods of 3 min at 0 and 30 min of the clamp, or infused systemically (to simulate spillover from ICV) with insulin for 70 min so that the total amount infused by either route was 500 μ g. Blood pressure (BP), heart rate (HR), femoral blood flow (FBF), glucose infusion rate to maintain euglycaemia (GIR), muscle glucose uptake

(2-deoxyglucose, 2DG), capillary recruitment by 1-methylxanthine metabolism and plasma insulin were determined. The position of the ICV needle was confirmed by dye infusion and sectioning post-mortem.

Results: Systemic infusion of 500 μ g of L-NMMA with insulin was insufficient to affect BP, HR, GIR, FBF, 2DG, capillary recruitment or plasma insulin when compared to insulin alone. However, ICV infusion of 500 μ g L-NMMA blocked insulin-mediated increases in FBF (2.08 \pm 0.09 to 1.57 \pm 0.16 ml/min), 2DG (16.5 \pm 1.4 to 9.8 \pm 0.4 μ g.g⁻¹.min⁻¹) and capillary recruitment (10.3 \pm 0.4 to 6.6 \pm 0.9 nmol/min) (data are means \pm SE and for each change P < 0.05, n = 5–8). Plasma insulin was 2430 \pm 240 (ICV L-NMMA) and 2060 \pm 150 pM (systemic L-NMMA). HR and BP were unaffected at this dose of L-NMMA given ICV but higher doses increased BP.

Conclusion: The present findings indicate that the effects of systemic insulin to increase femoral arterial blood flow and capillary recruitment may be regulated by a central pathway that is sensitive to the nitric oxide synthase inhibitor L-NMMA. We propose that a central NO-dependent vasomotor neuronal pathway is involved in insulin action to increase muscle capillary recruitment and thus glucose uptake.

Zaprinast acutely augments insulin-mediated capillary recruitment and glucose disposal in rats *in vivo*

A.J. Genders, E.A. Bradley, S.M. Richards, M.G. Clark, S. Rattigan
Menzies Research Institute, University of Tasmania, Hobart, Australia

Background and aims: Insulin increases glucose uptake into muscle *in vivo* in rats and humans by increasing delivery of hormones and nutrients through capillary recruitment. In addition, insulin-mediated capillary recruitment and vasodilatation has been thought to involve endothelial production of nitric oxide which then migrates to neighbouring smooth muscle cells to activate guanylate cyclase and produce cyclic GMP (cGMP). However, cGMP is degraded by a class of enzymes, the phosphodiesterases (PDEs) and inhibitors of these can amplify nitric oxide signalling by decreasing the degradation of cGMP. Thus PDE inhibitors have the potential for increasing capillary recruitment and enhancing insulin action. Accordingly, the aim of this study was to investigate the effect of the cGMP PDE inhibitor Zaprinast on insulin-mediated capillary recruitment and skeletal muscle glucose uptake.

Materials and methods: Hooded-Wistar rats were anesthetized and had cannulas surgically implanted into their carotid artery, for arterial blood glucose (BG) sampling and measurement of blood pressure (BP), and the jugular vein for intravenous infusions. A flow probe was positioned around the femoral artery for continual measurement of femoral blood flow (FBF) and heart rate (HR). The euglycaemic insulin-clamp (3mU.min⁻¹.kg⁻¹) was used to assess whether a dose of Zaprinast (1.6mg bolus followed by a 10 μ g.min⁻¹.kg⁻¹ infusion for the duration of the experiment) enhances insulin-mediated glucose uptake. Four experimental groups were studied; saline, insulin, saline + Zaprinast, insulin + Zaprinast. Arterial glucose and lactate, glucose infusion rate (GIR), whole body glucose appearance and disappearance (Ra and Rd by ³H-glucose tracer techniques), capillary recruitment by metabolism of infused 1-methylxanthine(1-MX), plasma levels of Zaprinast and 1-MX were determined.

Results: BG, BP and HR were not significantly different between the four treatment groups. Plasma Zaprinast concentration was 30 \pm 2.7 μ M (Zaprinast) and 25 \pm 1.6 μ M (Zaprinast + insulin). Zaprinast treatment alone resulted in a significant (P < 0.05, n = 8) increase in capillary recruitment, Rd and arterial lactate concentrations. Zaprinast treatment during the insulin-clamp significantly (P < 0.05) increased capillary recruitment, Rd, GIR and plasma lactate.

Conclusion: The main findings indicate that effects of acute infusion of Zaprinast *in vivo* are to potentiate insulin-mediated capillary recruitment, Rd and GIR. We propose that a Zaprinast-sensitive cGMP PDE specifically expressed in arterioles controlling blood flow entry to capillaries can be targeted to increase insulin action to recruit capillaries in muscle and therefore improve whole body insulin-mediated glucose disposal *in vivo*.

***In vivo* chronic hyperglycaemia induces endothelial insulin-resistance**P. Di Fulvio¹, A. Pandolfi², S. Di Silvestre², P. Di Tomo², A. Giardinelli², N. Di Pietro², G. Formoso¹, M. Marchisio³, A. Consoli¹¹Medicine and Aging Sciences, ²Biomedical Sciences, ³Biomorphology, G.d'Annunzio University, Chieti, Italy

Background and aims: Endothelium is an insulin target organ and endothelial insulin-resistance is thought to play a pivotal role for the increased cardiovascular risk associated to metabolic syndrome and type 2 diabetes. Hyperglycaemia, through glucotoxicity, has been shown to induce insulin-resistance at liver, skeletal muscle and adipose tissue site. Aim of our study was to determine whether chronic *in vivo* exposure to hyperglycaemia can induce insulin-resistance also in endothelial cells.

Materials and methods: We studied human tissues and endothelial cells (HUVEC) obtained from umbilical cords of women with Gestational Diabetes (H-GD) and women with normal carbohydrates tolerance (H-CT). In HUVEC cultured at low number of passages we studied NO production (conversion of 3H-arginin in 3H-citrulline) and Akt phosphorylation (Western blot) in the basal state and after 10 minutes stimulation with insulin (100 nM); eNOS expression (Western blot) in the basal state and after 24 hrs of stimulation with insulin (100 nM); and, only in the basal state, phosphorylation levels of Protein Kinase-C alpha (PKCα, Western blot), an enzyme potentially implicated in insulin-resistance. PKCα phosphorylation levels were also evaluated *ex vivo* on umbilical cords sections (immunohistochemistry).

Results: In H-CT, as expected, insulin stimulated NO production (+ 40% vs basal levels after 10 minutes stimulation), Akt phosphorylation (+35% vs basal levels after 10 minutes stimulation) and eNOS expression (+53% vs basal after a 24 hrs stimulation), in H-GD, instead, insulin failed to affect these parameters, which were not different from basal levels after insulin stimulation. Moreover, in H-GD, PKCα phosphorylation was increased up to 25% vs H-CT. Immunohistochemical analysis of tissue samples confirmed an increase in PKCα phosphorylation levels in umbilical cords from gestational diabetic women vs control.

Conclusion: Our data demonstrate that chronic *in vivo* hyperglycaemia, probably via a chronic activation of PKC isoforms, induces insulin-resistance at the IRS1/PI-3-Kinase/Akt/eNOS pathway in endothelial cells. This allows to speculate that hyperglycaemia induced endothelial insulin-resistance could contribute to mechanisms by which hyperglycaemia causes vascular damage.

Effect of ten days of bed rest on insulin action and endothelial function in subjects with and without increased risk of type 2 diabetesM.P. Sonne¹, L. Højbjørre¹, A.C. Alibegovic², B. Stallknecht¹, A. Vaag², F. Dela¹¹Department of Biomedical Sciences, Sections of Systems Biology Research, University of Copenhagen, ²Steno, Diabetes Center, Gentofte, Denmark

Background and aims: Sedentary lifestyle is a major and growing problem in the Western societies, contributing to lifestyle-related diseases such as type 2 diabetes and cardiovascular disease. We used bed rest as a model of physical inactivity to study the influence of physical inactivity on insulin action and endothelial function in a group of young healthy men with first degree relatives with type 2 diabetes (FDR) compared with matched controls (CON).

Materials and methods: 20 CON (25±1 years, BMI 24±0.5 kg m⁻²) and 13 FDR (26±1 years, BMI 25±1 kg m⁻²) participated in the study. Whole body insulin-mediated glucose uptake and forearm endothelial function was studied before and after 10 days of strict bed rest by intra arterial infusions of adenosine (Adn) and acetylcholine (Ach) in one arm while the other served as control, before and during a 3-hour hyperinsulinemic (40 mU/min/m²) isoglycemic clamp. Forearm blood flow was measured by venous occlusion plethysmography simultaneously in both arms. Diet was controlled before and under the intervention.

Results: Both before and after bed rest the FDR were more insulin resistant compared with the CON (both P<0.05). Insulin-stimulated glucose uptake decreased significantly in both groups in response to 10 days of bed rest but the decrease did not differ between the two groups (P>0.05). CON decreased

from 7.2 ± 0.5 to 4.9 ± 0.4 mg min⁻¹ kg⁻¹ (P<0.001) and FDR decreased from 5.0 ± 0.7 to 3.6 ± 0.3 mg min⁻¹ kg⁻¹. Before bed rest systemic hyperinsulinemia increased forearm blood flow in CON (3.0±0.3 to 4.3±0.7 ml 100ml⁻¹ min⁻¹, P<0.05), whereas in FDR no increase was observed. After bed rest hyperinsulinemia did not significantly increase forearm blood flow in either group. Before bed rest FDR demonstrated a significantly lower forearm blood flow response to Adn and Ach compared to CON. In both FDR and CON the ten days of bed rest did not change the forearm blood flow response to Adn and Ach +/- insulin-stimulation.

Conclusion: Short time physical inactivity induced whole body insulin resistance in both FDR and CON. The CON demonstrated impaired vascular insulin response after bed rest. The FDR demonstrated metabolic and vascular insulin resistance and endothelial dysfunction before bed rest compared with CON. Surprisingly the vascular responsiveness to Adn and Ach was unaffected after bed rest in both groups. It could be speculated that the FDR demonstrated a greater vulnerability to physical inactivity than CON since they after bed rest demonstrated a more severe degree of insulin resistance even though they were insulin resistant before hand.

GLP-1 inhibits glucagon secretion by affecting several cellular mechanisms

Y.Z. De Marinis¹, Q. Zhang², A. Salehi¹, L. Eliasson¹, P. Rorsman²¹Lund University Diabetes Centre, Dept of Clinical Sciences Malmö, Sweden,²Oxford Centre for study of Diabetes, Endocrinology, and Metabolism, University of Oxford, United Kingdom

Background and aims: Glucagon secretion is regulated by several agonists and antagonists and is dependent on the inactivation of voltage-dependent Na⁺-channels and influx of Ca²⁺ through N- and L-type Ca²⁺-channels. The incretin hormone GLP-1 inhibits glucagon secretion whereas it stimulates insulin secretion, making it an interesting candidate for new treatment of type 2 diabetes mellitus. The aim of this study was to investigate the cellular mechanism whereby GLP-1 inhibits whereas other cAMP-increasing agents, such as adrenaline, stimulate glucagon secretion.

Materials and methods: Glucagon secretion was measured on freshly isolated mouse islets and analysed using radioimmunoassay (RIA). The electrical properties of the A-cells such as ion channel currents, electrical activity and changes in membrane capacitance (to determine the exocytotic response) was measured on single A-cells using the perforated patch configuration of the patch clamp technique.

Results: We first investigated how the ability of GLP-1 to inhibit glucagon secretion is associated with membrane potential by measuring glucagon secretion at 1 mM glucose and increasing K⁺-concentration. At 4.5 mM K⁺ GLP-1 significantly inhibited glucagon secretion ($P < 0.001$; $n = 8$). At 15 mM K⁺ GLP-1 had no effect and at strongly depolarizing levels (70 mM) a small stimulation ($P < 0.05$; $n = 8$) was observed. However, at all K⁺ concentrations, glucagon secretion was significantly stimulated ($P < 0.001$) by other cAMP-increasing agents such as adrenaline (5 μ M) or forskolin (10 μ M). The inhibitory effect of GLP-1 was prevented by lowering extracellular K⁺ to 1.5 mM. Low concentrations of forskolin (10 nM) mimicked the inhibitory effect of GLP-1, suggesting that the inhibitory effect may be mediated by low cAMP levels whereas high concentrations stimulate release. In electrophysiological measurements on single A-cells, GLP-1 was found to reduce action potential amplitude from 37 ± 2 mV ($n = 4$) under control conditions to 18 ± 4 mV ($n = 4$; $P < 0.017$) but not inter spike time between the action potentials. Forskolin (10 μ M) did not affect the spike amplitude. At the level of exocytosis it was demonstrated, by measuring voltage-dependent changes in membrane capacitance, that forskolin, adrenaline and the cAMP-GEF2 agonist 8-Br-cAMPs all shift the voltage-dependence of exocytosis to a more negative potential, which do not occur in the presence of GLP-1. Thus, exocytosis occurs at much lower membrane potential than under control conditions using cAMP-increasing agents except for GLP-1.

Conclusion: We suggest that GLP-1 is unable to increase the cAMP-concentration in the A-cell to the same extent that other cAMP-increasing agents leading to inhibition of action potential amplitude, possibly via changing the inactivation properties of currents involved in A-cell action potential firing, and the inability to activate cAMP-GEF2 resulting in the observed failure to shift the voltage-dependence of exocytosis and reduced glucagon secretion.

Near normalisation of blood glucose improves the secretion of amylin during GLP-1 potentiation of glucose-induced insulin secretion in patients with type 2 diabetes

M. Asmar^{1,2}, P. Højberg², J. Holst¹, S. Madsbad²¹Department of Biomedical Sciences, University of Copenhagen,²Department of Endocrinology, Hvidovre Hospital, Denmark

Background and aims: Amylin is a 37-amino acid polypeptide produced in the pancreatic beta-cells, co-stored with insulin in the secretory granules and co-secreted with insulin on glucose stimulation. In type 2 diabetes mellitus, circulating levels of amylin decrease as amyloid deposits accumulate and β -cell function deteriorates. This study was undertaken to determine whether 4 weeks of near normalisation of blood glucose (BG) improves the secretion

of amylin during GLP-1 potentiation of glucose induced insulin secretion in type 2 diabetes mellitus.

Materials and methods: Nine obese patients with type 2 diabetes (T2DM) and poor glycaemic control (HbA1c 8.0 ± 0.4 %) were investigated before and after 4 weeks of near normalisation of BG using insulin treatment (mean BG 6.4 ± 0.3 mmol/l, HbA1c 6.6 ± 0.3 %). Nine matched healthy subjects were also studied. Amylin and C-peptide secretion were investigated before and after insulin treatment on two days using stepwise glucose infusions and infusion of saline or GLP-1 (1.0 pmol/kg/min), resulting in supraphysiological total GLP-1 concentrations of approximately 200 pmol/l.

Results: In T2DM, the AUC under the amylin curves during saline infusion, before and after near normalisation of BG, were 638 ± 103 and 726 ± 142 pM x min, p : NS. During GLP-1 infusion, the corresponding AUCs were 2450 and 4295 pM x min, $p = 0.004$. In the healthy subjects, the AUC was 4205 ± 352 pM x min during saline infusion and 7393 ± 439 pM x min during GLP-1 infusion, $p = 0.004$. The corresponding AUC under the C-peptide curves during the saline infusion in the T2DM patients before and after near-normalisation of BG were 124 ± 19 and 134 ± 16 nM x min, p : NS, and 268 ± 48 and 329 ± 47 nM x min, $p = 0.02$ during GLP-1 infusion. In the healthy subjects, the AUC was 267 ± 33 min during saline infusion and 454 ± 50 nM x min during GLP-1 infusion, $p < 0.001$. The ratios between TAUC amylin/TAUC C-peptide did not differ before and after insulin treatment in T2DM during saline infusion (0.51 % and 0.54%, respectively; p : NS.) but a significant difference was seen during the GLP-1 days, before and after insulin treatment (0.91 % before and 1.3 % after, $p = 0.004$). The ratios were higher on both GLP-1 days than on the saline days. In the healthy subjects, the corresponding ratios were 0.93 % during saline infusion and 2.7 % during GLP-1 infusion, p : NS. No significant difference was seen in the ratio during the saline and GLP-1 days in the healthy participants and during the GLP-1 day after insulin treatment in the T2DM.

Conclusion: These data imply that 4 weeks of near normalisation of blood glucose and a supraphysiological dose of GLP-1 enhances beta cell function, as estimated from the high circulating levels of amylin.

Insulin and exendin-4 stimulate proliferation of GLP-1-secreting cells

C.B. Miller¹, Q. Zhang¹, Å. Sjöholm²¹Karolinska Institutet, Research center, ²Karolinska Institutet, Internal medicine, Stockholm South Hospital, Stockholm, Sweden

Background and aims: Glucagon-like peptide-1 (GLP-1) is an incretin hormone, secreted from gut L-cells upon nutrient intake, and forms the basis for novel drugs against type 2 diabetes. Secretion of GLP-1 is impaired in type 2 diabetes. Glucagon, secreted from pancreatic α -cells, acts as the counterpart of insulin. Abnormalities in α -cell function contribute to hyperglycemia and insulin resistance in diabetes. Little is known about the influence of anti-diabetic drugs on α - and L-cell function and regeneration. The aim of this study was to investigate the long term impact of anti-diabetic agents on the proliferation of GLP-1- and glucagon-secreting cells and mechanisms underlying such effects.

Materials and methods: The GLP-1-secreting cell line GLUTag and glucagon-secreting α TC1-9 cells were cultured in DMEM media. Cell proliferation was evaluated by ³H-thymidine incorporation into DNA and by MTT assay after a 48 h incubation with the anti-diabetic agents.

Results: At a basal concentration of glucose (3 mM), insulin and the stable GLP-1 analogue Exendin-4 significantly increased proliferation of the GLP-1-secreting GLUTag cells, while not influencing proliferation of the glucagon-producing α TC1-9 cells. In contrast, metformin significantly inhibited proliferation of both GLUTag and α TC1-9 cells. Effects of the drugs on hormone secretion by these cells are now being investigated.

Conclusion: The present study shows that insulin and Exendin-4 significantly stimulate the proliferation of GLP-1-producing cells, whereas metformin does the opposite and also suppresses proliferation of glucagon-producing cells. The enhanced proliferation of GLUTag cells by Exendin-4 also suggests that GLP-1, secreted from these cells, may stimulate cell growth through a positive autocrine/paracrine feedback loop. Since serum GLP-1 levels are decreased in type 2 diabetic patients, the mitogenic stimulation of GLP-1-producing cells by insulin and Exendin-4 noted here suggests a novel beneficial long term effect of these antidiabetic drugs in clinical practice, i.e. by augmenting the incretin effect. Likewise, the inhibitory influence of metformin on the proliferation of glucagon-secreting cells may benefit diabetic patients

treated with this drug, as relative hyperglucagonemia contributes to impaired glycemic control in type 2 diabetes.

Down regulation of GIP receptor by hyperlipidaemia: possible contribution to impaired incretin effects in type 2 diabetes

G. Xu¹, R. Fan¹, X. Gu¹, X. Li¹, K. Li¹, R. Ma¹, H. Zhao¹, P. Tong¹, J. Chan¹, R. Laybutt²

¹Medicine and Therapeutics, The Prince of Wales Hospital, The Chinese University of Hong Kong, Hong Kong SAR, China, ²Diabetes and Obesity Research Program, Garvan Institute of Medical Research, St Vincent's Hospital, Sydney, Australia

Background and aims: Stimulation of insulin secretion by the incretin hormone, glucose-dependent insulinotropic peptide (GIP) has been found to be diminished in type 2 diabetes. We hypothesized that this impairment is due to a defect at the receptor level induced by the diabetic state. We have shown that hyperglycemia decreased expression of incretin receptors in β -cells associated with impairments of insulin secretion. In the present study we aim to examine the role of hyperlipidemia in the regulation of GIP receptor (GIP R) expression in pancreatic β -cells.

Materials and methods: Two insulin-secreting β -cell lines, MIN6 and INS-1E, were cultured in standard media supplemented with palmitate or oleate (both 0.4 mM coupled to 0.92% BSA) and RNA were extracted for analysis of GIP receptor expression. For in vivo experiments, islets isolated from *db/db* mice and pancreas from Zucker fatty rats were used to evaluate the expression of the incretin receptor.

Results: Gene expression levels of GIP R were significantly decreased in both insulin secreting cell lines after palmitate treatment for 24 hours, but were not changed with oleate treatment. *db/db* mice displayed higher blood glucose, plasma NEFA, and plasma triglyceride levels at 16 weeks of age compared with age-matched *db/+* (control) mice. Islets from hyperlipidemic *db/db* mice displayed a decrease in GIP R expression, with recovery when lipid levels were normalized by bezafibrate (Sigma), which selectively lowered plasma lipids. Hyperlipidemic Zucker fatty rats also displayed a decrease in GIP R protein expression in pancreatic β -cells by immunofluorescence staining with a GIP R specific antibody.

Conclusion: These data demonstrate that hyperlipidemia is associated with decreased GIP receptor expression and this decrease likely contributes to the impaired incretin effects found in diabetes.

GLP-1 is not a physiological mediator of glucose homeostasis in dogs

B.A. Aulinger¹, J. Heyl¹, C.T. Elfers¹, H.L. Rilo², D.A. D'Alessio¹

¹Division of Endocrinology and Metabolism, ²Department of Surgery, University of Cincinnati, United States

Background and aims: Glucagon-like-peptide 1 (GLP-1) is a gut peptide that plays a key role in the regulation of glucose homeostasis. GLP-1 is highly conserved across mammalian species and interference with the action of this peptide causes glucose intolerance in mice, rats and humans. Exendin-4 (Ex-4), an agonist of the GLP-1 receptor (GLP-1r), has become an effective drug for treatment of diabetes and acts primarily by enhanced insulin secretion, suppressed glucagon release and delayed gastric emptying in humans. Recent studies using canine models suggest that Ex-4 and GLP-1 maintain glucose homeostasis with only minimal changes of pancreatic hormone levels. The aim of this study was to determine the role of endogenous GLP-1 in postprandial glucose regulation in dogs.

Materials and methods: To test the effect of pharmacological levels of GLP-1r agonism Mongrel dogs weighing 11–14 kg underwent a mixed meal test (70 g sour cream with 25 g dextrose) after s.c. injection of either Ex-4 (10 μ g) or saline. For determination of gastric emptying D-xylose was added to the meal. On the morning of the test, fasted dogs were brought to the procedure room, and peripheral catheters were placed for infusions and blood draws. Fifteen min after giving either one of the treatments the dogs were fed and samples were taken for determination of glucose, insulin and D-xylose for 180 min thereafter. To investigate the role of endogenous GLP-1 the same meal test was done during infusion of the GLP-1r antagonist Exendin-9 (Ex-9) (750 pmol/kg/min) or saline. In another set of experiments insulin secretion during a 20 min hyperglycemic squarewave was compared when either GLP-1 (3 pmol/kg/min) or saline was given iv.

Results: Administration of Ex-4 before the meal resulted in profound blockade of gastric emptying measured by D-xylose appearance (AUC 22.0 ± 4.3 vs. 77.9 ± 3.2 mM \cdot min, $p < 0.001$). Postprandial blood glucose increased only moderately after Ex-4 treatment (basal 91, peak 103 mg/dl at 180 min), and there was no rise in plasma insulin. Saline treated dogs had typical postprandial glucose (95 to 122 mg/dl at 90 min) and insulin (35 to 131 pM at 90 min) profiles. Postprandial D-xylose, glucose or insulin levels did not differ between saline and Ex-9 treated animals, indicating that blockade of endogenous GLP-1 had no effect under these conditions. During fixed hyperglycemic conditions and either saline or GLP-1 infusion insulin levels did not differ, confirming a weak insulinotropic action of GLP-1 in dogs.

Conclusion: These findings suggest that dogs have a distinct pattern of GLP-1 actions. Pharmacologic GLP-1r agonism with Ex-4 had a marked effect to reduce gastric emptying and prevent a glycemic excursion. The failure of Ex-4 to stimulate insulin secretion in this setting was likely due to near normal glycemia, but limited insulinotropism mediated through the GLP-1r of dogs was evident during application of a dose of GLP-1 that is that is highly potent in humans. Importantly, blockade of the GLP-1r with Ex-9 suggests that GLP-1 secreted after our test meal did not affect gastric emptying, insulin secretion or glucose tolerance. These findings raise questions as to the physiological role of GLP-1 in dogs and suggest considerable variations of the incretin system across different species.

The twenty-four hour GIP responses are impaired in normoglycaemic men with the metabolic syndrome but not in men with type 2 diabetes

D.L. Goede¹, M.E. Tushuizen¹, J.J. Holst², R.J. Heine¹, M. Diamant¹

¹Endocrinology / Diabetes Centre, VU University Medical Centre, Amsterdam, Netherlands, ²Panum Institute, University of Copenhagen, Denmark

Background and aims: The incretins glucagon-like peptide (GLP)-1 and glucose-dependent insulinotropic polypeptide (GIP) are important in the regulation of the postprandial insulin response. Previous studies suggest that an impaired meal-induced GLP-1 response may contribute to the abnormal beta-cell secretion function as observed in patients with impaired glucose metabolism and type 2 diabetes mellitus (T2DM). However, the findings regarding GIP secretion in relation to T2DM and pre-diabetic states are as yet non conclusive. We studied the 24-h profiles of GLP-1 and GIP in males with the metabolic syndrome (MetS), in whom glucometabolic abnormalities were excluded by an oral glucose tolerance test (OGTT), in age- and BMI-matched males with T2DM and healthy males.

Materials and methods: We monitored the 24-h profiles of plasma glucose, insulin, triglycerides (TG), GIP and GLP-1 in 18 T2DM (mean \pm SD age 56 ± 5 yrs, BMI 33 ± 4 kg/m², HbA1c $7.0 \pm 1.0\%$), 14 MetS (age 56 ± 6 yrs, BMI 31 ± 3 kg/m², HbA1c $5.9 \pm 0.4\%$, fasting plasma glucose 5.5 ± 0.4 mmol/l, 2h-OGTT glucose 6.1 ± 0.8 mmol/l) and 18 healthy males. During day-time, subjects received three identical standardized high-fat mixed meals (900 kcal; 50g fat, 75g carbohydrate, 35g protein) as breakfast (t=0), lunch (t=4 h) and dinner (t=8 h), thus mimicking real-life situation. Blood samples were collected at 9 time-points throughout the 24-h period, at preset intervals. Patients were treated with diet and/or metformin and/or sulphonylurea drugs.

Results: T2DM versus MetS males had higher HbA1c, FPG and HOMA-IR, but similar BMI, waist, blood pressure, fasting TG and insulin. As expected, plasma 24-h AUC glucose, insulin and TG were increased in T2DM relative to controls ($P < 0.05$), but 24-h AUC TG and insulin were comparable with MetS ($P = 0.93$ and $P = 0.56$, respectively). Twenty-four hour AUC glucose was similar for the MetS and control subjects ($P = 0.38$). Fasting incretins and 24-h AUC GLP-1 did not differ among the 3 groups, whereas 24-h AUC GIP was significantly lower in MetS compared to T2DM and controls (1039 ± 600 vs 1689 ± 664 and 1420 ± 113 , respectively, $P = 0.01$). No significant differences were detected for 24-h AUC GIP between T2DM and controls ($P = 0.17$).

Conclusion: In well-controlled T2DM males, 24-h postprandial GLP-1 and GIP responses were comparable with healthy subjects, whereas in MetS without glucometabolic abnormalities, 24-h GIP secretion was significantly impaired. Since disruption of GIP signalling reportedly prevented diet-induced obesity in mice, the lower GIP secretion in men with the MetS may be an adaptation to insulin resistance and obesity. This hypothesis, however, needs to be confirmed in humans.

Reduced incretin effect in obese subjects with normal glucose tolerance as compared to lean control subjectsF.K. Knop^{1,2}, K. Aaboe¹, T. Vilsbøll¹, S. Madsbad³, T. Krarup¹, J.J. Holst²¹Department of Internal Medicine F, Gentofte Hospital, ²Department of Biomedical Sciences, University of Copenhagen, ³Department of Endocrinology, Hvidovre Hospital, Copenhagen, Denmark

Background and aims: The incretin effect (the enhancement of glucose-induced insulin secretion after oral glucose tolerance test (OGTT) compared to isoglycaemic intravenous (iv) glucose infusion) is markedly reduced in patients with type 2 diabetes mellitus (T2DM). Data support the notion that this deficiency is a consequence of the diabetic state. However, the impact of insulin resistance on the incretin effect in obese individuals who uphold a normal glucose tolerance (NGT) despite their insulin resistant state remains to be elucidated.

Materials and methods: The incretin effect was measured over 2 days by means of 4-hour OGTT (50 g of glucose) and isoglycaemic iv glucose infusion in four groups of volunteers: 1) Eight obese patients with T2DM (HbA_{1c}: 7.2 (5.9–10.2)% (mean(range))); BMI: 37 (35–41) kg/m²); 2) Eight lean patients with T2DM (HbA_{1c}: 6.8 (5.7–8.7)%; BMI: 24 (22–25) kg/m²); 3) Eight obese subjects with NGT (HbA_{1c}: 5.6 (5.4–5.8)%; BMI: 33 (35–38) kg/m²); and 4) Eight lean healthy subjects (HbA_{1c}: 5.6 (5.1–5.8)%; BMI: 23 (20–25) kg/m²).

Results: Isoglycaemia during the two glucose administration forms was obtained in all 4 groups. In patients with T2DM insulin resistance according to the homeostasis model assessment (HOMA) amounted to 7.7 ± 1.0 (mean \pm SEM) (obese) and 2.2 ± 0.6 (lean), $P < 0.05$; and in subjects with NGT HOMA amounted to 3.2 ± 0.6 (obese) and 1.1 ± 0.2 (lean), $P < 0.05$. As expected the incretin effect ($100\% \times (\text{AUC}_{\text{ins,OGTT}} - \text{AUC}_{\text{ins,iv}}) / \text{AUC}_{\text{ins,OGTT}}$) was significantly ($P < 0.05$) reduced in patients with T2DM (obese: $7 \pm 7\%$ (mean \pm SEM); lean: $29 \pm 8\%$; $P = \text{NS}$) as compared to subjects with NGT (obese: $41 \pm 4\%$; lean: $53 \pm 4\%$; $P < 0.05$).

Conclusion: Interestingly, as noted above, the incretin effect was significantly higher among lean insulin sensitive subjects with NGT as compared to obese insulin resistant subjects with equivalent glucose tolerance. This suggests that the incretin effect attenuates alongside the development of obesity-related insulin resistance thereby reflecting a very early pathophysiological trait in the development of T2DM.

Serum active ghrelin levels in hypothyroidismN.B. Tutuncu¹, M. Kulaksizoglu², S. Kulaksizoglu³¹Endocrinology and Metabolism, Baskent University Faculty of Medicine, Ankara, ²Endocrinology and Metabolism, Baskent University Faculty of Medicine, Konya, ³Biochemistry, Baskent University Faculty of Medicine, Konya, Turkey

Background and aims: Ghrelin is a 28 aminoacid peptide predominantly produced by the stomach oxyntic-XA like cells. Ghrelin has been discovered as a natural ligand of the growth hormone receptor but has effects on energy metabolism, food intake, gastric acidity and motility also on pancreas function. Alterations in thyroid function are associated with a large variety of symptoms, including changes in body weight and food intake. Unexpectedly, ghrelin levels in hyperthyroidism is found to be decreased. In the case of hypothyroidism controversial results have been reported. The aim of this study is to evaluate ghrelin levels in hypothyroidism.

Materials and methods: 30 hypothyroid patients were evaluated with 23 age, sex, body mass index matched controls. Fasting plasma TSH, fT4, fT3, anti-thyroglobulin, anti-thyroidperoxidase, total-LDL-HDL cholesterol, triglyceride, c-reactive protein, gastrin, insulin, glucose and ghrelin levels were studied. Ghrelin was evaluated with Linco active ELISA KIT. Aprotinin SIG-MA was added to samples. Samples were centrifugated at $+4^\circ\text{C}$ 1500g for 15 minutes. They were kept -40°C till the time for evaluation.

Results: Ghrelin levels were significantly elevated in the hypothyroid patients compared to the control group. After euthyroidism was achieved, ghrelin levels were found to be similar with the healthy controls. Ghrelin levels correlated negatively with fT3 and fT4 and positively with HDL levels.

Conclusion: Ghrelin could be the reason for weight gain and increased adiposity in hypothyroidism. Whether circulating ghrelin plays an important role in feeding behaviour and energy homeostasis is not still known. However, our results indicate that active ghrelin may have some critical actions in hypothyroidism induced weight gain. Further studies are needed to clarify the exact mechanism.

PS 047 Animal models: altered glycaemia and insulin resistance

639

Regulation of glycaemia in the absence of glucose production by the liverF. Rajas^{1,2}, E. Mutel^{1,2}, A. Stefanutti^{1,2}, G. Mithieux^{1,2}¹Unité 855, Inserm, ²Université Claude Bernard Lyon 1, IRF62, Lyon, France

Background and aims: Only three organs of the body - the liver, kidney and small intestine - have the capacity to release endogenous glucose, because they are the only tissues to express glucose-6-phosphatase (G6Pase). This enzyme catalyzes the last step common to glycogenolysis and gluconeogenesis, i.e., the hydrolysis of glucose-6-phosphate into glucose and inorganic phosphate. The inherited deficiency of the catalytic subunit (G6PC) of this enzyme (glycogen storage disease type 1a) underlies serious hypoglycaemic episodes in the post-absorptive period. The patients cannot use hepatic glycogen stores to produce glucose and develop hepatomegaly and steatosis. Up to now, hepatic glucose production is very often assimilated to endogenous glucose production. However, in some physiological states, renal and intestinal production of glucose might represent more than half of total production. In this work, we raised the question of the regulation of glycaemia in the absence of glucose production by the liver.

Materials and methods: We generated liver-specific G6Pase knockout mice (g6pc^{-/-}) using an inducible CRE-lox strategy. G6Pase expression was analysed in the liver, kidney and intestine of wt (g6pc^{+/+}), heterozygote (g6pc^{+/-}) and g6pc^{-/-} mice, ten days after induction of the liver g6pc deletion. Glycogen, G6P and triglyceride levels were determined from liver homogenates. The glycaemia of mice was followed during prolonged fasting (45h).

Results: Ten days after hepatic g6pc deficiency, G6Pase activity was inhibited by more than 95% in the liver of g6pc^{-/-} mice compared to wt mice (0.3 ± 0.1 vs 10.7 ± 0.7 U/g of tissue, $p < 0.01$). The livers of g6pc^{-/-} mice rapidly accumulated glycogen (23.9 ± 1.2 vs 10.1 ± 0.8 mg/g of tissue in wt mice, $p < 0.01$) and glucose-6-phosphate (1.4 ± 0.01 vs 0.4 ± 0.03 $\mu\text{mol/g}$ in wt mice, $p < 0.01$). These mice also developed hepatomegaly and liver steatosis, accumulating triglycerides (23.4 ± 1.4 versus 8.4 ± 1.1 mg/g of tissue in wt mice, $p < 0.01$), after 5 weeks of hepatic G6Pase deficiency. It is worth noting that hepatic g6pc^{-/-} mice were viable while mice with total inactivation of Glc6Pase die if not supplemented with glucose injection. Despite the absence of hepatic glucose production, the glycaemia of g6pc^{-/-} mice was similar to that of wild type mice in the fed state. During fasting (6 to 45 h), the lowering of glycemia was slightly more rapid in g6pc^{-/-} mice than in wt mice (90 ± 10 mg/dL vs 150 ± 13 mg/dL at 6 h), likely because of the lack of liver glycogenolysis. However, no significant difference was observed at a later time, between 12 and 45 h of fasting. This might be a consequence of the induction of an extra-hepatic glucose production. It was noteworthy that two groups of g6pc^{-/-} mice could be distinguished. In the first group, mice exhibited an increase of intestinal G6Pase activity, by two fold (3.8 ± 0.8 vs 1.9 ± 0.3 U/g of tissue in wt mice, $p < 0.01$), whereas renal G6Pase activity was unchanged (11.6 ± 0.5 vs 12.2 ± 0.5 U/g of tissue in wt mice). In the second group, mice exhibited an induction of renal G6Pase activity (17.3 ± 1.1 vs 12.2 ± 0.5 U/g of tissue in wt mice, $p < 0.01$), whilst intestinal G6Pase activity was unchanged (1.4 ± 0.2 vs 1.9 ± 0.3 U/g of tissue in wt mice).

Conclusion: These data suggest that: 1) glucose production by the liver is essential for the regulation of glycemia during the transition from the post-prandial to the post-absorptive period; 2) glucose production by the kidney and the small intestine are sufficient for the maintenance of glycemia during fasting.

ERK1 deficiency improved the insulin resistance of the obese ob/ob miceJ.-F. Tanti¹, J. Jager¹, V. Corcelle¹, T. Grémeaux¹, K. Laurent¹, G. Pages²,J. Pouyssegur², Y. Le Marchand-Brunel¹, R. Burcelin³, F. Bost¹¹Inserm, INSERM U895, Nice, ²Cnrs, CNRS UMR 6543, Nice, ³Inserm, INSERM U 858, Toulouse, France

Background and aims: Insulin resistance is a main feature of obesity and type II diabetes. Activity of MAP Kinase family members, including ERK, is increased in adipose tissue from obese and type II diabetic animals and patients. Strong evidences suggest that activation of MAPK is implicated in the

down-regulation of insulin signaling and action in insulin resistance state. We have shown that mice lacking ERK1 are resistant to high fat diet induced obesity and protected from insulin resistance due to a decrease in adipogenesis and a higher post-prandial metabolic rate. To investigate the role of ERK1 in the development of insulin resistance in obese mice, we generated leptin-deficient mice (*ob/ob*) invalidated for ERK1 (*ob/ob-erk1-/-*).

Materials and methods: *Ob/ob* mice lacking erk1 (*ob/ob erk1-/-*) was generated by crossing *ob/+erk1-/-*. The mice were studied at 12 weeks of age. Insulin sensitivity was investigated by glucose tolerance test and hyperinsulinemic euglycemic clamp. Genes expression was measured by real-time PCR.

Results: We found that *ob/ob-erk1-/-* mice remained as obese as *ob/ob* mice but their fed glycemia is markedly reduced (*ob/+* 160 mg/dl, *ob/ob* 326 mg/dl, *ob/ob erk1-/-* 200mg/dl). Glucose tolerance test showed an improved insulin sensitivity of *ob/ob-erk1-/-* mice. Using the hyperinsulinemic euglycemic clamp, we showed that glucose infusion rate (GIR) is increased by 50% in *ob/ob erk1-/-* mice compared to *ob/ob* mice (26.29 vs 17.47 mg/kg/min) and that glucose uptake in muscles of *ob/ob erk1-/-* mice is increased and more specifically in glycolytic muscles. We found that expression of inflammatory markers (TNFalpha, PAI-1 and IL-1beta) and of lipogenic genes are decreased in visceral adipose tissue of *ob/ob-erk1-/-* mice. Further, the level of circulating free fatty acids measured at the end of the clamp is 35% lower in the *ob/ob erk1-/-* mice compared to the *ob/ob* mice (12.53 vs 19.41 mg/dl) suggesting that the anti-lipolytic effect of insulin in adipose tissue is improved. We also demonstrated that *ob/ob-erk1-/-* are partially protected from liver steatosis with a reduction in liver triglycerides content (*ob/+* 2.10, *ob/ob* 119.92, *ob/ob erk1-/-* 64.04 mg/g of liver) and a reduction in acetyl-CoA carboxylase expression (*ob/+* 1.16 AU, *ob/ob* 5.05 AU, *ob/ob erk1-/-* 3.75 AU).

Conclusion: Our data suggest that the specific targeting of erk1 could protect obese mice against insulin resistance and liver steatosis by improving adipose tissue inflammation and by an increase in muscles glucose uptake. New pharmacological strategy that target ERK pathway and more specifically ERK1 could thus be of particular interest to fight obesity and insulin resistance.

High fat diet modifies the protective effects of adiponectin overexpression on streptozotocin-induced diabetes in transgenic mice

S. Ait El Mkaadem¹, R. Attoua¹, S. Zouaoui¹, L. Monnier¹, S.M. Brichard², F. Grigorescu¹

¹Molecular Endocrinology (EA4188), University of Montpellier 1, IURC, Montpellier, France, ²Endocrinology and Metabolism Unit, University of Louvain, Brussels, Belgium

Background and aims: Adiponectin (ApN) is an adipokine which plays a crucial role in glucose homeostasis and activation of vascular endothelial cells. Indeed, its levels are decreased in insulin-resistant states such as type 2 diabetes and metabolic syndrome. We recently generated a transgenic (Tg) mouse model overexpressing full-length ApN and discovered that Tg mice on standard diet (STD) are protected from streptozotocin (STZ)-induced diabetes. In the hypothesis that this protection was linked to the insulin-sensitizing effects of ApN, this study was aimed to explore the effects of ApN on diabetes under conditions of high fat diet (HFD).

Materials and methods: Tg and wild type (WT) mice (n = 5-9/group) were fed either a STD or a HFD and received multiple ip injections of low doses of STZ. Induction and duration of diabetes were followed until 8 weeks by measurements of glucose levels. Glucose intolerance was determined by ip glucose tolerance test (ipGTT) while insulin sensitivity was determined by insulin tolerance test (ITT). For molecular analysis, mice were sacrificed, tissues removed 5 min after insulin stimulation (5U) and proteins activation analyzed by immunoblotting using phospho-specific antibodies.

Results: Under STD conditions, STZ treatment induced progressive hyperglycemia in WT mice reaching in the fed state 350 mg/dl at 8 weeks, while glycemia of Tg mice remained significantly lower (< 200 mg/dl, P < 0.001). Similar differences were observed for fasting glycemia (217 ± 30.7 for WT vs 126.4 ± 12.5 mg/dl for Tg, P < 0.02). The ITT showed that WT mice developed severe insulin-resistance after STZ treatment while Tg mice showed extreme insulin-sensitivity. Under HFD, the protective effect of ApN on STZ-induced diabetes persisted on fasting glycemia with significant differences at 7 weeks between WT and Tg mice (266.8 ± 21 vs 162.6 ± 8.1 mg/dl, respectively, P < 0.0001). However, no difference was observed on glycemia in the fed state, which increased similarly (~ 230 mg/dl) in WT and Tg mice after STZ treatment. The ipGTT revealed that HFD induced glucose intolerance in WT animals. STZ treatment aggravated the glucose intolerance of WT and

Tg mice. However, glycemia at 2h of Tg mice dropped to 320 mg/dl while that of WT remained > 440 mg/dl. Molecular mechanisms involved in the protective effect of ApN under HFD are still unknown, but data obtained on hepatic tissue of mice under STD showed that in parallel to a ~2-fold increase of AMPK activity (Thr172), phosphorylation of Ser 632 of IRS-1 (a known negative regulatory mechanism of insulin action) was decreased after insulin stimulation in Tg mice when compared to WT diabetic animals. This potentialization of insulin signaling manifested by the ~3-fold enhanced Akt activity (Thr308) was explained by major reduction of phosphorylation on Thr389 of p70S6K in Tg mice.

Conclusion: Chronic over-expression of ApN exerts protective effects against experimental induced diabetes by modulating peripheral insulin resistance, although distinct effects were observed pending on fat content of the diet. These data will give a new insight into the molecular mechanism of cross-talk between ApN and insulin pathways *in vivo* and potential use of ApN as therapeutic agent for diabetes and related complications.

Effect of food protein on the repartition of endogenous glucose production among gluconeogenic organs, and on its sensitivity to insulin

B. Pillot, M. Soty, A. Gautier-Stein, C. Zitoun, G. Mithieux

Faculté de Médecine Laennec, Inserm U855 / UCB Lyon1, Lyon, France

Background and aims: Food proteins induce the gene expression of intestinal and renal gluconeogenic enzymes in rats. However, a normal glycemia is maintained in protein-fed rats. Furthermore, some parameters of glucose homeostasis are improved in type 2 diabetic patients fed with protein-enriched diet (PED). The aim of our study was to determine the impact of PED on the repartition of endogenous glucose production (EGP) among gluconeogenic organs and to test the effects of this diet on insulin sensitivity of EGP in rats.

Materials and methods: In rats fed on PED for 3 days (50% proteins vs. 17% in normal starch-enriched diet (SED)), we: 1) studied the expression of hepatic and renal gluconeogenic enzymes (glucose-6 phosphatase and phosphoenolpyruvate carboxykinase); 2) quantified renal glucose release by a combination of glucose tracer dilution and arterio-venous glucose balance; 3) estimated insulin action on EGP (insulin perfusion at 240 pmol/h) and on peripheral glucose utilization (insulin perfusion at 2880 pmol/h), using hyperinsulinemic euglycemic clamps; 4) quantified the hepatic glycogen content after the clamp.

Results: Glucose-6 phosphatase and phosphoenolpyruvate carboxykinase were markedly increased in the kidney, but not in the liver in PED-fed rats. The renal glucose release was strongly increased in PED-fed rats (26.0 ± 4.7 μmol/kg/min vs. 12.5 ± 1.9 μmol/kg/min in SED-fed rats) and represented about 40% of EGP, compared to 17% in SED-fed rats. However, EGP was similar in both groups. Hyperinsulinemic euglycemic clamps showed a stronger EGP suppression with PED (about -50% vs. -30% in SED-fed rats). There was no difference in glucose utilization at either dose of insulin infused. Moreover, hepatic glycogen content was markedly higher in PED-fed rats than in SED-fed rats (18 ± 3.5 vs. 4.7 ± 3.2 mg/g of tissues) at the end of the clamp.

Conclusion: Added to previous data relating to glucose production by the small intestine, we conclude that protein feeding induces a redistribution of glucose fluxes among gluconeogenic organs. This is accompanied by an improvement of insulin sensitivity of suppression of EGP, likely dependent on suppression of hepatic glucose production, linked to a sparing of hepatic glycogen storage. These results may explain at least in part the spectacular improvement of glucose homeostasis observed in type 2 diabetic patients, upon increasing the proportion of protein in their diet.

The chronological difference in the evolution of tissue insulin resistance

X.J. Li¹, J.L. Wang¹, Y.H. Wu¹, J. Li¹, X.W. Ran¹, X.X. Zhang¹, Y.C. Wang²

¹Endocrinology, ²Psychology, West China Hospital, Chengdu, China

Background and aims: It has well been documented that insulin resistance (IR) features notable tissue selectivity and heterogeneity. Less attention, however, has been paid to the chronological related events of different tissues in the evolution of IR. Recently, we and others showed that IR can be induced

Table. The dynamic changes of IRC in rat islets in both groups over 12 wks.

	1W	2W	4W	6W	8W	12W
NC	1.37±0.53	1.25±0.46	1.20±0.49	1.44±0.70	1.46±0.37	1.47±0.44
HF	0.95±0.28*	0.13±0.13**	0.57±0.36**	0.85±0.26**	0.48±0.33**	0.66±0.34**

in pancreatic α and β cells i.e. “islet cell insulin resistance” in high-fat-fed rats. This study is designated to observe the chronological difference of the appearance of IR in diverse tissues, with pancreatic islet, in particular.

Materials and methods: 60 Wistar rats were randomly allocated into high-fat fed (HF) and regular chaw fed control groups (NC). Rats in both groups were sacrificed and tissues i.e., pancreas, liver, m. selesus and epididymis fat pads were obtained at 1, 2, 4, 6, 8 and 12wk. respectively, for detecting insulin receptor (IRC) and IRS-1 protein and phosphorylation of their protein tyrosine kinase (PTK-P). (Western blotting and immunoprecipitation.) FPG, insulin (Fin), TG, FFA and Ch. were also measured at each occasion. HOMA-IR, ISI, were calculated by Fin and FPG.

Results: Significant increase of TG (2.34 ± 0.62 vs. 1.74 ± 0.4 mmol/L, $P<0.05$) at 6 wk, and of Fin (1.68 ± 0.35 vs. $1.16\pm0.08\mu\text{u/ml}$, $P<0.05$), FFA (785.5 ± 207.9 vs. $573.8\pm148.5\mu\text{mol/L}$, $P<0.05$), and Ch at 8 wk in HF rats vs. NC was found. FPG remained unchanged over 12 wk (4.88 ± 0.54 vs. 5.10 ± 0.45 mmol/L), ISI remarkably impaired at 12 wk in HF vs. NC (1.09 ± 0.02 vs. 0.17 ± 0.02 , $P<0.05$), whereas HOMA-IR was significant higher in HF than in NC (0.46 ± 0.19 vs. 0.21 ± 0.02 , $P<0.05$) at the same time. The following table shows the sequential changes of IRC in islets in both groups over the 12 wks.

* vs. NC, $P<0.05$, ** vs. NC, $P<0.01$. Similar changes of IRC PTK-P and IRS-1 in islets were found in which both variables were notable lower in HF vs. NC, occurring in the early stage (2wk), and remained low during the course of IR (123989 ± 26010 vs., 684142 ± 86844 and 0.34 ± 0.32 vs. 1.24 ± 0.7 , $P<0.01$, 2wk; and 118049 ± 40613 vs. 799344 ± 281085 , and 0.33 ± 0.29 vs. 1.33 ± 0.49 , $P<0.01$, 12 wk). However, significant decline of IRS-1-P did not occur until 12 wk. Similar changes of IRC were also found in liver (1.11 ± 0.22 vs. 1.59 ± 0.17 , $P<0.05$, 1wk, and 1.05 ± 0.32 vs. 1.63 ± 0.49 , $P<0.01$, 12 wk) with parallel changes of IRC PTK-P, IRS-1, and IRS-1-P. The appearance of muscle IRC reduction was delayed compared with islet and liver (0.68 ± 0.43 vs. 1.30 ± 0.44 , at 6wk), although changes of IRC-P, IRS-1, and IRS-1-P were similar to the former tissues. Fat IRC decline occurred at 12wk (0.57 ± 0.02 vs. 0.80 ± 0.19 , $P<0.05$), which was much more delayed than the above 3 tissues with no any meaningful change of IRC-PTK-P at 12wk.

Conclusion: Our dynamic observations showed that chronological differences exist in the genesis of IR in diverse tissues, and that islet cell IR and hepatic IR may precede peripheral IR. Further studies are needed to elucidate the implication of the phenomenon.

Regulation of liver glucokinase activity in intact normal rats and in rats with dietary-induced insulin resistance

L.M. Massa, J.J. Gagliardino, F. Francini

CENEXA Center of Experimental and Applied Endocrinology, National University of La Plata, Argentina

Background and aims: To study the regulation of liver glucokinase activity by its gene transcription, protein expression, cellular translocation and 6-phosphofructo-2-kinase/fructose-2,6-biphosphatase (PFK2), in rats with insulin resistance induced by a fructose-rich diet (FRD).

Materials and methods: Glycemia (GOD-PAP), triglyceridemia (enzymatic assay), insulinemia (RIA), GK activity (spectrophotometry), GK and PFK2 protein and gene expression (Western blot and real-time PCR) were measured in liver of control and FRD rats.

Results: FRD rats had significantly higher values of glycemia, insulinemia, and triglyceridemia. GK activity in the cytosolic fraction (CF) of FRD animals was also higher than in the control group (360 ± 9.9 vs. 100 ± 3.8 %; $P < 0.001$). GK protein level in CF was higher, though not significantly, in FRD animals (116 vs. 100%). On the other hand, GK activity was higher in the digitonin nuclear fraction (DNF) of C rats [69 ± 3.4 vs. 31 ± 1.2 % of total activity (DNF+CF); $P < 0.001$]. Opposite results were obtained in FRD animals, i.e., GK activity was lower in DNF than in CF [14 ± 1.1 vs. 82 ± 2.3 % of total activity (DNF+CF); $P < 0.001$]. GK transcription level was similar in both groups, while PFK2 gene expression was 4-fold higher in FRD animals. PFK2 protein expression in CF was 5-fold higher in FRD and its immunological blockage decreased significantly GK activity (70% decrease).

Conclusion: The regulatory effect of GK compartmentalization and PFK2 role upon liver GK activity reported *in vitro* fully operate in normal intact animals. According to the results of the immunological blockade of PFK2, in this model this enzyme would be the main responsible for the increase in GK activity. Thus, these two mechanisms (cellular translocation and PFK2 interaction) would participate in the adaptative response of liver metabolism to insulin resistance to maintain normal glucose homeostasis. These results provide a new potential site for therapeutic interventions in type 2 diabetes.

A high cholesterol diet increases the association between caveolae and insulin receptor in rat liver

M. Hahn-Obercyger¹, L. Graeve², Z. Madar¹

¹Institute of Biochemistry, Food Science and Nutrition, The Hebrew University of Jerusalem, Rehovot, Israel, ²Institute of Biological Chemistry and Nutrition, University of Hohenheim, Stuttgart, Germany

Background and aims: Caveolin-1, a component of caveolae, regulates signaling pathway compartmentalization by interacting with tyrosine kinase receptors and their substrates. Cholesterol is an essential structural component of lipid rafts and caveolae. Perturbations in caveolae lipid composition have been shown *in vitro* to displace proteins from lipid microdomains, thereby altering their functionality and subsequent downstream signaling. The role of caveolin-1 in insulin receptor (IR) signaling has been widely investigated *in vitro* in 3T3-L1 adipocyte cells. However, *in vivo* experiments investigating this connection in liver tissue have not been carried out. This may be due to the fact that the liver contains a lower level of caveolin-1. Nevertheless, it has been shown that caveolin-1 is located in liver parenchymal cells, with negligible levels detected in endothelial cells. The discovery that the IR is compartmentalized into caveolae introduced a new framework for the understanding of the molecular mechanisms whereby exposure to a high cholesterol diet may alter insulin signaling. Therefore, the aim of this study was to determine whether a high cholesterol diet modulates the hepatic caveolar lipid environment and IR microdomain localization and function *in vivo*.

Materials and methods: Twenty-four Sprague-Dawley rats were fed with a standard diet or a high cholesterol diet (1%) for 21 days. Half animals in each group received insulin (10U, i.p.) while the remainder received a saline injection. After 30 min liver tissue was removed and mRNA (RT-PCR) and protein (Western blot and Immunoprecipitation) analysis in total homogenate and lipid rafts fractions were performed.

Results: In comparison to a standard diet, a diet rich in cholesterol significantly altered liver caveolae by increasing both caveolin-1 (66%, $p<0.05$) and caveolin-2 (55%, $p<0.05$) expression while caveolin-1 mRNA levels were reduced. Concomitantly, a 25% increase in localization of the caveolae-resident signaling protein IR was observed. The distribution (see figure) of caveolar and non-caveolar phosphorylated IR was unaffected but insulin-induced IR activation was significantly enhanced following consumption of the high cholesterol diet (120%, $p<0.001$). Insulin stimulation failed to induce tyrosine phosphorylation of caveolin-1 in hypercholesterolemic rats.

Conclusion: It has been demonstrated, for the first time, that a high cholesterol diet can markedly alter protein composition of liver caveolae microdomains. These findings suggest a mechanism by which a high cholesterol diet altered caveolin-1 expression *in vivo* accompanied by altered IR localization and activity.

Insulin receptor localization in liver caveolae of hypercholesterolemic rats. Distribution of IR in caveolar and non-caveolar fractions in liver tissue of hypercholesterolemic rats were compared with control and rats treated with insulin prior to the liver removal. The results (n=3) were expressed as percents of total protein. Data represent Mean + SE

Effects of aging and calorie restriction on rat skeletal muscle glycogen synthase and glycogen phosphorylase

M. Montori-Grau¹, R. Minor², C. Lerin³, J. Allard², C. García-Martínez¹, R. de Cabo², A.M. Gómez-Foix¹

¹Bioquímica i Biologia Molecular, Universitat de Barcelona, Spain,

²Laboratory of Experimental Gerontology, National Institute on Aging,

Baltimore, United States, ³Research Division, Joslin Diabetes Center, Boston, United States

Background and aims: Aging in skeletal muscle is associated with loss of metabolic competences and glucose tolerance. Calorie restriction (CR) has been shown to prevent the age-associated impairment of glucose tolerance and metabolic functional decline of muscle tissue. Here we studied age-associated changes in glycogen metabolizing enzymes and the effects of CR, in oxidative soleus (SOL) and glycolytic tibialis anterior (TA) rat muscle.

Materials and methods: Muscle glycogen synthase (GS) and glycogen phosphorylase (GP) total enzyme activity, activity ratio, immunoblotted protein and mRNA levels have been examined as well as mRNA levels of glycogen-targeting protein phosphatase 1 subunits PTG and G_m/R_{GL} in old (24-month) compared to young (6-month) rats maintained in a normal or CR diet.

Results: GS activity and immunoblotted protein levels, but not muscle GS mRNA, were lower in SOL and TA in 24-month- compared to 6-month-old rats, maintained in a normal diet. GS activity ratio was also reduced, more in SOL than in TA, and this was correlated to a decrease in PTG mRNA levels. CR prevented the decline in GS activity and protein levels, in both SOL and TA and prevented the inactivation of GS and raised PTG mRNA levels, more in SOL than in TA. GP activity, but not muscle GP mRNA levels, was reduced in SOL of 24-month- compared to 6-month-old rats, but preserved in TA. Immunoblotted GP protein content changed inversely to GP activity in response to aging and muscle-type. GP activity ratio was considerably reduced in 24-month-old rats in TA only. CR did not prevent the decline in GP activity or the rise in GP protein in SOL, but it did prevent the inactivation of GP in TA.

Conclusion: A reduction in both GS and GP activity was observed in SOL in old (24-month) compared to young (6-month) rats, whereas in TA GS also was decreased, but GP was maintained. GS was inactivated in SOL and TA and GP was inactivated in TA alone. CR prevented the age-associated reduction in muscle GS activity/protein and the inactivation of GS and GP.

Induction of acute beta cell lipotoxicity in non-diabetic subjects genetically predisposed to type 2 diabetes mellitus

M. Mathew, P. Kumar, R. Ali, A. Gastaldelli, S. Wang, K. Cusi
Diabetes/Medicine, UTHSCSA, San Antonio, United States

Background and aims: Loss of first phase (0-10 min.) insulin secretion in response to intravenous glucose precedes the development of type 2 diabetes mellitus. We have previously shown a similar loss in first phase insulin secretion by a chronic low-dose lipid infusion in FH+ subjects, suggesting that it may be a marker for susceptibility to type 2 diabetes mellitus. However, the effect of an acute lipid infusion on insulin secretion has not been carefully studied in non-diabetic genetically predisposed subjects. To this end, we studied the effect/time-course of a 4-hour lipid infusion on acute glucose-stimulated insulin release (AIR 0-10 min.) in 20 lean subjects, divided into 3 groups well matched for age/BMI/ethnicity based on a positive (FH+) or negative (controls) family history of type 2 diabetes mellitus in first degree relatives, as well as on a screening OGTT: 1) 7 FH+ with IGT (FH+IGT) (age = 51 ± 3 yr, body mass index (BMI) = 27.3 ± 0.9 kg/m², fasting plasma glucose = 108 ± 2 mg/dl); 2) 7 FH+ with normal glucose tolerance (FH+NGT) (age = 36 ± 8 yr, BMI = 26.3 ± 1.1 kg/m², fasting plasma glucose = 93 ± 2 mg/dl) and 3) 6 controls with NGT (age = 47 ± 4 yr, BMI = 27.1 ± 1.9 kg/m², fasting plasma glucose = 95 ± 2 mg/dl).

Materials and methods: Patients were admitted twice to the research unit (GCRC). After an overnight fast, they received an infusion of either normal saline (SAL) or lipid (Liposyn III at 90 ml/h) for 4 hours and the time-course of AIR (0-10 min. C-peptide AUC) was assessed at 60 min. (AIR1), 120 min. (AIR2) and 240 (AIR3) min. following a 0.3 gram per kilogram glucose bolus. Glucose, insulin and FFA were also measured.

Results: Fasting plasma glucose was higher in FH+IGT vs. FH+NGT and controls ($p < 0.03$), but post-bolus glucose levels were similar among the 3 groups (AIR1, 2 and 3). Compared to controls, FH+IGT and FH+NGT were insulin resistant as calculated by the Matsuda index derived from the screening oral glucose tolerance test. During SAL, compared to controls, AIR in FH+IGT was significantly reduced by 40%, 47% and 25% for AIR1, AIR2 and AIR3, respectively ($p < 0.1-0.02$) and also in FH+NGT (25%, 21% and 34% for AIR1, AIR2 and AIR3, respectively ($p < 0.1-0.001$). Lipid infusion did not impair insulin secretion in controls, but markedly reduced AIR1, 2 and 3 in FH+IGT by 75%, 54% and 33% ($p < 0.02-0.04$ vs. SAL and $p < 0.05-0.001$ vs. controls) and to a lesser extent in FH+NGT, with a more modest decrease in AIR2 and 3 compared controls.

Conclusion: Subjects with a strong genetic predisposition to type 2 diabetes mellitus have early subtle defects in first phase insulin secretion. An acute lipid infusion significantly impairs insulin secretion in FH+ subjects with impaired glucose tolerance, but not as significantly in normal glucose tolerant FH+ subjects. This suggests that in more advanced stages of the “pre-diabetic” state (FH+ with IGT), lipotoxicity is an extremely relevant contributing factor in the progression to T2DM. This may explain, at least in part, the role of obesity in the development to type 2 diabetes mellitus. We speculate that an acute lipid infusion may potentially be a useful test to identify subjects at the highest risk of developing type 2 diabetes mellitus.

648

Association of serum free IGF-1 and IGFBP-1 with insulin sensitivity in impaired glucose tolerance (IGT) and type 2 diabetic subjects

M.G. Kabir¹, M.H. Mosaraf^{1,2}, S.N. Hassan^{1,2}, Z. Hassan³, I. Khan², Q. Nahar², M. Alauddin¹, M.O. Faruque⁴, L. Ali²

¹Biochemistry & Molecular Biology, University of Chittagong, ²Biochemistry & Cell Biology, BIRDEM, Dhaka, ³Physiology & Molecular Biology, BIRDEM, Dhaka, ⁴Biochemistry & Molecular Biology, BIRDEM, Dhaka, Bangladesh

Background and aims: Free IGF-1 and IGFBP-1 are associated with obesity which is one of the major features of insulin resistance. Although both the obesity and insulin resistance are involved in the development of diabetes, but very few studies exist on free IGF-1 and IGFBP-1 in diabetes and IGT subjects. The present study was undertaken to investigate the association of free IGF-1 and IGFBP-1 with insulin sensitivity in IGT and type 2 diabetic subjects.

Subjects and methods: Ninety one subjects with impaired glucose tolerance (IGT) and 68 with type 2 diabetes mellitus (DM) were studied along with age- and BMI-matched 61 healthy Controls without family history of diabetes or prediabetes. Serum glucose was measured by glucose-oxidase method, lipid profile by enzymatic-colorimetric method, and insulin, free IGF-1 and IGFBP-1 by standard ELISA method. Insulin secretory capacity (HOMA-B%) and insulin sensitivity (HOMA-S%) were calculated using fasting glucose and fasting insulin by HOMA-CIGMA software.

Results: Waist-hip ratio (WHR) [Control, 0.91 ± 0.05 ; IGT, 0.94 ± 0.05 ; DM, 0.93 ± 0.04] was significantly higher in DM ($p=0.01$) subjects compared to Controls. Median (range) of fasting serum insulin [pmol/l; Control, 51.7 (7.8–155.9); IGT, 67.7 (6.9–237.6); DM, 69.3 (17.4–525.3)] was significantly higher in IGT ($p=0.004$) and DM ($p=0.014$) group compared to Controls. HOMA-B% [Control, IGT and DM subjects were 99 (21–187), 99 (26–278) and 62 (14–296)] was significantly ($p=0.001$) lower in DM subjects compared to Controls. HOMA-S% [Control, IGT and DM subjects were 86 (29–554), 66 (20–661) and 59 (9–256)] was significantly lower in IGT ($p=0.001$) and DM subjects ($p=0.001$) compared to Controls. Fasting serum free IGF-1 level [pg/ml; Control, IGT and DM were 118.2 (39.4–486.1), 118.2 (19.9–465.9) and 140.1 (19.9–803.5)] was not significantly different among the study groups. Similarly fasting serum IGFBP-1 level [ng/ml; Control, IGT and DM were 11.5 (1.1–83.97), 13.8 (1.6–68.1) and 11.9 (0.68–146)] was not significantly different among the groups. When the study subjects were categorized on the basis of BMI cut-off point standardized for Bangladeshi population then the level of free IGF-1 was significantly ($p=0.03$) higher in type 2 DM [182.62 (72.32–365.45)] subjects with BMI ≤ 23 compared to Controls [95.70 (39.4–161.53)] with similar BMI range. Increased level ($p=0.05$) of free IGF-1 was also observed in healthy Controls with BMI >23 than Controls with BMI ≤ 23 . Binary logistic regression analysis with Control group have shown that both IGT and DM were associated with IGFBP-1 (IGT: $\beta=0.377$, $p=0.03$; DM: $\beta=0.075$, $p=0.028$) but not with free IGF-1. On multiple linear regression analysis of free IGFBP-1 concentration, after adjusting the confounding variables, showed that IGFBP-1 was positively ($b=0.152$, $p=0.052$) associated with HOMA S in the combined group of IGT and DM subjects.

Conclusion: Free IGF-1 is associated with body weight and it may not be directly associated with diabetes. On the other hand IGFBP-1 seems to be associated with insulin resistance in prediabetic and diabetic states.

Proteomic analysis identified novel signalling pathways activated in human pancreatic islets of type 2 diabetes patients

H.K. Nyblom¹, M. Bugliani², Y.M.E. Fung³, R.A. Zubarev³, P. Marchetti², P. Bergsten¹

¹Department of Medical Cell Biology, Uppsala University, Sweden,

²Department of Endocrinology and Metabolism, Pisa University, Italy,

³Department of Cellular and Molecular Biology, Uppsala University, Sweden

Background and aims: Islet dysfunction in type 2 diabetes mellitus (T2DM) is caused by genetic and environmental factors, which alter expressions of multiple genes. Given the complexity it is not surprising that, although specific β -cell genes that contribute to impaired function have been identified, the mechanisms for islet dysfunction remain unclear. The aims of the present study were to optimize the proteomic approach liquid chromatography Fourier transform ion cyclotron resonance mass spectrometry (LC FT-ICR MS) so that expression profiles can be determined from a small number of islets, generate protein expression data sets from freshly isolated human islets obtained from T2DM and control donors and analyze the results to reveal signaling pathways involved in destruction of islet function.

Materials and methods: Islets of Langerhans were isolated from five T2DM and ten control donors. The two groups were age and weight matched. Islets were either used for determination of insulin release in response to glucose or glibenclamide or for expression measurements. For the latter purpose islets were lysed and pooled resulting in one sample containing islet lysates from the T2DM individuals and one from the control individuals. The two samples were analyzed by LC FT-ICR MS and proteomic expression data sets generated. Subsequent analysis of the data sets determined differential signaling pathway activation between islets obtained from T2DM and control donors. In addition, key-node molecules of dominant signaling pathways were determined.

Results: Insulin release from control islets increased 4-fold when the glucose concentration was increased from 3 to 17 mM glucose. Similar rises were observed when glibenclamide was added. In contrast, insulin release

only increased 2-fold from islets isolated from T2DM donors when either the glucose concentration was raised or glibenclamide was added. Protein profiles of islet lysates from control and T2DM donors contained expression levels of approximately 400 identified proteins. When the data sets were used for signaling pathway analysis, a number of pathways were activated in islets of T2DM individuals compared to islets obtained from control individuals ($p<0.05$). Among the significantly activated pathways several associated with apoptosis were identified. Activation of these signaling pathways in T2DM was confirmed when the identified key-nodes were mapped onto known pathways.

Conclusion: The study is the first account of protein profiles of islets obtained from individuals with T2DM and demonstrates the feasibility of performing proteomic studies on as little as 100 freshly isolated human islets when using the LC FT-ICR MS approach. Mechanisms of islet dysfunction were delineated by subjecting the expression data sets to signaling pathway and key-node analyses, which revealed activation of apoptotic and other pathways in T2DM donors compared to control. Verification and validation of the discovered pathways as well as performing expression measurements on more individuals will determine the importance of the identified pathways for islet dysfunction in T2DM.

Reduced insulin secretion/insulin resistance (disposition) index is the primary determinant of glucose intolerance in the pre-diabetic state: results from the ACT NOW Study

R.A. DeFronzo¹, M.A. Banerji², G.A. Bray², T.A. Buchanan², S. Clement², R.R. Henry², A. Kitabchi², S. Mudaliar², N. Musi¹, R. Ratner², P. Reaven², D. Schwenke², D. Tripathy¹

¹Medicine/Diabetes, UTHSCSA, United States, ²Diabetes, ACT NOW Investigators, San Antonio, United States

Aims: To evaluate the relationship between insulin sensitivity, β -cell function and glucose tolerance at baseline in subjects with varying degrees of glucose tolerance in the ACT NOW study.

Methods: ACT NOW is multicenter study for the prevention (pioglitazone vs. placebo) of diabetes in subjects with impaired glucose tolerance (IGT). We present the baseline data from 602 IGT subjects from 8 US centers. During the screening process, 115 subjects with normal glucose tolerance (NGT) and 50 subjects with impaired fasting glucose (IFG = 110–125 mg/dl) were identified. Of 602 IGT subjects, 174 had isolated IGT (FPG <100 mg/dl; 2-h glucose = 140–199 mg/dl) and 428 had combined IGT plus IFG (FPG = 100–125 mg/dl; 2-h glucose = 140–199 mg/dl). Indices of insulin secretion and insulin sensitivity were derived from the plasma glucose, insulin, and C-peptide concentrations during the OGTT. The acute insulin response (AIR_{0-10} min) and insulin sensitivity (S_i) were measured with the frequently sampled intravenous glucose tolerance test (FSIVGTT) in IGT and IGT/IFG subjects.

Results: Matsuda index of insulin sensitivity from OGTT was similar in NGT and IFG subjects (6.5 ± 0.6 vs 5.8 ± 0.7 , $p=ns$), but worsened progressively moving from NGT to IGT (6.5 ± 0.6 vs 5.0 ± 0.2 , $p=0.03$) to combined IGT/IFG (3.9 ± 0.2 , $p<0.0005$). The insulin secretion/insulin resistance index ($\Delta I_{0-120}/\Delta G_{0-120} \times$ Matsuda index) was similar in NGT and IFG subjects but was markedly reduced in IGT versus NGT (4.5 ± 0.2 vs 11.5 ± 1.1 , $p<0.0001$) and was further decreased in subjects with combined IGT/IFG (3.2 ± 0.1 , $p<0.0001$). Late phase insulin secretion ($\Delta I_{60-120}/\Delta G_{60-120} \times$ Matsuda index and $\Delta ISR_{60-120}/\Delta G_{60-120} \times$ Matsuda index; ISR = insulin secretory rate by C-peptide deconvolution) were similar in NGT and IFG, but significantly decreased in IGT ($p<0.0001$) and combined IGT/IFG ($p<0.00001$). Subjects with combined IGT/IFG had a lower AIR_{0-10} (329 ± 18 vs 429 ± 26 , $p=0.002$) and disposition index ($AIR_{0-10} \times S_i$) (751 ± 43 vs 991 ± 86 , $p=0.01$) compared to subjects with isolated IGT. S_i correlated with the Matsuda index ($r = 0.518$, $p<0.0001$). When subjects were stratified according to FPG, the insulin AUC during OGTT progressively increased with increasing FPG; however, both $\Delta I_{0-120}/\Delta G_{0-120} \times$ Matsuda index and $\Delta ISR_{0-120}/\Delta G_{0-120} \times$ Matsuda index declined progressively with rising FPG concentrations. Subjects with FPG = 115–125 mg/dl had an 80% decrease in beta cell function compared to subjects with FPG = 70–90 mg/dl. Insulin sensitivity also decreased progressively by 40% over the same range of FPG.

Conclusion: (1) The decline in β -cell function (regardless of method of estimation: insulin and C-peptide levels during OGTT or IVGTT) is the primary determinant of worsening glucose tolerance in “pre-diabetic” subjects; (2) Impaired early insulin secretion (with normal/near normal insulin sensitivity)

ty) is the major defect hyperglycemia in subjects with isolated IFG; (3) insulin resistance and impaired early and late phase insulin secretion are responsible for post-glucose load hyperglycemia in IGT.

Progression of beta cell dysfunction in subjects at risk for type 1 diabetes

A. Mari¹, V. Nofrate¹, J. Skyler², E. Ferrannini³

¹Institute of Biomedical Engineering, National Research Council, Padova, Italy, ²Division of Endocrinology, Diabetes, & Metabolism, University of Miami Leonard M. Miller School of Medicine, Miami, United States, ³Department of Internal Medicine, University of Pisa School of Medicine, Italy

Background and aims: First-degree relatives of type 1 diabetic patients (FDR₁) have increased risk of developing diabetes. The pathophysiological mechanisms and mode of onset of diabetes in this high-risk group have not been investigated.

Materials and methods: In 325 islet-cell autoantibody-positive, non-diabetic FDR₁ from the DPT-1 Study (age=11 [9] years, median [interquartile range]), we analyzed 1,898 OGTTs (6 [6] per subject) performed between baseline and last follow-up (2.7 [2.8] years), when 113 subjects had developed diabetes (progressors, at 2.1 [2.0] years). The insulin-secretion/plasma glucose dose-response function was resolved by mathematical modelling of the OGTT glucose and C-peptide and beta-cell glucose sensitivity (β -GS, slope of the dose-response) and insulin secretion at 5 mM glucose (IS_5) were calculated. In the subjects with ≥ 4 OGTTs ($n=52$), time-series of individual parameters were fitted using a biphasic function (with an initial slope, a transition time and a final slope) to determine the temporal pattern.

Results: Transition to hyperglycaemia was clearly biphasic in 67% of subjects, monophasic in 8% and ill-defined in 25%. In the subjects with biphasic transition ($n=48$), 2-hour glucose sharply increased to diabetic levels (rate of change 12.9 [20.1] mM/year) following an initial stable phase (0.0 [1.3] mM/year). The time at which the transition occurred was 0.76 [1.04] years before diagnosis. In the non-progressors ($n=157$), only a slow drift (0.07 [0.4] mM/year) was observed in most subjects (~90%). Two-hour glucose levels were higher in the progressors during the entire observation period (6.7 [2.1] vs 5.9 [1.7], $p<0.01$ at baseline). Baseline β -GS was lower in progressors than non-progressors (46 [34] vs 87 [65] pmol min⁻¹ m⁻² mM⁻¹, $p<0.0001$). The temporal pattern of β -GS was less clearly defined than that of 2-hour glucose levels, in part due to noisier data. Using a linear approximation, the rate of decline of β -GS in progressors (-9.9 [12.6] pmol min⁻¹ m⁻² mM⁻¹ year⁻¹) was faster than in non-progressors (-4.2 [12.9], $p<0.0001$). In the 35 subjects in which 2-hour glucose was markedly biphasic, β -GS was initially flat (4.3 [25.5] pmol min⁻¹ m⁻² mM⁻¹ year⁻¹) and then rapidly declined (at a rate of -40.9 [33.7] pmol min⁻¹ m⁻² mM⁻¹ year⁻¹) starting 1.4 [1.2] years before diagnosis. In this subgroup, the time of the β -GS transition was correlated with the time of the 2-hour glucose transition ($r=0.42$, $p<0.02$) and anticipated the latter by 0.14 [1.17] years ($p<0.05$). In contrast to β -GS, IS_5 did not change over time in progressors (rate of change -0.1 [15.3] pmol min⁻¹ m⁻² year⁻¹, $p=ns$), though at baseline it was lower in progressors (53 [37] vs 69 [48] pmol min⁻¹ m⁻² year⁻¹, $p<0.05$). Insulin sensitivity (OGIS) showed an average decline similar to β -GS, though its phasic characteristics were less defined. In all progressors (660 OGTTs), 2-hour glucose was simultaneously related to both β -GS and insulin sensitivity ($r^2=0.41$, $p<0.0001$).

Conclusion: In FDR₁, (a) transition to diabetic hyperglycaemia occurs mostly in a biphasic time-course and is preceded by a similar biphasic change in β -GS; (b) subjects who develop diabetes have a reduced β -GS; and (c) both β -GS and insulin sensitivity are strong determinants of glucose levels.

Frequency of insulin resistance and beta cell dysfunction and their relations with clinical and biochemical features in newly-diagnosed type 2 diabetes

E. Bonora, V. Stoico, C. Negri, M. Trombetta, C. Tommasi, F. Grippaldi, C. Brangani, I. Pichiri, F. Tecilazich, M. Muggeo, R.C. Bonadonna
Endocrinologia e Malattie del Metabolismo, University of Verona, Italy

Background and aims: To evaluate the frequency of insulin resistance and beta-cell dysfunction and their relations with several clinical and biochemical features in newly-diagnosed type 2 diabetes.

Materials and methods: Insulin resistance and beta-cell dysfunction were assessed by hyperinsulinemic euglycemic clamp and minimal model analysis of C-peptide and glucose levels during OGTT with in 377 newly-diagnosed untreated type 2 diabetic patients. In these subjects the presence of chronic complications was explored by medical history, ophthalmoscopy, ECG, carotid and femoral-popliteal echo-doppler and albuminuria (micro and macro) assessment. Several biomarkers were measured, including FFA and adiponectin (markers of adipose tissue dysregulation), CRP, IL-6 and TNF- α (markers of inflammation), P-selectin, E-selectin, and ICAM-1 (markers of endothelial dysfunction), and oxidized LDL (marker of oxidant stress). Also standard clinical (e.g. waist circumference) and biochemical parameters (e.g., HbA1c) were assessed. Mean pre- and post-prandial glucose levels were computed based upon six time-points home blood glucose monitoring on 5 different days.

Results: Most subjects (86%) had both insulin resistance (glucose disposal during clamp, M-clamp, within the bottom quartile of 500 nonobese healthy subjects) and beta-cell dysfunction (beta-index computed with minimal model applied to OGTT within the bottom quartile of 125 nonobese healthy subjects), whereas 6% had isolated insulin resistance and 8% had isolated beta-cell dysfunction. The prevalence of chronic complications was as follows: background retinopathy 6.3%, proliferative retinopathy 0%, microalbuminuria 11.8%, macroalbuminuria 1.4%, CHD 4.9%, increased carotid IMT 55.4%, carotid plaques 5.9%, increased femoral IMT 48.8%, femoral-popliteal plaques 5.2%. After adjusting for sex, age, smoking, HbA1c, LDL cholesterol and blood pressure, no difference in insulin resistance or beta-cell dysfunction was found between subjects with or without microangiopathy or with or without macroangiopathy in any site. In multiple regression analyses which included also sex, age and smoking, M-clamp was independently associated with waist circumference, FFA, adiponectin, oxidized LDL and E-selectin, whereas beta-index was independently associated with waist circumference, FFA and HbA1c. In multiple regression analysis both M-clamp and beta-index were independently associated to HbA1c and blood glucose (fasting, 2-h OGTT, mean pre-prandial, mean post-prandial) but the strength of association with beta-index was two-fold higher.

Conclusion: Most subjects with newly-diagnosed type 2 diabetes have both insulin resistance and beta-cell dysfunction. On a cross-sectional basis, none of these pathogenetic features of type 2 diabetes seems to be associated with chronic complications. Adipose tissue dysregulation is associated, perhaps causally, with both insulin resistance and beta-cell dysfunction, whereas endothelial dysfunction and oxidant stress might contribute to (or are caused by) insulin resistance. Beta-cell dysfunction explains the degree of glucose control to a greater extent than insulin resistance.

TLR agonist induced changes in BRIN-BD11 clonal beta cell metabolism, signal transduction and insulin secretion

A.M. Kiely, P. Newsholme

Biochemistry Department, Conway Institute of Biomolecular and Biomedical Research, Dublin, Ireland

Background and aims: Insulin resistance associated with obesity and type 2 diabetes is commonly associated with changes in muscle, adipose tissue and liver signal transduction pathways. Pro-inflammatory cytokines (such as TNF- α and IL-1 β) can alter patterns of insulin signalling in these target tissues, resulting in resistance to the action of insulin. More recently evidence for involvement of innate immune product receptors, e.g. Toll like receptors, in insulin resistance has been published. TLR4 and TLR2, whose agonists include lipopolysaccharides and saturated fatty acids, are implicated in altered patterns of signalling in animal models of insulin resistance and obesity. Indeed loss of function mutations in the TLR4 receptor had a beneficial effect on the insulin signalling pathways in adipose, muscle and liver tissues in mice and improved insulin action.

Materials and methods: Clonal BRIN BD11 β -cells were treated for 24 hours with increasing concentrations of LPS. The media was removed and stored to determine chronic (24 h) insulin secretion and nutrient consumption. Acute (20 min) stimulated insulin secretion was subsequently determined. Glucose and glutamine concentrations were determined by enzymatic assays using the YSI 7100 MBS Multiparameter Bioanalytical System. Protein was extracted using RIPA buffer, subjected to SDS-PAGE and electrophoretically transferred onto a nitrocellulose sheet. The sheet was blocked in 5% milk protein, incubated with polyclonal anti IRS-1, p-IRS-1, Akt, p-Akt or IR β

(Isis), washed and probed with horseradish peroxidase and visualised with SuperSignal West Pico (Pierce).

Results: Incubation of BRIN-BD11 cells for 24 hours in the presence of increasing concentrations of the TLR4 ligand LPS significantly decreased chronic (24 hour) insulin secretion from 1.09 ± 0.19 to 0.76 ± 0.18 μg insulin / mg protein in the presence of 100 ng/ml LPS ($p < 0.05$). There was no change in acute (20 min) stimulated insulin secretion, or insulin content. The reduction in chronic insulin secretion was not accompanied by changes in nutrient (glucose or glutamine) consumption. IR β expression levels were increased significantly from 1 ± 0.52 to 8.6 ± 1.83 units ($p < 0.01$), and Akt phosphorylation was slightly reduced. There was no change in IRS-1 protein expression or phosphorylation after 24 hours. Incubation of treated cells for a further 24 hours in the absence of LPS demonstrated a recovery of chronic (24hr) insulin secretion.

Conclusion: We have demonstrated a small but significant reduction in insulin secretion associated with 24hr exposure to the TLR4 agonist LPS. It is known that glucose and insulin induce expression of IR β in pancreatic β -cells. Here we have demonstrated that LPS increased IR β expression and reduced insulin secretion. Insulin content was not altered. We also found exposure to LPS resulted in a reduction in the level of activated Akt which could potentially impair the viability of the β -cell after longer periods of incubation. However, the concentrations of LPS used in this study did not impair cell viability during the period of our experiments. Importantly, defects in insulin secretion associated with initial 24hr exposure to LPS were reversed after a further 24 hour incubation in the absence of LPS.

BLX-1002, a novel thiazolidinedione with no PPAR affinity, stimulates AMP-activated protein kinase activity, raises cytosolic Ca^{2+} and enhances glucose-stimulated insulin secretion in a PI3K-dependent manner

F. Zhang¹, D. Dey², R. Bränström³, L. Forsberg³, M. Lu³, Q. Zhang¹, Å. Sjöholm¹

¹Department of Clinical Science and Education, Karolinska Institutet, Stockholm, Sweden, ²Belex Pharmaceuticals, Inc., Union City, United States, ³Department of Molecular Medicine and Surgery, Unit of Endocrine Surgery, Karolinska Institutet, Stockholm, Sweden

Background and aims: BLX-1002 is an amino acid conjugated, novel small molecule (MW<500) with no affinity to PPAR receptors. It has been shown to lower blood glucose in type 2 diabetes without adipogenic effects *in vivo*. The function of the drug on pancreatic β -cells remains unknown. We have investigated effects of the drug on β -cell function in islet cells from *ob/ob* mice.

Materials and methods: Pancreatic islets were isolated from *ob/ob* mice by enzyme digestion and disrupted into cells in a Ca^{2+} -free buffer with EGTA. Insulin secretion was investigated in batch-incubation during 20 minutes. Cytosolic free Ca^{2+} concentration ($[\text{Ca}^{2+}]_i$) was measured in Fura-2 pre-loaded cells using a time-sharing spectrofluorometer. The activities of voltage-gated Ca^{2+} channels and ATP-dependent K^+ (K_{ATP}) channels were monitored using patch-clamp technique. Activation of AMPK was evaluated by Western blotting using anti-phospho-AMP-activated protein kinase (AMPK) α (Thr172). **Results:** Incubation of the β -cells with BLX-1002 enhanced high glucose-stimulated insulin secretion without affecting release of the hormone at glucose concentrations of 3 or 8 mM during a 20 min-incubation, while its major metabolite BLX-1015 had no effect. BLX-1002 also augmented $[\text{Ca}^{2+}]_i$ at high glucose, an effect that was abolished by pre-treatment of the cells with the Ca^{2+} -ATPase inhibitor thapsigargin. In contrast, BLX-1002 interfered neither with voltage-gated Ca^{2+} channel nor with K_{ATP} channel activities. Stimulation of the β -cells with BLX-1002 induced activation of AMPK at high glucose. The stimulatory effect of BLX-1002 on insulin secretion at high glucose was abolished by treatment of the cells with the selective PI $_3$ K inhibitors wortmannin or LY294002.

Conclusion: This study suggests that BLX-1002 potentiates glucose-stimulated insulin secretion in pancreatic β -cells in a PI $_3$ K-dependent manner. This stimulatory effect of BLX-1002 on insulin release occurs only in the presence of high glucose and is associated with AMPK phosphorylation and an enhanced $[\text{Ca}^{2+}]_i$ mediated through mobilization of Ca^{2+} from intracellular Ca^{2+} stores. Changes in voltage-gated Ca^{2+} channel or K_{ATP} channel activities do not seem to be involved in the increase in $[\text{Ca}^{2+}]_i$ induced by the drug. The glucose-sensitive stimulatory impact of BLX-1002 on β -cell function may translate into substantial clinical benefits of the drug in the management of type 2 diabetes, by avoidance of hypoglycemia.

Bisphosphonate prevents fat-induced beta cell dysfunction *in vitro* and *in vivo*

A.I. Oprescu¹, P. Han², S.A. Constantin-Marino², L. Lam², G.F. Lewis^{1,2}, I.G. Fantus^{1,2}, M.B. Wheeler², A. Giacca^{1,2}

¹Institute of Medical Science, ²Physiology, University of Toronto, Toronto, Canada

Background and aims: Fatty acids induce insulin resistance and chronically decrease β -cell function. The insulin signaling pathway plays a role in insulin secretion, however it is still unclear whether the FFA-induced decrease in β -cell function involves β -cell insulin resistance.

Materials and methods: To address the role of generalized and β -cell insulin resistance in FFA-induced β -cell dysfunction we coinfused with fat a bisphosphonate compound, bisphosphonate (bpV), in normal Wistar rats. bpV, a tyrosine phosphatase inhibitor, acts as insulin mimetic and is devoid of any antioxidant effect that could prevent β -cell dysfunction, unlike most insulin sensitizers. Two fat infusions were given iv to elevate plasma FFA by approximately 2-fold: a direct infusion of oleate in bovine serum albumin, or an emulsion of 20% olive oil ($5 \mu\text{L}\cdot\text{min}^{-1}$)+heparin ($50 \text{ U}\cdot\text{mL}^{-1}$) for 48h in Wistar rats, with or without bpV at $0.0025 \text{ pmol}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$. At the end of the 48h infusions we performed two-step hyperglycemic clamps to evaluate glucose stimulated insulin secretion (GSIS) *in vivo*, or we isolated islets to evaluate GSIS *ex vivo*. We also exposed the islets in culture conditions to 0.4 mM oleate in 0.5% BSA $\pm 4 \mu\text{M}$ bpV for 48h to evaluate GSIS *in vitro*.

Results: 48h infusion of oleate or olive oil impaired β -cell function *in vivo* ($p < 0.01$) as measured with the disposition index during a two-step hyperglycemic clamp (13 and 22 mM glucose), whereas coinfusion of bpV prevented the effect of oleate or olive oil. GSIS *ex vivo* in isolated islets of oleate or olive oil-treated rats was impaired (both oleate and olive oil $p < 0.001$ vs. control, at 13 and 22mM), but was restored by coinfusion of bpV (both oleate+bpV and olive oil+bpV $p = \text{NS}$ vs control), while bpV alone had no effect. Similar results were obtained in cultured islets, where 48h exposure to oleate impaired the GSIS at 13mM (oleate: $0.125 \pm 0.023 \text{ pmol}/\text{islet}/\text{h}$, $n=10$, $p < 0.001$ vs. control: $0.248 \pm 0.022 \text{ pmol}/\text{islet}/\text{h}$, $n=9$), and 22mM (oleate: $0.212 \pm 0.026 \text{ pmol}/\text{islet}/\text{h}$, $n=10$, $p < 0.001$ vs. control: $0.396 \pm 0.033 \text{ pmol}/\text{islet}/\text{h}$, $n=9$), an effect prevented by bpV (oleate+bpV: $0.367 \pm 0.111 \text{ pmol}/\text{islet}/\text{h}$ at 13mM, $n=7$, oleate+bpV: $0.539 \pm 0.147 \text{ pmol}/\text{islet}/\text{h}$ at 22mM, $n=7$, both $p = \text{NS}$ vs control), while bpV alone had no effect ($n=4$).

Conclusion: Our results suggest a role of FFA in decreasing β -cell function by impairing tyrosine phosphorylation at the β -cell level, consistent with the induction of β -cell insulin resistance.

Direct effects of rapid acting insulin analogues on insulin signalling in human pancreatic islets

V. D'Aleio¹, R. Lupi¹, R. Mancarella¹, S. Del Guerra¹, U. Boggi², F. Filipponi², P. Marchetti¹

¹Endocrinology and Metabolism, ²Department of Oncology, Transplantation and Advanced Technologies in Medicine, University of Pisa, Pisa, Italy

Background and aims: In recent years, rapid acting insulin analogs (RAIA: Lispro, Aspart and Glulisine) have been introduced to optimize insulin treatment in diabetes. These molecules have similar, but not identical, pharmacodynamic and pharmacokinetic characteristics. In particular, work with cell lines and rodents have suggested that RAIA may have different insulin signaling system (SigSys) properties. Since SigSys is present in pancreatic islets and can modulate beta-cell function and survival, we studied the effects of Aspart, Glulisine and regular insulin (RI) on isolated human islets (IHI).

Materials and methods: IHI were prepared by collagenase digestion and density gradient purification by the pancreas of multiorgan donors (age: 70 ± 13 yrs; gender: 1 male and 3 females; body mass index: $24.7 \pm 1.9 \text{ kg}/\text{m}^2$), and then cultured for 48h in the presence of 5.5 (g) or 22.2 (G) mmol/l glucose, either with or without the addition of Aspart, Glulisine or RI (10 nmol/l). Functional and molecular studies were performed at the end of the different incubation conditions.

Results: Endogenous insulin secretion (C-peptide, pmol/l) during the 48h culture was 1287 ± 540 at g and increased to 3130 ± 1666 at G ($p < 0.05$). The presence of RAIA or RI did not affect this feature significantly. IHI pre-cultured at g and acutely challenged with 3.3 and 16.7 mmol/l glucose released 26.6 ± 3.3 and $56.7 \pm 5.7 \mu\text{U}/\text{ml}$ insulin, respectively ($p < 0.01$). Pre-exposure

to G caused a significant ($p < 0.05$) increase of insulin secretion (IS) at 3.3 mmol/l glucose ($35.2 \pm 2.43 \mu\text{U/ml}$) and a reduction ($p < 0.05$) of IS in response to 16.7 mmol/l glucose ($44.2 \pm 6.4 \mu\text{U/ml}$). These corresponded to stimulation index (SI, ratio of stimulated over basal insulin release) values of 2.2 ± 0.5 and 1.2 ± 0.1 ($p < 0.01$), which were not further affected by the added insulins. Several changes at the level of molecules involved in the early steps of SigSys occurred at the end of the different incubation conditions. Compared to g, pre-exposure to G determined increased transcription of IRS-1 and IRS-2, and reduced expression of insulin receptor (IR), whereas phosphatidylinositol-3 kinase (PI3K, p110 α subunit) did not change significantly. Glutamine did not affect IR expression, which however was inhibited by RI in the islets kept at g and induced by Aspart and RI in the islets pre-cultured at G. Modest changes (within 10%) were observed as for the expression of IRS-1 and IRS-2, whatever the incubation condition. PI3K expression was significantly induced by Glutamine and Aspart at g, but not at G.

Conclusion: In summary, the results of the present study suggest that the tested RAI and RI have different effects on the expression of molecules involved in the early steps of the insulin signaling system in human islets, with the overall action also depending on the degree of glucose exposure.

Growth hormone increases intrahepatic rates of glycogen synthesis in growth hormone deficient adults

W. Schwenk¹, S. Kirmani²

¹Pediatrics and Adolescent Medicine, ²Medical Genetics, Mayo Clinic, Rochester, United States

Background and aims: We have previously shown that growth hormone replacement is associated with a 40% increase in intrahepatic rates of glycogen synthesis during refeeding in children with idiopathic growth hormone deficiency. Our aims were to see whether growth hormone replacement in adults with growth hormone deficiency would be associated with a similar increase in the rates of intrahepatic glycogen synthesis and to determine whether such an increase in the rates of intrahepatic glycogen synthesis was due to increased direct uptake of glucose by the liver (direct pathway) and/or increased rates of gluconeogenesis (indirect pathway).

Materials and methods: 5 adults with growth hormone deficiency were randomly studied twice, off and on growth hormone replacement (OFF and ON, respectively). Patients were fasted overnight and then infused with glucose ($15.7 \pm 0.4 \mu\text{mol/kg per min}$). Intrahepatic rates of glycogen synthesis were estimated by infusing [$1\text{-}^{14}\text{C}$]galactose to steady state, administering acetaminophen, and measuring the specific activity (SA) of [^{14}C]acetaminophen glucuronide in the urine in order to calculate steady state intrahepatic uridine diphosphate glucose (UDP-glucose) flux. The percentage of UDP-glucose coming from direct uptake of glucose was estimated by infusing [$3\text{-}^3\text{H}$]glucose, and measuring the SA of [^3H]acetaminophen glucuronide in the urine.

Results: Growth hormone replacement was associated with a 34 % increase in estimated rates of intrahepatic glycogen synthesis (4.42 ± 0.76 vs $5.90 \pm 0.81 \mu\text{mol/kg per minute}$ for OFF and ON, respectively; $p < 0.05$). The percentage of glucose coming from direct uptake of glucose was not affected by growth hormone treatment (44.6 ± 5.9 % vs 47.4 ± 5.8 % for OFF and ON, respectively). In summary, growth hormone treatment in growth hormone deficiency adults increased estimated rates of intrahepatic glycogen synthesis by increasing the amount of glucose entering UDP-glucose via the direct and indirect pathways equally.

Conclusion: Growth hormone appears to increase intrahepatic rates of glycogen synthesis not only by stimulating gluconeogenesis, but also by increasing direct uptake of glucose.

Liver is the primary site for 11 β HSD1 gene expression in splanchnic tissues in humans

A. Basu¹, R. Basu¹, M. Grudzien², P. Jung², P. Jacobson², M.G. Sarr³, R.A. Rizza¹

¹Endocrinology, Metabolism & Nutrition, Mayo Clinic College Of Medicine, Rochester, ²Global Pharmaceutical Research & Development, Abbott, Abbott Park, ³Surgery, Mayo Clinic College Of Medicine, Rochester, United States

Background and aims: Experiments in the awake dog model suggest that the liver is the primary site for splanchnic cortisol production with minimal cortisol production occurring in the viscera. The purpose of this study was to compare gene expression between liver and omental fat in obese humans for genes regulating the glucocorticoid receptor (NR3C1), and 11 beta hydroxysteroid dehydrogenase enzymes (11 β HSD1 and 2). 11 β HSD1 converts inactive cortisone to active cortisol while 11 β HSD2 converts cortisol to cortisone. These enzymes modulate the availability of cortisol to bind to its receptor (NR3C1). Since splanchnic cortisol production has been implicated in obesity and type 2 diabetes, this information would be key for future development of tissue-specific therapeutic targets.

Materials and methods: Liver and omental fat tissue from subjects ($n=7$; age 53 ± 3 yrs; BMI $46 \pm 3 \text{ kg/m}^2$) were collected during routine abdominal surgery. Samples from each subject were quick frozen with liquid nitrogen and stored in dry ice. 150mg (liver) and 200mg (fat) sections were weighed and lysed using an appropriate amount of Qiazol Lysis Reagent and mechanical homogenization. Qiazol homogenates were used to isolate total RNA using automated Qiagen RNeasy technology on the Qiagen BioRobot 3000. Reverse transcription and PCR were performed at standard temperatures using the

Invitrogen SuperScript III Platinum One-Step Quantitative RT-PCR System. All samples were analyzed for RNA integrity using the Agilent 2100 Bioanalyzer. The samples were run in triplicates. Data analysis was performed by first normalizing all data to the Total Human Reference RNA standard curve for each gene to achieve a relative amount of target RNA (ng). Then, each sample was normalized to the average amount of RNA (ng) for the three control genes (PPIA, RPLPO, and RPL19). This approach permitted assessment of relative expression between samples of interest for a specific target gene. However comparison of absolute amounts of expression between genes was not possible.

Results: NR3C1 gene expression was detected in all tissues tested, with no difference in expression between liver and omental fat. 11 β HSD1 gene expression was highly abundant in liver. 11 β HSD1 expression in liver and fat was variable between subjects, but expression was ~9 fold higher in liver tissue versus omental fat. In contrast, although detected, 11 β HSD2 gene expression was very low (< 0.5 relative ng of human reference RNA standard curve) in both liver and omental fat and neither tissue type had elevated expression over the other.

Conclusion: These data shows that in obese humans, gene expression of 11 β HSD1 occurs predominantly in the liver compared to omental fat. This implies that the liver is likely to be the primary site of splanchnic cortisol production in humans.

Combined treatment with epoetin- β and testosterone (mix of esters) of males suffering with diabetes of type 1 and receiving haemodialysis

A. Lepetukhin¹, N. Goncharov¹, M. Shestakova¹, A. Mordik², N. Biskaeva²

¹Diabetic nephropathy, Research Center of Endocrinology, ²Diabetic nephropathy, Extracorporeal therapy center "Fespharm", Moscow, Russian Federation

Background and aims: investigation of androgenic deficit impact on erythropoietin and correction of anemia among males who suffer from with diabetes mellitus of type 1 (T1 DM) and receive haemodialysis by virtue of combined therapy with epoetin- β (EPO- β) and testosterone (mix of esters, TME).

Materials and methods: 43 males suffering with type1 (T1DM) and receiving haemodialysis were included in investigation. Males younger than 40 years old (median age is 34.0 \pm 3.9 years) comprised group 1. Males of 40 years old and older (median age is 47.3 \pm 3.5 years) comprised group 2. Level of total testosterone (tT) was 21.2 \pm 6.6 nmol/l. tT level in group 2 was 9.8 \pm 3.9 nmol/l. Subgroups for treatment (combined treatment with EPO- β and TME) and control subgroup (treatment only with EPO- β) were organized: A (n = 14) and B (n = 6) in group 1 and C (n = 14) and D (n = 9) in group 2, respectively. Subgroups for treatment and control didn't differ by age, duration of DM and haemodialysis therapy, by level of HbA1c (%), Hb (g/l), tT (nmol/l). Duration of investigation comprised 6 months. EPO- β was prescribed in according to Hb level, 1/0 ml of TME was prescribed once in three weeks. tT level after injection of TME was measured 24 hours, 1, 2, and 3 weeks after the injection and was equal to 60.4 \pm 12.9, 26.7 \pm 6.8, 17.2 \pm 3.4, and 11.9 \pm 3.9 nmol/l, respectively. Statistic processing of data was performed with use of non-parametric methods (p), data are presented as M \pm SD.

Results: no authentic and reliable increase of Hb level was observed in group 1. Increase of Hb level by 16.2% was observed in subgroup C. Decrease of EPO- β dose by 32.1% and 41.1% a week was observed in subgroups A and C, respectively. Authentic and reliable decrease of EPO- β dose in a week was not observed in control groups (see Table).

Indicants before and after treatment (M \pm SD)

Groups	Indicants	Before treatment	6 months after treatment	p-value
Group1	A Hb(g/l)	118.1 \pm 9.6	118.2 \pm 6.7	0.8
	B	113.0 \pm 5.7	109.6 \pm 9.4	0.17
	A EPO- β (ME/week)	3857.1 \pm 1231.4	2428.5 \pm 851.6	0.007
	B	3334.3 \pm 1032.8	3666.6 \pm 1505.5	0.5
Group2	C Hb(g/l)	94.9 \pm 5.7	113.5 \pm 6.3	0.009
	D	98.4 \pm 7.0	99.4 \pm 6.8	0.5
	C EPO- β (ME/week)	7428.5 \pm 1452.5	4285.7 \pm 1325.9	0.001
	D	7111.2 \pm 1242.9	7233.3 \pm 1414.2	0.7

Conclusion: reduction of testosterone level in blood of males with type 1 DM receiving haemodialysis is of age-dependent nature. Combined treatment with EPO- β and TME contributes to increase of Hb level in blood of senior age group and to reduction of need in EPO- β irrespective of patient age.

Dehydroepiandrosterone (DHEA) reduced preadipocyte proliferation via androgen receptor

T. Ishizuka, K. Kajita, T. Ikeda, I. Mori, Y. Uno, K. Fujioka, H. Morita

Department of General Internal Medicine, Gifu Graduate School of Medicine, Japan

Background and aims: A great number of evidences indicate that DHEA administration results in reduced adiposity in men and animals. On the other hand, recent researches revealed that low testosterone (TEST) levels are associated with type 2 diabetes and obesity in men. Considering the fact that androgen receptor (AR) deficient mice represent obesity, AR acts to prevent fat accumulation in whole body. We have previously shown that senescence associated β -galactosidase (SA- β -Gal) was detected in adipose tissue isolated from obese animal was prevented with DHEA administration. In this study, we have further examined the effect of DHEA on telomere length and preadipocyte distribution in adipose tissue. Moreover, we assessed the role of AR in DHEA-induced growth suppression in preadipocyte.

Materials and methods: Male Otsuka Long Evans Fatty (OLETF) rats, hereditary obese type 2 diabetic animals derived from Long Evans Tokushima (LETO) rats, LETO rats were fed with or without (control) 0.4% DHEA containing food for 52 wk. Two μ g genomic DNA isolated from adipose tissue was digested with restriction enzyme, Hinf I/RsaI, and then Southern analysis was performed to measure telomere length. Moreover, 3T3-L1 preadipocytes were treated with DHEA and TEST for 24 hr, and then cell proliferation was assayed with BrdU uptake. We also assessed the effect of flutamide, AR inhibitor, and fulvestrant, estrogen receptor (ER) inhibitor, on DHEA-induced reduction of cell growth utilizing siRNA.

Results: Treatment with DHEA for 52 wk reduced body weight and fat weight, but not food consumption, in LETO and OLETF rats. These results clearly demonstrated that treatment with DHEA for 52 wk decreased fat mass without affecting food intake. Decreased telomere length was observed in genomic DNA isolated from adipose tissue in control OLETF, which was prevented with DHEA administration. These results indicated that accelerated cell division associated with obese adipose tissue resulted in rapid telomere shortening. These results suggested that DHEA-induced growth suppression in preadipocyte may lead to attenuate subsequent differentiation, which resulted in increased preadipocyte cell number. Actually, incubation with DHEA and TEST decreased BrdU uptake to the similar extent in 3T3-L1 preadipocyte. Pretreatment with flutamide, but not fulvestrant abolished this effect. AR siRNA also inhibited DHEA-induced decreases in BrdU uptake. Moreover, we found that no difference was observed between DHEA and TEST on cell growth. Recently, three major mechanisms of DHEA action, precursor of sex steroid, neurosteroid and activator of calcium-gated potassium channels, have been postulated. Especially, researchers have revealed that inactive steroid hormones are selectively uptaken and converted into active form, of which mechanism is named intracrine, with terminal steroid transforming enzymes, such as 17 β -HSD and 3 β -HSD in peripheral tissue. Our results of inhibitor and siRNA study revealed that this effect was mediated via AR.

Conclusion: These results suggested that DHEA-induced suppression of preadipocyte proliferation, might lead to anti-obesity and anti-senescence effect.

Molecular analysis of postprandial glucagon responses in patients with type 2 diabetes mellitus

K.J. Hare^{1,2}, F.K. Knop¹, S. Tor ng², S. Madsbad³, T. Krarup¹, T. Vilsb ll¹, J.J. Holst⁴

¹Department of Internal Medicine F, Gentofte Hospital, Hellerup,

²Department of Biomedical Sciences, University of Copenhagen,

³Department of Endocrinology, Hvidovre Hospital, ⁴Department of Biomedical Sciences, University of Copenhagen, Denmark

Background and aims: Hyperglucagonemia and lack of postprandial glucagon suppression, as measured by conventional C-terminal radioimmunoassay (RIA) is thought to contribute to the hyperglycemia in patients with type 2

diabetes mellitus (T2DM). The proglucagon (PG) gene is expressed both in pancreatic alpha-cells and in intestinal L-cells. Processing of the gene is different in the two cell types as glucagon is only secreted from the alpha-cell. The aim of this study was to clarify the nature of the hypersecreted glucagon in patients with T2DM - is it fully processed glucagon or is it an intestinally derived PG product?

Materials and methods: Ten patients with T2DM (age: 64 [51–80] years; body mass index (BMI): 23 [21–26] kg/m²; HbA_{1c}: 6.9 [6.2–8.7]%; mean values [range]) and ten healthy control subjects matched for sex, age and BMI were studied. Blood was sampled following a 50-g OGTT. In the control subjects an appropriate suppression of glucagon was observed during the first 45 min of the OGTT (−36±12 mM x 45 min) whereas the patients hypersecreted glucagon in response to the OGTT (10±16 mM x 45 min). Plasma samples (obtained at the time of the glucagon peak) were pooled, acidified and applied to a HPLC Vydac C₁₈ column. Eluted fractions were analyzed with 3 different glucagon RIAs with antibodies directed towards the mid region and the N- and C-terminals of the molecule.

Results: There was high glucagon immunoreactivity in samples from patients with T2DM, but very little in samples from control subjects due to adequate suppression of glucagon. The analysis of the fractionated plasma from T2DM showed that over 80% of the immunoreactivity identified by the C-terminal RIA was due to fully processed glucagon (33–61) (coelution with glucagon standard, identification in all 3 assays).

Conclusion: We conclude that the postprandial hyperglucagonemia in T2DM represents fully processed glucagon and therefore probably results from inappropriate secretion of the pancreatic alpha-cell rather than representing intestinally derived forms.

Prednisolone-treatment increases fasting glucose and insulin levels, but does not affect hepatic and peripheral insulin sensitivity

A.J. Laskewitz¹, T.H. van Dijk¹, A. Grefhorst¹, D.J. Reijngoud¹, W. Dokter², F. Kuipers¹

¹Research lab Pediatrics, University Medical Center Groningen, Netherlands, ²Department of Pharmacology, NV Organon, part of Schering-Plough Corp., Oss, Netherlands

Background and aims: Synthetic glucocorticoids, such as prednisolone and dexamethasone, are widely used as anti-inflammatory and immunosuppressive drugs for treatment of chronic inflammatory diseases. However, chronic use of glucocorticoids is limited by their severe side effects. Insulin resistance is commonly associated with chronic use of glucocorticoids. The underlying mechanisms of glucocorticoid-induced insulin resistance, however, are still elusive. To identify these mechanisms we characterized glucocorticoid-induced insulin resistance in C57Bl/6J mice fed either a chow diet or a high fat diet to induce a state of compromised insulin sensitivity.

Materials and methods: C57Bl/6J mice were fed a normal chow (C) diet or a high fat (HF 36%) diet for 6 weeks and were treated with either vehicle (V) or prednisolone (P) (10 mg/kg) for the last 7 days. Mice were extensively characterized for general metabolic parameters. Insulin resistance was assessed by a whole body glucose test (WBGT), a hyperinsulinemic euglycemic clamp (HIEC) and *in vivo* measurements of hepatic carbohydrate metabolism by employing mass isotopomer distribution analysis (MIDA) after an overnight fast. For the WBGT mice were injected with a trace amount of [U-¹³C]-glucose from which endogenous glucose production (EGP) and metabolic clearance rate (MCR) were calculated. For MIDA procedure, mice were infused with a solution containing [U-¹³C]-glucose, [2-¹³C]-glycerol, [1-²H]-galactose and paracetamol to quantify relevant fluxes of hepatic glucose metabolism.

Results: Prednisolone treatment in combination with a high fat diet increased the HOMA-score (CV 0.96 ± 0.47 vs CP 2.32 ± 2.59, ns; HFV 3.59 ± 3.44 vs HFP 7.27 ± 3.48 p<0.05). In addition, plasma cholesterol (CV 2.96 ± 0.32 vs CP 3.38 ± 0.61, ns; HFV 5.85 ± 0.41 vs HFP 7.27 ± 0.99 mmol/l, p<0.05) and triglycerides (CV 0.74 ± 0.19 vs CP 1.03 ± 0.28, p<0.05; HFV 1.29 ± 0.18 vs HFP 1.88 ± 0.39 mmol/l, p<0.05) were increased upon prednisolone treatment. An increased endogenous glucose production and reduced metabolic clearance rate normalized for insulin levels in the WBGT suggested glucocorticoid-induced insulin resistance in prednisolone-treated mice. However, when insulin resistance was assessed with the “gold standard”, i.e., HIEC, no evidence for insulin resistance on the basis of glucose infusion rates (CV 617 ± 28 vs CP 612 ± 23, ns; HFV 232 ± 25 vs HFP 253 ± 24 μmol/kg/min, ns) was observed, although high fat diet clearly reduced the glucose infusion

rate required to maintain euglycemia, establishing diet-induced insulin resistance. At hepatic level, a clearly negative glycogen balance was induced by prednisolone treatment (CV −0.48 ± 3.7 vs CP −23.68 ± 3.22, p<0.05; HFV 9.8 ± 4.0 vs HFP −11.8 ± 7.5, p<0.05), indicative for adapted glucose-6-phosphate flux to glycogen.

Conclusion: Our results demonstrate that prednisolone does not induce a clear insulin resistance in mice, but strongly affects hepatic glucose metabolism. In addition, this study clearly establishes that fasting glucose and insulin levels, routinely translated into a HOMA-score, do not necessarily reflect insulin sensitivity in mice.

Acute and subacute exposure to glucocorticoids differentially impair various aspects of beta cell function in healthy males

D.H. van Raalte¹, A. Mari², M.C. Bunck¹, V. Nofrate², U. Nässander³, W.H.A. Dokter³, R.J. Heine¹, M. Diamant¹

¹Department of Endocrinology / Diabetes Centre, VU University Medical Centre, Amsterdam, Netherlands, ²Institute of Biomedical Engineering, National Research Council, Padova, Italy, ³NV Organon, part of Schering-Plough Corporation, Oss, Netherlands

Background and aims: Glucocorticoids are the most frequently prescribed anti-inflammatory agents, but their use is also associated with dysmetabolic side-effects, including glucose intolerance and diabetes. Although glucocorticoid-induced insulin resistance is well-established, the effects of glucocorticoids on beta-cell function, and in particular under physiological conditions, are less well characterized.

Materials and methods: We conducted a randomized, double-blind trial in healthy men (age 25.5 ± 4.8 yrs; BMI 24.1 ± 1.7 kg/m²). Participants (n=23) received either prednisolone 30 mg or placebo once daily for a period of 15 days (study 1). In study 2, a single oral dose of 75 mg prednisolone was administered to 6 healthy men. High-fat mixed-meal tests (34g protein, 50g fat, 75g carbohydrates) were performed before and during glucocorticoid therapy (studies 1 and 2), and after discontinuation (study 2). Insulin secretion rate was calculated by C-peptide deconvolution and beta-cell function was evaluated with a model that describes insulin secretion rate as a function of absolute glucose levels (insulin secretory tone and glucose sensitivity), the glucose rate of change (rate sensitivity), and a potentiation factor.

Results: At day 15, prednisolone 30 mg daily increased fasting glucose (p = 0.023), and decreased insulin sensitivity (p = 0.03), without affecting non-esterified fatty acid- and triglyceride-levels. During the meal, prednisolone augmented the area under the glucose response curve (AUC_{gluc}) (p < 0.001), despite a marked increase in insulin secretion (p = 0.049). Prednisolone impaired various indices of beta-cell function, including the insulinogenic index adjusted for insulin sensitivity (p = 0.08) and potentiation (p = 0.007), however, glucose- and rate sensitivity were unaltered. A single dose of 75 mg prednisolone acutely induced insulin resistance, and markedly decreased the insulin response to the meal test, resulting in an increased AUC_{gluc} (p = 0.003). Acute high-dose of prednisolone impaired glucose sensitivity (p = 0.033) and potentiation (p = 0.032), but did not affect rate sensitivity. One day after discontinuation of the single high prednisolone-dose, all values had normalized, except for insulin secretion which rose during the meal test (p < 0.001).

Conclusion: Acute and short-term exposure to glucocorticoids differentially affect beta-cell function. Collectively, these abnormalities, in addition to glucocorticoid-induced insulin resistance, may account for glucocorticoid-related diabetogenic effects.

664

Characterisation of alpha cell function in Africans with ketosis-prone non-autoimmune diabetes during insulin-free remission

S. Choukem¹, E. Sobngwi^{1,2}, P. Boudou³, L.-S. Fetita¹, P. Vexiau¹, F. Calvo⁴, J.-F. Gautier^{1,5}

¹Endocrinology and Diabetes, Saint Louis Hospital, Paris, France, ²Institute of Health and Society, University of Newcastle, United Kingdom, ³Hormones Laboratory, Saint Louis Hospital, Paris, France, ⁴Clinical Investigation Centre, Saint Louis Hospital, Paris, France, ⁵Umr872, INSERM, Paris, France

Background and aims: Ketosis-prone non-autoimmune diabetes (KPD), also known as idiopathic type 1 or type 1B diabetes is a syndrome of un-

clear pathogenesis found mainly in people of sub-Saharan African ancestry. It is characterised by an acute onset with ketosis or ketoacidosis that requires urgent insulin treatment. This is followed by a prolonged long-term near-normoglycaemic remission without insulin treatment in more than 50% of patients. The aim of this study was to characterize the alpha cell function during remission.

Materials and methods: We studied 19 sub-Saharan Africans with KPD during insulin-free remission ($HbA_{1c} \leq 7\%$ for ≥ 3 months without insulin) along with 19 control subjects with normal glucose tolerance, matched for age (44.5 ± 2.4 vs. 43.7 ± 1.9 years respectively), sex and geographical origin. Glucagon levels were measured in response to oral glucose (75g-OGTT), to IV glucose (200-min glucose ramp from 2 to 10 $mg \cdot kg^{-1} \cdot min^{-1}$ glucose infusion), to arginine (5g IV at the end of the glucose ramp) and to induced hyperinsulinaemia (euglycaemic hyperinsulinaemic clamp). The product glucagon \times glucose ($10^{-3} pg \cdot mmol \cdot ml^{-2}$) was used as a surrogate of the resistance to glucagon suppression by glucose during OGTT. During the glucose ramp, the slope of glucagon decrement per glucose increment was used to measure the dose-response effect. The incremental area under the curve (AUC_c) and the acute glucagon response to arginine ($AGR = [\text{mean glucagon concentration from 2 to 5 min post-arginine bolus}] - [\text{glucagon concentration prior to the bolus}]$) were estimated in response to arginine. Results are expressed as percentage or mean \pm standard error. Comparison between groups was performed using the non-parametric Mann-Whitney U test.

Results: Basal glucagon level prior to each test was similar between groups. During OGTT, the resistance index was 881.4 ± 105.5 vs. 614.5 ± 48.7 ($p = 0.028$) at baseline, 1576.9 ± 138.7 vs. 1188.4 ± 130.2 ($p = 0.049$) at 30 min, and 1680.8 ± 147.2 vs. 652.6 ± 39.9 ($p < 0.001$), at 120 min in patients and controls respectively. During the glucose ramp, each glucose increment of 1 mmol/l lead to a $1.6 \pm 0.2\%$ ($1.9 \pm 0.3 pg/ml$) decrease in glucagon concentrations in patients vs. $4.5 \pm 0.6\%$ ($5.3 \pm 0.9 pg/ml$) in controls ($p = 0.001$). During the hyperinsulinaemic clamp, the glucagon levels decreased from baseline by the same extent in both groups (patients: 119.9 ± 10.7 to $81.3 \pm 7.1 pg/ml$, controls: 124.4 ± 9.3 to $89.0 \pm 8.2 pg/ml$; $p = NS$). After adjustment to insulin and glucose levels prior to the arginine bolus, no difference was found between groups in response to arginine using either the AUC_c or the AGR .

Conclusion: During remission, patients with KPD display alterations of glucagon suppression in response to oral and IV glucose similar to those reported in patients with type 2 diabetes. These results suggest that KPD should be considered as a form of type 2 diabetes.

A NO/sGC/cGMP dependent mechanism is involved in the regulation of net hepatic glucose uptake by hepatic nitric oxide *in vivo*

Z. An, J.J. Winnick, M.C. Moore, D. Neal, B. Farmer, T. Rodewald, W. Snead, A.D. Cherrington

Department of Molecular Physiology and Biophysics, Vanderbilt University School of Medicine, Nashville, United States

Background and aims: Our previous study showed that portal but not peripheral infusion of a nitric oxide donor (SIN-1) reduced net hepatic glucose uptake (NHGU) in the presence of the portal glucose delivery, hyperglycemia and hyperinsulinemia, suggesting that the increased hepatic NO resulting from portal SIN-1 infusion regulates NHGU. Because NO has been shown to activate soluble guanylate cyclase (sGC), the aim of the present study was to determine whether a sGC/cGMP dependent mechanism could be involved in the regulation of NHGU by hepatic NO.

Materials and methods: Studies were performed on two groups of 42-h-fast-d conscious dogs that had undergone laparotomy for vascular cannulation ~16 d before study. After a basal period (-30 to 0 min), somatostatin was given peripherally along with 4X basal insulin and basal glucagon intraportally. At 0 min, glucose was delivered at a variable rate via a leg vein to increase the hepatic glucose load to 2X basal. At 90 min, an intraportal infusion of a sGC inhibitor (ODQ, 0.8 $\mu g/kg/min$) was started in the ODQ group ($n=10$) while saline was given in the CON group ($n=10$).

Results: No significant hemodynamic changes were observed in either group. The arterial insulin levels were 4X basal (22 ± 2 and $21 \pm 2 \mu U/mL$) while glucagon was basal (40 ± 4 and $39 \pm 4 pg/mL$) in the CON and ODQ groups, respectively. NHGU ($mg/kg/min$) was 2.4 ± 0.3 and 2.3 ± 0.3 in the CON and ODQ groups, respectively prior to ODQ infusion (0-90 min). During the last half hour of the ODQ infusion period (240-270 min), NHGU was 3.2 ± 0.3 and 4.9 ± 0.5 ($P < 0.05$) in the CON and ODQ groups respectively.

Conclusion: The NO/sGC/cGMP dependent pathway has the ability to regulate net glucose uptake by the liver *in vivo* in the conscious dog.

The changes of plasma FGF-21 levels in type 2 diabetic mellitus, diabetic ketosis and normal subjects

G. Yang¹, L. Li², M. Yang¹, N. He¹

¹Department of Endocrinology, the Second Affiliated Hospital, ²Department of Clinical Biochemistry, Chongqing Medical University, Chongqing, China

Background and aims: Fibroblast growth factor-21 (FGF-21) has been recently characterized as a potent metabolic regulator, but its pathophysiologic role in humans remains unknown. In this study we investigate whether plasma FGF-21 level is different in patients with type 2 diabetes mellitus (T2DM) and diabetic ketosis (T2DK).

Materials and methods: Sixty-eight patients with T2DM, 41 subjects with T2DK, and 52 sex-and age - matched normal controls participated in the study. Plasma FGF-21 levels were measured with a radioimmunoassay. The relationship between plasma FGF-21 levels and anthropometric and metabolic parameters was also analyzed.

Results: Plasma FGF-21 levels were higher in patients with T2DK and T2DM than in controls (4.05 ± 0.18 and 2.82 ± 0.14 vs. $2.28 \pm 0.16 \mu g/L$, $P < 0.01$ and $P < 0.05$, respectively). And it was higher in patients with T2DK than T2DM ($P < 0.01$). Fasting plasma FGF-21 was found to correlate positively and significantly with SBP ($r=0.17$, $P < 0.05$), DBP ($r=0.18$, $P < 0.05$), FBG ($r=0.52$, $P < 0.01$), 2hPBG ($r=0.57$, $P < 0.01$), HbA_{1c} ($r=0.43$, $P < 0.01$), HDL-C ($r=0.18$, $P < 0.05$) and FFA ($r=0.18$, $P < 0.05$), but negatively with fasting plasma insulin ($r=-0.38$, $P < 0.01$), 2hIns ($r=-0.54$, $P < 0.01$) and $HOMA_{-IS}$ ($r=-0.54$, $P < 0.01$). Multiple regression analysis showed that DBP, WHR, 2hIns, 2hPBG and FFA were independent related factors influencing plasma FGF-21 levels ($Y_{FGF-21} = 3.186 + 0.058X_{2hPBG} - 0.007X_{2hIns} + 0.491X_{FFA} - 3.206X_{WHR} + 0.021X_{DBP}$). Multivariate logistic regression analysis showed that plasma FGF-21 level was also significantly associated with T2DM and T2DK even after controlling for anthropometric variables, blood pressure and lipid profile. Increasing levels of FGF-21 showed a significant linear trend and were independently associated with T2DM, especially when concentrations were analysed both by Mow Mean Scores and Cochran-Armitage Trend Test

Conclusion: Our results of elevated FGF-21 in T2DM and T2DK indicate that FGF-21 may play a role in the pathogenesis of T2DM and T2DK. However, further experiments need to be done to clarify the role of FGF-21.

Blood glucose homeostasis of patients with type 1 diabetes mellitus: effects of physical activity at high compared to low altitude

T. Siegmund¹, B. Gutt¹, A. Wiesmeth¹, S. Graf², R. Fischer², P.-M. Schumm-Draeger¹

¹Endocrinology, Diabetes and Vascular Medicine, Klinikum Munich GmbH,

²Medical Department, University Hospital Munich, Germany

Background and aims: Increasing numbers of patients with type 1 diabetes practice intense forms of physical activity at higher altitudes, including high-altitude trekking, mountain climbing, mountain biking and skiing. To date only marginal data is available comparing blood glucose (BG) homeostasis at low and high altitudes.

Materials and methods: We conducted a study with 10 patients with type 1 diabetes performing an insulin pump therapy. All participants performed two standardized endurance trainings periods (75 watts over 2 hours) on a bike ergometer at low altitude (L), in Munich 530m above sea level and at high altitude on the Zugspitze mountain (H), Environmental Research Station Schneefernerhaus, 2650m above sea level. To evaluate differences in BG homeostasis BG measurements as well as the continuous glucose monitoring system (CGMS, Medtronic) were used. Consumption of carbohydrates (C) and insulin for BG stabilisation was allowed.

Results: Data is presented as medians and ranges. Before the exercise BG was similar at L (0 min: 7.7 mmol/l [6.4–15.8]) and H (0 min: 8.9 mmol/l [4.1–12.2], n.s.). Two hours after starting the endurance training BG was significantly lower in L (6.3 mmol/l [3.6–7.9]; $p=0.04$) as well as H (6.6 mmol/l [2.6–12.5]; $p=0.04$). Ingested C were comparable (L: 42 gr. [0–96]; H: 36 gr. [0–84]; n.s.). In L, 8 out of 10 participants showed a trend of initial BG rising, after 80 min, BG levels returned to their starting level. After 120 min BG was significantly lower (6.2 mmol [3.8–7.7]; $p=0.04$). In contrast at H, 8 out of 10 participants showed an immediate BG drop, after 25 min BG was significantly lower (6.9 mmol/l [2.2–11.2]; $p=0.03$ and stayed significantly lower until the end of the exercise.

Conclusion: At high altitude (2650 m) physical activity caused a significantly early BG drop compared to low altitude (530 m). Patients with type 1 diabetes should reduce insulin dose appropriately or ingest more carbohydrates when exercising at high altitude.

Moderate intensity exercise was more effective in body fat loss, but vigorous exercise improved the insulin resistance in overweight type 2 diabetes mellitus

K. Han, B. Koo, H. Kim, H.-J. Kim, K. Pak, K. Min, E. Kim

Department of Internal Medicine, Eulji university, Seoul, Republic of Korea

Clinical practice guidelines on the application of exercise intervention in Type 2 diabetes do not provide much detail regarding the intensity of exercise. The purpose of this study was to evaluate the effect of exercise of differing intensity on body fat, adipokines and insulin sensitivity, especially comparing with dietary caloric restriction. 57 overweight female subjects with type 2 diabetes were randomly assigned to each five groups and completed four different 12-week weight loss program; control(C), diet group(DG), moderate intensity exercise group(MExG), and vigorous intensity exercise group(VExG), and diet plus exercise group(DEG). Participants were encouraged to take the calorie restriction (< 1300 kcal /day) for DG. Increase of activity energy expenditure (> 300 kcal/day) with moderate intensity exercise for MExG, with vigorous intensity exercise for HExG, and both for DEG. We monitored the subject's diet with self reported diet diary and exercise with the accelerometer. We assessed body mass index(BMI), total fat(ATF), subcutaneous fat(ASF) and visceral fat(AVF) at abdomen, liver(LF) and spleen fat(SF), and subcutaneous(TSF), subfacial(TSF), and intramuscular fat(TIMF) at thigh level using computed tomography, insulin sensitivity by insulin tolerance test (K_{ITT}) and fasting serum levels of several adipokines before and after intervention. At baseline, age and BMI were not different the differences across 5 groups (age:55.4±7.7 years, BMI: 27.2±2.5kg/m²). After intervention, BMI, ATF and ASF were greater reduced in DG, MExG and DEG, but not in HExG and loss of AVF was greater in DG and MExG, but not in DEG and HExG, compared with C (Table 1). The changes of LF, SF, TSF, TSE, and TIMF were not different among 5 groups. Retinol binding protein-4 (RBP-4) increased by 42% in DG which was significantly different with other three intervention groups. Vaspilin showed smaller increase in DG than in C and MExG. Adiponectin was significantly changed with ASF, leptin with AVF, RBP-4 and apolipoprotein B with both ASF and AVF during 12 weeks trial after adjusted with age. Compared to baseline, K_{ITT} was improved only within HExG and DEG ($P<0.01$) without the difference across groups. By stepwise multiple regression analysis, major determinants of the percent changes of K_{ITT} were baseline K_{ITT} and activity energy expenditure during trial ($P<0.01$). The equivalent energy expenditure from moderate and vigorous activity resulted that moderate activity was more effective in body fat loss, vigorous exercise might improved the insulin resistance, although diet restriction was superior to exercise in weight reduction in overweight type 2 diabetes mellitus. Adiponectin, leptin, and RBP-4 changed with different compartments of body fat.

Table 1. Change of the body fat and adipokines during 12 week weight reduction program.

	Control N=11	Diet N=10	Moderate Intensity Exercise N=9	Vigorous intensity Exercise N=14	Diet and Exercise N=10	Significance

Effect of exercise on gene transcript profiles in skeletal muscle of individuals with and without a family history of diabetes

O. Hansson, T. Elgzyri, H. Parikh, K.-F. Eriksson, L. Groop
Clinical Sciences, Lund University, Malmö, Sweden

Background and aims: It is well established that the risk of developing type 2 diabetes (T2D) increases with age, obesity and reduced physical activity, but the effect of the environment seems to be exaggerated by a family history of type 2 diabetes (FH+). It has previously been shown that the expression of genes involved in oxidative phosphorylation is co-ordinately down regulated in human diabetic muscle and that this reduction in gene expression is correlated with total-body aerobic capacity. It is, however not known whether down-regulation of these genes is primary (genetic) or secondary to reduced physical activity. One way to test this hypothesis is to study whether there is a difference in gene transcript profiles in skeletal muscle between individuals with and without a FH+ and whether this is reversible by a 6 month exercise period.

Materials and methods: 19 male subjects with and 20 without a FH matched for age, BMI and VO₂max were after basal muscle biopsy (from vastus lateralis), a VO₂ measurement and OGTT exposed to 6 months of aerobic training (3 group-training sessions per week, ~60 min training / session) whereafter the measurements and biopsies were repeated. Gene expression profiles were measured using Affymetrix expression arrays. The expression data have been analysed using pathway analysis tools, including Gene Set Enrichment Analysis (GSEA). Key changes in gene expression have been verified using rt-Q-PCR.

Results: FH+ individuals had reduced expression of mitochondrial genes and of genes associated with fatty acid metabolism in skeletal muscle, including PGC1α, NDUFB3, CPT1, CPT2 and malonyl-CoA decarboxylase compared with FH- subjects. In FH+ subjects exercise training up-regulated mitochondrial genes, as well as genes involved in electron transport, e.g. NDUFB1, NDUFB5, NDUFB9 and cytochrome C to the same extent as in FH- subjects, but had no effect on genes involved in fatty acid metabolism.

Conclusion: Individuals with a family history of T2D show down-regulation of mitochondrial genes in skeletal muscle, which is reversible by exercise. On the other hand, inability to upregulate genes in fatty acid metabolism could point at metabolic inflexibility.

Cause and effect in the relationship between body fat and physical activity in children: a longitudinal study

B. Metcalf, J. Hosking, A. Jeffery, L. Voss, T. Wilkin

Endocrinology & Metabolism, Peninsula Medical School, Plymouth campus, United Kingdom

Background and aims: Several cross-sectional studies have concluded, based on weak inverse associations, that less activity leads to more body fat. However, such study designs cannot determine direction of causality, and the observed association may equally reflect the reverse - that more body fat leads to less activity. The aim of this study is to investigate the direction of causality between physical activity and body fat in children, applying the rule of temporality to longitudinal data.

Materials and methods: Physical activity (PA) was measured objectively by 7-day accelerometry (MTI Actigraphs) at four annual time-points - 6y, 7y, 8y and 9y. Percent body fat (%BF) was measured by DEXA at 7y and 8y. Time-lagged correlations between %BF and PA one year before ($PA_{[t-1]}$) and one year after ($PA_{[t+1]}$) the measurement of %BF_[t] were performed at two time-points ($t=7y$ and $t=8y$). Analysis was performed on 185 children (104 boys, 81 girls) from the EarlyBird Diabetes Study.

Results: The correlation of %BF_[t] with $PA_{[t+1]}$ was stronger than %BF_[t] with $PA_{[t-1]}$ when $t=7y$ (%BF₇-v- PA_{8} , $r = -0.21$, $p < 0.01$, %BF₇-v- PA_{6} , $r = -0.06$, $p = 0.40$) and again when $t=8y$ (%BF₈-v- PA_{9} , $r = -0.20$, $p < 0.01$, %BF₈-v- PA_{7} , $r = -0.13$, $p = 0.08$). On average the correlations were: %BF_[t]-v- $PA_{[t+1]}$, $r = -0.20$ and %BF_[t]-v- $PA_{[t-1]}$, $r = -0.10$ with the magnitude of the difference remaining even after controlling for $PA_{[t]}$.

Conclusion: Body fat is associated more strongly with PA measured one year later than with PA measured one year earlier, implying that fatness may influence activity more than activity influences fatness. The weakness of the association and its direction of causality could together be reasons why attempts

to tackle childhood obesity by promoting physical activity have been largely unsuccessful. If confirmed, the findings may shift the focus of prevention to calorie intake.

Standardised depletion of intramyocellular lipids (IMCL) in subjects with different degree of insulin resistance and exercise capacity

A. Egger¹, P.M. Huber², M. Ith³, I. Krull¹, J.-P. Schmid³, R. Kreis², E. Christ¹, C. Boesch²

¹Div. of Endocrinology, Diabetes and Clinical Nutrition, Inselspital, University Hospital, ²Department of Clinical Research, MR Spectroscopy and Methodology, University Bern, ³Department of Cardiology, Cardiovascular Prevention & Rehabilitation, Inselspital, University Hospital, Bern, Switzerland

Background and aims: Intramyocellular lipids (IMCL) are metabolically active fuel stores that are related to individual insulin sensitivity. Diet and physical exercise are important factors influencing IMCL, which can be measured non-invasively by ¹H magnetic resonance spectroscopy (¹H-MRS).

Depletion and subsequent replenishment of IMCL give insight into availability and dynamics of this energy store. The aim of the present study was to develop a standardized IMCL depletion protocol that is well tolerated by sedentary patients and sufficiently depletes IMCL in well trained athletes.

Materials and methods: 12 male subjects, including 4 patients with diabetes type 2 treated by oral antidiabetic drugs, were tested for physical performance and insulin sensitivity, by spirometry (VO_{2peak}) and a euglycaemic hyperinsulinaemic clamp, respectively. Using ¹H-MRS, IMCL were measured in m. tibialis anterior and m. vastus intermedius once before (day 1) and three times (days 5, 6, 7) within a week with daily moderate exercise (1 hour at 60% VO_{2peak}) and moderate low-fat (5% of energy expenditure) diet.

Results: The enrolled subjects intentionally showed wide ranges of BMI (between 21.5 and 31.7 kg/m²), physical performance (VO_{2peak} between 27.9 and 55.8 ml*min⁻¹*kg⁻¹), insulin sensitivity (glucose disposal rate per lean body mass between 4.7 and 15.3 mg*min⁻¹*kgLBM⁻¹) and age (between 24 and 63 years). While IMCL levels are higher in the vastus muscle as compared to the m.tibialis anterior, both muscles show the same behavior following exercise and low fat intake (Figure): compared to baseline IMCL measurements (day 1) a highly significant ($p < 0.001$ for each muscle) IMCL reduction is achieved after 3 days of moderate exercise and diet. During the following days, IMCL levels remain constant on a minimal level (day 4 and day 5). Depleted IMCL levels were independent of insulin sensitivity in both muscles. However, subjects with higher VO_{2peak} showed lower depleted IMCL levels (average over 3 days) in both muscles (correlation $p = 0.08$ for m.tibialis anterior and $p = 0.05$ for m.vastus intermedius).

Conclusion: These findings suggest that a) the presented protocol is robust and feasible in a wide range of subjects with large differences in physical performance and insulin sensitivity b) it leads to a "minimal IMCL" after 3 days, independent of previous diet and insulin sensitivity, and c) after reaching this "minimal IMCL" level, this protocol allows studies of replenishment in very different groups of subjects, including patients and athletes. To conclude, this protocol allows comparison of IMCL dynamics in a standardized fashion.

Tissue-specific regulation of adiponectin and its receptors by rosiglitazone and exercise treatment in obese diabetic OLETF rat

M. Nam, Y.-J. Oh, S.-H. Kim, Y.-S. Kim

Internal Medicine, Inha University College of Medicine, Incheon, Republic of Korea

Background and aims: Aerobic exercise is recommended with or without oral hypoglycemic agents, particularly thiazolidinediones (TZDs), for the treatment of obese type 2 diabetes mellitus. Adiponectin, an abundant adipose-derived cytokine, plays an important role in modulation of insulin sensitivity, and the metabolism of glucose and lipids. It is not fully understood whether the independent and combined effects of rosiglitazone and exercise treatments are associated with improvements in adiponectin resistance.

Materials and methods: We evaluated the independent and combined effects of aerobic exercise (15 m/min and 30 min/day) and rosiglitazone (3mg/kg/day) for 12 weeks on metabolic parameters, adiponectin and its receptors expression, glucose transport, fatty acid oxidation in an obese diabetic prone animal model, the Otsuka Long-Evans Tokushima Fatty (OLETF) rat.

Results: Increased lean body mass, decreased epididymal fat, and improved intraperitoneal glucose tolerance test were observed in both rosiglitazone plus exercise and exercise only groups (each group n=15). With regard to the plasma lipid profile change, significantly decrease in triglyceride levels were observed in both exercise and rosiglitazone groups but decreased LDL levels were shown in rosiglitazone only and rosiglitazone plus exercise group but not in the exercise only group. Decreased plasma adiponectin concentration and decreased adiponectin mRNA expression both in skeletal muscle and adipose tissue were observed in diabetic control group. Exercise training, but not rosiglitazone increased adiponectin, phosphorylation of AMP-activated protein kinase (AMPK) α /beta1, GLUT4 and decreased Acetyl-CoA carboxylase (ACC) in skeletal muscle. In contrast, rosiglitazone, but not exercise reversed adiponectin resistance in adipose tissue. However, the rosiglitazone and exercise combined group was able to reverse adiponectin resistance in both skeletal muscle and adipose tissue.

Conclusion: exercise training and rosiglitazone may act as complementary therapies for the treatment of adiponectin resistance in obese diabetes.

fasting blood samplings, DXA-scanning and measurements of physical fitness level on a bicycle ergometer.

Results: Heart rate measured during submaximal exercise at the same absolute work load (a marker for physical fitness level) was decreased in the patients of group 1 to an average of 126 (SD 12,4) bpm vs. baseline values of 134 (SD 11,4) bpm; ($p < 0.02$). Furthermore, they had an increase in lean body mass from 50,7 (SD 9,6) kg to 52,1 (SD 9,8) kg ($p = 0,002$), reduction of fat % from 38,4 (SD 6,5) to 36,8 (SD 7,1) ($p = 0,003$) and a decrease in plasma HbA1c concentration from 8,14 (SD 1,1) % to 7,74 (SD 1,18) % ($p = 0,03$) after the intervention. In group 2, no significant changes were observed.

Conclusion: An increase in aerobic fitness level after 10 weeks exercise intervention was associated with a significantly lowered HbA1c. This was obtained when exercise was performed even at low to moderate intensity levels. In spite of no changes in body weight, the activities lead to changes in body composition through increased muscle mass and lowered fat %. Furthermore, self-reported personal wellbeing (quality of life) was increased. The present study clearly demonstrates that in order to implement and maintain physical activity in the everyday life of patients with long term T2D, individually modified exercise programs, regular personal contact combined with supervised exercise are necessary; and that physical activity is realistic and possible to implement in clinical settings.

Supported by: Steno Diabetes Center

A model for implementation and maintenance of physical activity in patients with type 2 diabetesS.M. Sørensen^{1,2}, S. Larsen¹, K. Hove¹, T. Gjørup¹, A. Vaag¹, B. Kiens²¹Steno Diabetes Centre, Gentofte, Denmark, ²Copenhagen Muscle Research Centre, Department of Human Physiology, Institute of Exercise and Sport Sciences, University of Copenhagen, Denmark

Background and aims: The beneficial effects of physical activity in prevention and treatment of type 2 diabetes (T2D) are well documented. Although lifestyle intervention programs may work in some community settings and in early diabetic and/or prediabetic subjects, no models or guidelines are developed to implement training programs in a clinical diabetes setting involving patients with longer duration of disease. Therefore, the aim was to develop and test an individualized and supervised program to implement physical activity in such patients.

Materials and methods: One hundred and sixty two patients with T2D from the Steno Diabetes Centre were contacted by letter. Thirty responded positively and 21 sedentary patients (10 men and 11 women, aged 48-65 years, average duration of T2D 12,6 years) were enrolled in the study. For women and men, respectively, average values for body weight were 81,3 (SD 15,6) kg and 99,5 (SD 10,3) kg, BMI 31,4 (SD 5,2) kg/m² and 32,2 (SD 3,1) kg/m², body fat % averaged 43,2 (SD 4,5) and 34,7 (SD 3,7). Plasma [HbA1c] in the whole group averaged 8,03 (SD 1,00)%. The patients were randomly assigned to one of two intervention groups. Both included information about benefits of physical activity, and individual oral guidance on how to implement self-chosen physical activities in everyday life. Additionally, group 1 (5 men and 6 women) participated in group-sessions of supervised exercise twice a week in their local environments. On the remaining days of the week the patients were responsible for their own daily activity. Group 2 (5 men and 5 women) was on a daily basis requested to exercise individually or in self-established groups. In order to supervise the process, every second week, group 2 was contacted by their coach. Activities included Nordic walking, jogging, biking, water activities and resistance training. At baseline and after 10 weeks of intervention, all patients went through a standardised test protocol including

PS 051 Hypoglycaemia

Involvement of active ghrelin in glucose homeostasis: a protective role against the occurrence of hypoglycaemia

E. Disse, C. Veyrat-Durebex, N. Deblon, F. Rohner-Jeanrenaud
 Departement of Internal Medicine, Endocrinology, Laboratory of Metabolism, Geneva, Switzerland

Background and aims: Ghrelin, a 28-amino acid peptide predominantly produced by the stomach, is the most powerful orexigenic hormone in mammalian physiology. The deletion of ghrelin in ob/ob mice, a murine model of obesity, augments glucose-induced insulin secretion and markedly reduces the level of hyperglycemia exhibited by these mice. The aim of our study was to determine the influence of an acute peak of plasma ghrelin on glucose homeostasis and to determine in vivo the mechanisms of this hyperglycaemic effect. Furthermore, we wondered whether these ghrelin-elicited effects were physiologically relevant, using mice knock-out for the ghrelin receptor (GHSR1a^{-/-}).

Materials and methods: We IP administrated 10 nmol of acylated ghrelin or 250 µl of saline in Wistar rats with a chronic jugular catheter. Blood samples were taken every 30 minutes during the 4 following hours to quantify active ghrelin, glucose, insulin, glucagon, leptin, GLP-1, NEFA and adiponectin. We then performed a glucose tolerance test in these animals after an ICV injection of 250 pmol of ghrelin in a way to determine whether the ghrelin-elicited effects were centrally mediated. The physiological relevance of these effects was determined by testing GHSR1a^{-/-} mice during GTT, ITT and prolonged fasting. We finally worked on the ghrelin-elicited effects during insulin-induced hypoglycemia in C57Bl6 mice after the blockade of the autonomous nervous system which is implicated in the hormonal counterregulation to hypoglycaemia. We used a pharmacological blockade of the parasympathetic system (Atropine) and a genotypic blockade of the sympathetic system (mice deleted for the β1, β2 and β3 adrenoreceptors).

Results: The glucose AUC (Area Under Curve) was significantly increased in the ghrelin-treated group (42.552 ± 1.764 vs 32.305 ± 1.193 mmol x 240min, p<0.005), while the insulin AUC and the insulinosecretion index, AUC insulin-to-AUC glucose ratio, were significantly decreased (51.757 ± 9.549 vs 80.970 ± 9.549 pg x 240min, p<0.05 and 2.46 ± 0.2 vs 1.25 ± 0.4, p<0.005, respectively) after ghrelin injection. This hyperglycaemic and insulinostatic effect was also found after the ICV injection of 250 pmol of active ghrelin, demonstrating that the ghrelin-elicited effect was at least partially centrally mediated. In GHSR1a^{-/-} mice, glucose tolerance was unaltered, but mice exhibited deeper glycaemic nadir during the insulin-induced hypoglycaemia and lower glycaemic levels during prolonged fasting. The hyperglycaemic effect of ghrelin was still present in C57Bl6 mice during insulin-induced hypoglycaemia, in which endogenous insulin secretion is inhibited, but this effect was blunted in mice deleted for the three β-adrenoreceptors.

Conclusion: Altogether, these data suggest that ghrelin induces hyperglycemia. This effect is mediated through an inhibition of glucose-induced insulin secretion, partially centrally mediated and a mechanism independent of insulin secretion mediated through the sympathetic pathway. The ghrelin-elicited effects on glucose homeostasis could be physiologically relevant to a protective effect against the occurrence of hypoglycaemia.

The effects of acute insulin-induced hypoglycaemia on spatial ability in adults with type 1 diabetes

R.J. Wright¹, I.J. Deary², B.M. Frier¹

¹Department of Diabetes, Royal Infirmary of Edinburgh, ²Psychology Department, University of Edinburgh, United Kingdom

Background and aims: The effects of acute insulin-induced hypoglycaemia have been studied on several cognitive domains, both in people with diabetes and in non-diabetic subjects. However, the effects on spatial abilities have not been studied in detail. Spatial ability is important for the conduct of cognitively demanding tasks such as navigating whilst driving, and an adverse effect of hypoglycaemia could influence several daily activities.

Materials and methods: Sixteen people with type 1 diabetes (7 male; median age 28 years; median HbA1c 7.8%) underwent hyperinsulinaemic glucose

clamps on two separate occasions. Arterialised blood glucose was maintained at 4.5 mmol/l for 30 minutes, and either continued at this level (euglycaemia condition) or lowered to 2.5 mmol/l (hypoglycaemia condition), for 60 minutes. The experimental conditions were counter-balanced. The Digit Symbol Substitution Test (DSST) and a battery of specific spatial ability tests, derived from the French and Ekstrom Kit of Factor-referenced Cognitive Tests, were applied during each experimental condition. Results were analysed using repeated measures ANOVA with condition as a within-subjects factor.

Results: Digit symbol substitution was significantly impaired during hypoglycaemia (p<0.001), as anticipated. The Hidden Patterns, Card Rotations, Paper Folding and Maze Tracing tests were all impaired significantly (all p≤0.001) during hypoglycaemia, as was the Cube Comparisons test (p=0.03). The Map Memory test was not significantly affected by hypoglycaemia. The results are shown in Table 1 (as mean [SD]).

Conclusion: In the first detailed examination of this cognitive domain, the ability to perform several tests of spatial ability was significantly impaired during hypoglycaemia, when compared with performance during a euglycaemic control period. This has important implications for people with type 1 diabetes in the performance of everyday tasks.

Table 1: Results of spatial ability testing

Spatial Test	Euglycaemia score	Hypoglycaemia score	p-value
Hidden Patterns	94.5 (21.8)	73.7 (21.0)	<0.001
Card Rotations	51.9 (15.5)	40.4 (18.7)	0.001
Cube Comparisons	11.7 (4.1)	9.4 (5.7)	0.03
Paper Folding	6.0 (1.9)	4.7 (2.0)	0.001
Map Memory	8.6 (3.1)	7.8 (2.1)	0.3
Maze Tracing	11.1 (3.0)	9.4 (2.5)	<0.001

No effect of GLP-1 on human brain glucose delivery during hypoglycaemia

S. Lerche¹, B. Brock¹, J. Rungby¹, H. Boetker¹, N. Moeller¹, K. Vang², J.J. Holst³, A. Gjedde², O. Schmitz¹

¹Department of Pharmacology, Aarhus University, ²PET center, Aarhus University Hospital, ³Department of medical Physiology, Copenhagen University, Denmark

Background and aims: The brain almost exclusively depends on circulating glucose. Hypoglycaemia therefore is deleterious to brain function. The Michaelis-Menten formalism describes the magnitude of blood-brain glucose transfer across the blood-brain barrier (BBB) at glucose concentrations in arterial plasma ranging from hypo- to hyperglycaemia. Glucagon-like-peptide-1 (GLP-1) inhibits blood-brain glucose exchange at normoglycaemia and predictably also at hyperglycaemia. We believe that this action may explain GLP-1's neuroprotective effect at normal or higher glucose levels. However, the Michaelis-Menten formalism predicts that hypoglycaemia minimizes the effect on glucose transport of GLP-1's action on the maximum glucose transport capacity.

Materials and methods: To test this prediction of the effect of GLP-1 in hypoglycaemia, we determined glucose transport and consumption rates in 7 healthy men in a randomized, double-blinded placebo-controlled cross-over experimental design. The acute effect (independent of insulin) of GLP-1 on glucose transfer in the brain was measured by positron emission tomography (PET) during a pituitary-pancreatic stepwise hypoglycaemic clamp with 18-fluoro-deoxy-glucose (FDG) as tracer of glucose.

Results: The plasma glucose (PG) during PET averaged 3.0 mM with an insulin infusion rate of 0.8 mU/kg*min. We initially maintained growth hormone (GH) and glucagon close to baseline but both increased significantly in the hypoglycaemic phase, as did epinephrine levels. PG, insulin, glucagon, GH, epinephrine levels and glucose infusion rate were similar with GLP-1 and placebo. Total and intact GLP-1 levels stayed in the pharmacological range. In total cerebral grey matter, the cerebral glucose uptake remained unchanged during hypoglycaemia with GLP-1, 0.37 ± (SEM) 0.03 (GLP-1) vs. 0.40 ± 0.02 micromol/cm³/min (placebo), (P=0.25). The cerebral metabolic rate for glucose remained unchanged at 0.29 ± 0.01 vs. 0.30 ± 0.01 micromol/cm³/min, (P=0.28) with GLP-1, as was the intracerebral glucose concentration at 0.63 ± 0.05 vs. 0.76 ± 0.16 mmol/L, (P=0.39).

Conclusion: The results complement our previous study of GLP-1 in normoglycaemia. The confirmation that the effect of GLP-1 on glucose transport

rates is too small to measure at low glucose concentrations contributes to the understanding of GLP-1's generally beneficial action also in hypoglycaemia.

Insulin VIAject™ and regular human insulin in patients with type 1 diabetes: efficacy and safety in an open-label multicenter clinical trial

F.M. Flacke¹, D. Klonoff², B. Sethi³, T. Forst⁴, P. Simms⁵, L. Heinemann⁵, A. Pfuetzner⁴, S.S. Steiner¹

¹Clinical, Bidel Inc., Danbury, United States, ²Clinical Research, Mills Peninsula Health Service, San Mateo, United States, ³Clinical Research, Care Hospital, Hyderabad, India, ⁴Clinical Research, IKFE, Mainz, Germany, ⁵Clinical Research, Profil, Düsseldorf, Germany

Background and aims: VIAject™ (VIA) is an ultra-rapid acting formulation of regular human insulin (RHI). The aim of this ongoing 6 month open-label, parallel-group, multi-center study (USA, Germany, India) is to study metabolic control and safety in >400 patients with type 1 diabetes using VIA compared to RHI for prandial insulin therapy.

Materials and methods: Patients with type 1 diabetes (age 41±14 years; 264 male, 184 female; BMI 26±4.9 kg/m²) were sequentially recruited for this trial. During their first visit, body weight, BMI, and current insulin regimen were recorded. After randomization, all patients were switched to an intensified insulin treatment with insulin Lantus as basal insulin, while their prandial insulin was changed to either VIA or RHI. Subsequent visits recorded their weight and insulin dose. Adverse events were recorded as well.

Results: Weight changes could be analyzed for 210 patients for the first half of the study. For those on VIA (n=102), no change in weight compared to baseline was observed, while a weight gain (1.4±2.9 kg) was seen in the patients (n=108) on RHI (p<0.001). With comparable glycaemic control between the groups, prandial insulin dose was reduced in the first 6 weeks of the study with VIA (n = 106) by 34% compared to baseline (p<0.001) whereas there was only a non-significant decrease of -2.4±15.3 units with RHI. Analysis of 811 mild and moderate hypoglycaemic events recorded thus far showed a lower number of incidents in the VIA group (3691; p<0.001) than in the RHI group (4420).

Conclusion: Prandial insulin therapy with VIA showed less weight gain, lower insulin dose requirements and less hypoglycaemia in patients with type 1 diabetes compared to RHI. This confirms that the more rapid onset of action and reduced variability seen with VIA in previous short term clinical studies translates into clinically significant advantages in this long term Phase 3 pivotal trial.

678

Insulin VIAject™ and regular human insulin in patients with type 2 diabetes: efficacy and safety in an open-label multicenter clinical trial

S. Steiner¹, A. Pfuetzner², B. Sethi³, T. Forst², D. Klonoff⁴, P. Simms⁵, R. Pohl¹, F. Flacke¹

¹Clinical, Bidel Inc, Danbury, United States, ²Clinical, IKFE, Mainz, Germany, ³Clinical, Care Hospital, Hyderabad, India, ⁴Diabetes, Mills Peninsula, San Mateo, United States

Background and aims: VIAject™ (VIA) is an ultra-rapid acting formulation of regular human insulin (RHI). The aim of this ongoing 6 month open-label, parallel group, multi-center study (USA, Germany, India) is to compare metabolic control and safety in >400 patients with type 2 diabetes using VIA vs. RHI for prandial insulin therapy. Data presented here include safety information and first efficacy results.

Materials and methods: Patients with type 2 diabetes (age 56±9 years; 249 male, 181 female; BMI 33.5±6.1 kg/m² (mean±SD)) were sequentially recruited into this trial. During their first visit, body weight, BMI, and current insulin regimen were recorded. After randomization, patients were switched to an intensified insulin treatment with insulin Lantus as basal insulin, while their prandial insulin was changed to either VIA or RHI. Patients entering the study on TZDs or Metformin stayed on their oral treatment. Subsequent visits recorded their weight and insulin dose. All adverse events were recorded.

Results: Weight changes were analyzed for 353 patients for the first six weeks of the study. With VIA (n= 173) a weight reduction (-0.5±4.7 kg) compared to baseline was observed. In contrast, a weight gain (0.8±6.2 kg) was observed in the patients (n=180) on RHI (p<0.05) for a net difference of 1.3 kg. With comparable glycaemic control, patients on VIA reduced their dose of prandial insulin by 35.9% on average (16 units; p<0.001 compared to baseline). Pa-

tients on RHI increased their dose 15% (6 units; p<0.01) for a net difference of 50.9%. Analysis of the 2438 mild and moderate hypoglycaemic events reported thus far showed 47% fewer number of incidents with VIA (844 events) compared to the patients receiving RHI (1594 events, p<0.001).

Conclusion: Patients receiving VIA in this pivotal Phase 3 clinical trial showed weight loss, reduced insulin requirements and fewer hypoglycaemic events compared to RHI. Prandial insulin therapy with this novel regular insulin formulation showed benefits with respect to weight gain, insulin dose and hypoglycaemic events in comparison to the RHI in this large clinical study. The physiological profile of VIA leads to clinically relevant improvements in intensive insulin therapy in patients with type 2 diabetes.

679

Recurrent severe hypoglycaemias and licence to drive. A community based study

M.T. Honkasalo¹, O.M. Elonheimo², T.A. Sane³

¹Diabetes care unit, Nurmijärvi Health Centre, Nurmijärvi, ²Network of Academic Health Centres, Helsinki University, ³Department of Endocrinology, Helsinki University Central Hospital, Finland

Background and aims: The knowledge of the incidence of severe hypoglycaemias (SH) is quite limited and even controversial in insulin treated patients with diabetes. In our retrospective study we analyzed the incidence and predisposing factors of SH in two medium sized Finnish communities, altogether with 67261 inhabitants. In the present study we evaluated whether diabetic patients with recurrent (at least 3 or more) episodes of SH during the year investigated hold a valid licence to drive. According to the current medical standards for diabetes and driving the driving licence should be at least temporarily cancelled in a diabetic patient with recurrent episodes of SH until the driving fitness is properly maintained with adjustment of treatment. Moreover the insulin treated diabetic patients with unawareness of hypoglycaemia and occurrence of any SH should be restricted of having licence to drive commercial vehicles (lorry, minicab and taxi).

Materials and methods: From our target population we identified altogether 1776 medically treated diabetic patients, of whom 1326 (74.7%) filled a questionnaire and reported the number of SH episodes during the preceding 12 months. Data on the occurrence of SH during the same year was also collected from electronic patient records used in primary health care centres and local hospitals offering 24 hour emergency room service and from the 24 hour ambulance service registers of these two communities. SH was defined as a hypoglycaemic episode requiring help from another person. The data of the current driving licenses was received from the local police authorities.

Results: During the preceding year 27.3 % of the patients with T1DM and 12.1 % of insulin treated patients with T2DM reported at least one SH (the incidence rates of SH 66.7/100 and 26.5/100 pt years, respectively). Of non-insulin treated patients with T2DM 3.8 % reported at least one SH with incidence of 6.0/100 pt years. Of the patients with T1DM 10.4 % and of the patients with T2DM 3.2 % needed ambulance care of SH (incidence rates of SH 24.3/100 and 3.4/100 pt years, respectively). Of all insulin treated patients 56 (7.3 %) reported three or more episodes of SH during the preceding year. Thirty seven (66 %) of them still hold a licence to drive, and even 11 (20 %) of them hold a license to drive commercial passenger or goods carrying vehicles up to 3.5 tons (lorry, minicab and taxi).

Conclusion: Our community based data shows that the incidence of SH is more common than expected both in insulin treated patients with T1DM and T2DM, although the episodes of SH were clustered in a minority of patients. Recurrent episodes of SH occurred in 7.3 % of insulin treated patients, which may impair their fitness to drive and increase the risk to driving mishaps. Two thirds of these patients still hold a valid license to drive and some of them were even licensed to drive commercial vehicles. Our data indicate that the current EU medical standards for diabetes and driving are not very well known among the Finnish doctors.

The clinical and economic burden of hospital encounters due to hypoglycaemia among diabetic patientsJ.L. Natoli¹, C.M. Alexander², T. Haidar¹, R.W. Dubois¹, S.M. Curkendall¹¹Cerner LifeSciences, Cerner, Beverly Hills, ²Outcomes Research, Merck and Co., Inc., Whitehouse Station, United States

Background and aims: Limited data are available describing the direct medical costs of hypoglycemia and associated economic burden. Although several economic analyses using claims data in managed care plan have been conducted, these studies are relatively old and provide little insight into the resource utilization associated with hypoglycemia. The primary objective of this retrospective study was to estimate the burden (including costs, mortality, and length of hospital stay) of a hospital visit for hypoglycemia among diabetic patients.

Materials and methods: Data from 70 hospitals participating in Cerner's *Health Facts* EMR database were used to identify all encounters during 2000–2006 for adult diabetic patients. Of these, encounters for which hypoglycemia was the primary reason for the hospital visit were defined as those with a primary inpatient (IP) diagnosis or any emergency department (ED) diagnosis of hypoglycemia (ICD-9-CM code 251.0, 251.1, or 251.2). Total costs (2006US\$) were calculated based on the encounter type. For ED-only encounters, costs were calculated by using a 50% cost-to-charge ratio. For encounters with an IP component (IP-only, or ED encounters with subsequent admission [ED to IP]), costs were based on the estimated US average Medicare payment in 2006 for the encounter's DRG. Other outcomes were subsequent IP admission among ED patients, IP length of stay (LOS), and in-hospital mortality.

Results: Of 519,317 hospital encounters of diabetic patients, there were 732 encounters (0.14%) due to hypoglycemia, including 667 ED-only, 24 ED to IP, and 41 IP-only encounters. Overall, the mean cost for these encounters was \$1,089. The mean cost was \$627 for ED-only encounters, \$5,081 for ED to IP encounters, and \$6,272 for IP-only encounters (see Table). The mean total cost for an encounter with any IP component was \$5,844. Of the 691 encounters that began in the ED, 24 (3.5%) were subsequently admitted. Mean LOS was 4.8 days for ED to IP or IP-only encounters. In-hospital mortality was 0.5% for ED-only and 4.6% for ED to IP or IP-only encounters.

Conclusion: The average cost for diabetic patients presenting to an acute care facility with hypoglycemia was \$1,089. This mean was influenced by the fact that the majority of hypoglycemia encounters were confined to the ED with a mean cost of only \$627; however, the hospitalization cost for diabetic patients presenting to an acute care facility with hypoglycemia was \$5,844, more than 9 times higher than for an ED encounter.

Table. Hypoglycemia diagnosis (ICD-9-CM codes 251.0, 251.1, or 251.2) and outcomes

	ED only (n = 667)		ED to IP or IP Only (n = 65)	
	N	Mean or %	N	Mean or %
Mortality	3	0.5%	3	4.6%
Length of Stay	–	–	65	4.8 days
Total Costs (2006US\$)	582	\$627	64	\$5,844

Prevalence of impaired awareness of hypoglycaemia in insulin-treated type 2 diabetes and its effect on hypoglycaemia frequency

J.E. Schopman, J. Geddes, B.M. Frier

Diabetes Department, Royal Infirmary of Edinburgh, United Kingdom

Background and aims: While impaired awareness of hypoglycaemia (IAH) is a major limitation to maintaining strict control in Type 1 diabetes, in insulin-treated Type 2 diabetes (T2DM) the prevalence of this syndrome and its influence on hypoglycaemia frequency have seldom been examined. The present study sought to ascertain the prevalence of IAH in people with insulin-treated T2DM and how it influenced their exposure to hypoglycaemia.

Materials and methods: Participants completed a questionnaire documenting baseline characteristics and assessing their symptomatic awareness status using a validated method (Gold et al, *Diabetes Care*, 1994; 17: 697). Capillary blood glucose (BG) was then monitored prospectively four times a day, over

a 4-week period; any episode of biochemical hypoglycaemia (defined as BG < 3.0 mmol/L) was identified and any associated symptoms were recorded and classified. Severe hypoglycaemia (defined as requiring external assistance) was estimated retrospectively over the preceding year.

Results: Data were obtained from 122 people with insulin-treated T2DM (63 male; mean (SD) HbA1c 8.4 % (1.5); median (inter quartile range, IQR) age, 67 (58–72) years; duration of T2DM, 15 (10–20) years; duration of insulin therapy, 6 (4–9) years). The prevalence of IAH was 9.8%. The patients with IAH had a five-fold higher incidence of episodes of biochemical hypoglycaemia over the 4-week monitoring period compared to those with normal awareness of hypoglycaemia (mean (SD) 2.34 (4.39) vs 0.46 (1.21) episodes; $p < 0.001$). By extrapolation, those with normal awareness of hypoglycaemia would have an annual incidence of 6 episodes per person per year of biochemical hypoglycaemia, compared to 29 episodes per person per year in the cohort with IAH. No symptomatic differences were observed in the reported intensity of symptoms experienced between the groups during biochemical hypoglycaemia (autonomic symptoms $p = 0.42$; neuroglycopenic symptoms $p = 0.52$). In the year preceding the study, the incidence of severe hypoglycaemia as reported by those with IAH was 17-fold higher than in people with normal hypoglycaemia awareness (0.83 (1.12) vs. 0.05 (0.28) episodes per patient; $p < 0.001$).

Conclusion: The observed prevalence of IAH in insulin-treated T2DM (9.8%) was consistent with a previous estimate from our centre based on clinical history alone (8%). While IAH in insulin-treated Type 2 diabetes occurs less commonly than in Type 1 diabetes, in those affected it is associated with a greatly increased risk of biochemical and severe hypoglycaemia. The presence of IAH in people with insulin-treated T2DM should therefore be evaluated routinely at clinical review.

PS 052 Drug effects on insulin sensitivity and insulin action

682

Stimulation of GLUT4 vesicles transport and tethering is coupled to improved insulin sensitivity in human adipose tissue in response to rosiglitazone: resolution by proteomics

M. Ahmed^{1,2}, F. Karpe¹

¹Oxford Centre for Diabetes, Endocrinology and Metabolism, University of Oxford, United Kingdom, ²Department of Physiology, Ibrahim Medical College, Dhaka, Bangladesh

Background and aims: Adipose tissue plays a crucial role in regulation of lipid and carbohydrate metabolism and many of these actions are regulated by insulin. The present study aims to detect potential novel protein targets for insulin sensitization in human adipose tissue by using unbiased proteomic approaches.

Materials and methods: Ten healthy moderately obese men aged 42±2 years were treated with rosiglitazone 4 mg BD for 14 days and adipose tissue biopsies and plasma samples were taken at day 0 (without medication), day 1 and day 14. Adipose tissue protein profiles were obtained by two-dimensional gel (2-DG) electrophoresis and label-free LC-MS/MS.

Results: Fasting serum insulin was reduced by 20% after two weeks treatment with rosiglitazone. This suggested a whole body effect towards insulin sensitization. Analysis revealed distinct up- or down-regulation (≥2-fold) in multiple proteins. On the 2-DG images, treatment with rosiglitazone increased the expression of annexin A1, annexin A2, calmodulin, ferritin light chain, guanine nucleotide-binding protein G(I)/G(S)/G(T) subunit β1 (GNB1), GNB3, heat shock 27 kDa protein, LIM and SH3 domain protein 1, moesin, myosin-9, superoxide dismutase [Mn], transferrin, tubulin β-1 chain and vimentin. LC-MS/MS based comparative proteomics validates the data from 2-DG and also ascertain differential expression of additional proteins, such as exocyst components, sec5, sec6, sec8, Exo84 and Exo70, involved in GLUT4 tethering and exocytosis in human adipose tissue.

Conclusion: Some of major adipose tissue proteomic changes were involved cytoskeletal rearrangement, inflammatory and redox signals, whereas co-ordinated up-regulation of GLUT4 granule transport and fusion in human adipose tissue was seen. Such orchestrated changes in expression of multiple proteins belonging to the same pathway provide insights into the mechanism underlying the increased uptake of glucose and improvement of insulin sensitivity in response to rosiglitazone treatment.

683

Peroxisome proliferator-activated receptor gamma ligands suppress the transcriptional activation of PED/PEA-15 gene

P. Mirra, F. Oriente, S. Iovino, G. Botta, V. D'Esposito, I. Esposito, P. Formisano, P. Ungaro, F. Beguinot
Dipartimento di Biologia e Patologia Cellulare e Molecolare & IEOS-CNR, Università Di Napoli, Italy

Background and aims: The phosphoprotein enriched in diabetes/phosphoprotein enriched in astrocytes (*PED/PEA-15*) gene is overexpressed in tissues of individuals with type 2 diabetes. In cultured cells and *in vivo*, *ped/pea-15* overexpression impairs insulin activation of protein kinase C zeta (PKCzeta) and glucose disposal. Indeed, transgenic mice ubiquitously overexpressing *ped/pea-15* feature impaired glucose tolerance and insulin resistance. However, it is still unknown how *ped/pea-15* gene expression is regulated. Recently, we have obtained evidence that Thiazolidinediones (TZDs), a class of peroxisome proliferator-activated receptor (PPAR)gamma ligands, repress *ped/pea-15* expression both at mRNA and protein levels. PPARgamma is a member of the nuclear hormone receptor superfamily that modulate gene expression upon ligand binding. Ligand-mediated activation of PPARgamma has been linked to glucose homeostasis, cellular differentiation, apoptosis and anti-inflammatory responses. The aim of this work is to study how activated PPARgamma may exert its action on *PED/PEA-15* expression.

Materials and methods: *ped/pea-15* protein expression was determined in tissues from C57BL/6J mice. Differentiated L6 myotubes were used as an *in vitro* skeletal muscle model. Luciferase assay and Electrophoretic Mobility Shift Assay (EMSA) were conducted in HeLa cells.

Results: In L6 skeletal muscle cells, the TZDs rosiglitazone and troglitazone decreased *ped/pea-15* protein expression leading to the activation of PKC

zeta and increased 2-deoxy-glucose uptake. TZDs also reduces *ped/pea-15* mRNA levels by 40%. Consistent with the *in vitro* data, muscle tissue from control mice showed a 90% decrease of *ped/pea-15* levels upon 10 days treatment with rosiglitazone (26mg/Kg/die). HeLa cells treated with TPA, the prototypical AP-1 activator showed an increase in *PED/PEA-15* mRNA levels. This finding was confirmed also on the *PED/PEA-15* promoter activity by luciferase assays. Interestingly, serum and TPA effect were suppressed by rosiglitazone in a concentration dependent-manner. Since PPARgamma activation by TZDs blocks AP-1-mediated gene transcription, we hypothesized that PPARgamma transrepression of the *ped/pea-15* gene is due to competition for limiting amounts of coactivators present in the cell. Indeed, the suppressive effect of rosiglitazone on *PED/PEA-15* was blocked by overexpressing a dominant negative form of PPARgamma that lacks the ability to recruit the coactivator CBP/p300 (CREB-binding protein). EMSA also revealed that TPA caused an increased binding to the CRE site (a putative AP-1 binding site) on the *PED/PEA-15* promoter, an effect that was suppressed by rosiglitazone. Supershift and Chip experiments are ongoing in our laboratory in order to identify the component of the DNA binding complex.

Conclusion: Taken together, these results indicate that regulation through the CRE site on *PED/PEA-15* promoter induces *PED/PEA-15* transcription. This effect was blocked by treatment with PPARgamma ligands. Finally, the results of this study identify *PED/PEA-15* gene as a potential target for PPARgamma-based therapeutic action.

684

Thiazolidinedione enhancement of insulin action in skeletal muscle and liver cells: role of protein kinase C delta (PKCδ)

T. Brutman-Barazani, V. Attali, M. Horovitz-Fried, C. Brodie, S.R. Sampson

Life Sciences, Bar-Ilan University, Ramat-Gan, Israel

Background and aims: Thiazolidinediones (TZDs) are a class of oral antidiabetic agents that improve insulin sensitivity and glucose homeostasis in type 2 diabetic patients, as well as in various animal models of diabetes. The TZDs have been in use in clinical practice but the mechanisms by which TZDs improve insulin sensitivity are not yet fully understood. An important family of proteins that has been implicated in the insulin signaling cascade is the PKC family of serine threonine kinases. PKCδ. Thiazolidinediones (TZDs) are a class of oral antidiabetic agents that improve insulin sensitivity and glucose homeostasis in type 2 diabetic patients, as well as in various animal models of diabetes. The TZDs have been in use in clinical practice but the mechanisms by which TZDs improve insulin sensitivity are not yet fully understood. An important family of proteins that has been implicated in the insulin signaling cascade is the PKC family of serine threonine kinases. PKCδ was found to play an essential role in the mediation of insulin-induced glucose uptake in skeletal muscle. In addition, insulin has been shown to rapidly increase PKCδ protein levels in skeletal muscle. In this study we examined the possibility that PKCδ may also be involved in TZD enhancement of insulin effects in skeletal muscle and liver cells.

Materials and methods: Studies were performed on the AML-12 (Alpha Mouse Liver) and L6 skeletal muscle cell lines. Activation of PKB and GSK3 downstream proteins was examined by Western blotting using phospho-specific antibodies. Glucose transport was determined by the measurement of [³H]2-deoxy-D-glucose (2-DG) uptake. Inhibition of PKCδ was achieved pharmacologically with the use of Rottlerin and by infection with specific dominant negative (DN) adenovirus constructs. PKCδ was over expressed by infection with wild type (WT) adenovirus constructs.

Results: TZDs induced an increase in PKB activity and GSK phosphorylation similar to insulin. The rate of 2-DG uptake was elevated by both insulin (165%) and TZD (138%). Results indicate that pretreatment of the AML-12 cells with TZD followed by insulin treatment increased the effect of insulin. The effects on 2-DG uptake appeared to be additive. We examined the possibility that PKCδ may be involved in the effect of TZD on the insulin signaling pathway. Inhibition of PKCδ decreased both TZD- and insulin-induced elevation in 2-DG uptake. In contrast, over expression of WTPKCδ increased 2-DG uptake in response to TZD. Finally, TZD was found to rapidly increase PKCδ protein levels in both skeletal muscle and liver cells in a manner similar to insulin.

Conclusion: The results indicate that PKCδ plays an important role in the mediation of TZD-induced effects on glucose metabolism. Moreover, TZD may increase insulin sensitivity via PKCδ.

Timed dopamine agonist therapy induces a postprandial-selective insulin sensitivity

M. Ezrokhi, S. Luo, J. Cincotta, A.H. Cincotta

Research and Development, VeroScience, Tiverton, United States

Background and aims: Once daily, morning administration of Cycloset, a quick-release formulation of bromocriptine (BC) (a dopamine D2 receptor agonist), improves post-meal glycemic control in insulin resistant and type 2 diabetes subjects across the 3 standard meal periods of the day. However, Cycloset is substantially removed from the circulation before the noon meal. Pre-clinical studies have identified aberrant hypothalamic fuel-sensing pathways potentiating insulin resistance that are normalized by timed daily BC administration. Collectively, these findings suggest that timed administration of Cycloset exerts, via the hypothalamus, a postprandial-selective improvement in insulin sensitivity and this would represent a novel therapeutic mechanism for improving glycemic control in insulin resistant states. Given the impact of elevated postprandial glucose (G) on cardiometabolic risk, it is important to delineate such a bromocriptine impact on post-meal metabolism. The aim of this study was to identify any differences in bromocriptine influence on insulin sensitivity in the euglycemic (to approximate fasting glucose) versus hyperglycemic (to approximate postprandial glucose) states and to examine the impact of bromocriptine on hepatic intermediary glucose metabolism that may affect post-meal hepatic glucose disposal.

Materials and methods: Obese, insulin resistant male 15 month old Syrian hamsters were held on 14 hour daily photoperiods from birth and treated for 14 days with either BC (4.4 mg/kg) or vehicle at 1 hour after light onset and then subjected to a euglycemic-hyperinsulinemic clamp (insulin 3 mU/kg*min, ^3H -3-G 0.2 $\mu\text{Ci/kg*min}$, steady state glucose (SSPG) 110 mg/dL) followed by a hyperglycemic-hyperinsulinemic clamp (insulin 3 mU/kg*min, ^3H -3-Glucose infusion 0.2 $\mu\text{Ci/kg*min}$, SSPG 170 mg/dL). Livers isolated from similarly treated animals were analyzed for G-6-phosphatase and G-6-phosphate dehydrogenase activities by spectrophotometric methods.

Results: Basal plasma G and insulin (I) levels were 116 ± 11 mg/dL and 120 ± 6 mg/dL and 3.8 ± 0.5 ng/ml and 4.8 ± 0.5 ng/ml, respectively for BC and vehicle treated animals, respectively ($p=0.06$ for I difference). During the euglycemic clamp, BC treatment increased G disposal rate by 21% from 20.1 ± 0.9 mg/kg*min to 25.4 ± 0.6 mg/kg*min ($p=0.02$) and decreased hepatic G output (HGO) by 26% from 3.4 ± 0.4 mg/kg*min to 2.6 ± 0.1 mg/kg*min ($p<0.05$). However, during the hyperglycemic clamp period, BC increased G disposal rate by 50% from 28.3 ± 1.9 mg/kg*min to 42.4 ± 2 mg/kg*min ($p<0.0001$), and decreased HGO by 38% from 3.4 ± 0.2 mg/kg*min to 2.1 ± 0.3 mg/kg*min, ($p=0.005$). Insulin levels during the clamp did not vary between the groups (BC: 5.4 ± 0.5 ng/ml, vehicle 6.5 ± 0.6 ng/ml). The difference in BC impact on G disposal rate during hyperglycemia versus euglycemia was also significant ($p<0.01$). BC treatment increased the Km for G-6-phosphatase activity by 27% (from 2.6 ± 0.1 to 3.3 ± 0.15 M, $p<0.05$) and increased G-6-phosphate dehydrogenase activity by 62% (from 2.6 ± 0.4 to 4.2 ± 0.2 nm/min/mg, $P<0.05$). Such a shift in G flux enzymatic activities can potentiate hepatic G utilization by reducing HGO and stimulating the pentose phosphate pathway.

Conclusion: Timed BC administration exerts a postprandial-selective insulin sensitizing effect to reduce HGO and increase peripheral glucose uptake. This unique mechanism of action may in turn reduce cardiovascular risk associated with postprandial hyperglycemia.

686

CVT-3619, a partial A_1 adenosine receptor agonist, potentiates the anti-lipolytic effect of insulin

A.K. Dhalla, M. Santikul, L. Belardinelli

Pharmacology, CV Therapeutics, Inc., Palo Alto, United States

Background and aims: Adenosine mediates its anti-lipolytic effects via A_1 adenosine receptors. In addition, adenosine also modulates insulin actions and sensitivity in skeletal muscle and adipose tissue. Previously, we have shown that CVT-3619, a partial A_1 receptor agonist, lowers circulating free fatty acid (FFA) levels and improves insulin sensitivity in rodents. The present study was undertaken to determine the interaction between the anti-lipolytic effects of insulin and CVT-3619.

Methods: The in-vitro anti-lipolytic effects of CVT-3619 and insulin were determined by measuring the release of FFA from adipocytes from normal (SD) and diabetic (ZDF) rats, whereas the in-vivo effects on circulating FFA were determined in awake unrestrained SD and ZDF rats.

Results: In adipocytes from normal SD rats, CVT-3619 or insulin inhibited lipolysis with IC_{50} s of 63 nM and 36 pM, respectively. CVT-3619 (10 nM) caused a leftward and downward shift of the insulin concentration-response curve. Adipocytes from ZDF rats were highly resistant to the anti-lipolytic effects of insulin ($\text{IC}_{50} = 30$ nM) but only slightly to CVT-3619 ($\text{IC}_{50} = 130$ nM). CVT-3619 (10 nM) restored insulin's sensitivity to inhibit FFA release from ZDF adipocytes ($\text{IC}_{50} = 110$ pM). Similar to isolated adipocytes from ZDF rats, the anti-lipolytic effect of insulin was markedly reduced in ZDF rats. CVT-3619 (0.5 mg/kg, a dose associated with a very small FFA lowering effect) caused a 10-fold increase in the potency of insulin to lower plasma concentrations of FFA.

Conclusion: CVT-3619 potentiates the anti-lipolytic effect of insulin, both in-vitro and in-vivo, especially in ZDF rats which are highly insulin resistant. Thus, CVT-3619 could be useful in insulin resistant states where anti-lipolytic effect of insulin is impaired resulting in higher rate of lipolysis leading to high circulating levels of FFA.

Testing efficient carriers for intracellular PIP3 delivery to induce insulin actions using biomimetic liposomes and cellular model systemsI. Kachko - Chernetsky¹, T. Traitel¹, R. Jelinek², A. Rudich³, J. Kost¹¹Department of Chemical Engineering, ²Department of Chemistry,³Department of Clinical Biochemistry, Ben-Gurion University of the Negev, Beer-Sheva, Israel

Background and aims: Production of phosphatidylinositol-3,4,5-trisphosphate (PIP3), induced by insulin is a major signaling step in the induction of insulin's metabolic actions in muscle and fat, and is impaired in various states of insulin resistance. Intracellular delivery of PIP3 into cells might therefore constitute an approach for bypassing such a signaling defect. However, this approach is challenged by the need to overcome permeability barriers through the plasma membrane, and to introduce the agent in well-defined spatial-temporal coordinates corresponding to endogenous PIP3 generation. Exogenous PIP3 may be introduced into cells using polycationic carriers which should mask its negative charges. However so far, these approaches only partially mimicked insulin's effects in normal, insulin sensitive cells, and displayed poor efficiency and low reproducibility. The overall aim of this work was to assess the therapeutic potential of intracellular delivery of exogenous PIP3 to overcome cellular insulin resistance.

Materials and methods: Membrane-complex interactions and cellular localization were verified using biomimetic liposomal (lipid/polydiacetylene) membrane model and in L6 muscle cells in culture with fluorescent-PIP3 and live-cell microscopy. The ability of PIP3-carrier to induce insulin signaling and metabolic effects were evaluated in L6 myoblasts and in 3T3-L1 adipocytes electroporated with GFP-GLUT4myc plasmids.

Results: A polymeric carrier, polyethyleneimine (PEI), was utilized at different molecular weights and branched/linear backbone to generate efficient electrostatically bound PIP3-carrier complexes. Fluorescent liposomes surface perturbation and ESR (Electron Spin Resonance) analyses revealed that PIP3-PEI formed complexes and penetrated the lipid bilayer. Branched PEI (25kDa) carrier was more efficient in membrane internalization than linear PEI of the same molecular weight. Maximal liposome-complex interaction occurred at 40 min. Live-cells kinetic studies revealed that the branched PEI-PIP3 complex enabled the retention of PIP3 at the cell periphery as compared to PIP3 alone. PIP3 delivered with PEI was found biologically available for binding to its intracellular ligand (GRP-PH) and for generating signaling effects, resulting in increased PKB phosphorylation, higher than that observed with neomycin as a carrier. Moreover, PIP3-carrier exposure increased Glut4 translocation and externalization in 3T3-L1 adipocytes.

Conclusion: We demonstrated a polymeric system for exogenous PIP3 delivery that can induce insulin signaling and metabolic effect in muscle and fat cells based on biomimetic liposomes and cellular systems. Inducing insulin

actions by intracellular PIP3 delivery in insulin resistant cells will shed light on the potential therapeutic use of this technology.

Nebivolol prevents insulin resistance and enhances plasma nitrates in sucrose-fed rats

M.P. Guarino¹, M. Mota-Carmo¹, A.I. Santos², P.F. Costa², A.B. Rendas¹
¹Pathophysiology, ²Physiology, Faculdade Ciências Médicas, Lisbon, Portugal

Background and aims: Nebivolol is a β -1 selective adrenergic receptor antagonist, which also increases nitric oxide (NO) bioavailability. NO is required for physiological insulin action, suggesting that nebivolol may improve insulin sensitivity in pathologies where the NO signaling pathway is compromised. The High-Sucrose Diet Rat (HSu) is an animal model of insulin resistance with impaired NO signaling pathway. We hypothesized that HSu rats treated with nebivolol would show enhanced insulin sensitivity, correlating with an increase in plasma nitrates, a marker of endogenous NO production. These results were compared with the effect of atenolol, a β -blocker non-promoter of NO release, on insulin sensitivity.

Materials and methods: Rats were divided into six groups according to the composition of water supplied for four weeks, namely: Control - regular animal facility water; S - 35% sucrose solution; N - nebivolol 1mg/kg/day; SN - 35% sucrose plus nebivolol 1mg/kg/day; A - atenolol 10mg/kg/day; SA - 35% sucrose plus atenolol 10mg/kg/day. Insulin sensitivity was evaluated with the Insulin Tolerance Test and calculation of the rate of blood glucose decay (K_{ITT}). NO metabolites were determined in arterial blood samples using a NO/ozone chemiluminescence technique

Results: K_{ITT} was 5.02 ± 0.42 %/min in the Control Group (n=8) and 2.52 ± 0.33 %/min in the S Group (n=8, $p < 0.001$). The lower K_{ITT} value found in the S Group was suggestive of insulin resistance.

In the N Group, the K_{ITT} was 4.21 ± 0.44 %/min (n=8), which was not significantly different from Control. Atenolol decreased insulin action as shown by a K_{ITT} in the A group of 3.08 ± 0.57 %/min (n=7, $p < 0.05$ from Control). In the SN Group, K_{ITT} was 4.21 ± 0.44 %/min (n=8, $p < 0.01$ from S group). In the SA group, K_{ITT} was 2.67 ± 0.64 %/min, n=6, not significant from S group). These results show that nebivolol prevented the development of insulin resistance induced by the sucrose diet. Atenolol, on the other hand, did not restore insulin sensitivity in HSu rats. Plasma NO/ NO_3^- was 61.7 ± 13.5 μ M in the Control Group and 51.3 ± 1.7 μ M in the S Group ($p < 0.05$). In the SN Group, nebivolol increased plasma NO/ NO_3^- concentration to 83.0 ± 13.5 μ M. Plasma NO/ NO_3^- in the SA Group was 39.7 ± 3.3 μ M.

Conclusion: We concluded that nebivolol prevents the development of insulin resistance induced by a high-sucrose diet, as opposed to atenolol. Also, the enhancement of insulin sensitivity induced by nebivolol correlated with an increase in endogenous NO production, which is in agreement with the proposed hypothesis.

The role of HSP70 on *in vitro* ENPP1 expression and insulin receptor activation and *in vivo* insulin resistance-related traits

R. Di Paola¹, A. Marucci¹, G. Miscio¹, L. Padovano¹, W. Boonyasrisawat¹, J.C. Florez^{2,3}, A. Doria^{4,2}, V. Trischitta^{1,5}

¹Research Unit of Diabetes and Endocrine Diseases, Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy, ²Department of Medicine, Harvard Medical School, Boston, United States, ³Diabetes Unit/Center for Human Genetic Research, Massachusetts General Hospital, Boston, United States, ⁴Research Division, Joslin Diabetes Center, Boston, United States, ⁵Department of Clinical Sciences, University "Sapienza", Rome, Italy

Background and aims: Ectonucleotide pyrophosphatase phosphodiesterase 1 (ENPP1) inhibits insulin receptor (IR) signaling and, when over-expressed, induces insulin resistance. Understanding the regulation of ENPP1 expression may unravel new molecular mechanisms of insulin resistance. We sought to identify trans-acting proteins binding the ENPP1-3'UTR and investigate their role on ENPP1 expression and insulin resistance.

Methods: We demonstrated binding of the heat shock protein 70 (HSP70) to ENPP1-3'UTR by RNA electrophoresis mobility shift analysis and tandem mass spectrometry. We used quantitative real time-PCR (QRT-PCR) and western blot analysis to investigate the effect of HSP70 on ENPP1 expression and IR-autophosphorylation. We genotyped HSP70 gene variants in 924 nondiabetic Italian subjects and measured HSP70 mRNA by QRT-PCR.

Results: By binding ENPP1-3'UTR, HSP70 stabilizes ENPP1 mRNA and increases ENPP1 transcript and protein levels. Through the positive modulation of ENPP1 expression, HSP70 inhibits insulin-induced IR autophosphorylation. The minor alleles at rs9281590 and rs2763979 in HSP70 are associated with better glucose and lipid levels in nondiabetic Europeans. Associations with lipid levels are replicated in a family-based sample, and those with glucose levels in the Diabetes Genetics Initiative sample. The minor allele at rs9281590, was also associated with reduced HSP70 expression in lymphomonocytes from nondiabetic subjects.

Conclusion/Interpretation: HSP70 increases ENPP1 expression and decreases IR activation. The HSP70 rs9281590 variant is associated with reduced HSP70 expression and lower glucose and lipids levels. Taken together, these data suggest that HSP70 may be a novel mediator of insulin resistance. Impaired insulin signalling is associated with decreased transformation potential of the skin

J. Russ¹, G. Weingarten¹, J. Takeda², C. Kahn³, E. Wertheimer¹

¹Pathology, Sackler Medical School Tel Aviv University, Tel Aviv, Israel, ²Dermatology, Osaka University Medical School, Osaka, Japan, ³Joslin diabetes center, Harvard Medical School, Boston, United States

Background and aims: One of the major complications of diabetes mellitus is impaired wound healing. Traditionally, this pathology is believed to develop secondary to the neuropathy and microangiopathy associated with diabetes. However, we have previously demonstrated that insulin plays a direct role in normal skin turnover, including regulation of skin proliferation and differentiation, suggesting that insulin resistance might be directly involved in the development of diabetic skin complications. In order to further substantiate our findings on the importance of insulin signaling on skin proliferation and differentiation, in the present study we applied cellular transformation protocols on murine skin and primary keratinocytes lacking insulin signaling, aiming to demonstrate that lack of insulin signaling will result in decreased skin transformation potential.

Materials and methods: Our hypothesis was tested in skin-specific insulin receptor (IR) knockout mice (SIRKO), where disruption of IR expression is restricted to the epidermal layer of the skin. Skin tumors were induced according to a well characterized initiation-promotion carcinogenesis protocol and the kinetics of tumor formation, histopathology and expression of specific epidermal markers was followed.

Results: We found that lack of IR expression in skin resulted in a marked decrease in tumor induction efficiency and tumor proliferation capacity. Next we analyzed which stage in the carcinogenesis was disrupted by the abrasion of the IR. There was no difference in the initiation stage, the stage when the initial mutation leading to the development of the tumor is induced chemically. However, a marked decrease was observed in the response of the IR lacking skin to the promoting agent, which is applied for further support and development of the transformed initiated cells. In order to reveal the mechanism underlying the decreased carcinogenic potential, we studied cultured primary skin epidermal cells, isolated from the SIRKO and control mice. Interestingly, the transformation of the murine primary keratinocytes in culture was inefficient in the SIRKO cells; they exhibited impaired spindle formation and appearance of multinuclear senescent cells.

Conclusion: Our data provide evidence that complete abrasion of the IR in the epidermis leads to changes in both skin turnover *in vivo* as well as in the intrinsic properties of the keratinocytes. Further understanding the regulation of skin turnover by insulin signaling might lead to development of new treatments for various skin pathologies associated with impaired insulin signaling.

Glucosamine-induced insulin-resistance in L6 skeletal muscle cells is associated with endoplasmic reticulum stress

G.A. Raciti¹, L. Ulianich¹, C. Iadicicco¹, A. Lombardi², F. Andreozzi³, B. Di Jeso³, C. Garbi¹, P. Formisano¹, F. Beguinot¹, C. Miele¹

¹Dipartimento di Biologia e Patologia Cellulare e Molecolare & IEOS-CNR, University of Naples, ²Dipartimento di Scienze e Tecnologie Biologiche e Ambientali, University of Lecce, ³Dip di Medicina Sperimentale e Clinica, University of Catanzaro, Italy

Background and aims: Endoplasmic reticulum (ER) stress might play an important role in the pathogenesis of insulin-resistance and Type 2 diabetes. Hyperglycaemia causes insulin resistance and this process appears to be linked to ER stress. Glucosamine, generated by hexosamine pathway during hyperglycaemia, also causes insulin resistance and disturbances similar to glucose toxicity. Here, we sought to evaluate the possible role of ER stress on the insulin-resistance induced by glucosamine in skeletal muscle cells

Materials and methods: L6 skeletal muscle cells were incubated either with 10 mM glucosamine (GlcNac) or with 0.5 μ M thapsigargin (Thap), a well known ER stressing agent, in the presence or in absence of insulin (100nM).

Results: Upon 24 hours of GlcNac treatment, L6 cells showed a 6-fold increase of the ER stress marker BiP/GRP78 mRNA levels ($p < 0.001$) and a reduced uptake of the glucose analogue 2-deoxy-D-[3H]-glucose (2DG) in response to insulin ($p < 0.01$). These effects were paralleled by a 70% decrease of both mRNA and protein levels of the insulin-sensitive glucose transporter GLUT4. GLUT4 regulation was, very likely, at the transcriptional level, as demonstrated by parallel mRNA downregulation of two transcription factors known to regulate GLUT4 expression, such as MEF2A and PGC1. Time course experiments showed that GLUT4 expression was reduced by 30% after 4 hours ($p < 0.001$), and by 70% after 8 hours ($p < 0.001$) following GlcNac treatment. MEF2A mRNA showed a similar kinetic. Furthermore, immunofluorescence confocal imaging experiments showed that GlcNac, besides its effect on GLUT4 transcription, impaired also the insulin induced GLUT4 translocation onto the plasma membrane. The use of the chemical chaperon 4-Phenyl Butyric Acid (PBA), known to alleviate ER stress conditions, prevented both BiP/GRP78 induction and GLUT4 downregulation. As for GLUT4, also MEF2A and PGC1 mRNA levels did not show any appreciable variation when L6 cells were treated with GlcNac in the presence of PBA. Furthermore, PBA treatment restored insulin-induced 2DG uptake to levels comparable to those of L6 control cells. Interestingly, GlcNac caused a 60% increase of both mRNA and protein levels of the glucose transporter GLUT1 ($p < 0.01$), suggesting that GLUT1 gene could be considered an early target of ER stress. Indeed, bioinformatics researches revealed the presence of four ERSE (ER stress Responsive Element) consensus sequence for ER stress activated transcription factors in the proximal region of the rat GLUT1 promoter sequence.

Conclusion: Glucosamine-induced ER stress may play a role in insulin-resistance of L6 skeletal muscle cells through the modulation of the expression and localization of the glucose transporters GLUT1 and GLUT4.

S-adenosyl-L-methionine inhibits IkappaB kinase- β activity

M. Moon¹, M. Kim¹, H. Lee², Y. Cho¹, Y. Park¹, S. Choi¹, H. Jang¹, K. Park¹, H. Lee¹

¹Internal Medicine, Seoul National University College of Medicine, ²Internal Medicine, Seoul National University Boramae Hospital, Seoul, Republic of Korea

Background and aims: S-adenosylmethionine (SAM) was reported to improve insulin sensitivity in OLETF rats. SAM has not only several features as a good antioxidant but also anti-inflammatory property. Both of oxidative stress and activation of I κ B kinase β (IKK- β)/NF- κ B pathway by inflammation are possible mechanism in the development of insulin resistance. We investigated the effects of SAM on the activity of IKK- β , NF- κ B binding activity, glucose transport and insulin signaling in rat L6 cells.

Materials and methods: The kinase activity of IKK- β was determined by a colorimetric ELISA assay. NF- κ B activities were determined by Electrophoretic mobility shift assay. Phosphorylation of IRS-1(Y612) and Akt(Ser473) were determined by western blot analysis. Glucose transport was measured by the 2-deoxy-[³H]-D-glucose uptake.

Results: Treatment with 1mM of SAM could inhibit the activity of IKK- β by 60 % compared to control material ($P < 0.05$). Treatment of cells with 1mM of SAM could decrease NF- κ B binding activity by about 20 % compared to those activated with TNF- α . Treatment of L6 cells with 0.5mM of SAM increased basal and insulin-stimulated glucose transport to 17.2 % ($P < 0.001$) and 12.8 % ($P = 0.014$), respectively, of that in untreated cells. 1mM of SAM also increased basal and insulin-stimulated glucose transport to 77.8 % ($P < 0.001$) and 73.5 % ($P < 0.001$), respectively, of that in untreated cells. Both of 0.5mM and 1M of SAM increased the tyrosine phosphorylation of IRS-1 and Akt in L6 cells.

Conclusion: SAM inhibited the activity of IKK- β and binding activity of NF- κ B induced by TNF- α . SAM also improved glucose transport and insulin signaling in L6 cells. These results suggest that SAM could have a beneficial role on the treatment of type 2 diabetes.

Study of sam68 implication in insulin receptor signalling by BRET

C. González-Yanes¹, S. Najib¹, C. Blanquart², T. Issad², V. Sánchez-Margalet¹

¹Medical Biochemistry and Molecular Biology, Virgen Macarena University Hospital, Sevilla, Spain, ²Cellular Biology, Institut Cochin, Paris, France

Background and aims: Sam68 is a RNA-binding protein belonging to the signal transduction and activation of RNA metabolism (STAR) family and it was first identified as a target of the tyrosine kinase Src. STAR proteins are characterized by a hnRNP K domain (KH) embedded in a high conserved region called GSG domain, which is required for homodimerization and sequence-specific RNA binding. Sam68 has been implicated in the regulation of cell cycle progression, RNA processing and apoptosis. Self-association of Sam68 has been previously described and RNA binding is necessary for this interaction. Sam68 phosphorylation by Src disrupts this oligomerization and RNA binding. Tyr-phosphorylation of Sam68 enables the molecule to interact with SH2-domain containing proteins involving Sam68 in signal transduction. We have previously shown that Sam68 is implicated in insulin receptor (IR) signalling as an adaptor protein mediating metabolic and proliferative effect of insulin. In this work, we aimed to further investigate Sam68 interactions with IR signalling proteins by using bioluminescence resonance energy transfer (BRET).

Materials and methods: We first prepared the constructs for BRET technology: Sam68-EYFP, Sam68-phRLuc, Sam68-pcDNA3 and we have also used IR-phRLuc, IRS1-EYFP and p85a-EYFP previously employed for study of IR signalling by BRET. Transient transfections with phRLuc and/or EYFP fusion or other constructs were performed in HEK293T cells. Twenty four hours post-transfection cells were detached and distributed in 96-well microplates. BRET experiments were performed on the following day. Upon the addition of 5 μ M of coelenterazine bioluminescence resulting from its degradation and the energy transferred to EYFP was detected. The BRET signal (BRET ratio) was quantified by calculating the 530nm/480 nm light-emission ratio.

Results: We have tested the interaction of Sam68 with IRS-1, and the homopolymerization of Sam68. We found that Sam68 interacts with IRS-1 measuring BRET signal using Sam68-Luc/IRS1-EYFP. This association is

potentiated by the overexpression of IR, and insulin stimulation further enhances the Sam68-IRS-1 association. On the other hand Sam68 self-association was confirmed by BRET studies.

Conclusion: In HEK293, IR overexpression and insulin stimulation positively modulates protein-protein interaction increasing the BRET signal of Sam68/IRS-1 and Sam68/Sam68 interaction. These results demonstrate the implication of Sam68 in the first steps of IR signalling.

Glucose deprivation simultaneously upregulates BiP/GRP78 and downregulates pIRS1(Ser312) in human adipocytes

E.M. Murphy, G. Ceolotto, A. Avogaro

Clinical and Experimental Medicine, University of Padua, Italy

Background and aims: Adipocytes play a critical role in energy metabolism. Their ability to respond appropriately to extracellular glucose concentrations, storing energy in the form of triglycerides when glucose is abundant, and releasing FFAs into the circulation when glucose is scarce, is dependent on adequate insulin signaling. IRS1 phosphorylation at Ser 312 has been shown to decrease IRS1 tyrosine phosphorylation and to consequently impair insulin signal transduction. Impaired insulin signaling has been shown to be associated with endoplasmic reticulum (ER) stress in some tissues. In cells deprived of glucose, ER stress may be activated and therefore may modulate insulin signal transduction by molecular mechanisms not completely known. Our aim was therefore to examine the link between glucose deprivation, IRS1 phosphorylation at Ser312, and ER stress activation in adipocytes, using BiP/GRP78 (Binding Protein/ 78 kDa Glucose-Regulated Protein) as a marker for ER stress activation.

Materials and methods: We differentiated a cell line of normal human white preadipocytes (HWP) into mature adipocytes. Cells were incubated for 18 hours in DMEM:F12 containing 2.5 mM L-glutamine and 3% FBS, with either 0 mM glucose (glucose deprivation) or 5.5 mM glucose (normal glucose), with and without insulin (100nM). Protein expression of pIRS1(Ser312), IRS1, BiP/GRP78 and GAPDH were determined by immunoblotting with specific antibodies.

Results: We found that glucose deprivation induced a decrease in protein expression of both unphosphorylated IRS1 and phosphorylated pIRS1(Ser312), both in the absence and presence of insulin, with a reduced ratio of pIRS1(Ser312) to unphosphorylated IRS1 under glucose deprivation. BiP/GRP78 expression was increased in glucose-deprived cells in comparison to cells grown at normal glucose levels. The decrease in IRS1(Ser312) phosphorylation is associated with an increase of BiP/GRP78 protein expression.

Conclusion: The ER stress induced by glucose deprivation in human white adipocytes is associated with a downregulated phosphorylation of IRS1 at Ser312. This downregulation may provide a novel mechanism by which cells improve insulin sensitivity when glucose is scarce. IRS1(Ser312) phosphorylation is sensitive to glucose deprivation even in the absence of insulin, demonstrating an insulin-independent effect of glucose on insulin signaling.

695

Insulin resistance by oxidative stress through the life-span determinant p66^{shcA} and the mTOR/S6K cascade

G. Pani, S. Chiatamone Ranieri, S. Fusco

Institute of General Pathology, Catholic University Medical School, Rome, Italy

Background and aims: Mitochondrial oxidative stress and hyperfunction of the nutrient-sensitive signaling pathway triggered by the mammalian Target of Rapamycin (mTOR) have been independently linked to the establishment of peripheral insulin resistance. While mTOR downregulates Insulin Receptor (IR) signaling through the S6 kinase-dependent inhibitory phosphorylation of the IR Substrate-1 (IRS-1), molecular mechanisms linking generation of Reactive Oxygen Species (ROS) to impaired Insulin responses are still largely elusive. The life-span determinant p66shcA mediates cellular damage and cell death by oxidative insult in a number of pathophysiological conditions including diabetic glomerulopathy, and participates in the generation of mitochondrial ROS; however, a potential role for this molecule in oxidant-induced IR desensitization has not been investigated. Aim of the present study is to clarify the molecular mechanism underlying insulin resistance by oxidative stress, and the potential involvement of p66shcA in this phenomenon.

Materials and methods: Undifferentiated 3T3L1 pre-adipocytes were serum-starved for 24 hours in the presence of redox stimuli (Catalase, 2500 U/ml; Glucose Oxidase [GOX], 5mU/ml), Rapamycin (200 ng/ml) or glucose-free medium, and stimulated with insulin (100 ng/ml) for 10'. Phosphorylation of AKT/PKB, IRS-1, S6K and S6 were evaluated by phospho-specific immunoblotting of total protein extracts. P66 WT and p66KO pre-adipocytes were isolated from mice of the corresponding genotype and stimulated in vitro as described above. To induce insulin resistance cells were kept for ≥ 2 days in the presence of TNF-alpha (10 ng/ml), GOX (5 mU/ml) or FFA (1 mM) before insulin challenge.

Results: In the preadipocytic 3T3L1 cell line, exposure to insulin led to the robust phosphorylation of AKT and, in parallel, to activation of the mTOR/S6K cascade, as monitored by the phosphorylation of the S6 ribosomal protein and the S6K-dependent, inhibitory phosphorylation of IRS-1 on Serine 1101. mTOR blockade by Rapamycin or by glucose withdrawal from the culture medium strongly inhibited mTOR-dependent events, while AKT phosphorylation was unaffected or slightly increased. Interestingly, a very similar response was elicited by cell treatment with the peroxide scavenger Catalase; conversely, generation of peroxide by GOX inhibited AKT responses and increased both mTOR activity and IRS-1 (Ser-1101) phosphorylation, suggesting that oxidants downregulate early insulin signaling, at least in part, through the redox-dependent activation of the mTOR/S6K pathway. In adipocyte precursors lacking p66shcA, nutrient and insulin activation of the mTOR cascade was defective with respect to WT controls. P66 deficient cells also displayed reduced IRS-1 phosphorylation, while both basal and insulin-induced phosphorylation of AKT/PKB was increased, especially under resistance-inducing (TNF-alpha, GOX and excess free fatty acids) conditions.

Conclusion: The above findings outline a model whereby oxidative stress attenuates early insulin signaling, at least in part, by activating a retro-inhibitory loop brought about by the mTOR/S6K cascade. Importantly, p66shcA plays a major role, upstream of mTOR, in such inhibitory circuit. The p66-mTOR axis may therefore represent a novel target for the pharmacological control of Type II Diabetes.

Resveratrol ameliorates high insulin-induced insulin resistance in skeletal muscle cells by regulating mTOR and p70 S6K phosphorylation

E. Tsiani, B. Faubert, T. Sanli

Community Health Sciences, Brock University, St Catharines, Canada

Background and aims: Insulin resistance, the hallmark of type 2 diabetes mellitus, is linked to hyperinsulinemia, which develops to counterbalance peripheral hormone resistance. In vitro and in vivo studies indicate that chronically elevated levels of insulin (HI) may lead to skeletal muscle insulin resistance by causing defects within the insulin-signalling cascade. Hyperinsulinemia is thus both a result and a cause of insulin resistance. Recently, the polyphenol resveratrol (RSV) has been shown to have anti-diabetic properties *in vitro* and *in vivo*. In the present study we examined the effect of RSV on HI-induced insulin resistance in skeletal muscle cells in vitro and investigated the mechanisms involved.

Materials and methods: L6 rat skeletal muscle cells were used. ^3H -2-deoxy-glucose (2DG) uptake was measured and total and phosphorylated levels of specific proteins were examined by western blotting.

Results: Chronic incubation (16–24 h) of L6 cells with 100 nM insulin decreased acute insulin (INS)-stimulated 2DG uptake (INS: $179 \pm 9\%$, HI+INS: $101 \pm 4\%$ of control) indicating insulin resistance. However, in the presence of 25 μM RSV (16–24h) insulin resistance (the effect of HI) was prevented (RHI+INS: $175 \pm 7\%$ of control). The serine/threonine kinases mTOR and p70 S6K have been implicated to mediate insulin resistance by causing phosphorylation of serine³⁰⁷ of the insulin receptor substrate 1 (IRS-1) which leads to impaired downstream insulin signalling and inhibition of Akt phosphorylation/activation. HI significantly increased the phosphorylation levels of mTOR ($170 \pm 14.5\%$ of control, $P < 0.01$) and p70 S6K ($227 \pm 33.6\%$ of control, $P < 0.05$) and RSV completely abolished these HI-induced responses (mTOR: $79 \pm 21\%$ of control, $P < 0.001$, p70 S6K: $117 \pm 19\%$ of control, $P < 0.05$). Furthermore, HI increased ser³⁰⁷ phosphorylation of IRS-1 ($270 \pm 79\%$ of control), and RSV was able to bring it back to normal ($130 \pm 31\%$ of control). In addition HI reduced insulin-stimulated Akt phosphorylation and RSV significantly blocked this inhibition.

Conclusion: Our results indicate that chronic HI induces skeletal muscle insulin resistance, and RSV can prevent it by regulating mTOR and p70 S6K phosphorylation. Resveratrol may be used towards preventing and/or treating insulin resistance and Type 2 diabetes.

Long-term mTOR inhibition exacerbates insulin resistance and glucose intolerance induced by high fat diet

C. Veyrat-Durebex¹, M. Vinciguerra², X. Montet³, N. Deblon¹, M. Fournier², G. Porcheron², C. Maeder², F. Rohner-Jeanrenaud¹, M. Foti²

¹Internal Medicine, ²Cell physiology and Metabolism, ³Radiology, University of Geneva, Switzerland

Background and aims: The mammalian target of rapamycin (mTOR) has been recently shown to induce IRS1 degradation and thus to act as a negative regulator of insulin signalling. In addition, mTOR activation by fatty acids was shown to trigger hepatic steatosis by inducing PTEN downregulation in the liver. In this study we evaluate the hypothesis that blockade of mTOR activity could alleviate metabolic disorders, such as insulin resistance and hepatic steatosis.

Materials and methods: High fat diet-induced obese Wistar rats were treated with sirolimus (2 mg/kg/day ip) during 21 days. Body weight, food intake and the main metabolic parameters were measured. Glucose tolerance and insulin sensitivity were evaluated *in vivo* using glucose and insulin tolerance tests. In addition, the effects of mTOR inhibitors on insulin signalling, glucose and fatty acid metabolism were evaluated in explanted tissues from Wistar rats and in cultured cell lines.

Results: Sirolimus-treated rats showed lower body weight gain, food intake, plasma free fatty acid and triglyceride levels than control obese rats. PTEN downregulation and lipid accumulation in the liver induced by the high fat diet were decreased in sirolimus-treated rats. However, sirolimus treatment markedly worsened glucose intolerance and insulin resistance, despite a 4-fold increase in insulinaemia. Interestingly, IRS1 mRNA levels were strongly downregulated in explanted skeletal muscles and livers from sirolimus-treated rats, suggesting that long-term mTOR inhibition alters insulin signalling and glucose metabolism by reducing IRS1 expression. Consistent with these *in vivo* data, glucose uptake and glycogen synthesis were impaired in rat L6 myotubes exposed 24h to the mTOR inhibitor, rapamycin.

Conclusion: Long-term inhibition of mTOR with rapamycin analogues prevents the development of hepatic steatosis in obese rats, but concomitantly impairs insulin sensitivity and glucose metabolism in skeletal muscles. These data call for cautiousness in the clinical use of rapamycin analogues as immune suppressors or anti-cancer therapy.

Prediction of the Minimal Model insulin sensitivity index through one hour intravenous glucose tolerance test data

A. Tura, S. Sbrignadello, G. Pacini
ISIB, CNR, Padova, Italy

Background and aims: Minimal Model (MM) analysis of intravenous glucose tolerance test (IVGTT) data is widely used to estimate insulin sensitivity (IS). However, this requires a computer program and relevant expertise to run the mathematical model properly. Furthermore, reliable results based on MM require many plasma insulin and glucose samples for a time interval of at least three hours after glucose injection. The aim of this study was: i) developing a predictor of MM IS index from IVGTT data limited to one hour or less, calculated with empirical parameters not requiring complex mathematical models; ii) assessing its performance in different groups of subjects with specific clinical characteristics.

Materials and methods: We studied 114 control subjects with normal glucose tolerance, CNT (age= 33.8 ± 1.4 yrs, BMI= 23.4 ± 0.4 kg/m², basal glucose, $G_b = 4.6 \pm 0.05$ mmol/l (mean \pm SE)), 127 subjects with impaired fasting glucose or impaired glucose tolerance, IFG/IGT (42.8 ± 1.4 ; 28.0 ± 0.6), 55 subjects with chronic renal disease, REN (age= 44.3 ± 2.9 ; BMI= 25.7 ± 1.0), and 10 subjects with hyperparathyroidism, PAR, before and after surgery (age= 64.3 ± 2.3 , BMI= 25.8 ± 1.6 before and 25.4 ± 1.5 after). All the subjects underwent a 3-h frequently sampled IVGTT. IS index was estimated by MM analysis (S_i). A predictor of S_i was calculated as $CS_i = T \times K_G / \Delta AUC_{INS}$, where K_G is the rate of glucose disappearance and ΔAUC_{INS} is the area under the insulin curve above basal. T is the time interval between 10 and 50 min when both K_G and ΔAUC_{INS} are computed: ie, T=40 min.

Results: In CNT S_i and CS_i showed strong correlation ($R^2 = 0.87$, $P < 0.0001$). The slope of the regression line was 0.285, and that value was used to correct the CS_i value in each subject of the other studied groups. Strong correlation was then found in IFG/IGT (slope=0.97, $R^2 = 0.82$, $P < 0.0001$; figure) and in REN (slope=0.92, $R^2 = 0.80$, $P < 0.0001$). Both slopes were not significantly different from unit. In PAR, CS_i was again strongly correlated with S_i and able to detect the increase in IS after surgery, similarly to S_i ($CS_i = 3.84 \pm 0.55 \cdot 10^{-4} \text{ min}^{-1} (\mu\text{U/ml})^{-1}$ before, 5.91 ± 0.87 after, $P = 0.006$; $S_i = 3.23 \pm 0.54$ before, 4.97 ± 0.70 after, $P = 0.018$).

Conclusion: A few studies have developed simplified methods for IS from IVGTT data and they were based on small datasets, while the simplified approach proposed in this study has been tested in large and heterogeneous groups of patients. CS_i revealed to be an excellent predictor of IS. Since the evaluation of the early part of IVGTT is a reliable method for quantifying insulin secretion, our method will allow a combined estimation of IS and beta cell function in a single individual with an easy procedure.

Application of mathematical model to evaluate insulin sensitivity and secretion function from the 3-hour OGTT

Y. Xie
Metabolic Disease Hospital, Tianjin Medical University, China

Background and aims: To establish a mathematical model to assess insulin sensitivity and secretion function from the 3-hour OGTT.

Materials and methods: The mathematical model LMM (linear minimal model) has been developed from five physiological assumptions to evalu-

ate insulin sensitivity and secretion function from the 3-hour OGTT (oral glucose tolerance test). The equations are $dG/dt = P - aG - bI - v(G) + f(t)$ and $dI/dt = c(G - G^*) - dI$, where a is the coefficient of plasma glucose autogenous regulation, b is the coefficient of plasma glucose reduction due to the effect of insulin, c is the coefficient of insulin secretion stimulated by plasma glucose, d is the coefficient of insulin degradation, P is the critical rate of plasma glucose increase caused by hepatic glucose output, $v(G)$ is the rate of plasma glucose decrease caused by urine glucose output and $f(t)$ is the rate of plasma glucose increase caused by glucose ingested from intestines and stomach. The coefficients b and c were defined as the insulin sensitivity index LMM-ISI and secretion function index LMM-BCI respectively after being processed by fuzzy mathematics. The insulin sensitivity index LMM-ISI and secretion function index LMM-BCI can be calculated from the plasma glucose values and insulin values at five time points (0min, 30min, 60min, 120min and 180min) in the 3-hour OGTT by a computer program developed from the model LMM. Using the data from the euglycemic clamp test, IVGTT and the 3-hour OGTT on 99 non-diabetic American Pima Indians (NGT 47 subjects and IGR 52 subjects, BMI was 35.53 ± 8.13), the feasibility of LMM-ISI and LMM-BCI was studied in this paper.

Results: The Pearson's correlation coefficient between LMM-ISI and GIR (glucose infusion rate at steady state of the euglycemic clamp test) was 0.82 ($P < 0.001$), which was larger than those corresponding values calculated from QUICKI, HOMA-ISI, IAI (insulin action index, $IAI = 1/(G_0 \cdot I_0)$, Supamai-ISI and Composite-ISI ($= 10^{4/(G_0 \times I_0 \times G_{\text{mean}} \times I_{\text{mean}})^{0.5}}$)), the respective values of which were 0.54, 0.58, 0.58, 0.67 and 0.66. After correcting the effect of GIR, the partial correlation between LMM-BCI and plasma glucose level (G_{120} or $G_{\text{trapezoid}}$, the mean value of plasma glucose concentrations within 180 minutes during the OGTT calculated by the trapezoid method) was most significant ($r = -0.52, -0.56$ respectively, $P < 0.001$) among the six insulin secretion function indices (AIR (acute insulin response), HOMA- β , $\Delta I_{30}/\Delta G_{30}$, $\Delta I_{60}/\Delta G_{60}$, MBCI (modified beta cell index, $MBCI = G_0 \times I_0 / (G_{60} + G_{120} - 7)$) and LMM-BCI). Combination of LMM-ISI and LMM-BCI could explain the change of $G_{\text{trapezoid}}$ better (the coefficient of determination R^2 was 0.73, $P < 0.001$).

Conclusion: Thus LMM-ISI is a relatively good insulin sensitivity index, while LMM-BCI is quite a reliable insulin secretion function index derived from the oral glucose tolerance test.

Impact of postprandial or postabsorptive administration of $^2\text{H}_2\text{O}$ on estimates of gluconeogenesis in diabetic and non-diabetic humans

R. Basu, A. Basu, R. Rizza

Endocrinology, Metabolism & Nutrition, Mayo Clinic College Of Medicine, Rochester, United States

Background and aims: The deuterated ($^2\text{H}_2\text{O}$) water method commonly is used to measure gluconeogenesis. The fifth carbon (C5) is labeled with deuterium during gluconeogenesis whereas the second carbon of glucose (C2) is labeled during both gluconeogenesis and glycogenolysis. The C5/C2 glucose ratio is used to estimate the percent of plasma glucose derived from gluconeogenesis. However, glycogen cycling (plasma glucose to glucose-6 phosphate to glycogen to glucose-6 phosphate to plasma glucose) is believed to occur in both the fed and fasted state. Since gluconeogenically derived C5 glucose can pass through glycogen before entering plasma, the C5/C2 glucose ratio and therefore estimates of gluconeogenesis may be influenced by the time between eating and $^2\text{H}_2\text{O}$ administration.

Materials and methods: 10 non-diabetic and 9 with type 2 diabetes ate a meal at 1800 and were randomized to receive 1.67gms/kgFFM of $^2\text{H}_2\text{O}$ in divided doses at either 1800, 2000 and 2200 (postprandial) or 2200, 2400 and 0200 (postabsorptive); plasma samples for C5 glucose, C2 glucose and plasma $^2\text{H}_2\text{O}$ enrichment were collected at 0800 the following morning.

Results: Postprandial and postabsorptive plasma C5 glucose, C2 glucose, and $^2\text{H}_2\text{O}$ enrichments did not differ in either the non-diabetic (0.26 ± 0.02 vs. 0.24 ± 0.02 ; 0.48 ± 0.01 vs. 0.40 ± 0.03 ; 0.52 ± 0.03 vs. 0.44 ± 0.03) or diabetic (0.29 ± 0.03 vs. 0.23 ± 0.02 ; 0.46 ± 0.05 vs. 0.42 ± 0.03 ; 0.53 ± 0.04 vs. 0.48 ± 0.03) subjects. This resulted in a comparable estimate of the percent of plasma glucose derived from gluconeogenesis (i.e. the plasma C5/C2 glucose ratio) following postprandial and postabsorptive $^2\text{H}_2\text{O}$ administration in the non-diabetic (0.54 ± 0.04 vs. 0.59 ± 0.03) but lower ($p < 0.02$) estimates with postabsorptive administration in the diabetic subjects at 0800 (0.64 ± 0.01 vs. 0.54 ± 0.02) but not when glycogen is further depleted with 4 additional hours of fasting (0.72 ± 0.04 vs. 0.64 ± 0.06). Plasma C2 glucose and $^2\text{H}_2\text{O}$

enrichments also did not differ following postprandial and postabsorptive $^2\text{H}_2\text{O}$ administration indicating adequate time for $^2\text{H}_2\text{O}$ to equilibrate with the hepatic C2 glucose pool.

Conclusion: Administration of $^2\text{H}_2\text{O}$ immediately following or 4 hours after the evening meal results in an equivalent estimate of gluconeogenesis by 0800 the following morning in non-diabetic subjects consistent with extensive nocturnal hepatic glycogen cycling. In contrast, the higher C5/C2 glucose at 0800 but not at 1200 when $^2\text{H}_2\text{O}$ is given immediately after meal ingestion in diabetic subjects implies increased postprandial labeling of glycogen with C5 glucose via the indirect pathway. Therefore, the timing of $^2\text{H}_2\text{O}$ administration relative to ingestion of the evening meal influences estimates of gluconeogenesis measured the following morning in diabetic but not non-diabetic subjects.

Prediction of postprandial blood glucose level according to the amount of carbohydrates consumed during a meal in type 2 diabetes patients

S. Franc, D. Dardari, J.-P. Riveline, G. Charpentier

Department of Diabetes, Centre Hospitalier Sud Francilien, Corbeil, France

Background and aims: Identification of the 'main meal' (i.e. the meal with the highest postprandial blood glucose [PPBG]) in patients with Type 2 diabetes mellitus (T2DM) can help optimise glycaemic control in basal-bolus insulin regimens, which may initially use a single prandial insulin injection to target the main meal as a stepwise approach towards intensifying insulin therapy. However, the main meal can vary with the dietary habits of patients and remains an unpredictable factor in the treatment of T2DM. The aim of our study was to determine the relationship between the amount of carbohydrate consumed and PPBG in T2DM patients in order to predict the main meal.

Materials and methods: Three-day blood glucose (BG) profiles were measured in 37 T2DM patients treated with sulfonylurea, metformin and well titrated on insulin glargine (mean \pm SD HbA_{1c}: $7.7 \pm 0.8\%$), using a continuous glucose-monitoring system (CGMS) either once ($n=5$) or twice (1 month apart; $n=32$). During the three CGMS days, food intake from 680 meals was accurately recorded by patients and quantified by a dietitian.

Results: Overall analysis of the 680 meals failed to show a correlation between BG excursion ($\Delta BG = \text{PPBG}_{\text{max}} - [\text{fasting blood glucose}]$) and carbohydrate amount, even after standardisation with body weight. In contrast, analysis of the data according to the meal showed a correlation and a simple global relationship could be established; breakfast: $\Delta BG \text{ (mg/dL)} = 65 \times \text{carbohydrate/body weight} + 73$; the slope was reduced by half at lunch and by a third at dinner. A quadratic polynomial equation including several parameters (body weight; C-peptide; Howorka-defined K insulin sensitivity index; HbA_{1c}; mean carbohydrate; and lipid and protein intake) was used to improve the ΔBG model. This model was more reliable at predicting ΔBG in the whole population ($R^2=0.26$) but had high inter-individual variability. Two groups of patients could be identified: 'responder' patients, whose ΔBG was well correlated with carbohydrate amount ($R^2 \geq 0.30$, $n=8$), and 'non-responder' patients, who showed less correlation ($R^2 < 0.30$, $n=29$). 'Responder' versus 'non-responder' patients were leaner (BMI, 27 ± 3 vs. $30 \pm 4 \text{ kg/m}^2$; $p=0.019$), had higher mean PPBG excursions (mean ΔBG , 113 ± 23 vs. $92 \pm 21 \text{ mg/dL}$; $p=0.022$) and consumed on average more lipids (28 ± 7 vs. $23 \pm 6 \text{ g}$; $p=0.045$). Three variables appeared to be independent and predictive factors for a 'responder' (contribution in descending order): 1) extent of the mean PPBG excursion (relative risk [RR] 1.2; $p=0.04$); 2) mean carbohydrate load (RR 0.89; $p=0.03$); and 3) mean lipid load (RR 1.3; $p=0.05$). For these responder patients, the quadratic polynomial equation was much more reliable at predicting ΔBG ($R^2=0.51$).

Conclusion: In conclusion, besides carbohydrate counting, other factors play a role in the extent of the PPBG excursion in T2DM patients. Characterisation of these factors and of their respective roles may improve T2DM management by providing new therapeutic targets.

Influence of hepatic and peripheral insulin resistance on glucose tolerance in non-diabetic subjects: the RISC studyA. Gastaldelli¹, G. Pacini², A. Mari², the RISC investigators¹Institute of Clinical Physiology, National Research Council, Pisa, ²Institute of Biomedical Engineering, National Research Council, Padova, Italy

Background and aims: Fasting hyperglycemia is prevented as long as hepatic autoregulation maintains endogenous glucose production (EGP) within the normal range. On the other hand, postprandial glycemia starts to increase long before hepatic autoregulation is lost, mainly because of insulin resistance both at the level of the muscle and of the liver (through impaired suppression of EGP). The contribution of hepatic insulin resistance (HIR) to fasting and/or postprandial glucose concentration is still unknown. Aim of this study was to evaluate EGP and HIR in a large group of non-diabetic subjects and the relationships with peripheral insulin resistance and β -cell function.

Methods: The RISC study recruited 1,290 non-diabetic subjects (age 30–60 years) without hypertension or dyslipidaemia in 19 centers in Europe. Body composition, liver enzymes, lipid profile, peripheral insulin sensitivity (by hyperinsulinaemic clamp), β -cell function and glucose tolerance (from the OGTT) were measured. In a subgroup of subjects ($n=398$), 6,6-²H-glucose was used to determine EGP and glucose disposal (Rd) during fasting and clamp. HIR was calculated as the product of fasting EGP and fasting plasma insulin concentration.

Results: Both fasting EGP ($6.43 \mu\text{mol min}^{-1} \text{kg}_{\text{ffm}}^{-1}$) and HIR ($87\text{--}3045 \mu\text{mol min}^{-1} \text{kg}_{\text{ffm}}^{-1} \text{pM}$) ranged widely. When subjects were divided into HIR quartiles (Q1 to Q4: 197 ± 5 , 329 ± 4 , 480 ± 5 , $905 \pm 37 \mu\text{mol min}^{-1} \text{kg}_{\text{ffm}}^{-1} \text{pM}$, respectively), graded increases in both fasting plasma glucose (from 4.8 ± 0.1 mmol/l in Q1 to 5.2 ± 0.1 mmol/l in Q4, $p=0.0002$) and 2-hour plasma glucose concentrations (from 5.3 ± 0.1 mmol/l in Q1 to 6.1 ± 0.2 mmol/l in Q4, $p=0.001$) was observed. On the clamp, Rd ranged $15\text{--}151 \mu\text{mol min}^{-1} \text{kg}_{\text{ffm}}^{-1}$. Across HIR quartiles, fasting Rd increased from 13.9 ± 0.3 in Q1 to $18.8 \pm 0.6 \mu\text{mol min}^{-1} \text{kg}_{\text{ffm}}^{-1}$ in Q4 ($p=0.0001$), while clamp Rd decreased from 64 ± 2 in Q1 to $46 \pm 2 \mu\text{mol min}^{-1} \text{kg}_{\text{ffm}}^{-1}$ in Q4 ($p=0.0001$). Both fasting and clamp Rd correlated positively with adiponectin ($r=0.20$ and 0.32 respectively, $p<0.0001$). No correlation was found between fasting and clamp Rd. Residual EGP measured during clamp varied from -27 to $26 \mu\text{mol min}^{-1} \text{kg}_{\text{ffm}}^{-1}$ (15% of measurements with negative values). A weak, if significant, positive correlation ($r=0.18$, $p=0.0004$) was found between fasting and clamp EGP. HIR was associated with decreased adiponectin (partial $r=-0.21$, $p<0.0001$, after adjusting for sex, age, BMI and centre), decreased hepatic insulin clearance (partial $r=-0.24$, $p<0.0001$), increased total insulin response during the OGTT (partial $r=0.31$, $p<0.0001$) and decreased potentiation of insulin release (partial $r=-0.15$, $p<0.005$). In multivariate models adjusting for sex, age, BMI and centre, fasting glucose was predicted by HIR (partial $r=0.17$, $p=0.0009$) while 2-hour glucose was predicted by clamp Rd (partial $r=-0.23$, $p<0.0001$).

Conclusion: In non-diabetic subjects, hepatic insulin resistance is the main factor associated with an increase in fasting glucose concentration while peripheral insulin-mediated glucose uptake is the main factor associated with postprandial glucose concentration.

Insulin-mediated ablation of nocturnal glycaemic excursion in type 2 diabetes improves daytime glycaemia and insulin sensitivity by suppressing nighttime glucose production

J. Radziuk, S. Pye

Medicine, Ottawa Hospital (Civic Campus), Ottawa, Canada

Background and aims: Fasting hyperglycaemia in type 2 diabetes (T2DM) represents peak glucose levels in a circadian cycle of glucose levels and endogenous glucose production (EGP) which rise during the night and decrease in daytime. It has been suggested that the transition from a steady state glucose to such a cyclic EGP and glucose levels, is characteristic of the nonlinear nature of the glucose system. This study was designed to examine the daytime metabolic effects of insulin-mediated suppression of the nocturnal increase in EGP, and thus an abrogation of the cyclic changes in EGP.

Materials and methods: 10 subjects with T2DM underwent 2 studies. In both they fasted from 10:00h on day 1 of the study. An infusion of [U-13C]glucose and [3-14C]lactate was initiated at 17:00h and continued until 18:00h on day 2. During the second study (I) a variable insulin infusion was used to normalize glycemia to the extrapolated baseline (nadir) levels determined in the first study (B). Glucose fluxes (EGP), glucose removal, metabolic clearance rate

(MCR) and an index of gluconeogenesis) were determined using compartmental modelling of glucose kinetics.

Results: Glucose concentrations initially were 7.7 ± 0.5 and 7.8 ± 0.5 mmol/L in B and I respectively, peaking at 9.1 ± 0.6 and 7.2 ± 0.4 mmol/L ($p<0.05$) at 8:00h on Day 2 and falling to 6.6 ± 0.4 and 5.7 ± 0.3 ($p<0.05$) mmol/L by 18h. Insulin concentrations were initially 120 ± 12 and 114 ± 12 pmol/L in B and I, rising to 162 ± 18 at 4:30h in I during its infusion (vs 102 ± 12 pmol/L for B, $p<0.05$). Initial EGP was 8.4 ± 0.5 and $8.4 \pm 0.25 \mu\text{mol/kg}^{-1} \text{min}^{-1}$ in B and I, rising by 1.71 ± 0.30 and $0.55 \pm 0.21 \mu\text{mol/kg}^{-1} \text{min}^{-1}$ ($p<0.05$) at 7:00h on day 2 and decreasing to 6.7 ± 0.3 and $6.8 \pm 0.2 \mu\text{mol/kg}^{-1} \text{min}^{-1}$ by 18:00h. The increase in EGP was explained by a peak gluconeogenic index of 3.8 ± 0.3 and $2.4 \pm 0.2 \mu\text{mol/kg}^{-1} \text{min}^{-1}$ in B and I ($p<0.05$). Glucose removal decreased uniformly in both studies from 8.8 ± 0.4 to $7.2 \pm 0.3 \mu\text{mol/kg}^{-1} \text{min}^{-1}$. The decrease in glycemia at 18:00h (Day 2) was therefore explained by an increase in MCR from 1.11 ± 0.07 (B) to $1.25 \pm 0.05 \text{ ml/kg}^{-1} \text{min}^{-1}$ (I), ($p<0.05$) at this time. The increase in MCR in (I) occurs with lower insulin levels 78 ± 6 (I) vs 96 ± 6 pmol/L (B).

Conclusion: The suppression of nocturnal gluconeogenesis in type 2 diabetic subjects, not only improves morning EGP and glycemia, but exerts more remote effects by improving glycaemia and increasing insulin sensitivity the following afternoon. This may be another expression of the nonlinear behaviour of the glucose system.

Physically active but insulin resistant subjects have features of lipotoxicity

J. Nolan, H. Thabit, N. Burns, S. Shah, the RISC investigators

Metabolic Research Unit, St James Hospital, Dublin, Ireland

Background and aims: We reported that patients with early onset type 2 diabetes mellitus had no improvement in insulin sensitivity despite aerobic exercise training for 3 months. We hypothesised that this non-response is mainly due to lipotoxicity.

Methods: In the RISC study, 807 healthy non-diabetic subjects underwent a 2-hour hyperinsulinaemic euglycemic clamp for measurement of glucose disposal rate (M/I) as well as measurement of physical activity by Actigraph accelerometers. We compared two sub-groups from this population, the active (top tertile for physical activity) but insulin resistant (bottom tertile for M/I) (AIR) and the inactive (bottom tertile for physical activity) but insulin sensitive (top tertile for M/I) (IIS) groups.

Results: The AIR subjects had higher Actigraph counts (561533 vs 197977 counts, $p<0.005$) and lower M/I values (77.1 ± 21.2 vs $217.5 \pm 93.5 \mu\text{mol min}^{-1} \text{kg}_{\text{ffm}}^{-1} \text{mM}^{-1}$, $p<0.005$). Both groups were of similar age (43.2 ± 8.2 vs 44.5 ± 8.5 years, $p=0.36$). There were more males in the AIR group compared to the IIS group (63% vs 24%). In comparison with the IIS group, the AIR subjects had elevated waist: hip ratio, 2-hour glucose post OGTT, fasting insulin, NEFA and reduced adiponectin and HDL-C (1.3 ± 0.3 vs 1.6 ± 0.4 , $p<0.005$). However, when males and females were looked at separately there were no differences in age, weight or fat mass between AIR and IIS. There were no differences in waist: hip ratio between AIR males and IIS males. However, AIR females had higher waist: hip ratio (0.85 ± 0.1 vs 0.79 ± 0.07 , $p=0.01$) and waist circumference (83.6 ± 11.4 vs 77.6 ± 8.7 cm, $p=0.012$) than IIS females. NEFA was higher in AIR compared to IIS in either males or females (0.53 ± 0.2 vs 0.35 ± 0.2 mmol/l, $p=0.008$ in males, and 0.64 ± 0.2 vs 0.53 ± 0.2 , $p=0.03$ in females). Adiponectin and HDL-C were lower in AIR compared to IIS only in females (8.2 ± 3.2 vs 10.8 ± 3.8 mg/l, $p=0.007$, and 1.4 ± 0.3 vs 1.7 ± 0.3 mmol/l, $p=0.003$ respectively).

Conclusion: Thus the key distinguishing features of physically active, but insulin resistant, subjects are consistent with abnormal lipid metabolism, which may impair skeletal muscle response to exercise.

Table 1. Data are expressed as Mean (SD). P value <0.05 are significant

	AIR subjects (N=54)	IIS Subjects (N=85)	p value
BMI (kg/m^2)	25.8 (3.8)	23.6 (3.2)	<0.005
Waist:hip ratio	0.9 (0.09)	0.82 (0.08)	<0.005
Fasting Glucose (mmol/l)	5.2 (0.5)	5.1 (0.4)	0.08
2-Hour Glucose post OGTT (mmol/l)	6.2 (1.4)	5.2 (1.2)	<0.005
Fasting Insulin (pmol/l)	47.1 (22.6)	28.0 (12.2)	<0.005
Non-esterified fatty acid (mmol/l)	0.57 (0.2)	0.49 (0.2)	0.031
Adiponectin (mg/l)	6.7 (3.1)	9.9 (3.9)	<0.005

Mechanism of hyperglycaemia after oral glucose ingestion in men with type 2 diabetes

V. Rigalleau¹, M.-C. Beauvieux¹, J.-L. Gallis¹, H. Gin¹, P. Schneider², L. Tappy²

¹Nutrition Diabetologie, Hopital Haut Leveque USN, Pessac, France, ²Institut de Physiologie, Université de Lausanne, Switzerland

Background and aims: Postprandial hyperglycaemia may be due to insufficiently suppressed Endogenous Glucose Production in Type 2 Diabetes, but this has not been demonstrated in conditions of controlled hyperglycaemia.

Materials and methods: Eight men with T2D (age: 52±7 yrs; BMI:26.6±2.3 kg/m²; fasting glycaemia: 7.1±1.5mmol/L, without any oral antidiabetic agent) were compared to eight healthy controls (age: 51±5; BMI: 24.6±2.9; glycaemia: 4.9±0.4). Their glucose turnover rate and hepatic cycle were measured by a [2H7]glucose infusion with m+7 and m+6 enrichments monitoring, 3 hours before and four hours after the ingestion of [6,6-2H2] labelled glucose, while their glycaemia was maintained at 10 mmol/L by the pancreatic clamp technique.

Results: Insulin levels were similarly increased for T2D (from 84±5 to 201±16 pmol/L) and control subjects (from 41±9 to 160±10 pmol/L), with prompt C-peptide suppression after the onset of the somatostatin-insulin infusions. Glucagon levels remained slightly, but non significantly, higher in T2D (96±25 ng/L) than controls (61±7 ng/L). Seventy-one percent of the 700 mg/kg oral glucose load appeared in the systemic circulation of the T2D subjects (63% for controls, NS). The results are summarized in the table.

Conclusion: When T2D subjects are compared to normal subjects with similar controlled hyperglycaemia after oral glucose ingestion, they mainly differ on peripheral glucose uptake, not Endogenous Glucose Production. By contrast with the fasting situation, the main mechanism of postprandial hyperglycaemia in T2D is a reduction of glucose utilization. The low hepatic glucose cycle rate argues against any role for a putative Glucose-6-Phosphatase overactivity in the postprandial hyperglycaemia of T2D.

Rates as mg/kg/min, before and after oral glucose ingestion

		T2D	Controls	p
Peripheral Uptake	Before	4.5±1.3	7.8±2.5	<0.01
	After	5.7±2.4	9.3±2.9	<0.05
Endogenous Production	Before	0.48±0.87	0.14±0.56	NS
	After	0.14±0.39	0.37±0.59	NS
Hepatic Cycle	Before	0.29±0.22	0.51±0.21	NS (p=0.06)
	After	0.44±0.56	0.62±0.26	NS

PS 055 Insulin sensitivity and glucose metabolism in humans: various mechanisms

706

Decreased glucose transport into the thalamus in type 1 diabetes

O. Heikkilä^{1,2}, N. Lundbom³, M. Timonen³, P.-H. Groop^{1,2}, S. Heikkinen⁴, S. Mäkimattila¹

¹Institute of Genetics, Folkhälsan Research Center, ²Division of Nephrology, Department of Medicine, Helsinki University Hospital, ³Helsinki Medical Imaging Center, University of Finland, ⁴Laboratory of Organic Chemistry, University of Helsinki, Finland

Background and aims: In type 1 diabetes (T1D), both severe hypoglycemia and recurrent hyperglycemia have been associated with cognitive impairment and regional brain volume differences. Hyperglycemia disrupts cellular homeostasis resulting in end-organ damage that may pertain also the brain. In rats, chronic hyperglycemia has been shown to down-regulate glucose transport into the brain. In humans, the effect of acute hyperglycemia has been studied in T1D patients with recurrent hypoglycemia and in occipital cortex only; no down-regulation was observed. We studied if the brain of T1D patients who are used to high plasma glucose excursions is more resistant to acute hyperglycemia compared to non-diabetic subjects. We also searched for possible regional variation in glucose transport into the brain.

Materials and methods: We studied seven 22-43-year old men with T1D (duration 12 ± 3 yrs), and eleven age- and weight-matched men without T1D. The men with T1D had high mean amplitude of glucose excursions (11.3 ± 2.9 mmol/l) but no history of severe hypoglycemia. Glucose, N-acetyl aspartate, creatine, choline, and myo-inositol (mI) in frontal cortex (FC), frontal white matter (FWM) and in thalamus (TH) were quantified with proton magnetic resonance spectroscopy during basal fasting glycemia and twice during 2h hyperglycemic clamp that aimed to increase plasma glucose by 10 - 15 mmol/l. To avoid endogenous insulin secretion and its possible effect on brain metabolism, the non-diabetic men received somatostatin.

Results: Plasma glucose increased 11.6 ± 3.0 (from 7.7 ± 2.8 to 19.3 ± 2.4) mmol/l in diabetic vs. 12.3 ± 1.0 (from 4.7 ± 0.4 to 17.0 ± 1.0) mmol/l in non-diabetic men (p = NS). Serum insulin concentrations were equal between the groups throughout the study. During basal fasting glycemia, the diabetic men had higher glucose level in the FWM ([39.3 ± 10.9] · 10⁻⁶ vs. [26.6 ± 6.1] · 10⁻⁶, p = 0.03) compared to the non-diabetic men, but equal in the FC ([43.0 ± 12.0] · 10⁻⁶ vs. [37.4 ± 9.2] · 10⁻⁶) and TH ([34.1 ± 14.0] · 10⁻⁶ vs. [28.3 ± 12.6] · 10⁻⁶). In the diabetic men, no regional variation of brain glucose was found. In the non-diabetic men, glucose level in FC was higher than in FWM during basal fasting glycemia (p = 0.02) and acute hyperglycemia (p = 0.04). During hyperglycemic clamp, the brain glucose levels increased significantly in both groups: in FC by 2.0 ± 0.7 vs. 2.7 ± 0.9 (NS), in FWM 1.5 ± 0.7 vs. 1.7 ± 0.7 (NS), in TH 1.1 ± 0.4 vs. 2.3 ± 0.7 mmol/l (p = 0.01) for diabetic and non-diabetic men. The diabetic men had higher mI in the FWM at baseline and during hyperglycemia, and in the FC during hyperglycemia.

Conclusion: During basal fasting glycemia, regional variation in brain glucose levels was found in non-diabetic subjects but not in T1D patients. During hyperglycemic clamp, the glucose transport into the TH was attenuated in T1D, which is a new finding and may sign down-regulation of glucose transport. The increased mI signal in diabetic FC and FWM may either arise from the increased glucose level or represent osmotic adaptation of the diabetic brain. Our results suggest that in T1D, high glucose excursions result in regional changes of glucose transport that may underlie the functional and structural pathology of the brain.

PTEN expression in the adipose and skeletal muscle tissue in type 2 diabetics versus healthy controls

P. Plomgaard, A.R. Nielsen, C. Broholm, O.H. Mortensen, C.P. Fischer, S. Taudorf, B.K. Pedersen
Centre of Inflammation and Metabolism, Rigshospitalet, Copenhagen, Denmark

Background and aims: Phosphatase and tensin homolog deleted on chromosome 10 (PTEN) is a lipid phosphatase, which has been proposed as a negative regulator of insulin sensitivity. PTEN dephosphorylates PtdIns(3,4,5)P₃ thereby inhibiting the intracellular signal transduction of insulin. *In vitro* studies have demonstrated that TNF- α increase the expression of both PTEN mRNA and protein in myotubes resulting in an impaired insulin mediated glucose uptake. This is in line with *in vivo* studies in mice where inhibition of PTEN has improved insulin sensitivity. In humans PTEN promoter polymorphisms in relation to diabetes have given conflicting results. The aim of the present study was to investigate if PTEN mRNA in muscle and adipose tissue were differentially expressed in healthy human subjects compared to type 2 diabetic patients.

Materials and methods: Two groups of age- gender and BMI-matched subjects were evaluated; healthy control (n=103) subjects with type II diabetic patients (n=96). The subjects underwent a clinical examination including having a blood sample drawn, and a DXA scanning for fat mass determination. Furthermore, a biopsy was obtained from the subcutaneous adipose tissue and the skeletal muscle tissue. In the plasma samples fasting glucose and insulin were measured as well as TNF- α and IL-6. The content of PTEN mRNA was quantified by use of real-time PCR. In a subpopulation of obese and non-obese diabetic and healthy controls (n=40) PTEN protein expression was assessed by western blot.

Results: Type 2 diabetics were compared to the healthy controls, and a higher plasma level of fasting insulin (26 pmol/L, $P<0.0001$) and glucose (3.9 mmol/L, $P<0.0001$) was found in type 2 diabetic patients, furthermore TNF- α ($P<0.001$) and IL-6 ($P<0.05$) were 0.3 pg/ml higher in type 2 diabetic patients compared to the control group. However no significant difference was observed in the fat mass, still WHR was 3.2 cm ($P<0.05$) increased in the diabetic patients. PTEN mRNA expression in the adipose and muscle tissue were not different between the groups. However PTEN mRNA in the adipose tissue was negatively associated with WHR ($P<0.001$) and muscle PTEN mRNA negatively associated with plasma TNF- α . The western blot analysis did not reveal any difference in PTEN protein expression in relation to diabetes or obesity.

Conclusion: The present study demonstrates that PTEN mRNA in muscle and adipose tissue is not associated with insulin resistance. However, an association did exist regarding PTEN mRNA content in the adipose tissue in relation to WHR. In accordance with the mRNA expression of PTEN in the skeletal muscle no difference was observed on the protein expression of PTEN. These data imply that PTEN mRNA content in muscle and adipose tissue is of limited clinical significance in relation to insulin resistance.

Higher iron content in liver associates with insulin resistance in subjects with thalassemia minor

P.C.Y. Tong¹, C.Y. Yeung¹, A.P.S. Kong¹, R.C.W. Ma¹, W.W.M. Lam², C.W. Lam³, M. Ng⁴, F.C.C. Chow¹, J.C.N. Chan¹

¹Department of Medicine & Therapeutics, ²Department of Diagnostic Radiology and Organ Imaging, ³Department of Chemical Pathology,

⁴Department of Anatomical and Cellular Pathology, The Chinese University of Hong Kong, Shatin, Hong Kong

Background and aims: Chinese subjects with thalassaemia minor have raised inflammatory marker levels and are insulin resistant. In a sib-pair analysis, we examined the relationships between thalassaemia minor, insulin resistance, iron content and oxidative stress.

Materials and methods: Forty-two pairs of sibs with or without thalassemia were recruited. All subjects had a family history of diabetes in their first degree relative, and had normal glucose tolerance on oral glucose tolerance test. Insulin resistance (HOMA-IR) was derived from the homeostasis model assessment. Oxidative stress was measured by plasma (P-IsoP) and red cell membrane isoprostanes (M-IsoP) level. Iron content was determined by MRI-reciprocal T2 relaxation time (r-T2*) in the liver and in the pancreas.

Results: When compared with siblings with no hemoglobinopathy, subjects with thalassemia minor had higher fasting plasma glucose ($2.5\pm 8.0\%$, $p=0.04$), higher fasting plasma insulin ($37.7\pm 83.8\%$, $p=0.01$) and higher degree of insulin resistance as estimated by HOMA-IR ($42.7\pm 89.0\%$, $p<0.01$). Iron content was higher in subjects with thalassemia minor as reflected by higher reciprocal of T2 relaxation time measured by MRI liver ($12.7\pm 30.5\%$, $p=0.01$) and pancreas ($13.0\pm 38.3\%$, $p=0.04$). Oxidative stress, as measured by plasma isoprostane and membrane isoprostanes, was not significantly different among two groups. On linear regression analysis, HOMA-IR was associated with waist circumference, high-sensitive CRP, white cell count and r-T2* in the liver among subjects without hemoglobinopathy. In subjects with thalassemia minor, HOMA-IR was related to waist circumference, white cell count, P-IsoP, r-T2* in the liver, age, sex and urate.

Conclusion: Results from this sib-pair study suggest that thalassemia minor causes further degree of insulin resistance in subjects that are at high risk of developing diabetes. The presence of higher hepatic iron content in thalassemia minor may induce abnormality in glucose metabolism via inflammatory and oxidative stress pathways.

Circulating RBP4 concentration might reflect insulin resistance-associated iron overload

W. Ricart¹, J. Moreno-Navarrete¹, J. Bassols¹, F. Ortega¹, G. Pardo¹, J. Vendrell², J. Fernandez-Real¹

¹Endocrinology, Hospital of Girona, Spain, ²Endocrinology, Hospital of Tarragona, Spain

Background and aims: The mechanisms behind the association between retinol binding protein 4 (RBP4) and insulin resistance are not well understood. An interaction between iron and vitamin A status, of which RBP4 is a surrogate, has long been recognized. We hypothesized that iron-associated insulin resistance could be behind the impaired insulin action caused by RBP4.

Materials and methods: Serum ferritin and RBP4 concentration, and insulin resistance were evaluated in a sample of middle-aged men (n=132), and in a replication, independent study. Serum RBP4 was also studied before and after iron depletion in patients with type 2 diabetes. Finally, the effect of iron on RBP4 release was evaluated *in vitro* in adipose tissue.

Results: A positive correlation between circulating RBP4 and log serum ferritin ($r=0.35$ and $r=0.61$, $p<0.0001$) was observed in both independent studies. Serum RBP4 concentration was higher in men than women in parallel to increased ferritin levels. On multiple regression analyses to predict serum RBP4, log serum ferritin contributed significantly to RBP4 variance after controlling for BMI, age and HOMA value. Serum RBP4 concentration decreased after iron depletion type 2 diabetic patients (percent mean differences -13.7 (-25.4 to -2.04, $p=0.024$). The iron donor lactoferrin led to increased dose-dependent adipose tissue release of RBP4 (2.4 fold, $p=0.005$) and increased RBP4 expression while apotransferrin and deferoxamine led to decreased RBP4 release.

Conclusion: The relationship between circulating RBP4 and iron stores, both cross-sectional and after iron depletion, and *in vitro* findings suggest that iron could play a role in the RBP4-insulin resistance relationship.

Men with hyperferritinaemia and diabetes do not have a higher iron overload than those without diabetes. Results from a genetic screening programme for hereditary haemochromatosisJ.-M. Gonzalez-Clemente¹, N. Freixenet¹, O. Giménez-Palop¹, A. Caixàs¹, F. Blanco-Vaca², À. Remacha³, C. Cabistañá⁴, Y. Sánchez⁴, V. Bach⁵, M. Baiget⁵, J. Felez⁴¹Diabetes, Endocrinology and Nutrition, Hospital de Sabadell, Spain,²Biochemical Laboratory, Hospital de Sant Pau, Barcelona, Spain,³Hematology, Hospital de Sant Pau, Barcelona, Spain, ⁴CAP Canaletes, Institut Català de la Salut, Cerdanyola del Vallès, Spain, ⁵Genetics, Hospital de Sant Pau, Barcelona, Spain

Background and aims: Recent studies showed that a decrease in beta cell function (BCF) instead of a decrease in insulin sensitivity, is the main pathogenic factor involved in the development of diabetes associated with hereditary hemochromatosis (HH). However, most subjects with hyperferritinemia do not have HH, although it is well-known that they have a lower insulin sensitivity and a higher prevalence of the components of the metabolic syndrome (MS). Our aim was to evaluate whether BCF and IS were different or not in diabetics as compared to the non-diabetics, in a group of men with hyperferritinemia none of them with HH.

Materials and methods: During 1-year period, 150 men (age: 54.0±13.1 yrs), were genetically screened for HH (mutations of the HFE gene: C282Y, H63D, S65C) because of hyperferritinemia (SF > 200 µg/L, twice, one month apart). They were classified into two groups, with and without type 2 diabetes (current American Diabetes Association criteria) and were evaluated for the components of the MS (current ATP III criteria), insulin sensitivity (HOMA%S) and insulin secretion (HOMA%B), high-sensitivity C-reactive protein (hs-CRP), transferrin saturation index and the soluble fraction of the transferrin receptor (sTfR).

Results: Subjects with type 2 diabetes (n=51) were older than those without (n=99) (60.3±9.0 vs 55.1±12.3 yrs, respectively, $p=0.012$). They also had a lower BCF (HOMA%B: 54.1 (26.6–80.2) vs 101.1 (67.4–142.6%); $p<0.001$) than those without diabetes, but no significant differences were found between both groups, regarding body mass index (28.8±3.2 vs 28.9±3.6 kg/m²), waist circumference (1.00±0.84 vs 1.00±0.93 m), systolic blood pressure (138±15 vs 141±18 mmHg), diastolic blood pressure (81±9 vs 82±11 mmHg), HDL cholesterol (1.34±0.33 vs 1.37±0.37 mmol/L), triglycerides (1.62(1.23–1.99) vs 1.59 (1.13–2.48) mmol/L), insulin sensitivity (HOMA%S: 55.4(26.9–86.7) vs 79.5(27.8–146.6 %), serum hs-CRP (2.52(1.34–4.20) vs 2.02 (1.06–4.12) mg/L), ferritinemia (576±184 vs 586±214 µg/L), transferrin saturation index (34.0 (26.0–42.0) vs 34.7 (26.4–39.9) %), sTfR (2.30 (2.01–2.77) vs 2.49 (2.07–3.15) mg/L) and the allelic frequency of the mutations of the HFE gene of the HH. The differences between groups in BCF persisted after adjustment for differences in age.

Conclusion: The main determining factor for type 2 diabetes in men with hyperferritinemia is BCF. No differences exist in iron overload parameters and insulin sensitivity between hyperferritemic men with and without type 2 diabetes.

Glycaemic disorders in patients with schizophrenia: The METEOR Study K. Shaw¹, M. De Hert², B. Falissard³, M. Mauri⁴, T. Wetterling⁵¹Queen Alexandra Hospital, Portsmouth Hospitals NHS Trust, Portsmouth, United Kingdom, ²UPC KUL, Campus Kortenberg, Belgium, ³Inserm u669, Maison de Solenn, Paris, France, ⁴Clinica Psichiatrica, Università di Pisa, Italy, ⁵Klinik für Psychiatrie, Vivantes Klinikum Hellersdorf, Berlin, Germany

Background and aims: An association between schizophrenia and increased risk for type 2 diabetes mellitus has been suggested for many decades and may reflect contributions from lifestyle risk factors, a risk associated with the underlying pathophysiology of schizophrenia and an effect of antipsychotic drug treatment. Atypical antipsychotic drug use has been associated with metabolic disorders such as weight gain, dyslipidaemia and hyperglycaemia. Most of the available information comes from retrospective analyses, mostly from North America, where the distribution of lifestyle risk factors differs from Europe. To complement these studies, a large, observational, cross-sectional

pharmacoepidemiological study was initiated in 2006 in order to determine the prevalence of diabetes and other metabolic disorders in patients with schizophrenia receiving atypical antipsychotic drugs in twelve countries in Europe. Secondary objectives included identification of risk factors for metabolic disorders.

Materials and methods: The study included adult outpatients fulfilling DSM-IV-TR diagnostic criteria for schizophrenia and treated for at least three months by an antipsychotic drug. In each country, patients treated with classical or atypical antipsychotic drugs were recruited into two parallel strata in a ratio of 1:3. The study consisted of a single visit at which a fasting blood sample was taken and height, weight, waist and hip circumference and blood pressure measured. Information was collected on socio-demographic variables, lifestyle, comorbidities and co-medications, metabolic and cardiovascular risk factors, psychiatric history and antipsychotic drug history. Biochemical parameters assessed included fasting blood glucose (FBG), insulin, HbA1c and serum lipids. An oral glucose tolerance test was performed in certain centres (284 patients).

Results: Overall, 2463 patients (54.6% male) were included with a median age of 41.0 years. Of these, 86 patients were treated for diabetes (3.8%), but an additional 75 untreated patients (3.4%) also presented an FBG > 126 mg/dl and 484 (25.8%) an FBG between 100 and 126 mg/dl. Multivariate logistic regression analyses identified age > 40 years (OR: 2.00 [1.48;2.70]), weight circumference > 95 cm (OR: 1.81 [1.23;2.66]), serum triglycerides > 200 mg/dl (OR: 1.69 [1.23;2.33]), female gender (OR: 1.32 [1.07;1.64]) and clozapine treatment (OR: 1.90 [1.37;2.62]) as being associated with FBG > 100 mg/dl. In contrast, amisulpride treatment was associated with a lower risk of FBG > 100 mg/dl (OR: 0.50 [0.33;0.75]). In addition, 9.1% of patients presented a HbA1c level > 6% and 31.6% a fasting serum insulin concentration > 12 mU/l. Blood glucose levels were > 140 mg/dl two hours after oral glucose challenge in 16.7% of tested patients. No difference was observed in the proportion of patients with glycaemic disorders between the classical or atypical antipsychotic strata.

Conclusion: Our results indicate a relatively high prevalence of diabetes and dysglycaemia in patients with schizophrenia treated with antipsychotic drugs. Diabetes was underdiagnosed, undertreated and inadequately controlled. The findings emphasise the need for active physician follow-up of glycaemia in this patient group.

Dose seriousness of depressive symptoms influence on insulin resistance - a study using hyperinsulinaemic euglycaemic clampS. Asghar¹, A. Magnusson¹, Å. Halsne², G. Vinje², A. Hussain³, P.M. Thorsby^{2,4}¹University of Oslo, Inst. for Psychiatric Research, ²Aker University Hospital, Hormone Laboratory, ³University of Oslo, Department of International Health, ⁴Aker University Hospital, Aker- Ullevål Diabetes Research Centre, Oslo, Norway

Background: Epidemiological data have shown that depression is a significant risk factor for the development of diabetes. The association between depressive symptoms and insulin resistance has been inadequately investigated.

Objective: To assess the association of elevated levels of depressive symptoms on insulin resistance.

Materials: In a depression treatment study of 24 middle aged women in Norway of immigrant origin (Pakistani), we use hyperinsulinemic euglycaemic clamp to evaluate insulin resistance. Depression is evaluated using Montgomery and Åsberg Depression Rating Scale (MADRS), and all included have depressive symptoms (MADRS score > 20). Those suffered from major personality disorder or co morbid conditions or pregnant are excluded from the study. Reinvestigation for insulin resistance is performed in the same individuals following the same procedure after treatment from depression (therapy and medication), when their MADRS score is lowered to less than 10. So far we have investigated 18 women at baseline and 9 at follow up. Before inclusion all have performed a OGTT to exclude IGT and diabetes and non received treatment for depression.

Results: At baseline (n=18), mean age 42.5 years (11.2, SD), with a depression score (MADRS) of 30.1 (4.0), GDR 5.0 mg/kg/min (3.0), FBG 5.8 mmol/l (0.96), BMI 27.5 kg/m² (4.2) and waist circumference 88.7 cm (10.5). There was a significant negative correlation between insulin resistance and BMI ($r=-0.51$, $p<0.05$) and waist circumference ($r=-0.48$, $p<0.05$). Controlling for BMI, depression score (MADRS) had a significant association with insulin

lin resistance (GDR) at baseline ($r^2=0.51$, $p=0.005$) and the contribution of each parameter to variation in GDR was equal (MADRS $r^2=-0.53$, $p=0.015$, BMI $r^2=-0.69$, $p=0.003$) following a linear regression model. The paired mean difference from the 1st examination (depressed) to the 2nd examination (improved from depression) ($n=9$) was MADRS 20.9 (3.8, $p<0.001$) and GDR 0.4 mg/kg/min (1.4, ns)

Conclusion: There appears to be an association between insulin resistance and seriousness of depression. Insulin resistance in turn is also significantly correlated with BMI and waist circumference. Psychiatric intervention and lifestyle change such as weight reduction in depressed patients, may improve the degree of insulin resistance.

Adiponectin plasma levels in patients with schizophrenia and schizoaffective disorder: relationships with metabolic syndrome and glucose abnormalities

A.J. Scheen¹, L. Hanssens², R. van Winkel³, M. Wampers⁴, D. Van Eyck⁴, J. Collette⁵, J. Peuskens⁴, M. De Hert⁴

¹Diabetes, Nutrition & Metabolic Disorders, CHU Liège, University Liège, Belgium, ²Epidemiology & Public Health, University Liège, Belgium,

³Psychiatry & Neuropsychology, University Maastricht, Netherlands,

⁴Psychiatry, University KU Leuven, Kortenberg, Belgium, ⁵Clinical Biology, CHU Liège, Belgium

Background and aims: Schizophrenic patients have increased rates of hyperglycaemia, dyslipidaemia, metabolic syndrome, leading to a higher incidence of cardiovascular disease. The underlying mechanism, however, is poorly understood. Low levels of adiponectin are associated with metabolic abnormalities such as abdominal obesity, insulin resistance, type 2 diabetes and cardiovascular disease in the general population. The present study aims at investigating the relationships between plasma adiponectin levels and metabolic abnormalities in patients with schizophrenia and schizoaffective disorders.

Materials and methods: Fasting adiponectin levels were measured in a cross-sectional sample of 386 patients with schizophrenia or schizoaffective disorder. All patients were on monotherapy of second-generation antipsychotics (SGA) and underwent an extensive metabolic screening including an oral glucose tolerance test (OGTT). Glucose abnormalities were divided into impaired fasting glucose (IFG), impaired glucose tolerance (IGT) or diabetes (based on fasting and/or 2-h post-OGTT glucose levels). Metabolic syndrome (MetS) was defined according to adapted National Cholesterol Educational Program -Adult Treatment Panel (NCEP-ATP)-III or International Diabetes Federation (IDF) criteria.

Results: The demographic characteristics were as follows - mean (STD) - : age 35.9 (11.8) years; 64% males; 99% Caucasians; body weight 78.7 (16.0) kg; BMI 26.1 (5.0) kg/m²; 28% with family history of diabetes. Mean fasting adiponectin levels were 8385 (6016) ng/ml, being lower in men than in women ($p<0.0001$). Adiponectin plasma levels were inversely correlated with BMI ($p<0.0001$), and differed between patients with normal weight, overweight or obesity ($p<0.05$). Plasma adiponectin levels negatively correlated with waist ($r=-0.341$), triglycerides levels ($r=-0.298$), systolic blood pressure ($r=-0.119$) and fasting glucose levels ($r=-0.202$), whereas a positive correlation was observed with HDL levels ($r=0.404$) (all $p<0.0001$). Patients with MetS (NCEP-ATP-III : 29.3%; IDF: 31.9%) had significantly lower adiponectin levels than patients without MetS ($p<0.0001$). Patients with diabetes (5.7%) had significantly higher adiponectin levels than patients without glucose abnormalities (78%) ($p<0.05$). Patients with prediabetes (IFG and/or IGT) (16.3%) had intermediate adiponectin levels. After controlling for components of MetS and sex, antipsychotic medication independently influenced adiponectin levels, with the lowest levels in patients on clozapine and olanzapine ($p<0.0001$).

Conclusion: Adiponectin levels in schizophrenic patients mirror what is observed in the general population, with the lowest levels in the most metabolically compromised subjects. However, antipsychotic medication may also influence adiponectin regulation independently, a finding that should be confirmed in longitudinal studies. The role of low adiponectin levels in the higher prevalence of glucose abnormalities associated with clozapine and olanzapine remains to be elucidated.

714

BGP-15, a novel type insulin sensitiser inhibits insulin resistance and body weight gain induced by atypical antipsychotic drugs

K. Tory¹, L. Jaszlits², Z. Literati-Nagy¹, A. Bajza², S. Bernath², A. Kolonics¹, B. Peitl³, B. Literati-Nagy³, Z. Szilvassy³, P. Literati-Nagy²

¹Department of Molecular Pharmacology, N-Gen Research Laboratory,

²Department of Pharmacology, N-Gen Research Laboratory, ³Department of Pharmacology and Pharmacotherapy, University of Debrecen, Hungary

Background and aims: BGP-15 (R,S-O-(3-piperidino-2-hydroxy-1-propyl)-nicotinic-acid-amidoxime) is an insulin sensitizer drug candidate. Its activity has been demonstrated in different diabetic animal models as well as in insulin-resistant patients by hyperinsulinemic euglycemic clamp method. JUN kinase mediated inhibition of insulin signaling is a common pathogenic mechanism in insulin resistance associated with obesity, inflammation and mitochondrial dysfunction. Inhibiting JUN kinase activation via stimulating stress protein (Hsp70) expression by BGP-15 has been demonstrated as an essential and novel insulin sensitizing mechanism. Atypical antipsychotic drugs frequently cause serious metabolic side effects such as insulin resistance, weight gain and increased risk of cardiovascular diseases. The available antidiabetic agents fail to provide sufficient protection against these side effects. Aim of the study is preclinical and clinical evaluation of the efficacy of BGP-15 on the metabolic side effects of atypical antipsychotic agents.

Materials and methods: Material and Methods: Atypical antipsychotic agents (olanzapine, clozapine, risperidone) were administered in rat, guinea pig and rabbit to provoke metabolic side effects. Insulin sensitivity of control, antipsychotic, antipsychotic + BGP-15 treated groups was determined by hyperinsulinemic euglycemic clamp method. BGP-15 treatment was applied orally. The pharmacokinetic interaction of olanzapine (10 mg) and BGP-15 was studied in 42 healthy individuals during a 17-day treatment period. The effect of BGP-15 on drug-induced insulin resistance was evaluated by hyperinsulinemic euglycemic clamp and weight gain was measured.

Results: In preclinical experiments, five-day olanzapine treatment (1mg/kg, b.i.d., p.o.) resulted in significant (50-65%) decrease in insulin sensitivity in rat, guinea pig and rabbit. Simultaneously applied BGP-15 treatment (10 mg/kg) either greatly improved or normalized insulin induced glucose utilization. BGP-15 efficiently reduced olanzapine induced insulin resistance and inhibited body weight increase during a 28-day treatment period. Insulin sensitizing activity of BGP-15 was evident on the already established insulin resistance following the 28-day clozapine treatment. In addition, BGP-15 (20 mg/kg, p.o.) prevented risperidone-induced increase in food intake and body weight gain in rats. In the human clinical study, the treatment period has been completed. Laboratory pharmacokinetic and limited efficacy data will be available by the time of the meeting.

Conclusion: Preclinical experiments suggest that BGP-15 is a new drug candidate able to control the metabolic side effects of atypical antipsychotic drugs.

Visfatin overexpression ameliorates insulin sensitivity and lipid profile by up-regulating PPAR γ activities - twice euglycaemic-hyperinsulinaemic clamps in identical individual

C. Yulan^{1,2}, L. Li^{1,2}, G. Yang³, R. Li^{1,2}, K. Li³

¹Department of Clinical Biochemistry, ²The Key Laboratory of Laboratory Medical Diagnostics in Ministry of Education, ³Department of Endocrinology, the Second Affiliated Hospital, Chongqing Medical University, Chongqing, China

Background and aims: Visfatin is an adipose-derived hormone proposed to exert insulin-mimicking effects and play a positive role in attenuating insulin resistance. However, the precise mechanisms underlying the beneficial effects of visfatin on insulin sensitivity remain largely unknown. To further characterize the physiological role of visfatin on the correction of metabolic abnormalities, we therefore examined the effects of visfatin gene overexpression on glucose-lipid metabolism and insulin sensitivity in identical individual as an own control in rats.

Materials and methods: Four-week-old male SD rats were randomly divided into three groups. Two groups were fed a normal-chow diet and the another group was fed a high-fat diet for 16 weeks. On day 4 after the surgery, Euglycemic-hyperinsulinemic clamps were performed with awake and unrestrained rats. Blood samples were obtained for determination. At the end of Clamp, normal-chow rats were subdivided into two groups. One group (NT, n=10) was given visfatin plasmid that constructed recombinant plasmids of pcDNA3.1-visfatin. Another group (NC, n=5) was given pcDNA3.1 as control. High-fat rats (HT, n=10) were given pcDNA3.1-visfatin plasmid. On postinjection day 4, insulin sensitivity was assessed using another euglycemic-hyperinsulinemic clamp in identical individual. Metabolism gene mRNA expression were measured by RT-PCR, and plasma visfatin protein by Western blot.

Results: In both normal-chow (NT) and high-fat diet (HT) animals with pcDNA3.1-visfatin treatment, plasma visfatin protein levels were significantly increased (NT, from 0.99 ± 0.08 to 1.54 ± 0.06 , $P < 0.01$ and HT, from 0.99 ± 0.16 to 1.92 ± 0.18 , $P < 0.01$). Total cholesterol (TC) and high-density lipoprotein cholesterol (HDL-C) were significantly decreased (TC from 1.76 ± 0.22 to 1.31 ± 0.10 mmol/L for NT; from 2.36 ± 0.22 to 1.60 ± 0.21 mmol/L for HT, both $P < 0.05$; HDL-C, from 0.95 ± 0.15 to 0.59 ± 0.04 for NT; from 1.41 ± 0.24 to 0.88 ± 0.11 mmol/L for HT, both $P < 0.05$) On day 3 after plasmid injection. During two glucose clamp, the glucose infusion rate required to maintain euglycemia was increased by approximately 28 % in the NT rats and 36 % in the HT compared with before plasmid injection (both $P < 0.01$). After plasmid injection, the mRNA expression of PPAR γ in liver tissue was significantly up-regulated in NT and HT compared with NC (0.98 ± 0.08 and 1.59 ± 0.15 vs. 0.68 ± 0.09 , both $P < 0.05$). In addition, sterol regulatory element binding protein 2 (SREBP2) and HMG-CoA reductase mRNA expression in liver was also significantly increased in NT and HT compared with NC (SREBP2, 0.37 ± 0.06 and 0.36 ± 0.07 vs. 0.21 ± 0.04 , both $P < 0.05$; HMG-CoA reductase, 0.89 ± 0.12 and 0.55 ± 0.16 vs. 0.37 ± 0.07 , $P < 0.01$ and $P < 0.05$). Elevated visfatin increased the extent of IRS-1 tyrosine phosphorylation in response to insulin in liver tissues in NT and HT than in NC ($P < 0.05$).

Conclusion: These results indicate that visfatin could exert its increasing insulin sensitivity and hypocholesterolemic effects at least partially through regulation of the tyrosine phosphorylation of IRS-1 protein and the up-regulation of PPAR γ and SREBP2 activation.

Apelin, a new beneficial adipokine with anti-diabetic properties

C. Dray, C. Knauf, D. Daviaud, A. Waget, J. Boucher, P.D. Cani, M. Buleon, C. Guigne, C. Carpenne, R. Burcelin, I. Castan-Laurell, P. Valet
U858, INSERM, Toulouse, France

Background and aims: Our team has recently identified apelin as an adipocyte-derived factor secreted and produced by adipocytes in humans and mice. Apelin is a bioactive peptide which is the endogenous ligand of APJ, a G protein-coupled receptor. Apelin and APJ mRNA are widely expressed in mammalian tissues. In adipose tissue, apelin is regulated by key factors involved

in diabetes like insulin and TNF α . In addition, the amount of apelin in blood is largely increased in obese and different mouse models of obesity. Although a tight relation exists between insulin and apelin, the effect of apelin on glucose utilization has not been addressed so far. Thus, the effects of apelin on glucose metabolism were studied in mice.

Materials and methods: A catheter has been indwelled into the femoral vein of anesthetized mice, sealed under the back skin, and glued on the top of the skull in order to inject apelin. Oral glucose tolerance test (OGTT), basal glucose turnover and hyperinsulinemic euglycemic clamp were performed in control and high-fat fed C57Bl6/j mice. In vitro, both glucose transport and the signalling pathway involved in apelin response were measured in soleus muscle.

Results: Apelin injection (200 pmol/kg) in normo-ponderal mice induced a significant decrease of glycemia and clearly improved glucose tolerance after oral glucose load. In basal conditions, apelin significantly increased glucose turnover by stimulating whole-body glycolysis and glycogen synthesis rate compared to saline-injected mice. Infusion of 2 deoxy-(3H)-glucose during the last hour of hyperinsulinemic euglycemic clamp showed that apelin specifically increased glucose utilization in adipose tissue and skeletal muscles. This effect was direct since, in vitro, apelin increased in a dose-dependent manner glucose uptake in soleus muscle. Interestingly, 10 nM apelin was able to increase maximal insulin-stimulated glucose transport suggesting an additive effect. Thus, in order to determine apelin signalling in soleus muscle, we focused on cellular targets belonging to insulin-independent pathways. Apelin stimulated muscle glucose transport both in vivo and in vitro by endothelial nitric oxide synthase (eNOS), AMP-activated protein kinase (AMPK) and Akt-dependent pathways. Finally, in obese and insulin resistant mice, apelin is still able to improve glucose tolerance and stimulated glucose utilization in skeletal muscles and white adipose tissue.

Conclusion: This work clearly demonstrates for the first time that apelin is involved in glucose metabolism by using AMPK and eNOS pathways in soleus muscle. The relative contribution of apelin, besides other adipokines (leptin, adiponectin), is of major interest and should yield new insights into the physiology and pathophysiology of energy metabolism. Finally, since apelin exhibits a sustained effect on glucose utilization in insulin resistant mice, it appears to be a very promising target for the treatment of type 2 diabetes.

Expression analysis and functional characterisation of EGFL6, a novel secreted protein of the human adipose tissue

R. Oberauer, H. Stahl, W. Rist, M. Lenter, B. Hamilton, H. Neubauer
Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach, Germany

Background and aims: With increasing rates of obesity driving the incidence of type 2 diabetes and cardiovascular diseases to epidemic levels, understanding the role of adipose tissue in the pathogenesis of these morbidities is focus of current research. Identification and characterization of novel adipocytokines could provide further insights into the endocrine function of adipose tissue and potential new therapeutic targets. We recently presented the identification of the epidermal growth factor like 6 (EGFL6; EASD 2007) as a novel secreted protein of the human adipose tissue showing increased expression in obesity and decreased expression after weight loss. The aim of this work was to analyze EGFL6 expression during human *in vitro* adipogenesis on RNA and secreted protein level. Further, in order to identify the target cell of secreted EGFL6 in adipose tissue, the human protein was expressed, purified and analyzed for its binding capability to human preadipocytes by FACS analysis.

Materials and methods: For expression analysis, human stromal-vascular cells were isolated from adipose tissue biopsies (n=5), cultured and induced for *in vitro* adipogenesis. During adipogenesis, monitored by Oil-Red-O staining, total RNA and conditioned media samples were obtained and the EGFL6 expression profile was analyzed by quantitative RT-PCR, direct ELISA and Western blotting. Full-length hEGFL6 with a C terminal His-tag was expressed in a Baculovirus insect cell system and full-length recombinant protein and defined N terminally truncated versions were purified from conditioned media by affinity chromatography and gel filtration. For FACS analysis, human preadipocytes were incubated with rec. hEGFL6-His proteins and binding was measured with an anti-C terminal His-tag antibody.

Results: The weak expression of EGFL6 observed in human preadipocytes increased significantly during human *in vitro* adipogenesis (10-fold on RNA level). In agreement with this, both direct ELISA and Western blotting, showed significantly increased levels of secreted hEGFL6 in the conditioned media of differentiated adipocytes (1.6 fold increased compared to non-dif-

ferentiated preadipocytes on day 14, $p < 0.01$). For identification of a molecular target cell of EGFL6, human preadipocytes were pre-incubated with rec. hEGFL6-His full-length and purified N terminally truncated proteins. Differential and domain-dependent binding of the proteins to the surface of the cells was observed by FACS analysis and will be discussed.

Conclusion: Increased expression of hEGFL6 during human *in vitro* adipogenesis was shown on RNA and secreted protein level, indicating that EGFL6 is mostly secreted by adipocytes. The secreted rec. hEGFL6 protein was shown to bind to human preadipocytes with the binding being mediated by specific protein domains. Further studies are planned to define the binding partners and function of EGFL6 in human adipose tissue physiology.

Lipocalin-2 expression related to obesity and pioglitazone treatment in adipose tissue of rodent and humans

S.J. Yang¹, H.J. Yoo¹, T.N. Kim¹, J.R. Park¹, Y.J. Lee¹, H.Y. Kim¹, J.A. Seo¹, D.H. Shin², S.G. Kim¹, Y.H. Kim³, N.H. Kim¹, D.S. Choi¹, S.H. Baik¹, K.M. Choi¹

¹Endocrinology, Korea University, Seoul, ²Endocrinology, Bundang Jaesang hospital, Kyong-gi do, ³Endocrinology, Bundang Jaesang hospital, Kyong-gi do, Republic of Korea

Background and aims: Adipose tissue is not just an inert storage compartment for triglyceride, but is a metabolically dynamic endocrine organ. PPAR- γ agonist plays key roles in the regulation of the function of adipose tissue, energy homeostasis and inflammation. The Otsuka Long-Evans Tokushima Fatty (OLETF) rat is a useful animal model of metabolic syndrome. To clarify the hidden pathogenesis of metabolic syndrome, the OLETF rats have been used by many investigators. Therefore, in the present study, we examined the significant overlapping gene which increased in OLETF rat and regulated by PPAR- γ agonist simultaneously in adipose tissue using oligonucleotide microarray analyses and validated the significant gene using independent rodent and human samples.

Materials and methods: A standard diet fed *db/db* mice versus a synthetic PPAR- γ agonist treated *db/db* mice and OLETF rats versus LETO rats were used for two different kinds of oligonucleotide microarray analyses. And the overlapping gene was validated using independent rodent and human samples by real time RT-PCR. Six premenopausal obese women (BMI > 25 kg/m²) and age matched six non-obese premenopausal women (BMI < 23 kg/m²) who were scheduled for gynecologic surgery were enrolled in this study. Subcutaneous and visceral adipose tissue was obtained during the gynecological surgery and serum glucose, lipid profiles, IL-6, A-FABP levels and WBC counts were measured.

Results: We examined the significant overlapping gene which increased in OLETF rats and regulated by PPAR- γ agonist simultaneously in adipose tissue using oligonucleotide microarray analyses and as a result, we chose the lipocalin-2 as the significant overlapping gene which had to be validated by real time RT-PCR. The expression level of lipocalin-2 in visceral adipose tissue of pioglitazone treated *db/db* mice showed statistically significant decrease compared with that of normal chow fed *db/db* mice ($P < 0.001$), while there was significant increase of lipocalin-2 expression in visceral adipose tissue of OLETF rats compared with that of LETO rats ($P = 0.01$). In human study, the average of BMI in obese group was 29.2 ± 3.4 kg/m², whereas that of non-obese group was 21.4 ± 1.2 kg/m² ($P < 0.001$). In the obese group, there was significant increase of serum glucose ($P = 0.05$), WBC counts ($P = 0.004$), A-FABP ($P = 0.004$) and lipocalin-2 ($P = 0.03$) levels compared with those of the non-obese group. The expression level of lipocalin-2 in visceral adipose tissues of the obese group was significantly increased compared with that of the non-obese group ($P = 0.01$). However, there was no significant difference in the expression of lipocalin-2 in subcutaneous adipose tissue between the two groups ($P = 0.418$). And the expression of lipocalin-2 in visceral adipose tissue was significantly correlated with BMI ($r = 0.68$, $P = 0.015$), serum IL-6 ($r = 0.59$, $P = 0.044$), A-FABP levels ($r = 0.60$, $P = 0.04$) and WBC counts ($r = 0.72$, $P = 0.008$).

Conclusion: This study showed that lipocalin-2 is a significant obesity-related adipokine which is controlled by PPAR- γ agonist both in rodents and humans and further study is needed to clarify the functional role of lipocalin-2 in the pathogenesis of obesity and metabolic syndrome.

719

Serum lipocalin-2 concentrations are elevated in human subjects with impaired glucose tolerance and type 2 diabetes

Z. Che¹, Y. Tan¹, W. Zhou¹, P. Zhou¹, Z. Zhou¹, H. Zhang², A. Xu²

¹Diabetic Center, Metabolic Syndrome Research Center, Institute of Metabolism and Endocrinology, Central South University, Changsha, Department of Medicine and Research Centre of Heart, Brain, Hormone and Healthy Aging, University of Hong Kong, Hong Kong, China

Background and aims: Chronic low-grade inflammation is now recognized to be a key mediator in the development of type 2 diabetes. Lipocalin-2, a 25-kDa secreted glycoprotein, is abundantly expressed in adipose tissue and liver. It was recently reported that lipocalin-2 provide a link between obesity, insulin resistance and hyperglycemia in human. The results suggested that Lipocalin-2 can be considered a marker for monitoring obesity-related low-grade inflammation in humans. This study is aimed to evaluate whether lipocalin-2 can be an inflammatory marker in pre-diabetes.

Materials and methods: An in house enzyme-linked immunosorbent assay was developed to measure human lipocalin-2 serum concentrations, which were then compared with various parameters in subjects with normal glucose tolerance (NGT; $n = 131$), impaired glucose tolerance (IGT; $n = 81$), and type 2 diabetes (T2DM; $n = 50$).

Results: No gender-associated difference in serum lipocalin-2 levels was observed. Serum lipocalin-2 concentrations were positively correlated with body mass index (BMI), waist circumference (WC), fat percentage, and high sensitivity C-reactive protein (hsCRP) after adjusted for sex and age. Serum lipocalin-2 concentrations were negatively correlated with high density lipoprotein cholesterol (HDL-C). The hsCRP and HDL-C were found to be independent determinants for serum lipocalin-2 concentrations. Serum lipocalin-2 levels were higher in the IGT and type 2 diabetic groups than in the NGT group (median 32.25 [range (9.25–92.25)], 32.5 (9.75–89.5), and 27.0 (10.75–123.25) $\mu\text{g/L}$, $p = 0.006$ and 0.024 , respectively). However, no difference was found between serum lipocalin-2 concentrations in the IGT and type 2 diabetic groups.

Conclusion: Serum lipocalin-2 concentrations were found to be elevated in subjects with IGT or type 2 diabetes and to be related to various clinical parameters and inflammatory factor. Furthermore, we put forward for the first time that serum lipocalin-2 concentrations were elevated in subjects with IGT, suggesting that serum lipocalin-2 can be a useful marker for evaluating inflammatory status in pre-diabetes.

Visfatin induced expression of inflammatory mediators in human endothelial cells via NF- κ B pathways

W.H. Sheu¹, C.S. Wu², W.J. Lee³, C.M. Wu¹, L. Ho⁴, I.T. Lee¹

¹Dept of Internal Medicine, ²Dept of Medical Research and Education, ³Dept of Medical Education and Research, ⁴Dept of Life Science, National Chung-Hsing University, Taichung, Taiwan

Background and aims: Visfatin is an adipokine that is highly expressed in visceral fat and whose blood levels have been reported higher in subjects with obesity and/or type 2 diabetes mellitus. We studied effect of visfatin on endothelial dysfunctions and possible mechanisms.

Materials and methods: Primary human umbilical vein endothelial cells (HUVECs) pretreated with visfatin (1, 10, 50 ng/ml) were used to study the relationship between visfatin and endothelium dysfunction. Expression of adhesion molecules (ICAM-1, VCAM-1 and E-selectin) and cytokines (IL-6 and IL-8) affected by visfatin were investigated by ELISA, flow cytometry and real-time PCR. Activity of NF- κ B was examined by electrophoretic mobility shift assay (EMSA).

Results: At a visfatin concentration of 50 ng/ml, significant increases in IL-6, IL-8, ICAM-1, VCAM-1 and E-selectin gene expression along with increased IL-6, IL-8 and sE-selectin protein levels in the conditioned medium were detected. Visfatin significantly increased ICAM-1 expression on 10 ng/ml, and VCAM-1 expression on 50 ng/ml by flow cytometry. EMSA confirmed that visfatin increased DNA binding activity of NF- κ B. In addition, increased human monocyte cell line THP-1 attaching to HUVECs when pretreated with visfatin (10, 50 ng/ml) was also demonstrated.

Conclusion: We demonstrated that visfatin increased inflammatory and adhesion molecule expression, at least partly via up-regulation of NF- κ B activ-

ity. Our findings provide direct evidence that visfatin causes endothelial dysfunction, which may help establish a link between obesity and cardiovascular disease.

Effect of obesity on growth-related oncogen factor- α , thrombopoietin and tissue inhibitor metalloproteinase-1 serum levels

E. Maury¹, S.M. Brichard¹, L. Noël¹, Z. Pataky², A. Carpentier², A. Golay², E. Bobbioni-Harsch²

¹Endocrinology and Metabolism, Catholic University of Louvain, Brussels, Belgium, ²Service of Therapeutic Education for Chronic Disease, Geneva University Hospital, Switzerland

Background and aims: We have recently identified several adipokines oversecreted by omental adipose tissue of obese subjects: two chemokines [Growth-Related Oncogen factor- α (GRO- α), Macrophage Inflammatory Protein-1 β (MIP-1 β)], a tissue inhibitor of metalloproteinase (TIMP-1), an interleukin (IL-7) and a growth factor (thrombopoietin; TPO). As these adipokines are already known to be involved in cardiovascular disease, insulin resistance and type 2 diabetes, they may link obesity to its cardiovascular or metabolic co-morbidities. The aims of the present study were: 1) to examine whether the increased production by adipose tissue in obesity was reflected by higher circulating levels and 2) to attempt to identify the potential responsible factors.

Subjects and methods: Serum levels of GRO- α , MIP-1 β , TIMP-1, IL-7 and TPO were measured by ELISA in 32 lean, 15 overweight, 11 obese and 17 morbid obese age-matched women. Other anthropometric, metabolic and hormonal parameters were also determined: body composition, blood pressure, serum levels of lipids, glucose, insulin, leptin and adiponectin. Insulin sensitivity was evaluated by the euglycemic-hyperinsulinemic glucose clamp. Energy expenditure and substrate oxidation were determined by indirect calorimetry.

Results: Obese and morbid obese women exhibited several clinical or laboratory features of the metabolic syndrome. When compared to age-matched controls, they were characterized by higher blood pressure, hyperinsulinemia and insulin resistance, abnormal lipid profile, increased serum leptin and decreased serum adiponectin concentrations. Out of the five adipokines studied, three exhibited higher circulating levels in obese and/or morbid obese women than in lean ones ($\sim +20\%$, 30% and 55% for TIMP-1, GRO- α and TPO, respectively; $P < 0.05$ or less). Serum levels of these three adipokines did strongly positively correlate with BMI, fat mass and waist circumference ($P < 0.01$). Serum levels of GRO- α , TIMP-1 and TPO did positively correlate with hyperinsulinemia and/or negatively with insulin sensitivity ($P < 0.05$ or less). Serum levels of TIMP-1 did also positively correlate with leptin and blood pressure while TPO was negatively related to adiponectin but positively to circulating lipids levels (free fatty acids and triglycerides; $P < 0.05$ or less). Multiple regression analysis showed that fat mass was a significant independent determinant of GRO- α , TIMP-1 and TPO levels. Insulinemia and glycemia were two additional independent determinants of TPO.

Conclusion: As already shown for TIMP-1, we demonstrate that circulating levels of GRO- α and TPO were higher in obese and/or morbid obese women and related to adiposity. These higher systemic levels may, at least in part, reflect the exacerbated secretion of these adipokines previously described in omental adipose tissue in obesity. Herein, that adiposity *per se* was an independent determinant of these high systemic levels reinforces the concept that hypertrophied adipocytes and surrounding recruited macrophages are fundamental contributors to this “hyperadipokinemia”. Because circulating levels of these adipokines did correlate with several features of the metabolic syndrome, these levels may link obesity to its cardiovascular and metabolic disorders.

Osteoprotegerin and adiponectin are similarly related to insulin sensitivity in healthy adults

D.T. Ashley¹, E.P. O'Sullivan², N. Devlin¹, N.M. Moyna¹, D. Smith², D.J. O'Gorman¹

¹School of Health and Human Performance, Dublin City University,

²Diabetes and Endocrinology, Beaumont Hospital, Dublin, Ireland

Background and aims: Circulating osteoprotegerin (OPG), a member of the TNF receptor superfamily, correlates with severity of vascular calcification and coronary artery disease with higher serum levels in diabetic compared to non-diabetic controls. OPG is a decoy receptor for TNF-Related Apoptosis-Inducing Ligand (TRAIL) but little is known about the relationship between OPG and TRAIL and whether either or both factors are related to insulin sensitivity.

Materials and methods: A total of 102 subjects (38 lean, 42 overweight and 22 obese) without diabetes or cardiovascular disease volunteered for the study. Insulin sensitivity was estimated using a 3-hr oral glucose tolerance test with OGIS analysis. OPG, TRAIL and adiponectin were analysed using commercially available ELISA assays.

Results: OPG (6.0 ± 0.3 vs 4.8 ± 0.3 pmol l⁻¹) and adiponectin (10.5 ± 0.9 vs 5.9 ± 0.9 μ g ml⁻¹) were significantly decreased in the obese compared to lean subjects while the TRAIL-to-OPG ratio was greater (13.6 ± 1.3 vs 20.3 ± 2.7 , $p < 0.05$). There was a strong positive relationship between adiponectin and OPG ($r = 0.48$, $p < 0.05$) for all subjects. Both OPG and adiponectin were negatively correlated with body weight, BMI, waist circumference, and fasting plasma insulin while positively correlated with insulin sensitivity ($p < 0.05$). TRAIL was positively related to body weight ($r = 0.24$, $p = 0.02$) and waist circumference ($r = 0.26$, $p = 0.01$) and there was a tendency for a negative relationship with adiponectin ($p = 0.06$). The TRAIL-to-OPG ratio was positively related to body weight ($r = 0.35$, $p < 0.001$), BMI ($r = 0.26$, $p = 0.008$) and waist circumference ($r = 0.34$, $p = 0.001$) and negatively related with insulin sensitivity ($r = -0.32$, $p = 0.001$) and adiponectin ($r = -0.65$, $p < 0.001$).

Conclusion: The common relationships between OPG and adiponectin suggests a link between their release or function in healthy individuals. It is possible that the increase in OPG observed in type 2 diabetes may be a compensatory mechanism to maintain insulin sensitivity and that a change in the ratio of TRAIL-to-OPG may be a more important clinical determinant than OPG alone.

Adiponectin inhibits spontaneous lipolytic rate in human isolated adipocytes

J. Polak^{1,2}, Z. Hnevkovska^{1,2}, J. Dietrich¹, K. Kolostova³, Z. Kovacova¹, E. Klimcakova¹, M. Kovacikova¹, M. Vitkova¹, M. Bajzova^{1,2}, M. Duskova⁴, J. Broz², V. Stich^{1,5}

¹Sports Medicine Department, Third Faculty of Medicine, Charles University in Prague, ²2nd Internal Medicine Department, Vinohrady Teaching Hospital, ³Cancer Biology Department, Third Faculty of Medicine, Charles University in Prague, ⁴Plastic Surgery Department, Vinohrady Teaching Hospital, ⁵Franco-Czech Laboratory for a Clinical Research on Obesity, Charles University in Prague, Third Faculty of Medicine, Praha, Czech Republic

Background and aims: Adiponectin is an adipose tissue derived cytokine increasing glucose and fatty acid metabolism in muscle and improving whole-body insulin sensitivity. Plasma adiponectin level is decreased in obese, insulin-resistant and Type 2 diabetic patients. The aim of this study was to investigate the role of adiponectin in the regulation of adipocyte lipolytic activity.

Materials and methods: Adipocytes were isolated by collagenase digestion from abdominal adipose tissue obtained during selective surgical operations from 12 subjects (age 43.1 ± 14.3 years, BMI = 27.9 ± 5.5 kg/m², 3 men + 9 women). To obtain basal values of glycerol concentration (marker of lipolysis) in the culture media (Krebs Ringer Buffer with 10mM HEPES and 2% bovine serum albumin (KRBHA), pH 7.4), cells were incubated for one hour without any treatment at 37°C. Adipocytes were then subjected to three different conditions for the next 2 hours: 1) control incubation without any pharmacological substances (KRBHA) 2) incubation with recombinant human adiponectin (20 µg/ml) and 3) incubation with 0.5 mM AICAR - chemical activator of AMPK (adenosine monophosphate activated protein kinase) and glycerol concentrations in the adipocyte-conditioned media were determined colorimetrically.

Results: No differences in basal lipolysis were detected between tubes after 1st hour. Following the administration of adiponectin a reduction in spontaneous lipolytic rate by 18.1% (95% Confidence Interval for the mean reduction 5.1–31.0%, $p < 0.05$) was observed after 2 hours of subsequent incubation. AICAR suppressed spontaneous lipolytic rate by 65.3% (CI for the mean reduction 17.6–51.8%, $p < 0.05$).

Conclusion: Our results show that adiponectin in physiological concentration inhibits spontaneous lipolysis in isolated human adipocytes. This mechanism might be mediated by an activation of AMPK. We suggest, that inhibition of spontaneous lipolytic rate in adipose tissue by adiponectin is an important factor limiting release of free fatty acids (FFA) into circulation and thus leading to improved glucose metabolism and insulin sensitivity. This novel finding might help to explain how hypoadiponectinemia might contribute directly to elevated FFA levels and development of type 2 diabetes mellitus.

Adiponectin is an independent marker of glucose metabolism: a cross-sectional study in 4013 middle-aged men based on detailed oral glucose tolerance testing

P. Khalili¹, J. Jendle¹, F. Lundin², G. Engström³, J. Frydystyk⁴, A. Flyvbjerg⁴, P.M. Nilsson⁵

¹Internal Medicine, School of Health and Medical Sciences, Karlstad, Sweden, ²Internal Medicine, Värmland County Research Council, Karlstad, Sweden, ³University Hospital MAS, Department of Clinical Sciences, Malmö, Sweden, ⁴Aarhus University Hospital, Medical Research Laboratories, Denmark, ⁵Department of Clinical Sciences, School of Health and Medical Sciences, Malmö, Sweden

Background and aims: The adipocyte-derived plasma protein adiponectin has been implicated as a marker of insulin sensitivity and glucose metabolism. Previous studies have shown an inverse correlation between circulating adiponectin levels and measures of insulin resistance. The aim of this study was to examine whether adiponectin is an independent marker of glucose metabolism, adjusting for obesity, in middle-aged men.

Materials and methods: A preventive case-finding programme for detection of cardiovascular risk factors started in 1974 in southern Sweden, the Malmö Preventive Project (MPP). The aim was to find high-risk individuals for preventive interventions. Subjects were invited to participate in health screening, including a physical examination and laboratory tests. Blood samples have been stored and total adiponectin levels were analysed in a subgroup of 4013 middle-aged males, born in pre-specified years and living in Malmö, but not selected in any other way. The reason to select this subset of MPP was that all individuals performed an oral glucose tolerance test (OGTT) with multiple measurements of blood glucose (0, 10', 30', 60' and 120' min), thus enabling us to calculate the area under the curve (AUC) of glucose. The material was divided into quintiles (Q1–Q5) from lowest (Q1) to highest adiponectin levels (Q5). Baseline characteristics were analyzed and multiple regression analyses (MRA) were performed for examining the association between adiponectin and glucose metabolism.

Results: The mean age was 47 years (SD ± 3.3). Subjects in Q1 differed from Q5 in mean BMI, SBP, triglycerides, blood glucose (fasting, 2h, AUC) and HOMA-IR index. The means of these variables were significantly ($p < 0.05$) higher in Q1 than in Q5. Total cholesterol did not show any difference between quintiles. Blood glucose (fasting, 2h, AUC) and HOMA-IR index were each used as independent variables in separately performed MRA. Plasma adiponectin was significantly associated with all measures of glucose metabolism (all $p < 0.001$), after adjustment for age, BMI, SBP, cholesterol and log triglycerides.

Conclusion: An inverse and independent cross-sectional correlation exists between circulating total adiponectin levels and markers of glucose metabolism and insulin sensitivity in middle-aged men. This was independent of age and general obesity (BMI). Our findings support and expand previous observations in different populations.

The effects of shRNA-mediated adiponectin expression inhibition on insulin signalling and glucose turnover in the 3T3-L1 adipocytes

L. Jianlei^{1,2}, L. Li^{1,2}, G. Yang³, Y. Yang^{1,2}, K. Li³

¹The Key Laboratory of Laboratory Medical Diagnostics, Ministry of Education, ²Department of Clinical Biochemistry, ³Department of Endocrinology, the Second Affiliated Hospital, Chongqing Medical University, Chongqing, China

Background and aims: Adiponectin (Acrp30) is a physiologically active polypeptide hormone secreted by adipose tissue that shows insulin-sensitizing, antiinflammatory, and antiatherogenic properties. However, the underlying cellular and molecular mechanisms remain largely unknown. Therefore, we reasoned that a more limited reduction in adiponectin expression in 3T3-L1 cells using vector-mediated RNAi methodology may provide additional insight into the physiologic role of adiponectin. In this study, we investigated whether posttranscriptional gene silencing by vector-mediated RNAi will inhibit adiponectin expression and its effects on glucose turnover and some metabolism gene expression in 3T3-L1 cells.

Materials and methods: Oligonucleotides coding for a short hairpin RNA (shRNA) against Acrp30 were designed and adenovirus vector plasmids, pAd-U6-Acrp30-1 was constructed according to a two-step transformation protocol. A 3T3-L1 cell line was transfected with the Acrp30-shRNA adenovirus expression vector. Acrp30 mRNA expression and protein level were measured by RT-PCR and ELISA in these cells. Glucose turnover and gene expression were determined by LSC and RT-PCR.

Results: The Acrp30 mRNA expression and protein level in 3T3-L1 cells with adenovirus plasmids was statistically significantly lower than in controls (34% and 39%, both $P < 0.01$). The rate of glucose disappearance (G_{Ra}) and the uptake rates of glucose (GUR) was significantly decreased by 90% and 77% in adiponectin-deficient adipocytes compared with the controls ($P < 0.05$ and $P < 0.01$). PPAR- α mRNA expression in adiponectin-deficient cells with insulin-stimulated was significantly down-regulated by 66% ($P < 0.05$), and IRS-1 mRNA expression in these in both basal and insulin stimulated state was down-regulated by 52% and 72%, respectively (both $P < 0.05$). In addition, hormone-sensitive lipase (HSL) mRNA expression was down-regulated by 40% and 57% (both $P < 0.05$), and ATGL mRNA expression was also reduced by 75% after insulin-stimulating ($P < 0.05$). Another adipocytokines, visfatin mRNA expression was reduced by 83% in the basal and insulin-stimulated states of adiponectin-deficient cells.

Conclusion: These results show that the siRNA adenoviral vector against Acrp30 mRNA has been successfully constructed, and it effectively inhibits

the expression of Acp30 mRNA and protein in 3T3-L1 cells. Adiponectin deficiency exerts a negative effect on glucose transport and metabolism by down-regulating GLUT-1, GLUT-4 and IRS-1 expression, and also resulted in marked alteration of visfatin, HSL and ATGL mRNA expression.

Effects of angiotensin II on the production of adiponectin in 3T3-L1 adipocyte

T. Ikeda, K. Kajita, K. Fujioka, I. Mori, Y. Uno, H. Morita, T. Ishizuka
General Internal Medicine, Gifu University Graduate School of Medicine, Gifu, Japan

Background and aims: Various hormones, including glucagons, ACTH, parathyroid hormone and angiotensin II (AII), activate phorbol ester-sensitive PKC (c/nPKC) to obtain various hormone actions. We speculated that c/nPKC might regulate adipocyte-specific gene and cytokine-related gene, as c/nPKC activate NF-kappa B. Our previous research revealed that treatment with phorbol ester reduced the expression of PPAR gamma and related genes, such as aP2, lipoprotein lipase (LPL) and adiponectin in adipocyte. AII stimulation causes the inhibition of insulin signaling by serine phosphorylation of insulin receptor substrate I via activation of c/nPKC. In this study, we evaluated the effect of AII on the expression of cytokines including IL-6, IL-10 and monocyte chemoattractant protein-1 (MCP-1) in order to search the association between hypertension-induced insulin resistance and adiponectin production in adipocyte.

Materials and methods: We examined the effect of high glucose, insulin and AII on the mRNA expression of these genes in adipocytes. Fully differentiated 3T3-L1 adipocytes were incubated with 10nM TNF alpha, 100nM TPA, 10nM insulin, 15mM glucose (high glucose) and 50 nM AII for 24 hr. Total RNA was isolated to measure the expression levels of PPAR gamma, aP2, LPL, adiponectin, suppressor of cytokine signal-1 (Socs-1) and MCP-1 were measured with real-time PCR. Western blot was performed to determine activities of c/nPKC with anti-phospho MARKS antibody. NF-kappa B activity was assayed with commercially available kit. (Trans AMTM NF-kappa B, Active Motif).

Results: Treatment with 100 nM TPA, as well as 10 nM TNF alpha, decreased the PPAR gamma mRNA levels in 3T3-L1 adipocytes. Levels of aP2, LPL, FAS and adiponectin mRNA decreased concomitantly. TNF alpha markedly increased MCP-1 and Socs-1 mRNA level (522% and 232% respectively), however TPA slightly increased MCP-1 and Socs-1 mRNA levels (234% and 125% respectively). Treatment with 50nM AII, but not insulin and high glucose, decreased the PPAR gamma, aP2, LPL, FAS and adiponectin mRNA levels, whereas it did not alter Socs-1 and MCP-1 levels. Go6976, c/nPKC inhibitor, prevented the AII-induced reduction in levels of PPAR gamma mRNA. Incubation with TPA and AII, but not insulin and high glucose, for 24 hr increased c/nPKC and NF-kappa B activity.

Conclusion: These results indicate that activation of c/nPKC negatively regulates expression level of PPAR gamma and adiponectin in adipocyte, probably mediates via NF-kappa B activation. Moreover, AII also down-regulated adiponectin mRNA level, which might contribute to insulin resistance.

727

Adiponectin gene expression is significantly higher in subcutaneous adipose tissue of diabetic ZDF fa/fa rats than in nondiabetic ZDF fa/fa, diabetic Heterozygous ZDF or lean Zucker rats

B. Seyoum, A. Fite, A. Abou-Samra
Division of Endocrinology, Diabetes and Metabolism, Wayne State University, Detroit, United States

Background and aims: Zucker diabetic fatty (ZDF) rats have been used as a model for type 2 diabetes mellitus (T2DM) since the late 1980s. ZDF rats have a missense mutation in the leptin receptor gene (fa/fa), which results in decreased leptin signalling and defective receptor-mediated leptin transport into the central nervous system. Homozygous fa/fa ZDF rats naturally become hyperphagic, hyperinsulinemic, hyperlipidemic, develop substantial ectopic fat deposition in muscle cells and eventually develop T2DM. The mechanism by which ZDF rats develop metabolic syndrome and insulin resistance and the role of ectopic fat deposition in muscle tissues is not well understood. The communication between muscle and fat cells through adi-

pocytokines such as adiponectin may be important pathophysiologically for the obesity and diabetes phenotype of these rats. The purpose of this study was to characterize adiponectin gene expression in adipose and muscle tissues obtained from ZDF rats.

Materials and methods: Using real-time PCR, we analyzed adiponectin mRNA levels in total RNA prepared from skeletal muscles and subcutaneous and visceral adipose tissues from 4 different ZDF rat groups, homozygous or heterozygous for the leptin receptor mutation with contrasting metabolic conditions: fa/fa diabetic, fa/fa nondiabetic, fa/wt diabetic and wt/wt lean non-diabetic.

Results: One-way analysis of variance was used to calculate statistical significance. The data show dramatic differences in adiponectin gene expressions between diabetic and nondiabetic ZDF rats: in subcutaneous adipose tissues adiponectin mRNA expression was 16 fold higher in fa/fa diabetic than in fa/fa nondiabetic rat ($p = 0.003$); there was no statistical difference between diabetic fa/wt and wt/wt non-diabetic lean rats. In contrast, visceral fat adiponectin mRNA expression was 4 fold lower in the diabetic than in the nondiabetic fa/fa rats ($p < 0.05$); a similar trend was observed in the wt/fa diabetic rats when compared to the wt/wt non-diabetic rats. The levels of adiponectin gene expression in abdominal, thigh and leg muscles was different in the different animal groups. In abdominal, thigh and leg muscles, adiponectin mRNA was 3-4 fold higher in nondiabetic than in diabetic fa/fa rats ($p < 0.05$). The highest adiponectin mRNA level was observed in the fa/wt diabetic rat when compared to all the other groups.

Conclusion: The data obtained in skeletal muscles and visceral adipose tissues in fa/fa ZDF rats are consistent with the literature that diabetes is associated with low adiponectin expression. In contrast, diabetes was associated with higher expression of adiponectin mRNA in subcutaneous adipose tissues in the diabetic fa/fa rats compared to the non-diabetic fa/fa rats. The higher expression of adiponectin mRNA in subcutaneous adipose tissues of diabetic fa/fa ZDF rats may reflect a feedback up regulation of adiponectin gene transcription in subcutaneous fat by the diabetic state of the animal.

The relationship between skeletal muscle or plasma adiponectin concentration and insulin resistance in hereditary hypertriglyceridaemic rats

M. Cahova, M. Maxova, I. Markova, L. Kazdova
Department of Metabolism of Diabetes, Institute for Clinical and Experimental Medicine, Prague, Czech Republic

Background and aims: Adiponectin has been shown to have insulin-sensitising effect and it is well-documented that plasma adiponectin is lower in obese subjects and in obese diabetic patients. Although the association between adiponectin levels and adiposity is well-established, the causal relationship between age-related or dietary induced changes in insulin sensitivity and changes in adiponectin levels is still not fully understood. The aim of our study was to investigate the age-related changes in serum and tissue concentration of adiponectin and tissue insulin sensitivity in non-obese experimental model of insulin resistance - hereditary hypertriglyceridemic rats (HHTg) and control normotriglyceridemic (C) rats at age 3- and 18- months.

Materials and methods: The experiments were carried out on adult male HHTg and Wistar rats fed 8 weeks with high-sucrose diet (70 cal% as sucrose) at the age of 3- and 18- months. The adiponectin was determined by Elisa kit (B-Bridge Inc, USA). The insulin sensitivity of skeletal muscle and adipose tissue was estimated according to the insulin-stimulated ^{14}C -U-glucose incorporation into glycogen and lipids.

Results: Advancing age and adiposity was associated with the decrease in serum and muscle adiponectin in both control and HHTg animals. In both groups the serum adiponectin concentration was by 100% lower in the 18-month compared to the 3-month old animals. The age-related drop in muscle adiponectin concentration was more pronounced in HHTg than in the control group (110 vs 40%). Despite similar serum and tissue adiponectin levels in both groups, 3- month old HHTg rats exhibited an impaired glucose tolerance measured as glucose and insulin AUC during OGTT when compared with controls. This finding is in accordance with the impaired in vitro insulin sensitivity in adipose tissue and skeletal muscle in young HHTg animals. In aged animals, the glucose intolerance and in vitro insulin sensitivity was more severe in HHTg than in control animals in accordance with tissue but not serum adiponectin concentration.

Conclusion: Our data indicate that adiponectin serum concentration inversely correlates with age and thus the lower adiponectin levels may contribute to the development of age-related insulin resistance that is not associated

with obesity. Nevertheless, the decrease in insulin sensitivity is not directly proportional to the changes in plasma adiponectin concentration and seems to be associated more tightly with tissue (skeletal muscle) adiponectin levels. *Supported by: MH CR no. NR 9387-3.*

729

Association of insulin, leptin and adiponectin with fetal growth in term babies of nondiabetic and diabetic mothers

Z. Hassan¹, F.M. Khan², S. Jahan³, I. Khan¹, L. Ali²

¹Physiology and Molecular Biology, ²Dept of Biochemistry and Cell Biology, ³Dept of Obstetrics and Gynecology, BIRDEM, Dhaka, Bangladesh

Background and aims: Leptin and adiponectin play important roles in energy homeostasis. However, their precise role in the fetal growth and development, and their interaction with insulin still needs to be clarified in various ethnic groups due to the dependence of these hormones on genetic and environmental factors. The present study was designed to evaluate cord blood levels of insulin, leptin and adiponectin in full term newborn babies and to analyze the growth parameters of the fetus in relation to their insulinemic, leptinemic and adiponectinemic status.

Materials and methods: Blood samples from umbilical cord were taken from 128 newborn babies, out of whom 94 were of nondiabetic mothers (BNDM group) and 34 of diabetic mothers (BDM group). During analysis babies were classified as small for gestational age (BNDM-SGA and BDM-SGA) or average for gestational age (BNDM-AGA and BDM-AGA) based on WHO criteria. Weight and length of the babies as well as their anthropometric parameters (mid-arm circumference, head circumference, abdominal circumference) were measured following standard procedures. Leptin and adiponectin were measured by enzyme-linked immunosorbent assay (ELISA). Results were expressed as median (range).

Results: BDM had significantly lower total cholesterol (mg/dl) level compared to the BNDM [30 (13-80) vs 48 (18-108), $p < 0.001$] group. This tendency was more pronounced in BDM-AGA compared to both BNDM-AGA ($p = 0.001$) and BNDM-SGA ($p = 0.012$) groups. Even in the presence of normal birth weight and blood glucose values BDM group had significantly higher insulin ($\mu\text{IU/l}$) levels compared to BNDM group [5.1 (0.5-2.2) vs 3.39 (0.5-66.6), $p = 0.012$]. Higher level was also observed in BDM-AGA compared to BNDM-AGA [5.7 (0.5-17.8) vs 3.3 (0.5-66.6), ($p = 0.021$)]. No difference was observed between BNDM-SGA and BNDM-AGA groups. Cord blood leptin level (ng/ml) in BNDM and BDM did not show statistical difference ($p = 0.246$). BNDM-AGA [9.3 (0.5-48.0)] and BDM-AGA ([11.5 (1.03-89.9)]) had significantly higher leptin levels compared to BNDM-SGA [3.7 (0.6-29.6)] ($p = 0.013$ and 0.012 respectively). However, leptin levels between BNDM-AGA and BDM-AGA did not show any statistical difference ($p = 0.432$). Leptin levels showed positive correlation with fetal variables: birth weight ($r = 0.335$, $p = 0.001$), blood glucose ($r = 0.268$, $p = 0.009$) and maternal variables: BMI ($r = 0.338$, $p = 0.001$) and diastolic blood pressure ($r = 0.236$, $p = 0.023$) in absence of maternal diabetes. Multivariate analyses with leptin as dependent variable and birth weight, blood glucose, insulin and gender as independent variable revealed association with birth weight ($p = 0.001$ - <0.001) and blood glucose ($p = 0.019$ - 0.035) only in absence of maternal diabetes. But in cases of maternal variable, only BMI persistently showed significant association with leptin. Cord blood adiponectin level (ng/ml) between BNDM [68.2 (4.9-106)] and BDM [67.1 (21.4-91.8)] ($p = 0.650$) did not show any significant difference and the trend was similar in the subgroups. Correlation analyses also failed to demonstrate any association with adiponectin and fetal and maternal variables either in nondiabetic and diabetic groups.

Conclusion: Leptin, in association with insulin, seems to play a crucial role in fetal growth. Adiponectin does not seem to have any association with fetal development.

Comparison of adiponectin multimeric complexes secreted from adipose tissue explants with plasma levels in obese women: impact of very low calorie diet

Z. Kovacova¹, J. Polak^{1,2}, M. Vitkova^{1,3}, M. Kovacikova¹, E. Klimcakova¹, M. Bajzova^{1,2}, Z. Hnevkovska^{1,2}, L. Rossmeislova³, V. Stich^{1,3}

¹Department of Sport Medicine, Third Faculty of Medicine, Charles University, Prague, Czech Republic, ²II. Internal Medicine Department, Vinohrady Teaching Hospital, Prague, Czech Republic, ³Franco Czech Laboratory for the Clinical Research on Obesity, INSERM France and Third Faculty of Medicine Charles University, Prague, Czech Republic

Background and aims: Adiponectin is adipose tissue-produced adipocytokine with important role in glucose and lipid metabolism. It circulates in plasma as high, middle and small molecular weight isoforms (HMW, MMW, LMW). Plasma adiponectin levels are decreased in obese, insulin-resistant and Type 2 diabetic patients. The aim of our study was to investigate the secretion of adiponectin polymers from adipose tissue explants in relationship to plasma and to investigate the impact of low-calorie diet-induced weight loss on metabolism of specific adiponectin isoforms in adipose tissue.

Materials and methods: A novel ELISA assay (ALPCO Diagnostics, Salem, USA) and nondenaturing Western blot analysis were used to determinate adiponectin complex secretion from adipose tissue and distribution in plasma of 14 obese subject (11 women and 3 men of age 39.3 ± 6.73 years; BMI, $31.99 \pm 4.49 \text{ kg/m}^2$) before and after eight weeks' very low-calorie diet (VLCD). A needle biopsy of subcutaneous abdominal adipose tissue and blood samples were taken before and after dietary intervention. About 400 mg of adipose tissue cut in small pieces was incubated in culture medium for four hours and the medium used for analysis.

Results: The most abundant isoform in cultured media was the HMW form which represented 88.6 % of total secreted adiponectin into media (MMW was 11.4 % of total adiponectin; LMW was not detected in media). We compared this distribution to plasma samples where the percentage of HMW to total adiponectin was 54.2 % shifted to others isoforms (MMW 16.5 %; LMW 29.2 %). Western blot confirmed the results of ELISA with respect to the distribution of adiponectin polymers in both plasma and media. The subjects' body weight and BMI decreased (by 11.12% and 11.14% respectively) after VLCD. We found no effect of diet on the composition of polymeric isoforms produced from adipose tissue into culture media or appearing in plasma despite of the diet-induced improvement of insulin sensitivity.

Conclusion: Adiponectin secreted from human adipose tissue is represented predominantly by HMW isoforms. The proportion of HMW in secreted medium is different from that in plasma. The secretion profile of adiponectin was not affected by the diet-induced weight reduction associated with changes of insulin sensitivity. This suggests that the diet-induced change in insulin sensitivity is not related to changes in HMW polymers of adiponectin.

Effect of glomerular filtration rate on circulating adipokines in patients with type 2 diabetes mellitus

M. Al Arouj¹, A. Ben Nakhi¹, O. Mojiminiyi², N. Abdella³

¹Medicine, DASMAN Diabetes Center, ²Pathology, Faculty of Medicine, Kuwait University, ³Medicine, Faculty of Medicine, Kuwait University, Kuwait

Background and aims: Obesity and insulin resistance are known to contribute to the progression of renal disease via several potential mechanisms. We postulate that one of these mechanisms may involve retention of low molecular weight adipokines when glomerular filtration rate (GFR) decreases. Therefore, the main objective of this study was to evaluate the relationships between adiponectin (30kDa), resistin (12.5 kDa) and leptin (16 kDa) concentrations with estimated GFR (eGFR) in patients with Type 2 diabetes (T2DM) and varying degrees of diabetic nephropathy

Materials and methods: Fasting adiponectin, resistin and leptin were determined in 210 T2DM patients who were classified as normo- ($n = 139$) or microalbuminuric ($n = 71$). eGFR was determined by the abbreviated Modification of Diet in Renal Disease (MDRD) equation. Uni- and multi-variate regression (with inclusion of age, gender, waist circumference (WC), presence of coronary heart disease, hypertension and smoking status as potential

confounders) analyses were used to determine the associations of eGFR with adipokine concentrations.

Results: 37% of patients had eGFR < 60 ml/min/1.73 m² and in these patients mean WC (105 vs 107 cm) was lower but mean adiponectin (15.8 vs 14.3 ng/ml), resistin (24.7 vs 23.3 ng/ml) and leptin (39.9 vs 39.2 ng/ml) were higher than in patients with eGFR > 60 ml/min/1.73 m². Adiponectin ($r = -0.38$), leptin ($r = 0.45$) and resistin ($r = 0.49$) were significantly correlated with WC and these correlations remained significant after correction for eGFR and the above confounding variables. In uni- and multi-variate regression analyses, no significant associations were found between adiponectin, leptin and resistin and eGFR. Sub-group analysis of patients with eGFR < 60 ml/min/1.73 m² failed to show associations between adipokines and eGFR.

Conclusion: Our results reject the hypothesis that there is GFR dependent retention of adipokines in patients with T2DM in whom the degree of adiposity appears to be the most significant determinant of circulating adipokines.

Hepatoprotective effect of rimonabant is associated with upregulation of adiponectin in the obese, insulin resistant dog

M. Kabir, M.S. Iyer, D. Stefanovski, I.R. Hsu, O. Woolcott, D. Zheng, S.P. Kim, K.J. Catalano, J.D. Chiu, L.N. Harrison, M. Lottati, V. Ionut, R.N. Bergman, J.M. Richey
Physiology and Biophysics, USC, Keck school of medicine, Los Angeles, United States

Background and aims: Recent studies demonstrated that the CB-1 receptor antagonist Rimonabant (RIM) may have beneficial effects on liver disease. In a previous study, we showed that RIM improved hepatic insulin sensitivity and reduced both visceral and subcutaneous adiposity in the obese, insulin resistant dog model. In addition, RIM increased plasma adiponectin levels by two fold. Based on these data, we hypothesized that the effect of RIM on the liver may be mediated in part by an increase in the purported insulin sensitizer adiponectin. Hence, we undertook the current study to investigate the effect of RIM on liver morphology as well as adiponectin gene expression in subcutaneous (SQ) and visceral (VIS) fat depots.

Materials and methods: Dogs were fed a high fat diet (HF; 52% fat) to induce mild obesity and insulin resistance. After 6 wks of fat feeding, animals were continued on HF diet for an additional 16 wks either with placebo (P; n=4) or with RIM (1.25 mg/kg per day; RIM; n=4) treatment. Biopsies from liver and fat were obtained in RIM and P groups for histology and gene expression.

Results: After 16 weeks of high fat diet (P), histological examination of the liver revealed slight lipid accumulation, in addition to hydropic change. Administration of RIM reduced this hepatic lipid accumulation and improved hydropic change. Measurement of adiponectin expression, using real time PCR, demonstrated that RIM treatment increased adiponectin gene expression by 6 fold in the VIS depot ($P < 0.001$), while there was only a slight tendency to decrease VIS adiponectin expression in P group ($P = 0.058$). In addition, adiponectin gene expression increased 2 fold in SQ depots with both treatment groups ($P < 0.05$).

Conclusion: Increased gene expression of adiponectin from visceral fat may increase the delivery of adiponectin into the liver thereby improving hepatic sensitivity. Furthermore adiponectin and/or Rimonabant itself may have beneficial effects on the liver by reducing both fat accumulation and hydropic change. Thus, Rimonabant may play a hepatoprotective role in obesity and may have an important pharmacological application for obesity associated with liver disease.

Characterisation of the insulin signalling cascade defects in the liver of obese-insulin resistant baboons

A.O. Chavez¹, S. Kumath¹, R. Guardardo-Mendoza¹, G. Hubbard², E. Dick², A. Comuzzie², A. Gastaldelli¹, R.A. DeFronzo¹, F. Folli¹

¹Medicine/Diabetes, UTHSCSA, ²Diabetes Research, Southwest Foundation for Biomedical Research and Southwest National Primate Research Center, San Antonio, United States

Background and aims: Baboons are valuable models for the study of human disease, sharing 98% genetic similarity. Recently, we have demonstrated that the baboon is a pertinent model for the study of insulin resistance. In humans, obesity and type 2 diabetes are associated with impaired hepatic insulin sensitivity. However, the molecular abnormalities present in the human insulin resistant liver are largely unknown. In the present study, we analyzed key insulin signaling molecules in liver of baboons with varying degrees of adiposity and insulin sensitivity.

Materials and methods: Eight obese insulin resistant (IR) baboons (age=21±2 y, BMI=28±2* %BF=15±3* FPG=114±7 mg% Rd=2±0.3 mg/kg.min*, HOMA-IR=7.4±1.7*) and eight insulin sensitive (IS) baboons (19±2 y, BMI=22±1, %BF=4.5±0.2, FPG=97±8, Rd=11±1 mg/kg.min, HOMA-IR=2.0±0.8,*= all $p < 0.05$ between groups) were studied. After an overnight fast, a 60 mU/m2.min euglycemic insulin clamp was performed under general anesthesia. Prior to insulin, a baseline needle liver biopsy was performed, and repeated at 30 and 120 min after insulin. Insulin sensitivity was calculated as the mean rate of glucose uptake (Rd) from 90 to 120 min during the clamp. Insulin signaling cascade molecules including: phosphorylation (p) of insulin

receptor (Ins-R) at Tyr1146, Tyr1150/51 and Tyr1345, total IRS-1 and pIRS-1 (Ser612), total Akt, and pAkt (Thr308 and Ser473) were analyzed by ELISA in liver homogenates. To quantify insulin-stimulated phosphorylation, the delta between basal and 30 and 120 min after insulin stimulation were calculated. Differences between groups at different time points were analyzed by ANOVA and Pearson correlation was used to estimate the relationship between different metabolic parameters and insulin-stimulated signaling.

Results: In both IR and IS baboons hepatic pInsR-Tyr1146 increased significantly ($p < 0.05$) from baseline with a maximal response at 30 min; pInsR-Tyr1150 maximally increased at 120 min in both groups, ($p < 0.05$ vs. baseline) although to a lesser extent in the IR group. For pInsR-Tyr1345 the maximal response occurred at 120 min ($p < 0.001$ vs. baseline) similarly in IR and IS baboons. There was no difference in total IRS-1 or pIRS-1 (Ser612) between groups. Akt1 protein levels were significantly higher in the IR group at baseline ($p < 0.05$), and the stimulation of Akt phosphorylation (pAkt1/Akt1) was impaired in IR vs. IS ($p < 0.05$). pAkt-ser473 increased significantly after insulin with a peak at 30 min ($p < 0.001$ in both groups), but the response was markedly reduced in the IR vs IS group (25%, $p = 0.02$). pAkt1-Thr308 was maximally expressed at 120 min in both groups ($p < 0.01$ vs. basal), but in the IR group was 40% lower ($p = 0.02$). BMI was correlated directly with insulin receptor phosphorylation ($r = 0.60$, $p = 0.03$) and inversely with pAkt ($r = -0.65$, $p = 0.01$).

Conclusion: The signaling defects in liver from obese insulin resistant baboon are characterized by modest impairment at the insulin receptor tyrosine phosphorylation, and a severe defect in pAkt. These abnormalities are tightly related to BMI and insulin resistance. Because of the strong genetic similarity between humans and baboons study of the baboon provides an important model of hepatic insulin resistance in man.

Effects of high fat diet on metabolic parameters in ghrelin receptor (GHS-R) knockout mice

K. Dahl, K. Raun, T. Bødvarsdottir, K. Juhl, F. Strauss, L. Kristensen, C. Nilsson
GLP1 and Obesity Pharmacology, Novo Nordisk, Måløv, Denmark

Background and aims: Ghrelin is the endogenous ligand of the ghrelin receptor (GHS-R) and is the only known orexigenic gut hormone. For this reason ghrelin has been the focus of intensive research within the therapeutic areas of appetite regulation and obesity treatment. The aim of this study was to examine if abolished ghrelin action through the GHS-R is affecting standard metabolic parameters in mice fed a high fat diet.

Materials and methods: Fifteen female and 12 male C57BL/6 GHS-R knockout mice (GHS-R KO), and 10 female and seven male wild type C57BL/6 mice (WT) were subjected to an oral glucose tolerance test (oGTT). After the initial oGTT, mice were fed a high fat (HF) diet for seven months, where after the mice were subjected to a second oGTT. Body weight was followed and body composition (NMR scan) was performed after seven months of high fat diet.

Results: The initial oGTT showed no significant difference between WT and GHS-R KO mice in blood glucose area under the curve (AUC), neither for female (GHS-R KO: 263 ± 51 mM*min, WT: 235 ± 25 mM*min) nor male mice (GHS-R KO: 276 ± 36 mM*min, WT: 190 ± 35 mM*min). After seven months of HF diet there were still no significant difference in glucose tolerance between female GHS-R KO mice (420 ± 48 mM*min) and WT mice (307 ± 27 mM*min). A significant effect ($p < 0.05$) was seen for glucose tolerance in female GHS-R KO before HF diet as compared to after HF diet. This was not seen for female WT mice. After HF diet, male GHS-R KO mice exhibited a significantly impaired glucose tolerance as compared to male WT mice (GHS-R KO: 812 ± 92 mM*min vs. WT: 399 ± 29 mM*min, $p < 0.001$). There was also significantly reduced glucose tolerance after HF diet in male GHS-R KO mice when comparing with before HF diet ($p < 0.001$) and this reduction was not seen in WT mice after HF diet. Basal body weight, i.e. before HF diet, did not differ between GHS-R KO and WT mice, neither for females (GHS-R KO: 20.5 ± 0.4 g vs. WT: 21.7 ± 0.3) nor males (GHS-R KO: 30.0 ± 0.6 g vs. WT: 29.2 ± 0.6 g). After HF diet, all mice had a significantly increased body weight as compared to before HF diet ($p < 0.001$). The impact of age can with the present study design not be separated from the impact of HF diet. There were no significant effect on body weight after HF diet between male GHS-R KO mice (44.2 ± 1.5 g) and male WT mice (48.2 ± 2.1 g). In contrast, female GHS-R KO exhibited a significantly ($p < 0.001$) lower body weight after HF diet (40.9 ± 1.9 g) than female WT mice (50.6 ± 1.5 g). The reduction in body weight was in female GHS-R KO accompanied by a significant reduction ($p < 0.01$) in body fat as

compared to WT mice (GHS-R ko: 19.5 ± 2.4 g, WT: 29.3 ± 1.5 g). The amount of body fat was not significantly different for male GHS-R KO mice (16.2 ± 1.0 g) as compared to male WT mice (18.4 ± 1.1 g).

Conclusion: In conclusion, there were no differences in body weight and glucose tolerance between young GHS-R KO mice and WT mice exposed to normal diet. However, after exposure to seven months of HF feeding, male GHS-R KO mice exhibit a reduction in glucose tolerance compared to WT mice, whereas deletion of the GHS-R did not have any impact on glucose tolerance after HF feeding in female mice. In contrast, deficiency of ghrelin action through the GHS-R, resulted in female mice being less prone to develop diet induced obesity than wild type mice, which was not seen in male GHS-R KO mice. Results from this study indicate a gender specific influence of the metabolic actions of ghrelin via the GHS-R in mice.

735

Chemical derivatives of DHA in the treatment of obesity and glucose intolerance associated with high-fat feeding in mice

M. Rossmeisl¹, Z. Jilkova¹, T. Jelenik¹, M. Hensler¹, V. Mohamed-Ali², M. Bryhn³, K. Berge³, A.K. Holmeide³, J. Kopecky¹

¹Dept. of Adipose Tissue Biology, Institute of Physiology, Prague, Czech Republic, ²Adipokines and Metabolism Research Group, Dept. of Medicine, University College London, United Kingdom, ³Pronova BioPharma AS, Lysaker, Norway

Background and aims: n-3 polyunsaturated fatty acids, especially eicosapentaenoic acid and docosahexaenoic acid (DHA), exert hypolipidemic effects and prevent development of obesity and insulin resistance in animals fed high-fat diets. We sought to determine whether α -substituted DHA-derivatives could exert a higher efficacy as anti-obesity and anti-diabetic agents, compared to DHA.

Materials and methods: C57BL/6 mice were given a corn oil-based high fat (35% weight/weight) diet (cHF), or cHF with 1.5% of lipids replaced with α -methyl DHA ethyl ester (Substance 1), α -ethyl DHA ethyl ester (Substance 2), α , α -di-methyl DHA ethyl ester (Substance 3), or α -thioethyl DHA ethyl ester (Substance 4) for 4 months. We also investigated whether Substance 2 could reverse glucose intolerance in obese cHF-fed mice. Plasma markers of glucose and lipid metabolism, glucose tolerance, tissue morphology, lipid content and gene regulation were characterized.

Results: cHF induced obesity, hyperlipidemia, impairment of glucose homeostasis and adipose tissue inflammation. Except Substance 3, all other substances prevented weight gain and Substance 2 exerted the strongest effect (63% of cHF-controls). Glucose intolerance (area under the curve) was significantly prevented (~67% of cHF) by both Substance 1 and Substance 2. Moreover, Substance 2 lowered fasting glycemia, plasma insulin, triacylglycerols, and nonesterified fatty acids (73, 9, 47, and 81% of cHF-controls, respectively). Substance 2 reduced accumulation of lipids in the liver and skeletal muscle, as well as adipose tissue inflammation associated with obesity. It also reduced obesity and reverted glucose intolerance in the obese mice.

Conclusion: Substance 2 represents a novel compound with a promising potential in the treatment of obesity and associated metabolic disturbances.

¹Action Pharma A/S, Holte, Denmark, ²Rheoscience A/S, Rødovre, Denmark

Background: AP1030, the lead compound within a novel group of phenyl pyrrol aminoguanidines (PPAGs) with melanocortin (MCR) type 1 and 4 receptor modulating effects is an orally available small molecule intended for once daily treatment. After single dose administration to normal Sprague-Dawley (SD) rats AP1030 dose dependently reduced food intake without concomitant effects on locomotor activity or overt sign of malaise.

Aim and methods: The aim of the present study was to examine the effects of 33 days administration of AP1030 (25 mg/kg po) on feeding and metabolic parameters in male selectively breed SD, diet-induced obesity (DIO) rats (LR-rat) (18 weeks of age) on a high fat diet (4.41 kcal/g - Energy %: Carbohydrate 51.4%, Fat 31.8%, Protein 16.8%). Rats treated with vehicle (Veh) (20% PEG 200) were used as controls and Sibutramine (5 mg/kg po) treated rats were used as positive control. N=10 in all groups (all values given as mean \pm SE).

Results: Food intake at the end of the treatment period as % of baseline levels were as follows: Veh: $96.8 \pm 7.6\%$; AP1030: $85.0 \pm 17.1\%$, $p < 0.01$ vs Veh; Sibutramine: $84.3 \pm 16.4\%$, $p < 0.01$ vs Veh. Furthermore, AP1030 reduced weight gain with $\sim 10\%$ BW from baseline (day 0) and with a $\sim 15\%$ reduction when compared to vehicle treated animals (Veh: $105.9 \pm 2.2\%$; AP1030: $90.4 \pm 5.5\%$, $p < 0.01$) (Sibutramine: $92.8 \pm 2.3\%$). In AP1030 animals the changes in body fat was associated with a $\sim 50\%$ reduction in retroperitoneal and mesenteric fat depots in comparison to vehicle treated and by $\sim 25\%$ reduction in comparison to sibutramide treated rats. After 28 days of treatment with AP1030 fasting levels of glucose, insulin and cholesterol were reduced significantly in comparison to vehicle treated animals (Glucose: Veh: 7.09 ± 0.62 mM; AP1030: 6.42 ± 0.85 mM, $p < 0.01$), (Insulin: Veh: 544.8 ± 137.6 pM; AP1030: 375.5 ± 83.7 pM, $p < 0.01$), (Cholesterol: Veh: 2.72 ± 0.82 mM; AP1030: 1.29 ± 0.25 mM, $p < 0.01$). Finally, an oral glucose tolerance test (OGTT) was conducted at study day 28. Both AP1030 and sibutramine had beneficial effects on glucose metabolism: Peak glucose ($t=15$ min): Veh: 12.03 ± 2.02 mM; AP1030: 9.79 ± 1.15 mM, $p < 0.01$ vs Veh; Sibutramine: 11.05 ± 1.07 mM, NS vs Veh; Peak Insulin ($t=15$ min): Veh: 1063 ± 437 pM; AP1030: 429 ± 212 pM, $p < 0.01$ vs Veh; Sibutramine: 492 ± 207 pM, $p < 0.01$ vs Veh; Insulin sensitivity index (120 min): Veh: 2.40 ± 1.09 ; AP1030: 4.61 ± 1.20 , $p < 0.01$ vs Veh; Sibutramine: 4.44 ± 1.65 , $p < 0.01$ vs Veh.

Conclusion: In conclusion, these results show that once daily treatment with the novel melanocortin effect AP1030 in DIO rats exerts marked antiobesity and antidiabetic effects a strong body weight and glucose homeostasis and may prove to be feasible therapeutic route for the treatment of obesity and type 2 diabetes and related metabolic disorders.

Short-term high-fat feeding induces insulin resistance that is independent of adipose tissue macrophage infiltration and prevented by osteopontin deficiency

T.M. Stulnig¹, F.W. Kiefer¹, K. Gollinger¹, J. Todoric¹, T. Weichhart², R. Geyeregger¹, M. Zeyda¹

¹Dept. Internal Medicine III, Medical University Vienna, Clin. Division of Endocrinology and Metabolism, ²Dept. Internal Medicine III, Medical University Vienna, Clin. Division of Nephrology and Dialysis, Vienna, Austria

Background and aims: Obesity is associated with a state of chronic low-grade inflammation which is tightly linked to insulin resistance and type 2 diabetes and is associated with adipose tissue (AT) infiltration by macrophages. Osteopontin (OPN) is an inflammatory cytokine, the expression of which is strongly upregulated in AT during obesity. OPN was suggested to contribute to obesity-induced AT inflammation by promoting AT macrophage (ATM) accumulation. In the present study we examined effects of short-term (3 weeks) high-fat diet (HF) feeding on AT inflammation and insulin sensitivity in wild-type (WT) and OPN^{-/-} mice.

Materials and methods: OPN^{-/-} and WT control mice were placed for 3 weeks on HF and low-fat diet (LF). At the end of the feeding period an insulin tolerance test was performed. After sacrifice, blood plasma was collected and gonadal white AT was removed for immunological and gene expression analyses.

Results: Despite the absence of obesity and ATM accumulation by short-term HF, insulin sensitivity was reduced in both genotypes compared with LF ($P = 0.01$ for WT and OPN^{-/-}, respectively), indicating an early onset of insulin resistance independent of ATM infiltration. However, deterioration of insulin sensitivity was significantly less in HF-fed OPN^{-/-} mice compared with WT animals ($P = 0.03$). Short-term feeding of HF was sufficient to enhance gene expression of inflammatory cytokines in AT of WT and OPN^{-/-} mice. However, gene expression of TNF- α , MCP-1 and iNOS markedly less increased in OPN^{-/-} compared with WT animals indicating a role of OPN in HF-induced inflammatory alterations. Moreover, mRNA expression of insulin-sensitizing adiponectin was significantly higher in OPN^{-/-} vs. WT mice ($P = 0.04$) fed HF.

Conclusion: These data strongly indicate that short-term HF feeding impairs insulin sensitivity independent of ATM infiltration. Notably, the beneficial effects of OPN deficiency on short-term HF-induced insulin resistance could be mediated by interference with AT inflammation independent of ATM accumulation.

Induction of muscle thermogenesis by high-fat diet in mice: association with obesity-resistance

J. Kopecký¹, V. Kus¹, T. Prazak¹, P. Brauner¹, M. Hensler¹, O. Kuda¹, P. Flachs¹, P. Janovská¹, D. Medriková¹, M. Rossmeisl¹, Z. Jilková¹, B. Stefl²

¹Department of adipose tissue biology, Institute of Physiology, Academy of Sciences of the Czech Republic, ²Department of Physiology and Developmental Biology, Charles University, Prague, Czech Republic

Background and aims: Obesogenic effect of high-fat (HF) diet is counterbalanced by stimulation of energy expenditure and lipid oxidation in response to the meal. Aim of this study was to reveal whether muscle nonshivering thermogenesis could be stimulated by HF diet, especially in obesity-resistant A/J as compared with obesity-prone C57BL/6J (B/6J) mice.

Materials and methods: Experiments were performed on male mice born and maintained at 30 °C. Four-week-old mice were randomly weaned onto a low-fat (LF) or HF (60% calories from fat, mainly corn oil) diet for 2 weeks. Energy expenditure was evaluated using indirect calorimetry system (system INCA, So-medic, Horby, Sweden). Oxygen consumption in soleus or gastrocnemius muscle was followed *ex vivo*, using Oroboros Oxygraph (Paar KG, Graz, Austria). AMP-activated protein kinase (AMPK) activity was characterised using Western blots and antibodies against total and phosphorylated form of AMPK. Fatty acid oxidation in muscles was evaluated *ex vivo* using [¹⁴C(U)]-palmitate. Plasma leptin was assessed by a Mouse Leptin RIA Kit (LINCO Research, St. Charles, MO, USA). Gene expression in muscles was quantified using qRT-PCR.

Results: In the A/J LF mice, cold exposure (4 °C) resulted in hypothermia, while the A/J HF, B/6J LF and B/6J HF mice were cold-tolerant. Cold-sensitivity of the A/J LF mice was associated with a relatively low whole-body energy expenditure under resting conditions, which was normalized by HF diet (35.6 ± 2.6 vs 49.2 ± 1.9 ml oxygen/kg/min; measured at 30 °C during the light phase of the day; $p < 0.05$). In both strains, HF diet induced uncoupling protein 1-mediated thermogenesis (1.6- and 1.3-fold, in A/J and B/6J, respectively; measured as norepinephrine-induced respiratory rate in pentobarbital-anaesthetized mice using the INCA) in A/J mice. Only in A/J mice: (i) HF diet augmented activation of whole body lipid oxidation in cold (as revealed by indirect calorimetry); and (ii) at 30 °C, oxygen consumption in soleus muscle was increased by HF diet (145 ± 27 vs 255 ± 30 ml oxygen/mg protein/initial 5 min; $p < 0.05$), as well as total content and phosphorylation of AMPK, and AICAR-stimulated palmitate oxidation. Only in A/J mice, HF diet increased leptinemia compared with the LF diet-fed mice (3.35 ± 0.34 vs 9.42 ± 1.15 ng leptin/ml; $p < 0.05$). Gene expression data in soleus muscle of the A/J HF mice indicated a shift from carbohydrate to fatty acid oxidation.

Conclusion: Our results suggest a role of muscle nonshivering thermogenesis and lipid oxidation in the obesity-resistant phenotype of A/J mice and indicate that dietary fat could induce thermogenesis in oxidative muscle, possibly by the leptin-AMPK axis.

A central role for PI3K γ in obesity and insulin resistance

G. Solinas¹, B. Becattini¹, F. Zani¹, A.G. Dulloo¹, R. Marone², M.P. Wymann²

¹Medicine, Division of Physiology, University of Fribourg, ²Inst. Biochemistry & Genetics, Department of Biomedicine, University of Basel, Switzerland

Background and aims: Obesity is associated with a state of chronic low-grade inflammation (metabolic inflammation) that is believed to play an important role in the development of insulin resistance. Metabolic inflammation is characterized by macrophage (M ϕ) infiltration into obese adipose tissue. M ϕ s localize around dead adipocytes forming crown-like structures (CLS). The mechanisms leading to CLS formation are currently under investigation. Recent studies have identified an important role for the chemokine MCP1 and its receptor CCR2 in metabolic inflammation. Furthermore mice bearing a targeted mutation at the *ccr2* gene show decreased food intake and weight gain when placed in high fat diet. Interestingly, both MCP1 and CCR2 were implicated in the formation of atherosclerotic lesions, suggesting that CLS formation might share some molecular mechanisms with atherosclerotic plaque formation. The lipid kinase phosphoinositide 3-kinase γ (PI3K γ) has previously been shown to be central in chemotaxis in the response of myeloid cells to different chemoattractant, including MCP1. Recently, a role for PI3K γ has been defined in atherosclerosis. In this study we investigated the role of PI3K γ in diet-induced obesity and insulin resistance.

Materials and methods: To study the role of PI3K γ in diet-induced obesity and insulin resistance C57BL/6J mice (wt) and mice with a targeted Pi3ky locus (Pi3ky $^{-/-}$) were exposed to a high-fat diet (60% of calories from fat) for 16 weeks. Body weight was measured weekly to determine growth curves. Precise measurements of food intake was performed for 7 weeks, and lipid content of feces was determined by phenol-chloroform extraction. To test the role of PI3K γ in glucose homeostasis and insulin sensitivity we performed glucose and insulin tolerance tests.

Results: When placed on chow diet, no significant difference was observed between wt and Pi3ky $^{-/-}$ mice. When fed with high-fat diet, however, Pi3ky $^{-/-}$ mice were resistant to obesity. The quantification of food intake did not reveal a significant difference between wt animals and Pi3ky $^{-/-}$ mice. Hence, the obesity-resistant phenotype of Pi3ky $^{-/-}$ mice is not due to decreased food intake. Analysis of fecal chloroform/methanol extracts also revealed no difference among the two groups, indicating that the leaner phenotype of Pi3ky $^{-/-}$ mice observed on high fat diet was not due to reduced lipid adsorption. Our data illustrate that Pi3ky $^{-/-}$ mice are resistant to diet-induced obesity because of decreased efficiency of weight-gain per food intake. Interestingly, glucose tolerance was also improved in Pi3ky $^{-/-}$ mice placed on high fat diet for 16 weeks compared to Wt controls. Insulin tolerance was markedly improved in Pi3ky $^{-/-}$ animals versus wt mice, suggesting that the improved glucose tolerance might be due to increased insulin sensitivity.

Conclusion: In conclusion, we demonstrate here for the first time that the enzyme PI3K γ , a pro-inflammatory kinase specifically expressed in cardiomyocytes and hematopoietic cells, is directly involved in diet-induced obesity and glucose intolerance.

Thyroid transcription factor-1 mediates leptin signalling pathway in the hypothalamus

I. Nam-Goong, J. Kim, E. Kim, Y. Kim

Internal Medicine, Ulsan University Hospital, Ulsan, Republic of Korea

Background and aims: Thyroid transcription factor-1 (TTF-1) is a member of the NKx family of homeodomain genes. It has been known to play an important role in the control of neuroendocrine functions by our research group. We have recently reported a novel role of TTF-1 in the regulation of feeding behavior of rats. Leptin is an adipose tissue-derived hormone that suppresses appetite by regulating activities of satiety center in the brain. In this study, we determined TTF-1 function on the leptin-induced control of feeding behavior.

Materials and methods: For the experiment of intracerebroventricular (i.c.v.) administration of leptin (5 μ g), we used two month-old male Sprague-Dawley rats with 5 animals of each group, polyethylene cannula was stereotactically implanted into the lateral ventricle of rat. For immunohistochemical analysis, coronal sections of rat brain were hybridized with TTF-1 and STAT3 antibody.

Results: Administration of leptin via i.c.v. significantly decreased amount of food intake (10.1 ± 0.8 versus 7.4 ± 1.2 gram for 4 hour food intake, $p < 0.05$) and increased hypothalamic content of signal transducer and activator of transcription 3 (STAT3) (182 ± 22 percent of control, $p < 0.001$) that is well known to mediate leptin signaling pathway. The same treatment markedly reduced TTF-1 expression in the hypothalamus (33 ± 5 percent of control, $p < 0.001$). Immunohistochemical analysis showed that TTF-1 is co-localized in the STAT3-positive cells in the arcuate nucleus. TTF-1 physically interacted with STAT3 in the *in vivo* hypothalamic extracts as well as *in vitro* cellular extracts from the B-35 cells transfected with TTF-1 and STAT3 expression vectors. TTF-1 attenuated STAT3-induced increase of proopiomelanocortin and decrease of agouti-related protein transcription (1080 ± 110 percent of control and 54 ± 2 percent of control, respectively).

Conclusion: These data suggest that TTF-1 is involved in the regulation of central feeding behavior via leptin signaling pathway.

Liver fat and type 2 diabetes: specific roles of diabetes and overweight

L. Bozzetto¹, G. Annuzzi¹, A. Prinster², M. Mancini², R. Giacco³,

C. De Natale¹, M. Salvatore², G. Riccardi¹, A.A. Rivellese¹

¹Department of Clinical and Experimental Medicine, Federico II University, Naples, ²Department of Radiology, Federico II University, Naples, ³Institute of food sciences and technology, National Council of Research, Avellino, Italy

Background and aims: Fat accumulation in the liver is a common feature of conditions associated with insulin-resistance such as obesity and type 2 diabetes. Liver fat is often related to an increased abdominal visceral fat content. Nevertheless, the specific roles of insulin-resistance, obesity, and diabetes in relation to liver steatosis have not been clearly defined. To elucidate this issue hepatic fat content was determined in obese patients with and without type 2 diabetes and in normal weight subjects.

Materials and methods: Eleven diabetic obese subjects (DO), 9 non diabetic obese subjects (NDO), and 9 normal weight controls (C) were studied. All participants were male, aged 28–63 years, and with normal plasma triglyceride levels. Obese subjects with and without diabetes were matched for age, BMI and waist circumference. Diabetic patients were in good glycaemic control (HbA1c = $6.8 \pm 0.7\%$) ($M \pm SD$) under treatment with diet alone ($n=7$) or metformin ($n=4$). Anthropometric parameters were measured by standardized methodologies, liver fat content by ¹H-magnetic resonance (NMR) spectroscopy, abdominal fat distribution by NMR, and insulin sensitivity by hyperinsulinemic euglycaemic clamp (M/I: glucose infusion rate/plasma insulin concentration).

Results: DO had more liver fat ($13.0 \pm 7.3\%$) than NDO ($5.2 \pm 2.8\%$, $p < 0.05$) and C ($2.0 \pm 2.4\%$, $p < 0.001$). Abdominal fat content was higher both in DO and NDO compared with the lean normoglycaemic controls (visceral: DO 3184 ± 843 , NDO 2843 ± 1378 , C 1348 ± 742 cm³, $p < 0.001$; subcutaneous: DO 4029 ± 362 , NDO 5197 ± 1398 , C 1590 ± 504 cm³, $p < 0.001$), being visceral fat not significantly different between the two obese groups, and subcutaneous fat significantly less in DO than in NDO ($p < 0.05$). Whole-body insulin-sensitivity (M/I) was similar in DO (2.4 ± 1.1) and NDO (1.8 ± 0.8) in respect to controls (6.5 ± 2.9 , $p < 0.001$).

Conclusion: In type 2 diabetic patients with visceral adiposity and impaired insulin sensitivity, hyperglycemia plays an independent and additional role in the development of fat liver accumulation. It is likely that in diabetic obese patients increased liver fat content is part of a more general alteration of regional fat distribution, rather than the consequence of a simple increase of abdominal visceral fat.

Induction of the lipogenic pathway through ChREBP overexpression leads to hepatic steatosis without insulin resistance

C. Robichon, P.-D. Denechaud, F. Benhamed, M. Moldes, V. Fauveau,

J. Girard, C. Postic

Endocrinologie, Métabolisme et Cancer, Institut Cochin, Paris, France

Background and aims: Nonalcoholic hepatic steatosis is an excessive accumulation of triglycerides (TG) in liver and is part of a large spectrum of hepatic disorders called NAFLD (Nonalcoholic fatty liver disease). Hepatic steatosis is now considered as the liver component of the metabolic syndrome characterized by obesity, insulin resistance, dyslipidemia and hypertension. Fatty acids utilized for hepatic TG synthesis are available from the plasma non-esterified fatty acid pool or from fatty acids newly synthesized from glucose through de novo lipogenesis. Induction of lipogenic genes is under the concerted action of transcription factors Carbohydrate Responsive Element Binding Protein (ChREBP) and Sterol Regulatory Element Binding Protein-1c (SREBP-1c) in response to glucose and insulin, respectively. Despite the emergence of ChREBP in the control of lipid synthesis, its specific contribution to hepatic lipogenesis remains to be clearly established. Therefore, the aims of this study were to determine: 1) whether the overexpression of ChREBP in liver is sufficient to stimulate lipogenesis and 2) if excessive lipogenic rates can lead to the development of hepatic steatosis and/or insulin resistance.

Materials and methods: Physiological and metabolic consequences of adenoviral ChREBP overexpression were studied 10 days (short-term) and 30

days (long-term) after a single injection in C57BL/6/J mice. Gene expression was analyzed by real time quantitative polymerase chain reaction and western blot. Insulin and glucose tolerance tests were performed to evaluate the general insulin sensitivity of mice. Moreover activation of the hepatic insulin-signaling pathway after a 3 minutes insulin pulse in the portal vein was studied. Oil red-O staining and lipid species quantification by high performance liquid and gas chromatography were performed to study the development of hepatic steatosis.

Results: Short-term and long-term overexpression of ChREBP in liver induced glycolytic (L-PK) and lipogenic (ACC, FAS, SCD1) gene expression without any induction of SREBP-1c. Under long-term ChREBP overexpression conditions, oil red-O staining of hepatic cryosections showed an important lipid accumulation confirmed by lipidomic analysis. Interestingly, in spite of a three-fold increase in hepatic TG concentrations, mice overexpressing ChREBP in liver for 30 days did not develop insulin resistance as revealed by normal insulin tolerance and by the adequate phosphorylation of key effectors of the insulin-signaling pathway.

Conclusion: Our results show that stimulation of de novo hepatic lipogenesis through ChREBP overexpression is sufficient to induce hepatic steatosis but that intra-hepatic lipid composition and/or accumulation in this mouse model is not associated with insulin resistance.

The relationship between reactive oxygen species, insulin resistance and nonalcoholic fatty liver disease. A study using in vitro model

K.A. Lockman¹, C. Filippi², J. Baren³, C. Pembleton³, F. Howie⁴, P. Lee³, P. Cowan³, A. Pryde³, A. Jaap¹, P.C. Hayes³, J.N. Plevris³

¹Department of Diabetes, Royal Infirmary of Edinburgh, ²Scottish Centre of Regenerative Medicine, University of Edinburgh, ³Department of Hepatology, University of Edinburgh, ⁴Department of Biochemistry, University of Edinburgh, United Kingdom

Background and aims: Insulin resistance plays a vital role in the pathogenesis of nonalcoholic fatty liver disease (NAFLD). However, currently available human in vitro models of steatotic hepatocytes are yet to demonstrate evidence of insulin resistance. Indeed, it has previously shown that cell exposure to oleic acid increases insulin sensitivity despite extensive steatosis. The aim of this study is to develop an in vitro model of NAFLD that demonstrate evidence of insulin resistance. Our hypothesis is that the presence of high mitochondrial reactive oxygen species (ROS) is essential for the development of in vitro model that would exhibit insulin resistance.

Materials and methods: Human C3A cell line, a clonal derivative HepG2 cell line, was selected for its better differentiated hepatic phenotype. Cells were cultured for 3 days with various combination of; Lactate (L), Pyruvate (P), Octanoate (O) and Ammonia (N) and Oleic acid (OL). ROS were detected using MitoSox Red and quantified using fluorescence activated cell sorter. Triglyceride concentrations were measured using enzymatic assay. Mitochondrial function was assessed by microscopy using fluorescent probe JC-1. Insulin sensitivity was assessed by measuring endogenous glucose production (EGP) and glycogen breakdown in the presence of increasing insulin concentrations (0–10nM). Glucose, lactate and pyruvate production were measured according to Bergmeyer methods. Cell viability was assessed using propidium iodide staining.

Results: All preconditioning media induced intracellular fat accumulation but to different degree as demonstrated by triglyceride concentrations (OL>L PON>LPO>OCT>LP>CONTROL; $p<0.001$, $n=3$).

The different preconditioning groups showed various ROS synthesis unrelated to the degree of fat accumulation (LPON>LPO>OCT>LP>CONTROL>OL) with highest peak fluorescent intensity in LPON (LPON (mean \pm SEM) 49.67 ± 3.38 vs control 20.33 ± 6.43 , $p<0.01$; LPON 49.67 ± 3.38 vs OL 12.33 ± 4.37 , $p<0.0025$; $n=3$). Insulin resistance was most prominent in LPON whilst OCT, like OL, showed insulin sensitivity. In the absence of insulin, glycogen breakdown and EGP were highest in OCT but diminished with the addition of insulin in dose dependent pattern whilst EGP and glycogen breakdown increase with insulin in LPON (Preconditioning effect on EGP: $p<0.0001$; and on glycogen breakdown: $p<0.0001$; $n=3$).

JC-1 study of LPON cells showed a decrease of mitochondrial membrane potential when compared with control. Preconditioning did not affect cellular viability in all groups ($p=0.23$)

Conclusion: In addition to the intracellular lipid accumulation, LPON preconditioned cells produced significant amount of ROS, insulin resistance and mitochondrial dysfunction. Despite the presence of lipid accumulation in other groups, insulin sensitivity was preserved thus suggesting other factors

including ROS may have an important role in the pathogenesis of hepatic insulin resistance. Therefore, we propose that LPON preconditioned cells would be a viable in vitro model to complement the currently available in vivo model of NAFLD.

Small, dense LDL in metabolic syndrome and fatty liver

T. Matsumoto, I. Sugino, S. Nakano, K. Iso, K. Kuboki, H. Ueshiba, G. Yoshino

Division of Diabetes, Metabolism and Endocrinology, Department of Internal Medicine, Toho University School of Medicine, Tokyo, Japan

Background and aims: Small, dense LDL is known as an atherogenic lipoprotein and is often associated with not only patients with coronary artery disease but also metabolic syndrome (MS) subjects. High frequency of small, dense LDL (sLDL) is found in hypertriglyceridemic subjects. Also, Fatty liver is also often associated with MS. Therefore, the present study was conducted to examine plasma sLDL-cholesterol (C) level in MS patients with and without fatty liver.

Materials and methods: Two-hundred and seventy-two MS patients and 154 non-MS healthy subjects were enrolled in this study. Fatty liver was estimated by echogram and classified according to the stage of fatty liver (none, mild, moderate and severe). Presence of MS was diagnosed according to the Japanese Guidelines for the Definition of Metabolic Syndrome. Plasma sLDL-C was measured by the 2-step (precipitation and homogeneous) assay system established by Hirano et al. Plasma triglyceride and choline-esterase (CE) were measured by a standard autoanalyzer method. A one-way analysis of variance (ANOVA) was used to compare mean values among groups. Stepwise multiple linear regression analysis were performed to evaluate the relationship between sLDL-C and other parameters. All values are expressed as mean \pm SD. A significant difference was defined as $p<0.05$.

Results: sLDL-C of MS group was higher than that of non-MS healthy group (38.5 ± 18.0 vs 20.6 ± 6.3 mg/dl, $p<0.001$). There was slight but significant correlation between sLDL-C and fatty liver stage ($r=0.37$, $p<0.05$). On the other hand, there was a significant relationship between sLDL-C and plasma triglyceride ($r=0.47$, $p<0.01$). This became stronger in fatty liver stage (mild, moderate and severe) group ($r=0.53$, $p<0.001$). Furthermore, there was highly significant correlation between sLDL-C/LDL-C ratio and plasma triglyceride ($r=0.70$, $p<0.0001$). There was a weak relationship between plasma CE and fatty liver stage ($r=0.42$, $p<0.05$). Although a weak relationship was found between CE and sLDL-C, we failed to show a significant correlation between CE and sLDL-C/LDL-C ratio. Multiple regression analysis revealed that the most powerful determinant of plasma sLDL-C was triglyceride, followed by fatty liver stage and CE ($p=0.0002$, 0.014 and 0.028 , respectively).

Conclusion: The liver in MS may produce triglyceride from excess circulating glucose, free fatty acid and triglyceride, which may result in development of fatty liver. In order to avoid further triglyceride deposition, fatty liver may secrete large, triglyceride-enriched VLDL particles, which is recognized as a precursor of sLDL particles. In the present study, we found a significant relationship between sLDL-C and plasma triglyceride. Furthermore, this became stronger in fatty liver group, indicating that fatty liver may produce triglyceride-rich VLDL, thereby contributing to an appearance of sLDL particles in plasma of MS patients with fatty liver. Since correlation coefficient between sLDL-C/LDL-C ratio and plasma triglyceride was higher than that between LDL-C and plasma triglyceride ($r=0.70$ vs $r=0.47$), plasma triglyceride metabolism may have more influence on LDL peak sizes (sLDL-C/LDL-C ratio) than absolute value of sLDL-C.

Fatty infiltration of pancreas influences beta cell function in Korean type 2 diabetic patients

J.-Y. Yoon, J.-O. Chung, D.-H. Cho, D.-J. Chung, M.-Y. Chung
Department of Endocrinology and Metabolism, Chonnam National University Medical School, South Korea, Gwangju, Republic of Korea

Background and aims: Type 2 diabetes is characterized by progressive β -cell dysfunction as well as insulin resistance. Chronic exposure of the islet cells to nonesterified fatty acids cause β -cell damage. Some experimental studies suggest that fatty infiltration of pancreas may result in a decrease in β -cell mass and dysfunction. The majority of patients with type 2 diabetes in Korea are nonobese and β -cell dysfunction may be one of predominant features. We

studied whether fatty infiltration of pancreas is associated with β -cell dysfunction in type 2 diabetic patients.

Materials and methods: Fifty-six type 2 diabetic patients (M: 30, F: 26; mean age: 51.86 ± 10.08 years) and forty control subjects (M: 28, F: 22; mean age: 55.37 ± 9.66 years) were recruited. All subjects underwent assessment for the degree of obesity and measured fasting plasma glucose, fasting immunoreactive insulin, HbA_{1c} , fasting plasma C-peptide, fasting free fatty acid and lipid profiles. The homeostasis model assessment of insulin resistance (HOMA-IR) and HOMA- β were calculated. The degree of fatty infiltration of pancreas was assessed by ultrasonography and the echogenicity of the pancreas was compared with that of hepatic parenchyma and divided three different categories (lower or similar, higher, and distinctly higher).

Results: Type 2 diabetic patients had higher fasting plasma glucose (156.97 ± 60.91 vs. 92.42 ± 10.23 mg/dL; $P < 0.001$), HbA_{1c} (8.21 ± 1.90 vs. $5.56 \pm 0.25\%$; $P < 0.001$) and triglyceride (193.42 ± 178.12 vs. $124.87 \pm 80.83\%$; $P = 0.013$) than control subjects, and they had lower logarithmic HOMA- β (3.98 ± 1.15 vs. 5.22 ± 0.55 ; $P = 0.016$) than control subjects. Patients with type 2 diabetes were positively associated with pancreatic fatty infiltration ($r = 0.331$, $P = 0.001$). In type 2 diabetic patients, the higher degree of fatty pancreas showed the lower levels of fasting plasma C-peptide (2.79 ± 1.56 vs. 2.33 ± 0.98 vs. 1.73 ± 0.71 ng/mL, $P < 0.05$). The degree of fatty pancreas negatively correlated with fasting C-peptide ($r = -0.364$, $P = 0.011$). Gender, duration of diabetes, BMI, fasting free fatty acid, HOMA-IR, and HOMA- β were not different according to the degree of fatty infiltration of pancreas. On a multivariate analysis, fasting plasma C-peptide concentration was independently associated with pancreatic fatty infiltration.

Conclusion: This study suggested that fatty infiltration of pancreas was associated with β -cell dysfunction in type 2 diabetic patients.

Background and aims: The reduced glucose-stimulated insulin secretion (GSIS) associated to intrauterine growth restriction is well established however, the mechanistic basis of the secretory defect in pancreatic islets of is poorly understood. Rodents fed a low-protein diet during neonatal life show an impaired GSIS and a chronically elevated levels of NEFA serum. Since numerous studies attribute to high NEFA level a deleterious role on the GSIS, we carry on a study with pancreatic islets of undernourished rats to evaluate the effects of palmitate on GSIS and glucose and lipid metabolism.

Materials and methods: Rats were submitted to a control (17% protein, C group) or a low-protein diet (6% protein, LP group) from fetal life to 40 days old. Islets from C and LP rats were cultured at 5.6 mmol glucose/l in the absence (C and LP islets) or presence of 0.6 mmol palmitate/BSA/l (CP and LPP islets) during 72 h.

Results: Express as medium \pm SEM. At 2.8 mmol glucose/l the insulin secretion by CP was higher than C islets ($p < 0.05$) and similar to CP islets stimulated by 16.7 mmol glucose/l. LP and LPP islets shown the lowest insulin secretion at 2.8 mm glucose/l. At 16.7 mmol glucose/l the GSIS were similar between LP and LPP but both were significantly lower than C and CP islets ($p < 0.05$) (in ng/islet.90 min, at 2.8 mm glucose/l: C 0.95 ± 0.1 , CP 2.51 ± 0.83 , LP 0.52 ± 0.1 , LPP 0.32 ± 0.05 and at 16.7 mmol glucose: C 5.35 ± 0.64 , CP 2.52 ± 0.3 , LP 2.33 ± 0.36 and LPP 2.24 ± 0.35). LP and LPP islets showed lower glucose oxidation rate than C and CP islets ($p < 0.05$) while NS difference was seen between C and CP islets (in pmol/islet/h, C 13.5 ± 0.8 , CP 12 ± 1.3 , LP 10.8 ± 1.0 , LPP 9.2 ± 0.8). At 16.7 mmol glucose/l, LP islets showed higher palmitate oxidation compared with C (in nmol/100 islets.2h, LP 1.17 ± 0.08 and C 0.67 ± 0.09 , $p < 0.05$), but NS difference was observed among LP, LPP and CP islets. The $1\text{-}^{14}\text{C}$ -palmitate incorporation in total lipids was higher in LP and LPP compared with C and CP islets (in pmol/islet.h, C 0.096 ± 0.001 , CP 0.093 ± 0.003 , LP 0.123 ± 0.007 and LPP 0.117 ± 0.003 , $p < 0.05$).

Conclusion: Protein undernutrition causes an early damage in glucose metabolism, which can account for the reduced GSIS. However, a higher lipid incorporation, allowing the fatty acids to be available for exocytosis of insulin, and a high lipid oxidation, could indicate an important role of the free fatty acids in the maintenance of the GSIS in LP islets.

Human pancreatic steatosis: does it exist?

I. Lingvay¹, L.S. Szczepaniak²

¹Endocrinology, ²Internal Medicine and Radiology, University of Texas Southwestern Medical Center, Dallas, United States

Background and aims: Pancreatic steatosis, defined as excessive accumulation of fat within pancreatic tissue, is proposed based on studies in animal models of obesity. It is hypothesized that accumulation of fat in the pancreas contributes to the pathogenesis of type 2 diabetes through beta-cell lipotoxicity. To evaluate this hypothesis in humans we studied pancreatic triglyceride content in vivo using magnetic resonance imaging and spectroscopy (MRS).

Materials and methods: Fifty nine subjects of both genders and within age range from 18 to 65 years were studied. Subjects were excluded if: 1) using medications known to alter glycemic or lipid status; or 2) sustained significant change in lifestyle (diet, exercise) or weight within 6 months prior to enrollment. Glycemic status was evaluated with a standard 75 g oral glucose tolerance test. Metabolic risk factors were assessed through a structured interview and anthropometric measurements. Pancreatic triglyceride content was measured by localized spectroscopy using a 1.5 Tesla clinical magnetic resonance system (Philips Medical Systems) with utilization of respiratory gating and cardiac triggering during data acquisition. Results are reported as fat to water ratio (f/w%).

Results: MRS measurements of pancreatic triglyceride content were highly reproducible. The reproducibility of the method was assessed in 30 subjects with a wide range of pancreatic triglyceride content, by repeating the measurements 1-30 days apart. The pancreatic triglyceride content in subjects with normal weight and no family history of diabetes was up to 2%. The intraclass correlation coefficient was 0.92 ($P < 0.001$, Figure 1). Subjects were divided into 3 groups based on glycemic status (Figure 2). The pancreatic triglyceride content was 3-fold higher in subjects with impaired glucose tolerance and diabetes, compared with the normal glucose tolerance group ($p = 0.01$ for both comparisons). No significant correlation between the pancreatic triglyceride content and body mass index or age was observed.

Conclusion: MRS technique is a quantitative, reproducible, and non-invasive evaluation method for human pancreatic steatosis. Pancreatic steatosis is present in subjects with impaired glucose tolerance and type 2 diabetes, suggesting a possible link between ectopic fat accumulation in the pancreas and beta-cell dysfunction leading to type 2 diabetes.

Figure 1. Reproducibility of the pancreatic MRS procedure. The intraclass correlation coefficient (ICC)=0.92 ($p < 0.001$)

Figure 2. Comparison of pancreatic fat content in subjects with different degrees of glucose tolerance: * $p=0.01$; NGT – Normal Glucose Tolerance; IGT – Impaired Glucose Tolerance; T2D – Type 2 Diabetes

LDL glycated by methylglyoxal to physiological extent in vitro has increased binding of proteoglycan without impairment of LDL receptor binding

M. Xue, P.J. Thornalley, N. Rabbani

Clinical Sciences Research Institute, University of Warwick, Coventry, United Kingdom

Background and aims: Glycation of low density lipoprotein (LDL) is increased in diabetes and may be linked to increased risk of atherosclerosis. The major protein of LDL, apolipoprotein B100 (apoB100), is susceptible to glycation mainly on lysine residues by glucose. Methylglyoxal (MG) is a physiological dicarbonyl glycation agent with a plasma concentration increasing disproportionately (3–5 fold) with hyperglycaemia in diabetes. Glycation by MG is directed to arginine residues and may target functionally important arginine residues in apoB100, conferring dysfunctional metabolism of LDL in diabetes. Functional activity of LDL glycated by MG in vitro has been studied previously but to high, supraphysiological extents. The aim of this study is to assess the functional activity of human LDL modified to minimal, physiological extent by MG in vitro – particularly for binding activity to the LDL receptor, proteoglycan and scavenger receptor.

Materials and methods: LDL was isolated from venous plasma, stabilised with aprotinin, collected from fasted healthy human subjects by density gradient ultracentrifugation using Iodixanol and washed with argon-purged water by ultrafiltration over a 100 kDa microspin filter. LDL was glycated minimally by MG by incubation of LDL (8.4 mg/ml) with 100 μ M MG in phosphate buffered saline-0.6 mM EDTA at 37 °C for 24 h. The content of advanced glycation endproduct (AGE) residues was analysed after de-lipidation and exhaustive enzymatic hydrolysis by stable isotope dilution analysis with LC-MS/MS. LDL and MGmin-LDL were modified with iodine-125 using iodogen reagent. Cultures of human hepatocyte-like HepG2 cells and human macrophage-like THP-1 cells (differentiated with phorbol ester) were prepared with 24 h pre-incubation with lipoprotein deficient serum. Specific and non-specific binding of LDL and MGmin-LDL, competitive binding between these two ligands and with fucoidan, and proteoglycan binding (as heparin displaceable cell binding of LDL ligands) was characterised.

Results: LDL glycated minimally by MG had increased content of MG-derived AGE residues (mol/mol apoB100): the major AGE was hydroimidazolone MG-H1 – MGmin-LDL 4.08 ± 0.22 vs LDL 0.15 ± 0.01 . Incubation of HepG2 cells with MGmin-LDL showed similar binding kinetics and affinity to unmodified LDL for the LDL receptor and similar rates of catabolism. Binding of MGmin-LDL and unmodified LDL were competitive. Binding of MGmin-LDL to human THP-1-derived macrophages was low, competitive with LDL and non-inhibitable with the scavenger receptor ligand fucoidan. Binding of MGmin-LDL to cellular proteoglycan was increased over 2-fold compared to LDL.

Conclusion: These results suggest that the likely physiological effect of increased modification of LDL by MG in diabetes in vivo is increased proteoglycan binding and not increased binding of scavenger receptors directly. Consequently increased residence of MG modified LDL in the extracellular milieu is likely to increase its risk of oxidation and atherogenicity in vivo.

Different fatty acids inhibit apoB100 secretion by both common and unique molecular pathways

T. Ota¹, C. Gayet², H.N. Ginsberg²

¹Frontier Science Organization, Kanazawa University, Kanazawa, Ishikawa, Japan, ²Department of Medicine, Columbia University, New York, United States

Background and aims: Increased secretion of apolipoprotein B (apoB)-containing lipoproteins, particularly VLDL, and hepatic steatosis are characteristic concomitants of insulin resistance, the metabolic syndrome, and type 2 diabetes. Endoplasmic reticulum (ER) stress plays a central role in the devel-

opment of hepatic insulin resistance and steatosis. Recently, we have shown that oleic acid (OA)-induced ER stress causes selective inhibition of apoB100 secretion and steatosis (*J Clin Invest* 118:316,2008). However, it is not known if different fatty acids (FAs) induce ER stress or inhibit apoB.

Materials and methods: We compared the effects of palmitic acid (PA) and docosahexanoic acid (DHA) to those of OA on ER stress and secretion of apoB100 by incubating McA-RH7777 (McA) cultured liver cells with PA, DHA or OA and by infusing PA, DHA or OA into C57BL/6J mice.

Results: [*In vitro* study] Incubation of McA cells with OA, PA, or DHA (0–1.2 mM) for 16 hrs resulted in a dose dependent increases in cell TG. PA led to less accumulation of cell TG vs. OA or DHA (PA 86.5±17.9, OA 125.8±18.2, DHA 128.4±5.4 µg/mg cell protein at 0.4mM, $P<0.05$, PA vs OA or DHA). 0.4 mM OA for 16 hrs stimulated apoB100 secretion, this effect was lost at 0.8 mM OA and 1.2 mM OA actually inhibited apoB100 secretion. 0.4mM PA for 16 hrs did not stimulate apoB100 secretion and 0.8mM PA actually inhibited apoB100 secretion. 0.4mM DHA for 16hrs inhibited apoB100 secretion. None of these doses of FA affected apoB48, apoA-I, or albumin secretion. Incubation of McA cells with OA (0.2–1.2mM) for 3–16hrs caused increasing ER stress as evaluated by GRP78 and phosphorylation of eIF2α. PA increased GRP78 and phospho-eIF2α more than OA at all doses and all time points ($P<0.05$ vs OA). However, DHA did not stimulate ER stress responses at any doses and durations. Ceramide levels in McA cells were significantly increased with PA compared with control incubations (2.9-fold at 0.8mM, $P<0.05$) but were unchanged with OA or DHA. Inhibition of ceramide synthesis with myriocin reduced PA-induced ER stress to levels similar to OA-induced ER stress. Myriocin prevented PA-induced inhibition of apoB100 secretion. There was no effect of myriocin on inhibition of apoB100 secretion by either OA or DHA treatment. PA-induced ER stress responses were further enhanced by knockdown of stearoyl-CoA desaturase 1 (SCD1) by siRNA, while OA-induced ER stress was not affected by knockdown of SCD1. Knockdown of SCD1 enhanced PA-mediated inhibition of apoB100 secretion but had no effect on OA-mediated reductions of apoB100 secretion. Either vitamin E or desferoxamine prevented PA- or DHA- but not OA-associated inhibition of apoB100 secretion. [*In vivo* study] Intravenous infusions of either 6 mM OA or PA into male C57BL/6J mice for 6 hrs raised plasma FA levels 3–4 fold vs. saline and induced phosphorylation of eIF2α and increased GRP78 protein in the liver: infusion with PA caused more ER stress than OA. Infusion of OA, but not PA, significantly increased the secretion of apoB100 compared with saline. Infusion of 6mM DHA for 6hrs did not increase apoB100 secretion and did not induce ER stress.

Conclusion: Each FA, when administered for prolonged periods of time, can, at certain doses, inhibit apoB secretion in vitro and in vivo. The effects of OA and PA parallel their ability to induce ER stress; PA is more potent and acts, in part, via ceramide. DHA is the most potent inhibitor but this is independent of ER stress. It is not clear how OA causes ER stress or inhibits apoB secretion.

VLDL and cholesterol remnant levels following 3 consecutive meals are associated with liver fat in men with type 2 diabetes and men with the metabolic syndrome

M.E. Tushuizen¹, P.J.W. Pouwels², S. Bontemps¹, C. Rustemeijer³, N. Matikainen⁴, M.-R. Taskinen⁴, R.J. Heine¹, M. Diamant¹; ¹Endocrinology / Diabetes Centre, VU University Medical Centre, Amsterdam, Netherlands, ²Physics & Medical Technology, VU University Medical Centre, Amsterdam, Netherlands, ³Internal Medicine, Hospital Amstelland, Amstelveen, Netherlands, ⁴Department of Medicine, University of Helsinki, Helsinki, Finland

Background and aims: Abnormal postprandial metabolism, which is exaggerated and prolonged in insulin resistant states and type 2 diabetes (T2DM), is associated with increased cardiovascular disease (CVD) risk. Liver fat accumulation is related to components of the metabolic syndrome (MetS) and T2DM. We hypothesised that the severity of postprandial dyslipidaemic derangements during a 24-h period in subjects with T2DM and those with the MetS may be related to hepatic fat content.

Materials and methods: We monitored 24-h profiles of plasma lipids in 14 T2DM, 14 MetS and 14 healthy age-matched males, following a standardised high-fat mixed breakfast (9.00 am), lunch (1.00 pm) and dinner (5.00 pm), mimicking the real-life situation. Blood samples were collected before and at t=2, 4, 6, 8, 12, 16, 20 and 24h following breakfast. Liver fat was measured in the fasting state by localized proton MR-spectroscopy.

Results: Patients (mean±SD, age 55±4.2 yrs; HbA1c 7.2±1.1%) versus MetS subjects did not differ with respect to age, BMI, waist, blood pressure, triglycerides and HDL-cholesterol. 24h-AUC of triglycerides, apoB-100, and cholesterol remnants differed significantly between groups (all $P<0.05$), whereas AUC apoB-48 did not differ between T2DM and MetS males. Liver fat content was higher in T2DM compared to MetS and controls (median 17.8 (IQR 7.6–31.7)%, 7.6 (2.9–10.2)% and 3.9 (2.1–7.0)%, respectively, $P=0.001$). Liver fat content was associated with postprandial 24-h AUC triglycerides, apoB-100 and cholesterol rich remnants ($r=0.50$, $P=0.001$, $r=0.37$, $P=0.017$; $r=0.41$, $P<0.01$, respectively), but not with 24-h AUC apoB-48 particles ($r=0.14$, $P=0.38$).

Conclusion: Hepatic fat content was associated with postprandial dyslipidaemic responses in subjects with T2DM and those with the MetS. These findings suggest that targeting hepatic fat accumulation in these high-risk subjects, may favourably affect postprandial metabolic derangements and ultimately reduce CVD risk.

Measurement of postprandial triacylglycerol kinetics in both endogenous and exogenous lipoproteins using a novel immunoaffinity chromatography method

F. Sun¹, M. Stolinski¹, F. Shojaee-Moradie¹, R. Hovorka², A.M. Umpleby¹; ¹Diabetes and Endocrinology, University of Surrey, Guildford, ²Diabetes Modelling, University of Cambridge, United Kingdom

Background and aims: Abnormally elevated postprandial triacylglycerols (TAG) are a feature of metabolic syndrome and type 2 diabetes and are predictive of an increased risk of cardiovascular disease. The cause is poorly understood due to the lack of selective and sensitive methods to accurately quantify the kinetics of postprandial exogenous (chylomicrons) and endogenous (VLDL) TAG-rich lipoproteins. In this study postprandial TAG kinetics were measured in healthy subjects using a novel method to separate exogenous and endogenous lipoproteins.

Materials and methods: Six healthy volunteers (2M,4F), age 36.8±3.9yr, BMI 24.4±1.1kg/m² (mean±SEM) were studied on 2 occasions in random order 1] after an overnight fast and 2] during a continuous feeding protocol with 6 liquid meals (486kcal, 11% carbohydrate, 88% fat) every 2h. In both studies a bolus injection of [³H]₃-glycerol was administered to label TAG. Chylomicrons and VLDL1 ($S_{\text{f}}>60$) and small chylomicrons and VLDL2 ($S_{\text{f}}20-60$) were separated by sequential flotation ultracentrifugation. Endogenous and exogenous particles were isolated using a novel immunoaffinity method (Protein G Sepharose coupled to three monoclonal antibodies specific for apoB100- 4G3, 5E11 and Bsoll6) which allowed complete separation of apoB100 and apoB48 containing lipoproteins. TAG was extracted from the purified particles and glycerol enrichment measured by gas chromatography mass spectrometry. TAG fractional catabolic rate (FCR) was calculated using a mathematical model of the exogenous and endogenous TAG pathways.

Results: Plasma TAG concentration was 0.88±0.11mmol/L in the fasted study and 1.47±0.20mmol/L in the fed study. There was no difference in VLDL1 (V1) and VLDL2 (V2) TAG FCR between the fasted study (V1, 43.8±15.3 pools/day; V2, 26.8±4.4 pools/day) and fed study (V1, 52.2±14.1 pools/day; V2, 20.4±2.1 pools/day). In the fed study chylomicron TAG FCR (48.0±18.5 pools/day) was not different from VLDL1 FCR but small chylomicron TAG FCR (12.7±1.9 pools/day) was significantly lower than VLDL2 FCR ($p=0.022$).

Conclusion: Feeding did not change the clearance rate of VLDL1 and VLDL2 in healthy subjects. Although chylomicrons are cleared at the same rate as VLDL1 the clearance of small chylomicrons of the same density as VLDL2 is lower than VLDL2.

Nuclear magnetic resonance lipoprotein subfraction profile and early carotid atherosclerosis: the GOCADAN study

M. Masulli¹, L. Patti¹, G. Riccardi¹, O. Vaccaro¹, G. Annuzzi¹, S. Ebbesson², H. Wang³, B.V. Howard³, A.A. Rivellese¹

¹Department of Clinical and Experimental Medicine, "Federico II"

University of Naples, Naples, Italy, ²Norton Sound Health Corporation,

³MedStar Research Institute, United States

Background and aims: The relationship between lipoprotein subfractions and atherosclerosis is not often explored because laboratory measurement of lipoproteins is laborious and time-consuming. Proton Nuclear Magnetic Resonance (NMR) spectroscopy provides an advanced, rapid, and cost-effective method to measure directly the lipoprotein particle concentration, distribution, and size. The aim of this study was to evaluate the relationships between lipoprotein subfractions and early subclinical atherosclerosis in carotid vessels in a population based sample of Alaska Eskimos, characterized by a high cardiovascular risk.

Materials and methods: Seven hundred and sixty non diabetic Alaska Eskimos (age ≥ 35 yrs) were included in this analysis. Early atherosclerosis was investigated by ultrasound measurement of Intimal Media Thickness (IMT). Plaque was defined as the presence of focal protrusion of the vessel at least 50% greater than surrounding wall; plaque score was defined as the number of segments (0-7) of each carotid artery containing plaque. Subclasses (large, intermediate and small) of plasma VLDL, LDL and HDL were characterized for concentration and size by proton NMR spectroscopy, and related to tertiles of IMT (tertile 1 = 0.335-0.570 mm; tertile 2 = 0.575-0.675 mm; tertile 3 = 0.680-1.100 mm) and plaque score (group 1 = plaque score 0; group 2 = plaque score 1; group 3 = plaque score 2-7).

Results: Higher IMT values were associated with a) lower concentrations of large VLDL particles ($p < 0.05$), independently of other confounders, including plasma LDL cholesterol concentration, and b) higher concentrations of total ($p < 0.05$), intermediate ($p < 0.05$) and small ($p < 0.05$) LDL particles, independently of other confounders, including plasma triglyceride concentrations. Higher plaque scores were associated with (a) lower concentrations of either large or small VLDL particles ($p < 0.01$ for both), independently of other confounders, including LDL cholesterol, and (b) higher total ($p < 0.01$), large ($p < 0.02$) and intermediate ($p < 0.05$) LDL particles, independently of other confounders, including plasma triglycerides. Neither IMT nor plaque score were associated with HDL particle concentration and size.

Conclusion: In a population at high cardiovascular risk, NMR lipoprotein particle profile discriminates sub-clinical atherosclerosis in carotid arteries. The data in our study suggest an independent inverse effect of large VLDL particles and an independent direct effect of LDL particles on several stages of atherosclerosis.

Low HDL-cholesterol: prevalence and associated risk factors in a large French population

P.J. Lecomte¹, M. Rouvre¹, S. Vol², G. Gusto², O. Lantieri³, J. Tichet³

¹UCM, CHRU Bretonneau, Tours, ²Biostatistics, IRSA, La Riche, ³Directory, IRSA, La Riche, France

Background and aims: Besides LDL-cholesterol levels, HDL-cholesterol (HDLc) is routinely measured to evaluate cardio-vascular risk. However, only few studies have evaluated the prevalence of low HDLc levels in the general population and none in France. Our aims were i/ to estimate the prevalence of low HDLc levels in a French population using the definition of the NCEP-ATP III [$< 40/50$ mg/dL (men/women)] and ii/ to examine in this population the level of each component of the metabolic syndrome (NCEP-ATP III), other biological parameters and lifestyle conditions in subjects with regard to HDLc levels.

Materials and methods: The subjects were 21,590 men and 26,263 women aged 16 to 79 participating to a free routine medical and biological check-up. All participants completed a self-questionnaire about their socioeconomic and family status, personal and familial medical history, lifestyle behaviours (physical activity, smoking, dietary habits). Deprivation status was defined by EPICES score from 11 weighted questions related to material and social deprivation. The fatty liver index (FLI), an algorithm based on BMI, waist circumference, triglycerides and GGT estimated the prediction of fatty liver. Blood samples were collected after an overnight fast. Variables of interest were

studied in 3 groups defined by age and gender-specific percentiles classes: $\leq 5^{\text{th}}$ (HDL_s), 7 median percentiles (HDL_m) and $> 95^{\text{th}}$ (HDL₉₅). Data were analyzed by gender and adjustments on alcohol consumption and smoking habits were performed by logistic regression or GLM ANOVA. Gender-specific logistic regression models were built to select variables associated to HDL_s. The data were analysed using NCSS (Number Cruncher Statistical Systems) 2000.

Results: The prevalence of low HDLc levels was 12.1% in men and 28.1% in women and these figures decreased with age. A low percentage of subjects (9.1% of men and 5.6% of women) were treated with lipid-lowering drugs. The frequency of the metabolic syndrome decreased drastically when HDLc increased (HDL_s/HDL_m/HDL₉₅): 44%/7%/2% ($p < 0.00001$) in men and 42%/4%/1% ($p < 0.00001$) in women as for high FLI (FLI ≥ 60): 38%/24%/10% ($p < 0.00001$) in men and 31%/8%/3% ($p < 0.00001$) in women. When HDLc increased, sedentarity, current smoking and deprivation decreased ($p < 0.00001$) but energy intake (men only) and alcohol consumption increased ($p < 0.00001$). When data were adjusted on smoking and alcohol consumption, all differences were still significant, excepted energy intake in men. For both genders, the same variables were associated with HDL_s, a positive contribution for waist circumference, smoking, triglycerides, leucocytes, diabetes and a negative contribution for alcohol consumption, family history of cholesterol, cholesterol level. Smoking and abdominal obesity were the preponderant variables.

Conclusion: The prevalence of low HDLc levels in this French population was similar to that observed in Japanese but lower than that found in American. An HDLc level less than the age-gender specific 5th percentile was associated with cardiovascular risk factors (sedentary, smoking habits, high triglyceride levels, diabetes, obesity), metabolic syndrome, fatty liver and with deprivation. Most of these parameters should be abated by an adequate prevention policy and first of all, on smoking and abdominal obesity.

Intramyocellular triglyceride fatty acid composition implicates on muscle triglyceride turnover, insulin action and glycaemic control in man

S.B. Haugaard¹, S. Madsbad², H. Mu³, A. Vaag⁴

¹Clinical Research Centre, Copenhagen University Hospital, Hvidovre,

²Dept. of Endocrinology, Copenhagen University Hospital, Hvidovre,

³Dept. of Systems Biology, Technical University of Denmark, Lyngby, ⁴Steno Diabetes Centre, Copenhagen University, Gentofte, Denmark

Background and aims: In-vitro studies have shown that the concentration of palmitic acid (C16:0) in intramyocellular triglyceride (IMTG) correlates with insulin resistance. In the present study we investigated the fatty acid (FA) composition of IMTG and its relation to IMTG content, sex, and insulin resistance in obese and lean sedentary subjects with and without type 2 diabetes (T2DM), in whom we have reported previously that obese women possess twice as much IMTG as matched obese men and lean women.

Materials and methods: FA composition of IMTG was determined by gas-liquid-chromatography in skeletal muscle biopsies harvested from sedentary subjects, 34 women (27 obese, 7 T2DM) and 25 men (20 obese, 6 T2DM). Insulin resistance was assessed by homeostasis model assessment insulin resistance index (HOMA-IR).

Results: In all subjects (n=59) total saturated FA correlated inversely and total monounsaturated FA correlated positively with IMTG content. In gender specific analyses these associations were found in women only ($r=-0.54$, $P<0.002$, $r=0.43$, $P=0.01$, respectively) and were also significant in the group of obese women. Obese women exhibited lower total saturated FA and palmitic acid than obese men (13% and 9%, respectively, $P<0.001$), which remained significantly reduced after correction for IMTG. Total polyunsaturated FA and long-chain-polyunsaturated FA did not correlate with IMTG. Palmitic acid correlated with insulin resistance (HOMA-IR, $r=0.33$, $P=0.014$) and impaired glycaemic control (fasting plasma glucose, $r=0.41$, $P<0.002$) after correction for gender and IMTG content.

Conclusion: Excess IMTG content associates to decreased IMTG saturated FA, which could be secondary to a low turnover rate of excess IMTG, and, thus, longer duration of exposure of IMTG to enzymatic activity by in situ desaturases. IMTG FA composition implicates on insulin sensitivity and glycaemic control independent of sex and IMTG content.

Correlation between the level of glycaemic control (fasting glucose) and intramyocellular triglyceride (IMTG) palmitic acid in men (filled triangles) and in women (open circles). P-value and correlation coefficient are given. the correlation remained significant after correction for sex and IMTG content ($r=0.41$, $P<0.002$)

Smoking cessation increases insulin action, but does not change intramuscular triglyceride concentration or turnover

B.C. Bergman, L. Perreault, M.C. Playdon, A.M. Samek, R.H. Eckel
Endocrinology, University of Colorado Health Sciences Ctr, Denver, United States

Background and aims: Smoking has been shown to decrease insulin action and increase risk of type 2 diabetes in humans. Mechanisms responsible for smoking-induced insulin resistance are unclear. Smoking has been shown to increase adipocyte lipolysis, FFA concentration, and skeletal muscle LPL, but not change whole body fat oxidation suggesting muscle lipid accumulation in this group. We hypothesized smokers (SM) would have increased intramuscular triglyceride (IMTG) and diglyceride (DAG) concentration, but decreased IMTG fractional synthesis rate compared to non-smokers (CON) which would return to control levels after smoking cessation.

Materials and methods: CON (n=12, 20.4±0.6 yrs, 22.1±0.4 kg/m², 19.7±2% fat, 0 cig/day) and SM (n=10, 21.4±0.7 yrs, 22.3±0.5 kg/m², 17.9±2% fat, 17±1 cig/day) were studied in the fasted state after 3 days of a standardized diet, before and after a smoking cessation program. [U-13C]palmitate was infused for 4 hours after which a muscle biopsy was taken, and an IVGTT performed. Muscle biopsies were dissected free of visible fat, lyophilized, lipid fractions were isolated using solid phase extraction, and analyzed by GC/MS for concentration and GC/C/IRMS for enrichment. Western blots were performed using standard techniques.

Results: SM were less insulin sensitive compared to CON (Si: 5.5±0.5 CON vs 3.8±0.5 SM mU/L/min, $p=0.03$), which did not change in CON, but significantly increased in SM after smoking cessation (4.3±0.4 SM mU/L/min, $p=0.02$). We found no significant differences in basal IMTG (19.8±2.3 CON vs 24.3±2.7 SM ug/mg dry wt) or DAG (0.34±0.02 CON vs 0.34±0.02 SM ug/mg dry wt) concentration, or IMTG turnover (0.68±0.08 CON vs 0.61±0.10 SM %/hr) before or after smoking cessation. IMTG and DAG composition was more saturated in SM (IMTG: 31.8±1.0 CON vs 35.0±1.1 SM %, $p=0.04$) (DAG: 53.3±1.7 CON vs 59.5±1.9 SM %, $p=0.02$), which did not significantly change after smoking cessation. We found increased IRS-1 ser636 phosphorylation in SM compared to CON (0.84±0.09 CON vs 1.27±0.08 SM AU, $p=0.003$) which significantly decreased after smoking cessation (1.02±0.1 CON vs 0.96±0.08 SM AU, $p=0.04$). Significant positive relationships were found between IMTG and DAG saturation and IRS-1 ser636 phosphorylation (IMTG: $R^2=0.40$, $p=0.005$, DAG: $R^2=0.25$, $p=0.04$).

Conclusion: These data suggest: 1) insulin action is impaired in smokers, but increases after smoking cessation 2) differences in IMTG concentration and turnover are not related to alterations in insulin action in smokers compared to non-smokers, but may relate to 3) higher IMTG and DAG saturation in smokers 4) Basal inhibition of IRS-1 appears related to the saturation of IMTG and DAG, however, insulin signaling may be restored after smoking cessation independent of changes in IMTG and DAG saturation.

Elevated skeletal muscle TIP47 expression in obesity and type 2 diabetes

S. Bajpeyi, C. Moro, S.R. Smith
Endocrinology, Pennington Biomedical Research Center, Baton Rouge, United States

Background and aims: Proteins of the PAT family (Perilipin, Adipophilin (ADRP), Tail-interacting protein of 47kDa (TIP47), OXPAT, and S3-12), play an important role in the regulation of lipid storage/mobilization in many tissues [e.g. adipose tissue]. Recent data from our laboratory provide evidence that the dysregulation of intramyocellular lipid metabolism leads to insulin resistance; we refer to this as intramyocellular lipotoxicity. PAT proteins lie at the interface of the lipid droplet and the cytosol and therefore serve as logical candidates in the regulation of skeletal muscle intramyocellular lipid metabolism.

Materials and methods: We measured PAT protein gene expression by RT-qPCR in vastus lateralis samples from lean (BMI 22.9±1.0; n=8), obese (BMI 32.0±0.8; n=8), and type 2 diabetic subjects (BMI 38.6±2.8; n=8). Using cultured myotubes we also determined the localization of selected PAT proteins in relationship to intramyocellular lipids by confocal imaging.

Results: ADRP and TIP47 were highly expressed in human muscle tissue while S3-12 and perilipin were not detected and OXPAT was at the lower

limit of detection. TIP47 expression was increased in obese (2 fold) and type 2 diabetic (2.3 fold) subjects compared to lean ($p < 0.05$) while ADRP and OX-PAT were not different across the three groups. ADRP and TIP47 co-localized to lipid droplets in cultured myotubes.

Conclusion: The present data show for the first time that ADRP and TIP47 are highly expressed in human skeletal muscle and colocalize with lipid droplets. TIP47 gene expression is increased in obesity and T2DM, suggesting an important role in skeletal muscle lipid metabolism.

Utilization of intramyocellular lipids for oxidation in human skeletal muscle cells from lean and type 2 diabetic subjects

E. Corpeleijn¹, N.P. Hessvik², E.E. Blaak¹, G.H. Thoresen², M. Gaster³, A.C. Rustan²

¹Department of Human Biology, NUTRIM, Maastricht University, Netherlands, ²Department of Pharmaceutical Biosciences, School of Pharmacy, University of Oslo, Norway, ³KMEB, Department of Endocrinology, Odense University Hospital, Denmark

Background and aims: It is generally accepted that insulin resistance and type 2 diabetes (T2D) are associated with lipid accumulation in skeletal muscle. How this lipid storage and oxidation are regulated is less well known. Therefore, the regulation of lipid oxidation from intracellular and extracellular sources was studied in human myotubes established from healthy lean ($n = 8$) and obese T2D subjects ($n = 9$).

Material and methods: Myotubes were cultured from satellite cells, differentiated and pretreated with 100 μ M oleic acid (OA) for 2 days to upregulate lipid metabolism. The cells were treated with enriched 14 C-OA either during the pretreatment period or during the acute experiment, to distinguish between 14 CO₂-production from intracellular or extracellular lipid sources. OA oxidation was measured by trapping the production of 14 CO₂ during 4 hours of incubation. In this acute 4h-experiment, the cells were exposed to one of four conditions of variable glucose and OA availability: gf (0.1 mM glucose/5 μ M OA), gF (0.1 mM glucose/100 μ M OA), Gf (5.0 mM glucose/5 μ M OA), or GF (5.0 mM glucose/100 μ M OA). Group and treatment effects were analyzed with linear mixed model (SPSS 11.5).

Results: The T2D subjects were characterized *in vivo* by insulin resistance and metabolic inflexibility, i.e. an impaired switch from fat oxidation to carbohydrate oxidation after insulin-stimulation. The utilization of intracellular OA for oxidation (ICL_{ox}) was significantly and consistently reduced in myotubes from T2D subjects (gf: ICL_{ox} (lean) = 4.71 ± 1.0 nmol/mg protein, ICL_{ox} (T2D) = 3.36 ± 0.67 ; gF: ICL_{ox} (lean) = 3.64 ± 1.0 nmol/mg protein, ICL_{ox} (T2D) = 1.93 ± 0.46 ; Gf: ICL_{ox} (lean) = 4.50 ± 1.2 nmol/mg protein, ICL_{ox} (T2D) = 2.49 ± 0.45 ; GF: ICL_{ox} (lean) = 2.92 ± 0.8 nmol/mg protein, ICL_{ox} (T2D) = 1.38 ± 0.30 . Group effect $P = 0.002$). Also total OA oxidation was reduced (group effect $P = 0.003$). The *in vivo* fasting respiratory quotient (RQ) was consistently inversely associated with outcomes for *in vitro* lipid oxidation, including the oxidation of intracellular lipids under all conditions and the oxidation of extracellular lipids under increased (100 μ M) OA conditions (Spearman $r_{ALL} > -0.59$, $P_{ALL} < 0.05$). Myotubes established from T2D subjects showed an impaired adaptability of total OA oxidation ($P < 0.001$), which is the capacity to increase lipid oxidation in response to an increased OA availability. These myotubes also tended to show an increased suppressibility (gf vs Gf, $P = 0.036$, gF vs GF, $P = 0.136$), which is the sensitivity of the myocyte to the suppressive effect of glucose on lipid oxidation.

Conclusion: A low fasting fat oxidation *in vivo*, as exemplified by a high RQ, was reflected by a low lipid oxidation *in vitro*, suggesting that the characteristics of the *in vivo* phenotype are retained *in vitro* either by genetic, epigenetic or other unknown mechanisms. An impaired capacity to oxidize intracellular lipids, an impaired capacity to increase lipid oxidation and an increased sensitivity for the suppressive effect of glucose may contribute to the *in vivo* phenotype, characterized by insulin resistance and metabolic inflexibility, and may play a primary role in the development of insulin resistance and type 2 diabetes.

Dysfunction of skeletal muscle lipolysis contributes to lipotoxicity and insulin resistance in obesity and type 2 diabetes

C. Moro¹, S. Bajpeyi¹, A. Mairal², G. Liebisch³, S. Thomas¹, G. Schmitz³, D. Langin², S.R. Smith¹

¹Molecular and Experimental Endocrinology, Pennington Biomedical Research Center, Baton Rouge, United States, ²Obesity Research Laboratory, INSERM U858, Institute of Molecular Medicine, Toulouse, France, ³Institute of Clinical Chemistry, University of Regensburg, Germany

Background and aims: Insulin resistance is associated with elevated skeletal muscle lipid deposition. We hypothesized that a dysfunction of skeletal muscle lipolysis could produce *per se* lipotoxicity and insulin resistance.

Materials and methods: We measured triglyceride and diglyceride hydrolase activities, along with triglyceride, diglyceride and ceramide content in human *vastus lateralis* samples of lean ($n=10$), obese ($n=16$) and type 2 diabetes mellitus (T2DM) ($n=10$) subjects. We then investigated *in vitro* in cultured myotubes the relationship between dysfunction of lipolysis and insulin action.

Results: Across subjects, we found that the ratio diglyceride-to-triglyceride hydrolase activity was a determinant of insulin sensitivity and lipotoxicity. This ratio was reduced in obese and T2DM subjects (25%, $p < 0.01$), in line with elevated ATGL and reduced HSL protein expression in obese and T2DM subjects. Intramyocellular triglyceride, diglyceride and ceramide were elevated in T2DM subjects, while only diglyceride levels were increased in obese compared to lean subjects. We also show that adipose triglyceride lipase (ATGL) is an important determinant of skeletal muscle triglyceride hydrolase activity and requires CGI-58 for full enzymatic activation. In cultured myotubes, overexpression of ATGL or its coactivator CGI-58 elevated diglyceride and ceramide content ($p < 0.05$), and inhibited insulin-stimulated glycogen synthesis and Ser473-Akt phosphorylation ($p < 0.001$).

Conclusion: Altogether, these data indicate for the first time an imbalance between ATGL and HSL in skeletal muscle that leads to incomplete triglyceride hydrolysis, and highlight a new mechanism by which defective lipolysis produces intramyocellular lipotoxicity and insulin resistance.

Effects of trimetazidine on myocardial glucose and fatty acid metabolism and cardiac function in non-diabetic obese humans

M. Bucci¹, K. Nägren¹, J. Pärkkä¹, R. Maggio¹, R. Borra¹, H. Tuunanen¹, M. Taittonen¹, T. Viljanen¹, S. Rigazio¹, M. Komu¹, R. Parkkola², J. Knuuti¹, P. Nuutila¹, P. Iozzo^{1,3}

¹Turku Pet Centre, Turku Central University Hospital, Finland, ²Department of Radiology, Turku Central University Hospital, Finland, ³Institute of Clinical Physiology, CNR National Research Council, Pisa, Italy

Background and aims: Trimetazidine is a metabolic agent with anti-ischemic properties used in clinical practice in patients with coronary artery diseases. Only few studies have focused on its mechanism of action *in vivo*, in humans. The aim of the current study was to non-invasively investigate the effects of trimetazidine treatment on the heart lipid and glucose metabolism in obese non-diabetic subjects, with no cardiac complications.

Materials and methods: Positron Emission Tomography with 18 F-fluorodeoxyglucose and 11 C-palmitate was used to quantify the metabolism of glucose and fatty acids, respectively. Myocardial fatty acid oxidative (FAO) metabolism was determined by bi-exponential fitting of the heart 11 C-palmitate wash-out curve. Magnetic Resonance Spectroscopy and Imaging were used to quantify the content of lipids in the heart and assess cardiac function and dimensions.

Results: Eight obese subjects (BMI, 31.5 ± 3.4 kg/m², range 27–38) were studied in fasting conditions. The basal hemodynamic and Left Ventricular (LV) parameters in the study group were: Ejection Fraction (EF, %) 66 ± 6 , Cardiac Output (CO, l/min) 6.2 ± 0.6 , LV mass (g) 95.0 ± 25.1 , Stroke Volume (SV, ml) 98.1 ± 11.8 , Heart Rate (HR, bpm) 64 ± 9 , LV work (mmHg*l*min⁻¹) 655.3 ± 135.2 , Peripheral Vascular Resistance (mmHg*min*ml⁻¹) 16.9 ± 2.9 . Basal metabolic parameters, as assessed by PET, were: LV glucose uptake (LV GU, mol(glucose)*min⁻¹) 3.4 ± 4.6 , LV fatty acid uptake (LV FAU, mol(palmitate)*min⁻¹) 10.0 ± 3.2 . Heart lipid content (%) was 0.8 ± 0.7 and LV lipid content (g) was 0.8 ± 0.6 . After one month of trimetazidine treatment (35 mg q.i.d.), EF was increased by $6 \pm 4\%$ ($p < 0.01$), SV was increased by $9.0 \pm 6.4\%$ ($p < 0.01$). The heart lipid % content did not change significantly.

The late wash-out of fatty acids from the myocardium, accounting for a significant proportion of oxidized palmitate, decreased on average by 36.3% ($p=0.05$ range: from -74% to +0.1%). The BMI was positively associated with LV work, Rate Pressure Product ($r>0.85$, $p<0.01$) and FAO ($r=0.71$, $p<0.05$) and negatively related with SV ($r=-0.70$, $p=0.05$). In turn, LV FAU and FAO were positively correlated with the LV work ($r=0.85$ and 0.83 , respectively, $p\leq 0.01$). Changes in FAO positively correlated with changes in systemic triglycerides ($r=0.77$, $p=0.025$). LV GU and the SV were positively related ($r=0.76$, $p=0.029$). Changes in LV GU and CO after treatment were negatively associated ($r=-0.80$, $p=0.017$).

Conclusion: In conclusion, the degree of obesity is associated with higher cardiac work and FAO, and reduced SV. Trimetazidine improves LV function by reducing FAO in obese subjects.

Expression of a malonyl-CoA-insensitive CPT1 to decrease palmitate-induced apoptosis in muscle cells

C. Hénique, G. Fumey, J. Girard, C. Prip-Buus, I. Cohen

Endocrinology, Metabolism and Cancer, Cochin Institute - INSERM U567 - CNRS UMR 8104, Paris, France

Background and aims: Obesity is a prevalent metabolic disorder that is a major risk for other alterations including insulin resistance and type 2 diabetes. While fatty acids (FA) are vital metabolic substrates for many cellular processes, lipid overload leads to inappropriate FA accumulation in non-adipose tissues such as skeletal muscle, which is responsible for cell dysfunctions and death (lipoapoptosis). Both chronic exposure of skeletal muscle to elevated concentrations of lipids and altered long-chain fatty acid (LCFA) mitochondrial oxidation contribute to the muscular dysfunctions through accumulation of deleterious FA metabolites. LCFA are oxidized in the mitochondrial matrix and their entry involves the carnitine palmitoyltransferase (CPT) system. Because of its inhibition by malonyl-CoA, an intermediate of lipogenesis, CPT1 represents the rate limiting step of mitochondrial LCFA oxidation.

Materials and methods: To determine if an increase in CPT1 activity can protect muscle cells from palmitate-induced apoptosis, we have expressed in the C2C12 muscle cell line, using an adenovirus approach, a mutant form of CPT1 (CPT1mt) which is insensitive to malonyl-CoA inhibition.

Results: In C2C12 muscle cells, we demonstrate that palmitate, a saturated LCFA, induces myotube apoptosis in a time- and concentration-dependent manner. A 24 hours-incubation of the cells with 0.8 mM palmitate causes caspase 3 cleavage (a 50% decrease in caspase 3 precursor, determined by western blot) and enhances by 60% its proteolytic activity, as measured by flow cytometry. Compared with control cells, CPT1mt expression in C2C12 myotubes induces a 2.7-fold increase in CPT1 activity (1.6 ± 0.2 vs 0.6 ± 0.1 nmol/mg protein/min, $p<0.01$), which is maintained in the presence of $5\mu\text{M}$ malonyl-CoA (0.8 ± 0.1 vs 0.05 ± 0.03 nmol/mg protein/min, $p<0.001$). This leads to a 2.6-fold increase in LCFA oxidation flux (6.5 ± 0.3 vs 2.5 ± 0.2 nmol/mg protein/3h, $p<0.001$) whereas oxidation of medium-chain fatty acid, which enters the mitochondria independently of the CPT system, was unaffected. In the presence of high glucose (20 mM) and insulin (100 nM) concentrations, CPT1mt-expressing cells maintain a high rate of LCFA oxidation whereas this pathway is more inhibited in control cells (4.5 ± 0.2 vs 1.05 ± 0.05 nmol/mg protein/3h, $p<0.001$). In myotubes exposed to 0.8 mM palmitate for 24 hours, CPT1mt expression confers a less decrease in caspase 3 cleavage (a 10% decrease in caspase 3 precursor vs 50%, $p<0.001$). Thus, CPT1 exerts a protective effect against palmitate-induced apoptosis.

Conclusion: These results strongly favor the hypothesis that any strategy designed to enhance LCFA oxidation in muscle should protect cells from lipid-induced apoptosis and we propose CPT1 as a possible therapeutic target for the treatment of type 2 diabetes.

The differential impact of antiretroviral (ARV) therapies on mitochondrial and lipid metabolism genes in human adipose tissue

K.C. McGee¹, A.L. Harte¹, M. Hill¹, M. Boothby², J. Tomlinson³,

L.L. Gathercole⁴, S. Kumar¹, M. Shahmanesh², P. McTernan¹

¹Unit for Diabetes and Metabolism, University of Warwick, Coventry, ²HIV Medicine, University Hospital Birmingham, ³Division of Medical Sciences, University of Birmingham, ⁴Division of Clinical Sciences, University of Birmingham, United Kingdom

Background and aims: Our previous studies have shown that both central obesity and diabetic status impact on lipid metabolism and mitochondrial gene expression. However, less is understood on the impact of HIV infection itself and its treatments. HIV infection causes a disturbance in lipid metabolism, and some antiretroviral (ARV) regimens, such as those containing zidovudine (AZT), have been associated with lipodystrophy, diabetes and the metabolic syndrome. For this study we investigated the effect of (1) HIV status and (2) antiretroviral therapy on mitochondrial and lipid related genes.

Materials and methods: Subcutaneous adipose tissue (AT) biopsies from the ileac crest were obtained from 15 controls and 32 HIV subjects pre- and

post- 6 month ARV treatment (HIV: BMI: 25.5(mean±SD)±5.0kg/m²; Age: 35.9±9.49yrs; Control: BMI: 26.8±4.24kg/m²; Age: 34.8±9.7yrs). Patients were randomised to either AZT/3TC/EFV (zidovudine/lamivudine/efavirenz), or TDF/FTC/EFV (tenofovir/emtricitabine/efavirenz) treatment. Real time PCR examined genes related to mitochondrial metabolism and lipid metabolism including FAS, FABP4, LPL, and HSL. All PCR reactions were multiplexed with the housekeeping gene 18S.

Results: Mitochondrial related genes from human AT biopsies were increased in HIV patients, at baseline compared with non HIV case controls (COX3: $p<0.05$; CYTB: $p<0.05$; HCS: $p<0.05$; NRF-1: $p<0.05$). AT biopsies taken from HIV patients 6 months post-treatment showed that both AZT and TDF ARV therapy led to an overall significant increase in mitochondrial related gene expression of TFAM ($p<0.01$), HCS ($p<0.05$), ND-4 ($p<0.001$) COX-4 ($p<0.05$), in addition to lipid metabolic genes LPL ($p<0.001$), FABP4 ($p<0.001$), FAS ($p<0.001$) and HSL ($p<0.001$) as compared with naïve HIV patients. Individual analysis of the impact of each drug therapy highlighted that treatment of HIV patients with AZT/3TC/EFV for 6 months led to increased mitochondrial related gene expression of COX4 ($p<0.01$), ND-4 ($p<0.01$), whilst down-regulating CYTB ($p<0.001$) and COX-3 ($p<0.05$). TDF/FTC/EFV 6 month post treatment up-regulated TFAM (vs baseline HIV patients: $p<0.01$) and ND-4 (vs baseline HIV patients: $p<0.01$) but had little impact on CYTB or COX-3.

Conclusion: HIV patients, prior to ARV treatment, appear to have increased mitochondrial function compared with non-HIV case controls. In addition, short term ARV therapy increased mitochondrial related gene expression and lipid related genes, overall. Comparative analysis of the effects of the different ARV therapies on regulation of mitochondrial related gene expression highlighted that there was little difference between the AZT/3TC/EFV and TDF/FTC/EFV regimens, although there was significantly decreased expression of mitochondrially encoded CYTB and COX3 6 month post AZT/3TC/EFV treatment, thus suggesting a potential mitochondrial respiratory gene dysfunction. Future studies will be required to elucidate the influence of HIV status and drug therapies on human AT, which may affect the lipodystrophic phenotype and contribute to the reduction/progression of metabolic disease. Stability of mitochondrial DNA against reactive oxygen species generated in diabetes

O. Savu^{1,2}, A. Nikosjkov¹, V. Sunkari¹, I. Botusan^{1,3}, J. Grünler¹, K. Brismar¹, S.-B. Catrina^{1,3}

¹Molecular Medicine and Surgery, Karolinska Institute, Stockholm, Sweden, ²Diabetes, "N.C. Paulescu" National Institute, Bucharest, Romania,

³Endocrinology, University of Medicine and Pharmacy "Carol Davila", Bucharest, Romania

Background and aims: The hyperglycaemia-induced overproduction of reactive oxygen species (ROS) by the mitochondria was proposed to be the unifying mechanism in the pathogenesis of diabetic complications. Local hypoxia, which is another source of ROS, has also emerged as an important factor in the development of chronic complications of diabetes. Even though mitochondrial DNA (mtDNA) is a very sensitive target for oxidative damage there is few data available on the unevenly somatic point mutations and deletions of mtDNA in diabetes and only from transversal studies. Moreover there is no direct investigation on the influence of chronic hyperglycaemia and/or hypoxia on mtDNA stability and repair. We propose to study the stability of mtDNA against ROS overproduction in diabetic condition.

Materials and methods: mtDNA mutations were evaluated both by cloning and sequencing a 600 bp region from cytochrome B and by long fragment polymerase chain reaction (PCR) (~10 kbp) normalized for mitochondria copy number. *In vitro* studies were performed in primary human dermal fibroblasts and endothelial cells exposed to different glucose concentrations and oxygen tensions. The *in vivo* studies were performed in diabetic (db/db) mice at different phases of the disease and compared with their heterozygotes littermates. A special strain of a mtDNA mutator mice was used as positive control. Cellular oxidative stress was measured by dichlorofluorescein assay *in vitro* and by nitrotyrosine immunoblotting *in vivo*. Gene expression for manganese superoxide dismutase (MnSOD) and catalase (CAT) were analyzed by quantitative Real-Time PCR. Mitochondrial base excision repair (mtBER) activity was investigated by using abasic site-containing oligonucleotides as substrates.

Results: The combination of hyperglycaemia and hypoxia induced a higher incidence of mtDNA damage both in endothelial and in fibroblasts *in vitro*.

An increased incidence of point mutations was identified by sequencing in "old" (34 weeks) db/db mice ($p<0.05$) but not in the "young" db/db mice when compared with their age matched non diabetic littermates. Surprisingly we found a significantly decreased incidence of mtDNA damage in old diabetic mice than in controls ($p<0.01$ for any of organs analysed). However ROS overproduction was observed in diabetic conditions both *in vitro* and *in vivo* experiments. Gene expression for MnSOD and CAT was significantly higher ($p=0.002$, and $p=0.005$ respectively) in "old" db/db mice but not in "young" db/db mice when compared with their aged matched controls.

Conclusion: Our results reflect mtDNA instability in diabetic conditions but the mechanisms behind it are not clear yet. Gene expression studies suggest an up regulation of antioxidant defense in mitochondria which might reflect in an effective repair system *in vivo*.

Molecular and metabolic evidence for mitochondrial dysfunction associated with beta-cell failure in type 2 diabetes

H. Lu, V. Koshkin, A. Gyulkhandanyan, M.B. Wheeler

Department of Physiology, University of Toronto, Canada

Background and aims: The efficient coupling of glucose metabolism to energy production in mitochondria of β -cells is required for appropriate insulin secretion. The importance of this process is underscored by the observation that disrupting mitochondrial oxidative metabolism in β -cells blocks nutrient-mediated secretion. However, a specific relationship between mitochondrial dysfunction and β -cell failure has not been clearly established in type-2 diabetes (T2D). To explore this probable association, we studied the MKR mouse, a genetic model of T2D caused by an IGF-1 receptor mutation in skeletal muscle. The goal of the study was first, to determine the potential contribution of mitochondrial dysfunction to β -cell failure and second, to identify the molecular events responsible for mitochondrial dysfunction.

Materials and methods: Both metabolic and proteomic approaches were used in this study. MKR and age-matched control mice were characterized by the assessment of blood glucose, plasma insulin and glucose tolerance tests (GTT). Pancreatic islet cell morphology was examined using immunohistochemistry and electron microscopy, while islet secretory function was measured by glucose-stimulated insulin secretion. Islet mitochondrial metabolism was assessed by mitochondrial membrane potential, ATP, reactive oxygen species, mitochondrial Ca²⁺ accumulation and oxygen consumption. Global islet protein expression profiles were measured using iTRAQ proteomics.

Results: Three week-old MKR mice were insulin resistant, whereas 10 week-old mice were insulin resistant and hyperglycaemic. The GTT revealed that 10-week-old MKR mice displayed glucose intolerance with the loss of first phase insulin secretion, whereas 3-week-old MKR mice retained first-phase insulin secretion in response to glucose. *Ex vivo* MKR and control islets showed similar secretory responses to glucose at 3 weeks, but secreted 51% less insulin under high glucose (20mM) conditions at 10 weeks of age ($p<0.001$). Immunohistochemical analysis of islets showed no gross morphological changes in 3-week-old MKR mice, whereas 10 week-old MKR islets were hypertrophic and hyperplastic. Electron microscopy revealed the mitochondria from 10-week-old MKR β -cells were significantly swollen with abnormal cristae. Whole islets or dispersed cells from 10-week-old MKR mice exhibited 38% less ATP ($p<0.001$), 46% reduced glucose-stimulated hyperpolarization of the mitochondrial membrane potential ($p<0.001$), 50% attenuation in glucose-stimulated mitochondrial Ca²⁺ uptake ($p<0.001$), a 31% decrease in the cytochrome c oxidase-dependent oxygen consumption rate ($p<0.01$), and a two fold increase in reactive oxygen species (ROS) levels ($p<0.001$) compared to controls. In line with a defect in mitochondrial function, islet protein profiling revealed that the expression of 38 mitochondrial proteins were significantly dysregulated in MKR diabetic islets. Consistent with a defect in oxidative phosphorylation, there was a prominent downregulation of proteins (Ndufa9, Uqcrlh, Cox2, Cox4i1, Cox5a and Atp5j2) of the mitochondrial respiratory chain.

Conclusion: Our results indicate that the loss of glucose-stimulated insulin secretion in the diabetic MKR mouse is likely caused by a defect in mitochondrial function as demonstrated by gross abnormalities in mitochondrial morphology, function and the expression of proteins involved in electron transport.

Inhibition of liver fatty acid oxidation by Teglilar improves the hypoglycaemic effect of metformin both “*in vitro*” and “*in vivo*”

R. Conti, R. Liberati, S. Di Donna, P. Carminati, F. Giannessi

Endocrinology and Metabolism, sigma-tau industrie farmaceutiche riunite SpA, Pomezia, Italy

Background and aims: Metformin action in reducing hepatic glucose production includes mitochondrial Complex I inhibition, increase in AMP level and activation of AMPK.

Teglilar, a recently identified reversible inhibitor of the liver isoform of Carnitine palmitoyltransferase1 (L-CPT1), currently in clinical phase II, reduces gluconeogenesis by decreasing pyruvate carboxylase activity through inhibition of liver fatty acid oxidation. The aim of this study was to investigate, using Teglilar, the role of liver fatty acid oxidation on the hypoglycemic effect of Metformin, both *in vitro* on freshly isolated hepatocytes and *in vivo* on db/db mice.

Materials and methods: Sprague-Dawley rat liver cells, obtained after 24 hours of fasting, were incubated for 150 min at 37°C in 0.8 mL of gassed (95:5; O₂:CO₂) Krebs medium containing 2% defatted BSA, 1 mM glucose, 1 mM pyruvate, 9 mM lactate. The hepatocytes were preincubated for 30 min with the drugs prior to addition of 1 mM oleate. The *in vivo* study was performed on hyperglycemic db/db mice orally treated with a low dose of Teglilar (60 mg/kg/die) for four days. On the last day, Metformin (100 mg/kg) was given orally at time 0. Tail blood was collected at 60, 120 and 270 min and blood glucose measured by glucometer.

Results: Control hepatocytes linearly released glucose and ketone bodies in the medium (around 120 and 55 µg/10⁶ cells/h, respectively). Teglilar and Metformin, when tested alone, reduced glucose production (ED₅₀ = 10 µM and 1.2 mM, respectively). When increasing concentrations of Teglilar (1, 2 or 10 µM) were added to Metformin (0.3, 1.2 or 1.8 mM), a further reduction of hepatocyte glucose production was measured at all studied concentrations. As Metformin does not affect the reduction of ketone bodies operated by Teglilar (ED₅₀ = 1 µM), it is evident that inhibition of β-oxidation improves Metformin action. The mitochondrial redox state (by the β-Hydroxybutyrate/Aceto-acetate ratio), was profoundly increased by Metformin (8.5 at Metformin 1.8 mM vs 0.7 control) relating to a reduction in NADH utilization on the electron transport chain. In the presence of Teglilar, the redox state progressively dropped to much lower values, suggesting that most of the NADH production, under our conditions, is β-oxidation-dependent. The increase of mitochondrial redox state, related to Complex I inhibition, is in agreement with a reduced hepatocyte ATP content (-70% at 1.8 mM Metformin with respect to controls). Teglilar alone did not alter the ATP nor did it affect the Metformin-induced drop in ATP content. The potentiation of Metformin effect was also shown *in vivo* on db/db mice. Blood glucose, after a single low Metformin dose, following a subchronic low Teglilar dose, resulted 48% lower than with the two drugs alone.

Conclusion: Our results prove that the reduction of liver β-oxidation operated by Teglilar improves the hypoglycemic effect of Metformin.

766

Is the sub-normal insulin stimulation of muscle ATP synthesis in type 2 diabetes always a consequence of low rates of muscle glycogen synthesis?

E. Lim, M.I. Trenell, K.G. Hollingsworth, F.E. Smith, P.E. Thelwell, R. Taylor

Institute of Cellular Medicine, Newcastle Magnetic Resonance Centre, Newcastle upon Tyne, United Kingdom

Background and aims: Abnormalities in mitochondrial ATP synthesis in muscle of people with type 2 diabetes have been reported. Although these may be primary to the development of insulin resistance and type 2 diabetes, the measurement must be interpreted in the light of the energy demands of the muscle cell. In type 2 diabetes, the rate of muscle glycogen synthesis is reduced and this may lead to a lower requirement of mitochondrial ATP synthesis as a secondary phenomenon. We set out to test the hypotheses that a) the lower rates of mitochondrial ATP synthesis observed in muscle of type 2 diabetes is a consequence of subnormal rates of muscle glycogen synthesis rather than a primary defect in mitochondrial function and b) mitochondrial ATP synthesis can be restored by suppressing fatty acid oxidation.

Materials and methods: ¹³C magnetic resonance spectroscopy (MRS) was used for the direct *in vivo* measurement of the rates of muscle glycogen synthesis in response to an isoglycaemic-hyperinsulinaemic clamp. The preci-

sion of the measurement of muscle glycogen was improved by infusing ¹³C-enriched glucose. The rate of mitochondrial ATP synthesis was assessed by ³¹P MRS measurement of saturation transfer between ATP and inorganic phosphate in the calf muscle. Diabetic subjects (>2 years duration; BMI 28.3 ± 4.2 kg/m²; HbA_{1c} 6.6 ± 0.6%) were studied on 2 separate days - during an isoglycaemic-hyperinsulinaemic clamp and during the same with complete suppression of NEFA levels using acipimox. Normal controls were studied once only, without acipimox.

Results: In normal controls, after 20 min of insulin stimulation, the muscle glycogen signal rose by 30.0 ± 12.5% (blood glucose of 4.8 ± 0.4 mM) with a corresponding increase in ATP flux of 15 ± 26%. In the diabetic subjects, 20 min of insulin stimulation brought about no change in muscle glycogen signal (-1.3 ± 6.1%) during isoglycaemia (6.05 ± 0.50 mmol/l) and minimal change in ATP flux (4 ± 16%) on placebo day. Suppression of NEFA levels were achieved with acipimox 250mg given at -3 hours and at the start of the insulin clamp in diabetic subjects (at 15 min = 0.09 ± 0.02 vs. 0.62 ± 0.10 mmol/l with and without acipimox; p < 0.01). During NEFA suppression in the diabetic subjects, insulin stimulation brought about a 24 ± 10% increase in ATP flux by 20 min during isoglycaemia (5.6 ± 0.3 mmol/l). However, despite this significant increase in ATP flux, there was only minimal increase in muscle glycogen signal (5 ± 4%). Insulin-stimulated whole body glucose disposal was 3.79 ± 0.71 and 2.65 ± 0.09 mg/kg/min during isoglycaemia in controls and diabetic subjects respectively.

Conclusion: Although insulin stimulated glycogen and ATP synthesis rates are similarly sub-normal in type 2 diabetes, suppression of fatty acid oxidation created a condition in which the former remains unchanged despite increase in the latter. We conclude that that ATP synthesis rates are not primarily determined by glycogen synthesis rate and these two parameters can be separately modulated in type 2 diabetes. The subnormal muscle ATP synthesis rate of type 2 diabetes can be restored by suppressing fatty acid oxidation.

Mitochondrial nitric oxide is increased in the ob-/- mice model of metabolic syndromeP.V. Finocchietto, F.J. Barreiro, S.A. Holod, M.C. Carreras, J.J. Poderoso
Laboratory of Oxygen Metabolism, University Hospital University of Buenos Aires, Argentina

Insulin resistance (IR) is associated with the increase of visceral adipose tissue (WAT). Although the mechanism is unknown, there are several reports about mitochondrial abnormalities in metabolic tissues in IR. Nitric Oxide (NO) is a signaling molecule with many of its effects on cell function being elicited at the mitochondrial level. In different tissues, Nitric Oxide Synthase translocates to mitochondria (mtNOS) and synthesizes NO vectorially directed to the matrix. It is noteworthy that NO steady-state concentration modulates electron transfer, O₂ uptake, and the reactive oxygen species yield.

Aim: to determine the activity and expression of mtNOS in WAT, Muscle and Liver of leptin deficient Ob-/- mice.

Methods: we used Ob-/- and C57BL/6 WT mice (6-9 mo old); mice were divided in two subgroups with no intervention or receiving leptin replacement (6 µg bid IP 4 days). Epididymal WAT, muscle and liver were excised and isolation and purification of mitochondria was done by differential centrifugation. Mitochondrial NO was determined by flow cytometry with DAF in the presence or not of NOS inhibitor L-NMMA, the expression of mtNOS by Western Blot and RT-PCR and mitochondrial Complex I-IV activities were followed spectrophotometrically. Complexes were separated by BN-PAGE, and tyrosine nitration was detected by Western Blot. We evaluated mtNOS content and mitochondrial morphology by electronic microscopy.

Results: 1) Ob-/- have a significant increase of mtNOS activity and NO production in accord to 3-fold increase of expression. 2) Complex I activity resulted markedly reduced in WAT (-81% p < 0.05), muscle (-72% p < 0.05) and liver (-61% p < 0.05) from Ob-/-; there were no significant changes of the activity of Complexes II-III and IV. 3) According to its low activity, Complex I exhibited 3-4 fold increased tyrosine nitration in WAT, muscle and liver mitochondria from Ob-/- . 4) Leptin replacement completely normalized mtNOS activity and Complex I activity, with significantly decreased nitration to the same level of controls. 5) Electronic microscopy confirmed the variations of mtNOS content in mitochondria.

Conclusion: a) Mitochondria of Ob-/- mice tissues are exposed to high NO matrix concentration that conducts to Complex I nitration and subsequent reduced activity; b) Likewise, more than 60 % Complex I inhibition contributes to low Ob-/- O₂ uptake and obesity; c) Enhanced NO depends on high

mtNOS expression and as well preliminary data of our group indicate on that insulin increases mtNOS activity and leptin reduces mtNOS activity; d) thus, in this rodent model of metabolic syndrome, mitochondrial hypometabolism should depend on the balance between leptin deficiency and reduced sensitivity to insulin. These evidences show that after energy replenishment, the inhibition of mitochondrial respiration in metabolic tissues via NO permits substrates to be deposited as macromolecules; at hyperinsulinemia and leptin deficiency, persistent mtNOS activation could contribute to mitochondrial dysfunction with insulin resistance and obesity and therefore to the progression of the ob *-/-* metabolic syndrome.

Role of mitochondria-derived reactive oxygen species in fat-induced insulin resistance in liver

T. Takamura, N. Nagata, S. Nakamura, H. Takayama, M. Sugimori, H. Misu, S. Kaneko

Department of Disease Control and Homeostasis, Kanazawa University Graduate School of Medical Science, Japan

Background and aims: Insulin resistance is a key pathophysiological feature of metabolic syndrome. Visceral adiposity in obesity causes excessive free fatty acids (FFAs) flux into the liver via the portal vein and may cause fatty liver disease and hepatic insulin resistance. However, the initial events triggering the development of insulin resistance and its causal relations with dysregulation of glucose and fatty acids metabolism remain unclear.

Materials and methods: We investigated biological pathways that have the potential to induce insulin resistance in male C57BL/6J mice fed a high-fat diet (HFD) containing 60% fat. To investigate the direct and initial effects of FFAs on hepatocytes, we treated H4IIEC3 cells, a rat hepatocyte cell line, with a monounsaturated fatty acid (oleate, 0.25 mM) and a saturated fatty acid (palmitate, 0.25 mM) in the presence of 2% FFA-free bovine serum albumin.

Results: (1) Comprehensive gene expression analyses by using DNA chip technology revealed that the pathways for reactive oxygen species (ROS) production and oxidative stress are coordinately up-regulated in both the liver and adipose tissue of mice fed a HFD prior to the onset of insulin resistance and obesity through discrete mechanisms. (2) In the liver, a HFD up-regulated genes involved in sterol regulatory element binding protein (SREBP)-1c-related fatty acid synthesis and peroxisome proliferator-activated receptor (PPAR)- α -related fatty acid oxidation. (3) In the adipose tissue, however, the HFD down-regulated genes involved in fatty acid synthesis and up-regulated genes involved in forming the NADPH oxidase complex. (4) Increased ROS production preceded the elevation of TNF- α and FFAs in the plasma and liver. (5) Protein carbonyl was accumulated in the liver, but not in the adipose tissue of HFD mice before the onset of insulin resistance, partly due to up-regulation of gene for glutathione peroxidase, one of the redox proteins, only in adipose tissue. In cultured H4IIEC3 hepatocytes, (6) Palmitate, but not oleate, inhibited insulin-stimulated tyrosine phosphorylation of insulin receptor substrate 2 and serine phosphorylation of Akt, through c-Jun NH₂-terminal kinase (JNK) activation. (7) Among the well-established stimuli for JNK activation, ROS played a causal role in palmitate-induced JNK activation. (8) Etomoxir, an inhibitor of carnitine palmitoyltransferase-1, which is the rate-limiting enzyme in mitochondrial fatty acid β -oxidation, as well as inhibitors of the mitochondrial respiratory chain complex (thenoyltrifluoroacetone and carbonyl cyanide *m*-chlorophenylhydrazone) decreased palmitate-induced ROS production.

Conclusion: In the early stage during the development of fat-induced insulin resistance, there are compensatory alterations in the expression of genes that regulate fatty acid metabolism between the liver and adipose tissue. However, oxidative stress may be an initial key event triggering HFD-induced insulin resistance especially in the liver. Our findings in cultured hepatocytes indicate that palmitate inhibits insulin signal transduction through JNK activation, and that accelerated β -oxidation of palmitate causes excess electron flux in the mitochondrial respiratory chain, resulting in ROS overproduction. Thus, mitochondria-derived ROS induced by palmitate might be major contributors to JNK activation and insulin resistance in the liver.

Background and aims: EXT3 (exostosin tumor-like 3) was originally identified as a member of the exostosin tumor (EXT) family in human. This molecule functions as a glycosyltransferase involved in heparan sulfate (HS) proteoglycans (PGs) biosynthesis. Recently, sulfated PGs including HSPGs have been reported to be involved in pancreatic endocrine cell differentiation. However, it remains unclear whether EXT family plays an important role in pancreatic β -cell development and its function *in vivo*. EXT3 catalyzes both the initiation and the elongation of HS chain, and among EXT family members, its mRNA was observed to be expressed most abundantly in mouse pancreatic islet. We therefore generated pancreatic β -cell specific *Extl3* knockout (β Extl3KO) in order to clarify this issue.

Materials and methods: β Extl3KO mice were generated through gene targeting using the rat insulin promoter-Cre/loxP recombination system. Immunohistochemical analyses of pancreatic islets were performed in 1-, 2-, 4- and 8-week old mice using insulin and glucagon antibodies. The β -cell proliferation activity was determined by the percentage of insulin and proliferating cellular nuclear antigen (PCNA) double-positive cells against insulin-positive cells. For measurement of pancreatic insulin content, pancreata were removed from 2-, 4- and 8-week old mice and insulin was extracted by the acid-ethanol method. Glucose tolerance and insulin sensitivity were evaluated by an intraperitoneal glucose tolerance test and an insulin tolerance test, respectively, in 8-week old mice.

Results: Histological examination of pancreatic islets revealed an atypical organization (glucagon-positive cells existed in the central region of the islets) in β Extl3KO mice at 2–8 weeks old, and the β -cell number/islet cell number ratio was significantly diminished in β Extl3KO islets compared to that in control islets. In β Extl3KO mice, the β -cell proliferation activity determined by PCNA positivity was decreased to 29% (at 2 weeks) and 41% (at 4 weeks) of those in control mice ($p < 0.05$, $n = 3$), although it was not different from that in control mice at 8 weeks. Pancreatic insulin content in β Extl3KO mice was decreased to 80% of control at 2 weeks old ($p < 0.05$, $n = 5$). However, there was no difference in pancreatic insulin content between β Extl3KO mice and their controls at 8 weeks old. Although random blood glucose and plasma insulin concentrations were normal in β Extl3KO mice at 8 weeks, they showed glucose intolerance coupled to impaired insulin secretion upon glucose challenge. No insulin resistance was observed in β Extl3KO mice.

Conclusion: Our data indicate that HS plays important role(s) in β -cell proliferation and the mechanism of insulin secretion. *Extl3* may therefore be a candidate gene for diabetes mellitus, the abnormality of which leads to defective β -cell proliferation and insulin secretion.

770

Causes for diabetic hyperphagia in type 2 diabetic Goto-Kakizaki(GK) rats with normal body weight

A. Ando^{1,2}, M. Nakata¹, K. Dezaki¹, F. Maekawa¹, K. Eto², S. Nagasaka², S. Ishibashi², T. Yada¹

¹Integrative Physiology, ²Endocrinology and Metabolism, Jichi Medical University, Shimotsuke, Japan

Background and aims: Diabetic hyperphagia has been reported in several animal models, which include STZ treated type 1 diabetic rats showing insulin and leptin depletion and massively obese type 2 diabetic models such as *ob/ob*, *db/db* and *Ay* mice that lack leptin signaling. We have previously shown that GK rats, a type 2 diabetic model, display hyperphagia without

alteration in body weight at the young-adult ages of 6–13 weeks, in addition to hyperglycemia. This hyperphagia is associated with visceral fat accumulation at mesenteric and perirenal portions, central leptin resistance, and upregulated NPY mRNA expression in the hypothalamic arcuate nucleus. The aim of this study was to evaluate the mutual causal relationship between hyperphagia, visceral fat accumulation and hyperglycemia. For this purpose we examined the effect of restriction of food intake on adiposity and glucose homeostasis in GK rats. We also examined whether the neurons in the feeding center, the arcuate nucleus (ARC), are altered in GK rats in their ability to sense the peripheral metabolic factors, leptin, ghrelin and glucose.

Materials and methods: Wistar rats (n=6), GK rats (n=6) and pair-fed GK rats (n=6) were fostered for 7–14 weeks, and daily food intake was measured. In pair-fed groups, GK rats were given the chow whose amount was the same as that eaten by Wistar rats every day in average (pair feeding). Fat accumulation was measured at 14 weeks of age. Cytosolic Ca^{2+} concentration ($[\text{Ca}^{2+}]_i$) in isolated arcuate neurons was measured by fura-2 microfluorometry. Serum insulin and leptin levels were determined by ELA.

Results: Daily food consumption in GK rats was larger than that in Wistar rats during 7–14 weeks. Throughout the observation period, blood glucose levels were higher in both regularly-fed and pair-fed GK rats compared to Wistar rats. Pair feeding failed to correct the elevated blood glucose level of GK rats. Accumulations of both mesenteric and perirenal fats in GK rats were reduced by pair feeding ($p < 0.05$). At 14 weeks old, GK rats showed significantly elevated concentrations of serum leptin ($p < 0.05$) and insulin ($p < 0.01$) compared to Wistar rats, and pair feeding substantially reduced serum leptin levels ($p < 0.05$), but not serum insulin levels, in GK rats. At 13–14 weeks, to assess neuronal activities, $[\text{Ca}^{2+}]_i$ was measured in the neurons isolated from the ARC of rats. Lowering glucose to 1mM increased $[\text{Ca}^{2+}]_i$ in a subpopulation of the ARC neurons, and the amplitude of $[\text{Ca}^{2+}]_i$ increases was significantly ($p < 0.05$) larger in GK than Wistar rats at 14 weeks. By contrast, $[\text{Ca}^{2+}]_i$ responses to ghrelin and those to leptin were not altered in GK rats. In GK rats at early ages of 3–4 weeks, blood glucose level was already increased. Furthermore, although the amount of food eaten daily was almost similar to Wistar rats, body weight was smaller, resulting in increased food intake per body weight already at 3 weeks.

Conclusion: Visceral fat accumulation in GK rats was largely corrected by pair feeding, suggesting that visceral fat accumulation primarily results from hyperphagia. Blood glucose was continuously elevated at least from 3 weeks. At 14 weeks, glucose sensing (high glucose inhibition) of the ARC neurons was abnormal. The results suggest that hyperglycemia from early stages could influence the central glucose sensing in the ARC neurons and induce hyperphagia in GK rats.

The prediabetic period is characterized by islet microangiopathy in the Goto-Kakizaki rat, a spontaneous model of type 2 diabetes

F. Homo-Delarche¹, M.-H. Giroix¹, G. Lacraz¹, S. Calderari², M. Cornut³, J.A. Ehses⁴, F. Schmidlin⁵, J. Coulaud¹, M.-N. Gangnerau¹, P. Serradas⁶, J.-C. Irminger³

¹Paris-Diderot University, CNRS UMR 7059, Paris, France, ²Collège de France, INSERM U833, Paris, France, ³CMU, Dpt of Genetic Medicine & Development, Geneva, Switzerland, ⁴University Hospital of Zürich, Division of Endocrinology and Diabetes, Switzerland, ⁵Merck, Serono, Chilly Mazarin, France, ⁶Pierre & Marie-Curie University, INSERM U505, Paris, France

Background and aims: Endothelial signals are essential during pancreas development. Goto-Kakizaki (GK) rats have a 70% decrease in β -cell mass at E18, while it is similar at E13 to that of Wistar control rats. Because adult diabetic GK rats are hypercholesterolemic, we hypothesized that maternal hypercholesterolemia together with maternal/fetal hyperglycemia might alter perinatal pancreas development through islet microangiopathy (atherosclerosis) programming. Our aims were to: 1) demonstrate alterations of vascularisation in islets from 1-week-old GK rats, during the so-called prediabetic period; 2) measure systemic levels of lipids and various cytokines and chemokines around birth.

Materials and methods: 1) Sera were obtained from 1-week-old male Wistar and GK rats (except otherwise stated) for radioimmunoassays; 2) Islets from these rats were hand-picked after collagenase digestion; 3) Molecular approaches included Affymetrix gene array and low density arrays targeted at endothelium, angiogenesis and cardiovascular disease biomarkers (OligoGE-ArrayRat). Gene expression was confirmed by qRT-PCR.

Results: Affymetrix gene array (230A) showed differential expression of several genes which might be involved in inflammation in GK versus Wistar islets. Notably, the gene encoding epoxide hydrolase, the enzyme responsible for epoxyeicosatrienoic acids (EETs) conversion was decreased by 90%. EETs have anti-inflammatory and protective vascular effects. We then analysed expression of genes present on the 3 targeted arrays mentioned above (128 different genes/array). We obtained 20 up- and 8 down-regulated genes. Among the up-regulated genes were those encoding: caspase 1 (IL-1-converting enzyme, x10) that cleaves IL-1 and IL-18 into their active forms; various cytokines/chemokines involved in macrophage/granulocyte movements: CXCL2 (MIP-2 α , x4.1), CXCL-1 (chemokine KC, x3.9), IL-15 (x1.4) and IL-18 (x3.7); also fibronectin 1 (x2.3), ICAM-1 (x2.6), VEGFR3 (x2), carboxypeptidase 2 (TAFI, x1.9) and angiotensinogen (x1.9). These 3 groups have pro-atherosclerotic effects. Among the down-regulated genes were those encoding: osteopontin (x0.4), neuropilin 1 (x0.6), platelet-derived growth factor (x0.6), coagulation factor III (tissue factor, x0.4) and the neuropeptide Y (x0.1) that acts as vascular mitogen. These data suggest that angiogenesis is deficient in neonatal GK islets. Concomitantly, prediabetic 1-week old-GK rats had lower leptin and higher circulating cholesterol/HDL ratio, MCP-1 and MIP-1 α levels than Wistar rats. The latter data might reflect systemic vascular disturbances in GK neonates.

Conclusion: Soon after birth many pro-atherosclerotic genes were upregulated in GK islets, while pro-angiogenic genes were downregulated. These data highlight early deficient islet vascularisation that might be responsible for the GK β -cell mass defect and therefore may be of potential therapeutic value.

Adaptive compensation of beta cells in an animal model of reduced beta cell mass subjected to high fat diet

P. Masiello¹, M.-L. Peyot², M. Latour², M. Novelli¹, V. D'Aleo¹, R. Lussier², P.-Y. Boyer², E. Joly², C.J. Nolan³, M. Prentki²

¹Dept. of Experimental Pathology, University of Pisa, Italy, ²Montreal Diabetes Research Center, University of Montreal, Canada, ³Dept. of Endocrinology, Australian National University, Canberra, Australia

Background and aims: We have previously established a non-obese animal model of reduced β -cell mass (adult Wistar rats given streptozotocin plus nicotinamide, STZ-NA rats), characterized by mild stable hyperglycaemia, glucose intolerance, responsiveness to sulphonylureas, lack of insulin resistance. The aims of this study were: a) to develop an improved model of type 2 diabetes through induction of insulin resistance in STZ-NA rats by a high fat dietary regimen (HFD); b) to explore if a reduction in β -cell mass would result in more rapid failure of β -cell compensation in front of increased calorie/fat intake and overweight.

Materials and methods: Male Wistar rats (240 g b.w.) were given 200 mg/kg NA i.p. and 60 mg/kg STZ i.v., 15 min later. Three weeks after diabetes induction, rats were subjected to HFD (19% protein, 41% carbohydrate and 40% fat in calories, 4.5 kcal/g versus 3.4 kcal/g of chow) for 11 weeks. Food intake, body weight, plasma glucose, triglyceride (TG), free fatty acid (FFA) and insulin levels were monitored throughout the experiment. Glucose and insulin tolerance test (GTT and ITT) were also performed. At the end of the experiment, islets were isolated from a number of rats and challenged in vitro with glucose and FFA. The remaining rats were subjected to euglycaemic hyperinsulinaemic clamp to evaluate development of insulin resistance; their pancreatic β -cell mass was quantitated by immunohistochemical methods and morphometric analysis.

Results: In mildly hyperglycaemic STZ-NA rats, HFD induced a 2-fold increase in plasma FFA, TG and insulin levels, without any further augmentation of blood glucose. Of note, HFD-fed rats consumed less food than chow-fed animals, so that the excess in calorie intake was ~15%. During IVGTT, carried out after 4.5 weeks of HFD, the glucose intolerance of STZ-NA rats, due to a reduced acute insulin response, was aggravated in HFD-fed diabetic rats, despite a clear-cut enhancement in post-loading insulinaemia indicating a noteworthy compensatory adaptation of β cells. An ITT performed after 6 weeks of HFD showed a slightly delayed but substantially preserved insulin sensitivity in HFD-fed diabetic animals. However, after 11 weeks of HFD, both control and STZ-NA rats eventually developed a pronounced insulin resistance, as assessed by the euglycaemic hyperinsulinaemic clamp. In isolated islets from HFD-fed diabetic rats, an enhancement in glucose- and FFA-induced insulin secretion occurred, with a shift to the left of the dose-response curve. The compensatory adaptation in these animals was also testified by a

significantly higher β -cell mass with respect to chow-fed diabetic rats (60% versus 40% of that of healthy controls).

Conclusion: STZ-NA rats with reduced β -cell mass develop insulin resistance when fed with HFD for several weeks. Thus, they closely reproduce two major features of human type 2 diabetes. Surprisingly, in such a model, despite marked reduction in β -cell mass and chronic mild hyperglycaemia, compensatory mechanisms in residual β cells are able to match for long time the increased insulin demand driven by excess calorie intake and development of insulin resistance. Further investigations are needed to clarify the molecular mechanisms and the duration of such adaptation.

773

Mkr mice have increased dynamic glucose disposal despite metabolic inflexibility, hepatic and peripheral insulin insensitivity

B. Vaitheesvaran¹, D. LeRoith², I.J. Kurland¹

¹Medicine, State University of New York, Stony Brook, ²Medicine, Mt.Sinai School of Medicine, New York, United States

Background and aims: MKR mice (dominant negative IGF-1 receptor over-expressed solely in skeletal muscle), are lean, suggesting metabolic flexibility, but demonstrate early development of Type 2 DM with severe insulin resistance, measured by EU clamp. The EU clamp assesses static glucose disposal in response to an insulin step at basal glucose. Therefore this study was done to assess the metabolic flexibility, in vivo lipolysis and static basal versus dynamic glucose disposal during an ipGTT, in MKR and FVB-wt mice.

Materials and methods: Dynamic glucose disposal was assessed by determining the disappearance rate of [6,6-³H]-glucose (D2 glucose). Intraperitoneal glucose tolerance test was performed using [6,6-³H]-glucose (1mg/gram body weight). Static basal glucose disposal, which is equal to hepatic glucose production (HGP) in the fasted state, was determined by constant infusion of [U-¹³C₆]-glucose by Alzet minipump. In vivo lipolysis was assessed using 2-¹³C-glycerol. Production rate PR (mg/kg body weight/min) was determined using equation $PR = \text{infusion rate} \times (1/e_{\text{tracer}} - 1)$. Infusion rate (mg/kg/min) = miniosmotic pump rate (8 μ l/hr) \times plasma tracer concentration/mouse body weight (kg). Indirect calorimetry was done using a 8-chamber Oxymax system (Columbus Instruments, Columbus,OH)

Results: MKR mice had an approximately 50% ($p < 0.05$), increase in fasting insulin. The AUC for the D2 glucose response for MKR mice was decreased (80 ± 6 vs 120 ± 5 for MKR vs FVB-wt mice, $p < 0.05$), suggesting faster glucose disposal for MKR mice, despite a similar AUC for total glucose. This suggests HGP was less suppressible in MKR mice in the fed state, in accordance with previously published EU clamp results. HGP [U-¹³C₆]-glucose) was similar in the fasted state despite higher basal insulin (hepatic insulin resistance), however the fraction of glucose molecules (F) that recycled was decreased (28% vs 35%, $p < 0.05$), which may indicate decreased Cori cycling, and that glucose being utilized more than fatty acids peripherally. Glycerol production using 2-¹³C- glycerol was significantly increased in the fasted state of MKR mice, despite increased fasting insulin. This indicates insulin resistant lipolysis in MKR mice may be responsible for the decreased fat mass seen in MKR mice, despite increased FFA. Indirect calorimetry indicates metabolic inflexibility is present, in MKR mice. There is a significantly higher respiratory quotient (RQ) for MKR vs. FVB-wt mice in the 15 hour fasted state ($RQ = 0.884$ vs 0.774 , $p < 0.0001$), but not in the 5 hour refed state ($RQ = 0.95$ vs 0.978), which supports stable isotope measurements indicating glucose, rather than fatty acids, as a preferred fuel for MKR muscle.

Conclusion: These results suggest that hepatic and adipose insulin resistance is compensatory for preservation of fuel homeostasis in MKR mice. Glucose is the preferred fuel for MKR muscle. In contrast to static EU clamp glucose disposal results, dynamic glucose disposal is increased for the same dynamic insulin response, however elevated MKR basal insulin is needed for MKR mice to match static FVB-wt basal glucose disposal. Liver and adipose insulin resistances are secondary, and may be compensatory, serving to provide glucose, as well as an increased supply of fatty acids, for metabolic needs.

Alterations on both hypothalamic insulin and serotonin in a type 2 diabetes model

K. Gerozissis¹, E.M. Markaki¹, C. Rouch¹, S.M. Banas¹, F. Berthou², D. Bailbe¹, M. Taouis²

¹UMR 7059, University Paris 7, Paris, ²Neuroendocrinologie Moléculaire de la Prise Alimentaire,, University Paris-Sud 11, Orsay, France

Background and aims: Epidemiological studies associate depression and metabolic diseases (MD). Patients with clinical depression exhibit a reduced sensitivity to insulin, whereas the metabolic syndrome is associated with suppressed neuroendocrine responses to serotonin (5HT). However the molecular mechanisms involved are not clear. Two molecules acting in the brain seem to be of particular interest: insulin and 5HT, known to regulate in interaction, energy and glucose homeostasis. It is hypothesized that diminished efficiency or responsiveness of either molecule, contributes to the development of MD. The present study focuses on hypothalamic 5HT release and insulin gene expression in a T2D model, the Goto Kakizaki (GK) rat.

Materials and methods: Brain microdialysis was performed in awake male adult Wistar (W) and GK rats, one week after stereotaxic implantation of a guide in median hypothalamus, under anesthesia. Extracellular hypothalamic 5HT release in response to a laboratory chow meal (5% fat, 59% CHO) (LF) in rats fed either a LF or a high fat (40% fat, 15% CHO) (HF) diet, was measured by electrochemical detection following HPLC. Hypothalamic mRNA was assessed by real-time RT-PCR. Behavioral, endocrine and metabolic parameters were determined with appropriate methods. Statistics: One way and two way analysis of variance followed by a Fisher PLSD for 5HT, students' t-test for gene expression body weight (BW), food intake (FI), fatty acids and glucose. Significance was set at $p < 0.05$. N=7-10 rats per group.

Results: Compared to age matched W, glycemia and insulinemia was increased in GK rats, FI and BW were lower, free fatty acid plasma levels were identical, leptinemia was (marginally) increased. Basal 5HT levels were identical in W and GK rats. FI increased 5HT release. Compared to W, the increase of 5HT in GK rats, was significantly lower. The decreased 5HT responsiveness in GK was similar to that observed in W rats fed a HF diet for one week, a diet known to induce insulin resistance. Compared to LF fed W rats, hypothalamic insulin gene expression was reduced in LF fed GK rats, but mRNA of IR, IRS1 and IRS2 were similar in the two groups.

Conclusion: The present study indicates, in addition to peripheral changes, important modifications of hypothalamic 5HT responsiveness to FI and of insulin gene expression in a type 2 diabetes rat model. Gene expression of IR, IRS1 and IRS2, important elements of insulin signaling, are increased in W rats fed a HF diet, suggesting potential adaptive mechanisms, aiming to rapidly increase brain insulin efficiency and compensate altered regulatory action in the brain of peptides and neurotransmitters involved in energy and glucose homeostasis. In the diabetic rat, such a compensatory mechanism was lacking. Taken together with epidemiological studies and own previous observations indicating 1) insulin-5HT interaction in the hypothalamus 2) cross talk of the two neuroregulators in intracellular signaling pathways (STAT-3, MAPK, IRS/PI3K) in the neuronal and brain level, and 3) alteration of those signaling mechanisms in pathological situations, this study reveals an aspect of the central biological mechanisms potentially linking depressive disorders and diabetes.

775

Oral glucose tolerance test fails to detect substantial metabolic abnormalities induced by antipsychotic agents

M. Ader¹, J.M. Richey¹, K. Hucking¹, V. Ionut¹, K.J. Catalano¹, S.P. Kim¹, M. Kabir¹, R.N. Bergman²

¹Physiology and Biophysics, University of Southern California, Los Angeles, United States

Background and aims: Recent reports of metabolic abnormalities associated with atypical antipsychotic therapy have prompted calls for increased monitoring of treated patients. The oral glucose tolerance test (OGTT) is a common screening procedure for subjects at increased diabetes risk, and could potentially be applied to the psychiatric population receiving antipsychotic agents.

Materials and methods: To determine whether changes in glucose tolerance would reveal drug-induced alterations in key metabolic factors, we tested in conscious dogs the effects of 6-wk treatment with the antipsychotic olanzapine (OLZ; 15 mg/d, n=10) or placebo (n=6) on the following: (a) glucose

tolerance by 25 g OGTT, (b) insulin sensitivity (S_i) by euglycemic clamp, (c) β -cell function by hyperglycemic clamp, and (d) adiposity by MRI.

Results: OLZ induced marked decrements in hepatic SI (pre: 6.1 ± 1.0 , post: 1.5 ± 0.9 dl/min/kg per $\mu\text{U/ml}$; $p=0.009$), with substantial increases in both visceral ($+84 \pm 22\%$) and subcutaneous ($+106 \pm 24\%$) adiposity ($p<0.0001$). Moreover, OLZ prevented β -cell upregulation of insulin secretion (pre: 1.24 ± 0.15 , post: 1.07 ± 0.25 $\mu\text{U/ml}$ per mg/dl; $p=0.59$). But these defects in glucose homeostasis were not reflected in any deterioration of glucose tolerance, defined as total glucose area under the OGTT curve (AUC) (pre: 21484 ± 616 , post: 21492 ± 612 mg/dl; $p=0.98$). With OLZ, good tolerance was maintained by elevation in $\text{AUC}_{\text{insulin}}$ (pre: 5812 ± 643 , post: 9293 ± 1317 $\mu\text{U/ml}$; $p=0.009$). Maintenance of glucose tolerance during OLZ was similar to that observed with placebo (pre: 20934 ± 1092 , post: 19351 ± 1125 mg/dl; $p=0.98$), which demonstrated no defects in SI, β -cell function, and only modest (25–30%) increase in adiposity ($p<0.05$).

Conclusion: These data demonstrate that “normal” OGTT-measured glucose tolerance may well not reflect insulin resistance or altered β -cell function. Glucose tolerance from the OGTT may underestimate significant metabolic defects caused by antipsychotic agents.

Genetic-dependent differences in sensitivity and resistance of rat beta cells to interleukin-1-beta inducing inhibition of glucose stimulated insulin secretion

G. Aharon-Hananel¹, S. Lenzen², A. Jörns³, I. Raz¹, S.W. Zangen¹

¹Diabetes Center, Hadassah University Hospital, Jerusalem, Israel, ²Institute of Clinical Biochemistry, Hannover Medical School, Germany, ³Centre of Anatomy, Hannover Medical School, Germany

Background and aims: Interleukin-1-beta (IL-1 β) is a potent inhibitor of β -cell function. The Cohen diabetic sensitive (CDs) rats develop diabetes when fed a diabetogenic diet (DD) but maintain normoglycemia when fed regular diet (RD). The hyperglycemic CDs rat exhibit diminished insulin secretion that was recently shown to be associated with IL-1 β -positive macrophage infiltration in the exocrine pancreas. The resistant (CDr) rat maintains normoglycemia and does not exhibit these pancreatic pathologies. In contrast to the in vivo studies, islets isolated from hyperglycemic CDs rats exhibit adequate insulin secretion and proinsulin biosynthesis. We aimed to study the pathways by which IL-1 β triggers the in vivo reduction in glucose stimulated insulin secretion exhibited by the hyperglycemic CDs rat.

Materials and methods: In vivo, 5 male CDs and CDr rats were fed 30 days RD or DD. Blood glucose and insulin levels were assessed by IVGTT. Ultrastructural and immunohistochemical analysis of the endocrine and exocrine parenchyma was performed on pancreatic sections. In vitro, islets isolated from the CDs and CDr rats fed RD were pre-incubated for a period of 1h with or without IL-1 β (30 or 60 U/ml). Insulin secretion was evaluated in the presence of 1.7 and 3.3 mmol/l (basal insulin secretion) or 16.7 mmol/l glucose (stimulated insulin secretion).

Results: In vivo, the glucose AUC of CDs-fed DD was elevated ($P<0.009$) and insulin AUC was reduced ($P<0.01$) compared to the 3 other study groups. The AUC of both glucose and insulin of CDr-DD were in the normal range and were not different from CDs or CDr rats fed RD. Macrophages, showing ultrastructural signs of activation and expressing IL-1 β immunostaining were observed in the exocrine parenchyma of the CDs-DD rats. No macrophages were found in the exocrine tissue of CDr-DD rats or in rats fed RD. In vitro, insulin secretion from CDs islets incubated with 30 and 60 U/ml IL-1 β was reduced by 25% compared to the same islets incubated without IL-1 β . In contrast, insulin secretion of the CDr islets was not affected by exposure to IL-1 β (30 or 60 U/ml).

Conclusion: The abnormal insulin secretion exhibited by the hyperglycemic CDs rats in vivo may be reproduced in vitro by a short exposure of isolated islets to moderate levels of IL-1 β . In contrast, exposure of the CDr islets to similar levels of IL-1 β did not impair insulin secretion. This may suggest a genetic-dependent difference in the sensitivity and resistance of the CDs and CDr rat β -cells to IL-1 β . Using this in vitro set up, we are currently studying the pathogenic mechanism pathways providing sensitivity or protection of islets cells from the deleterious effect of IL-1 β .

The anti-inflammatory cytokine interleukin-1 receptor antagonist improves beta cell function and survival by maintaining nuclear PDX-1 expression

N.S. Sauter, F.T. Schulthess, K. Maedler

Centre for Biomolecular Interactions, University of Bremen, Germany

Background and aims: Sub-clinical inflammation is a recently discovered mechanism in type 2 diabetes (T2DM). Elevated cytokines impair β -cell function and survival. A recent clinical trial shows that blocking Interleukin-1 β (IL-1 β) signaling by Interleukin-1 Receptor Antagonist (IL-1Ra) improves β -cell secretory function in patients with T2DM. In the present study, we provide mechanisms of this protective effect.

Materials and methods: Six-week-old IL-1Ra overexpressing mice (IL-1Ra-OE) and their wildtype littermates (C57Bl/6) were fed a high fat/ high sucrose diet (HFD) or a control diet for 16 weeks. Body weight and food consumption were measured weekly, intra-peritoneal glucose and insulin tolerance tests (ipGTT/ ipITT) were performed every 4 weeks. After 16 weeks, mice were

sacrificed and their islets isolated and analyzed for insulin and PDX-1 mRNA expression, β -cell apoptosis and PDX-1 localization. Human islets were cultured for 72 h with increasing glucose concentrations or with 2 ng/ml IL-1 β with or without addition of recombinant human IL-1Ra, PDX-1 localization was analyzed in Bouin fixed islet sections.

Results: IL-1Ra improved glucose tolerance and insulin secretion *in vivo* in C57BL/6J mice fed a high fat/ high sucrose diet (HFD). Studies on isolated islets revealed that IL-1Ra specifically acted on the β -cell. IL-1Ra protected from β -cell apoptosis, induced β -cell proliferation and improved glucose-stimulated insulin secretion. Insulin mRNA was reduced in islets from mice fed a HFD, but normalized in the IL-1Ra group, whereas PDX-1 mRNA levels were oppositely regulated, increased by the HFD and normalized by IL-1Ra treatment. PDX-1 protein was localized in the cytosol in the HFD animals but remained in the nucleus in the IL-1Ra group. Importantly, IL-1Ra induced a similar restoration of PDX-1 nuclear translocation in human islets. We found the JNK-pathway as a possible link in the downstream signaling from IL-1Ra to PDX-1. In isolated human islets, phosphorylated JNK-levels were increased by 11.1 and 33.3 mM glucose or in the presence of IL-1 β , this was inhibited when IL-1Ra was added to the culture medium. Previous studies suggested that JNK-activation leads to PDX-1 export. Human islets were treated with 22.2 mM glucose or IL-1 β , with or without the addition of a small peptide that inhibits JNK-activity. In the glucose and IL-1 β treated cells, we found cells that co-express insulin and PDX-1 in the cytoplasm, as well as cells that showed cytoplasmic PDX-1 with almost no detectable insulin. JNK-inhibition prevented glucose- and IL-1 β -induced PDX-1 translocation and kept the transcription factor in the nucleus in most cells, indicating that the JNK-pathway is involved in regulating PDX-1 localization.

Conclusions: Our results show that IL-1Ra improves β -cell survival and function through maintaining PDX-1 expression in the nucleus and suggest a potential role for IL-1Ra in the treatment of diabetes.

Islet endothelial dysfunction in young adult GK rat, a spontaneous model of type 2 diabetes: reversal by IL-1Ra treatment

M.-H. Giroix¹, G. Lacraz¹, N. Kassir¹, J.A. Ehses², J.-C. Irminger³, F. Schmidlin⁴, J. Coulaud¹, B. Portha¹, M.Y. Donath², F. Homo-Delarche¹
¹Laboratory of Nutrition Physiopathology-CNRS UMR 7059, University Paris-Diderot, Paris cedex 05, France, ²Division of Endocrinology and Diabetes, University Hospital of Zürich, Switzerland, ³Department of Genetic Medicine and Development, CMU, University of Geneva, Switzerland, ⁴Merck, Serono, Chilly-Mazarin, France

Background and aims: Inflammation is recognized to be present in obesity, insulin resistance and type 2 diabetes (T2D), both at the systemic level and in adipose tissue. Recently, we showed that inflammation is an integral component in rodent and human islets in T2D. In the Goto-Kakizaki (GK) rat, we also demonstrated that extracellular matrix deposition progresses from intra-/peri-islet vessels, as in microangiopathy. In the present study, our hypothesis was that islet inflammation might have originated from endothelial cells (EC). Using a molecular approach we investigated: 1) EC activation in islets of 2-month-old GK rats, i.e., after 1 month of mild chronic hyperglycemia associated with hyperlipidemia; 2) the *in vivo* effects of IL-1 receptor antagonist (IL-1Ra), an immunosuppressive agent, which has been shown to improve type 2 diabetic patient state, on GK islet inflammation and glucose homeostasis.

Materials and methods: 1) Islets were isolated from 2-month-old male GK rats and Wistar control rats and expression of selected genes was analysed by qRT-PCR; 2) Immunohistochemistry was performed on whole pancreata; 3) GK rats were treated twice daily with IL-1Ra (Kineret, Amgen) at 2 different doses (10 and 50 mg/kg/day) or saline from weaning (1 month of age, at onset of diabetes) to 2 months of age (n = 5/group). Glycemia was measured 3 times/week, throughout the treatment period and pancreata and islets were processed as above.

Results: The selected genes encoding molecules known to be involved in EC activation were the following: plasminogen activator inhibitor 1 (Pa1), integrins (like Pecam1, Icam1, Vcam1, and E-selectin (Sele)), Toll-like receptor 4 (Tlr4), endothelin-1 (Edn1), angiotensin-converting enzyme 1 (Ace1), angiotensin receptor 1 and angiotensinogen (Agt), endothelial nitric oxide synthase (eNOS), prostacyclin synthase (Ptgis), cyclo-oxygenase 2 (Cox2), NADPH-oxidase 2 (Nox2) and hypoxia-induced factor-1 α (Hif1 α). All genes except Agt (that was decreased), were significantly up-regulated in 2-month-old GK islets. IL-1Ra treatment improved glucose homeostasis, islet mor-

phology and decreased islet fibrosis in the GK rat. At the molecular level, all genes that were assessed were significantly down-regulated in a dose-response manner by IL-1Ra treatment, except Sele and Hif1 α . We also found a significant decrease of genes encoding the following proteins: IL-6, GRO/KC (rodent IL-8 equivalent), MCP-1 and MIP-1 α , fibronectin, collagen I and III. **Conclusion:** The extensive endothelial activation that is at play during mild chronic hyperglycemia (from weaning onwards) and hyperlipidemia (from the perinatal period onwards) might alter β -cell microenvironment and consequently contribute to β -cell dysfunction in GK rats. The beneficial effect of IL-1Ra highlights the early and deleterious role of IL-1 in the GK endothelial dysfunction and offers a new therapeutic approach in T2D.

Elevated levels of the anti-inflammatory interleukin-1 receptor antagonist (IL-1Ra) precede, but do not prevent, the onset of type 2 diabetes (Whitehall II Study)

C. Herder¹, E. Brunner², A. Tabak², N.C. Schloot¹, D.R. Witte²

¹Institute for Clinical Diabetes Research, German Diabetes Centre, Duesseldorf, Germany, ²Department of Epidemiology and Public Health, University College London, United Kingdom

Background and aims: Low-grade inflammation has emerged as risk factor for the development of type 2 diabetes (T2D). Several cytokines and chemokines contribute to insulin resistance, and the pro-inflammatory cytokine interleukin-1 β (IL-1 β) has been reported to inhibit beta-cell function and promote beta-cell apoptosis. A randomised controlled trial recently demonstrated that the anti-inflammatory interleukin-1 receptor antagonist (IL-1Ra), a natural competitive inhibitor of IL-1 β , improves beta-cell function and glycaemic control in patients with type 2 diabetes. The aim of the current study was to investigate for the first time whether high systemic levels of IL-1Ra were associated with incident T2D in a prospective study.

Materials and methods: Serum levels of IL-1Ra were measured in a nested case-control study within the Whitehall II cohort. At baseline, participants were aged 50.8 years (SD: 6.2) and had an average BMI of 26.6 (SD 4.1). 366 controls with normal glucose tolerance at study baseline (75g OGTT; 1991-1993) and throughout follow up (up to 2002-2004) were compared with 189 individuals without T2D at baseline, with incident T2D during the follow-up period (cases). Controls were frequency-matched to cases for age, sex and BMI. Persons with prevalent or incident coronary heart disease, acute or chronic inflammatory conditions and non-white ethnicity were excluded.

Results: IL-1Ra concentrations at baseline were higher in cases (mean (95%CI) 296 (266-326 pg/ml) than in controls (mean (95%CI) 234 (222-246 pg/ml) (p<0.0001). An incremental increase in IL-1Ra of 100 pg/ml was associated with increased T2D risk (age and sex-adjusted OR (95% CI) 1.29 (1.14-1.47); p<0.001). This association remained significant after additional adjustment for BMI, lipids, blood pressure, fasting glucose, fasting insulin and C-reactive protein as potential confounders.

Conclusion: Our findings indicate that individuals who will develop T2D are not only characterised by an upregulation of pro-inflammatory cytokines and chemokines, but also by the upregulation of at least one anti-inflammatory immune marker. Given the therapeutic efficacy of IL-1Ra in a clinical trial it is tempting to speculate that high IL-1Ra levels cannot be considered as genuine risk factor. Our data rather point towards the presence of an early compensatory, anti-inflammatory response that precedes, but does not prevent, the development of T2D.

Plasma YKL-40 - a BMI-independent marker of type 2 diabetes

A.R. Nielsen¹, P. Plomgaard¹, J.S. Johansen², C.P. Fischer¹,
R. Krogh-Madsen¹, B.K. Pedersen¹

¹Centre of Inflammation and Metabolism - Rigshospitalet, Copenhagen,

²Department of Rheumatology, Herlev Hospital, Herlev, Denmark

Background and aims: YKL-40, a member of the “mammalian chitinase-like proteins,” is produced by macrophages, and serum concentrations of YKL-40 is elevated in patients with diseases characterized by inflammation. The possible relationship between YKL-40 and obesity, type 2 diabetes and inflammation was examined. Furthermore, using clamp technique, we assessed the effect of acute changes in blood glucose and insulin levels on circulating YKL-40.

Materials and methods: In 199 subjects divided into groups of normal glucose tolerant (n = 103) and type 2 diabetes (n = 96). These groups were subdivided on the basis of BMI (BMI < 30 or BMI ≥ 30). Blood samples and adipose tissue biopsies were obtained and fat mass was determined by DXA. Plasma YKL-40 and adipose tissue YKL-40 mRNA levels were measured using ELISA and real-time PCR, respectively. The relationship between circulating YKL-40, adipose tissue YKL-40 mRNA levels and parameters of obesity, parameters of type 2 diabetes and markers of inflammation were investigated. A second study, including healthy young male subjects (n = 7), investigated the acute effect of hyperglycaemia (plasma glucose: 15 mM) and hyperinsulinaemia (plasma insulin: ~900 pM) on plasma YKL-40 levels.

Results: Patients with type 2 diabetes had higher plasma YKL-40 levels (p = 0.0001), but not higher expression of adipose tissue YKL-40 mRNA (p = 0.2), compared to subjects with normal glucose tolerance. Obesity had no effect on plasma YKL-40 or adipose tissue YKL-40 mRNA levels. Multivariate regression analysis revealed that plasma YKL-40 was associated with fasting plasma glucose (p = 0.0004) and plasma IL-6 (p = 0.0303). In the intervention study, no effect of hyperglycaemia or hyperinsulinaemia was observed.

Conclusion: Plasma YKL-40 has been identified as an obesity-independent marker of type 2 diabetes, which is related to fasting plasma glucose and plasma IL-6 level. The second study suggests that the observed association between plasma glucose and YKL-40 in the circulation is not acutely regulated, but may be a consequence of a chronic dysregulated glucose homeostasis.

The chemokine IP-10 induces beta cell death through TLR4-signalling

K. Maedler, N.S. Sauter, F.T. Schulthess

Centre for Biomolecular Interactions, University of Bremen, Germany

Background and aims: In both, type 1 (T1DM) and type 2 diabetes (T2DM), β -cell destruction by apoptosis results in decreased β -cell mass and progression of the disease. We hypothesize that pro-inflammatory cytokines and chemokines contribute to the etiology. In the present study, we found that the Interferon-gamma-inducible Protein-10 (IP-10) plays an important role in triggering β -cell destruction.

Materials and methods: Isolated human islets were exposed to IP-10, β -cell apoptosis (by the TUNEL assay), replication (by Ki-67 staining) and glucose stimulated insulin secretion (GSIS) were measured. Additionally, cell viability was determined using the MTT colorimetric assay. IP-10 secretion, localization and mRNA were analyzed in isolated islets from healthy organ donors and donors with type 2 and type 1 diabetes. Akt and Pak-2 signaling were analyzed by western blot analysis. To identify the receptor which mediates the IP-10 effects in the β -cell we used the Dynabead technology. Paramagnetic beads were coated with IP-10 prior to incubation with human islet lysates and then investigated by western blot analysis. IP-10 signaling was also tested in TLR4^{-/-} mice.

Results: Islets isolated from patients with T2DM secreted IP-10 and contained 33.5-fold more IP-10 mRNA than islets from control patients. Pancreatic sections from patients with T2DM and T1DM expressed IP-10 in β -cells. Treatment of isolated human islets with recombinant IP-10 decreased β -cell viability. This was accompanied by impaired insulin secretion and decreased insulin mRNA. IP-10 induced sustained activation of Akt and JNK and downstream cleavage of p21-activated protein kinase 2 (PAK-2), switching Akt signals from proliferation to apoptosis. These effects were not mediated

by the commonly known IP-10 receptor CXCR3; islets from CXCR3^{-/-} mice showed also decreased β -cell viability. In contrast, we identified TLR4 as the receptor for IP-10 in the β -cells. We examined the ability of IP-10 to regulate TLR4 receptor expression. 0.1 ng/ml IP-10 caused a 2-fold induction of TLR4 mRNA. To investigate whether IP-10 signaling is TLR4 dependent, we tested the effect of IP-10 on islets isolated from TLR4^{-/-} mice and measured β -cell apoptosis. We used lipopolysaccharide (LPS), the major ligand for TLR4 as positive control to induce TLR4 dependent apoptosis. LPS induced a 2.9-fold induction of β -cell apoptosis, which was prevented in isolated islets from TLR4^{-/-}. IP-10 treatment induced a 2.2-fold induction of β -cell apoptosis in the wildtype islets, but not in the TLR4^{-/-}.

Conclusion: Our data suggest IP-10 as a marker for β -cell failure in diabetes. Strategies to block IP-10 signaling through blocking TLR4 signals could be a new target for maintaining β -cell survival.

Free fatty acids cause alterations in the insulin signalling pathway in JEG-3 cells

M. Lappas, A. Mitton, M. Permezel

Obstetrics and Gynaecology, University of Melbourne, Heidelberg, Australia

Background and aims: Free fatty acid (FFA) levels increase during normal pregnancy and have been implicated in the development of the progressive insulin resistance observed during normal pregnancy. Moreover, women with gestational diabetes mellitus (GDM) have a significant elevation in fasting FFA levels compared to normoglycaemic controls. Recent studies suggest that lipid- and fat-derived FFAs have been reported to induce insulin resistance *in vitro* and *in vivo*. Recent studies from our laboratory have shown that GDM women have defects in insulin signalling in placenta, however the effect of FFAs on insulin signalling in this tissue is not known. Thus the aim of this study was to elucidate the role of FFAs (saturated FFA palmitate (C16:0) and the monounsaturated FFA oleate (C18:1 ω 9) on the insulin signalling pathway in human placental JEG-3 cells.

Materials and methods: Human placental JEG-3 cells (3 independent experiments) were then incubated in serum free DMEM for 24 hours in the presence or absence of 0.2, 0.5 and 0.75 mg/ml oleate and palmitate. Cells were stimulated with 100 nM insulin for 1 hour. Cells were collected and lysed, and the effect of oleate and palmitate on the insulin signalling pathway (IR- β (total and phosphorylated), IRS-1 (total and phosphorylated), PI3K p110 and PI3K p85a) was determined by Western blotting.

Results: Incubation of JEG-3 cells with insulin caused an increase in IR- β and IRS-1 tyrosine phosphorylation. Both oleate and palmitate inhibited insulin stimulated insulin signalling in JEG-3 cells. Specifically, oleate and palmitate decreased the protein expression of insulin stimulated phosphorylation of IR- β and IRS-1.

Conclusion: The data presented in this study demonstrate that FFAs interfere with the initial steps of the insulin signalling cascade in human placental cells. A raised level of FFA may be responsible for the insulin resistance of GDM.

Insulin-resistance and low-grade inflammation in type 1 diabetes mellitus

G. Llauroad¹, R. Tirado¹, A. Megia², I. Simón², L. Gallart², A. Caixàs¹,

O. Giménez-Palop¹, J. Vendrell², J.-M. González-Clemente¹

¹Diabetes, Endocrinology and Nutrition, Hospital de Sabadell, Sabadell, ²Diabetes, Endocrinology and Nutrition, Hospital Universitari Joan XXIII de Tarragona. CIBERDEM, Spain

Background and aims: Subjects with type 1 diabetes (T1DM) have an increase in insulin resistance and insulin resistance is associated with a low-grade systemic inflammatory response. However, few data exist regarding the relationships between insulin-resistance and low-grade systemic inflammation in T1DM, although both factors have been associated with the presence of micro and macrovascular complications. We aimed at evaluating the relationship between insulin resistance and some inflammation-related plasma proteins in a group of subjects with T1DM, taking into account the presence of microvascular complications.

Materials and methods: One hundred and twenty subjects (60 men and 60 women), all diagnosed with T1DM 14 years before, were evaluated for (1)

sex, age, body mass index, waist-to-hip ratio (WHR), blood pressure, smoking, alcohol intake, insulin dose, HbA1c and lipid profile; (2) microvascular complications (neuropathy -peripheral and cardiovascular autonomic-, retinopathy and nephropathy); (3) concentrations of plasma-related inflammation proteins (soluble receptors type 1 and 2 of TNF- α , interleukin-6, adiponectin, leptin and high-sensitivity C-reactive protein (hs-CRP)); and (4) insulin resistance (by way of the Williams' mathematical estimation of the glucose disposal rate -eGDR-). Those subjects with an eGDR less than the median of the same sex group were classified as insulin resistant and the others were classified as non-insulin resistant.

Results: Insulin resistant men, as compared to non-insulin resistant, had higher WHR (0.89 ± 0.08 vs 0.83 ± 0.05 , respectively, $p < 0.01$), higher systolic (121 ± 9 vs 114 ± 10 mmHg; $p=0.01$) and diastolic blood pressure (72 ± 9 vs 70 ± 7 mmHg, $p=0.02$), higher HbA1c values (9.0 ± 1.2 vs 7.4 ± 0.9 %, $p < 0.01$) and higher concentrations of hsCRP ($1.16(0.61-3.10)$ vs $0.49(0.31-0.82)$ mg/dL, $p=0.01$). In contrast, they were no different from the other evaluated inflammation-related plasma proteins. Insulin resistant women, as compared to the non-insulin resistant, had higher WHR (0.83 ± 0.11 vs 0.74 ± 0.06 , respectively, $p < 0.01$) and HbA1c values (9.2 ± 1.7 vs 7.6 ± 1.1 %, $p < 0.01$), but no differences were found between both groups, regarding the other variables evaluated. After adjusting for age, sex, alcohol intake and smoking in males, hs-CRP correlated significantly with WHR ($r = 0.45$; $p < 0.01$) but not with blood pressure nor HbA1c.

Conclusion: Insulin resistant males with T1DM have an increase in plasma concentrations of hs-CRP, which were not confirmed in insulin resistant women. Central obesity is the main determinant of this increase in hs-CRP. Implication of AMPK and mTOR in brown adipocyte differentiation

M. Lorenzo, R. Vila-Bedmar, I. Nieto-Vazquez, L. Garcia-Guerra, S. Fernandez-Veledo

Bioquímica y Biología Molecular, Universidad Complutense, Madrid, Spain

Background and aims: Brown adipose tissue (BAT) is considered of metabolic significance in human physiology, since it plays an important role in regulating energy balance. Alterations in this tissue have been related to obesity and associated metabolic disorders, such as insulin resistance and type 2 diabetes. BAT is developed throughout fetal stage. However, the physiological signals and molecular mechanisms modulating this process are still unknown. In this study, we further examine some of the intracellular signaling pathways involved in brown adipocyte differentiation, as well as the ability of different nuclear receptor agonists to induce adipogenesis and thermogenesis.

Materials and methods: BAT differentiation was studied in a stable cell line obtained by immortalization of primary rat fetal brown adipocytes with a retroviral construct of SV40 Large T Ag. Differentiation was induced with a specific differentiation medium, supplemented with the PPAR γ agonist Rosiglitazone. Phosphorylation and expression of different kinases (MAPKs, mTOR-AMPK and Wnt pathways) were analyzed in the absence or presence of the different inhibitors and nuclear receptor agonists.

Results: Immortalized cells were able to differentiate, expressed specific adipogenic and thermogenic markers, and reproduced metabolic functions typical of BAT. Differentiation was accomplished by a sequential activation of p38MAPK and AMPK, and by a significant attenuation in the activation of ERK1/2 and mTOR-p70 pathways. The inhibition of either the mTOR or the AMPK cascades prevented cell differentiation. In addition, a degradation of beta-catenin, a major component of Wnt pathway, was detected throughout the differentiation process. This inactivation of Wnt pathway was dependent on mTOR signaling. On the other hand, an increase in adipogenic but not in thermogenic markers was observed in cells differentiated in the presence of the LXR agonist instead of Rosiglitazone.

Conclusion: These results show a critical role for AMPK and mTOR-p70, as well as for the Wnt signaling pathways, in regulating brown adipocyte differentiation. Nuclear receptor agonists differentially regulate adipogenic and thermogenic programs in brown adipose tissue.

Effects of the AMPK activators AICAR and metformin on basal and insulin-induced glucose-uptake in human adipocytes

J. Grisouard¹, T. Radimerski¹, D. Seboek Kinter¹, H. Zulewski¹, B. Kola², M. Korbonits², B. Müller³, U. Keller¹, M. Christ-Crain¹

¹Department of Biomedicine, Metabolism Group, University Hospital Basel, Switzerland, ²Centre for Endocrinology, Barts and the London Medical School, University of London, United Kingdom, ³Department of Internal Medicine, Kantonsspital Aarau, Switzerland

Background: Metformin and 5-aminoimidazole-4-carboxamide 1- β -D-ribofuranoside (AICAR) activate AMP-activated protein kinase (AMPK) in peripheral tissues. The role of AMPK in regulating glucose uptake in adipose tissue remains controversial since both, increasing and decreasing effects have been reported in rodent adipocytes. Very few data exist for primary human fat cells.

Materials and methods: Herein we have analysed the effects of AICAR and metformin on basal and insulin-mediated glucose uptake in human adipocyte culture *in vitro*. Human mesenchymal stem cells and human pre-adipocyte-derived adipocytes obtained from surgical biopsies were differentiated *in vitro* into adipocytes, and the effects of insulin (20 min, 100 nM), AICAR (24 h, 1 mM), metformin (24 h, 1 mM) and their combinations on glucose uptake were determined.

Results: Both, AICAR and metformin induced AMPK activity as mirrored by increased AMPK and ACC phosphorylation. Insulin increased glucose uptake to 204 ± 39 % of control ($P < 0.01$). In adipocytes treated with AICAR basal glucose uptake was not significantly altered (118 ± 15 % of control) whereas insulin-induced glucose uptake was reduced to 82 ± 9 % of insulin alone ($P < 0.05$). AICAR increased GLUT-4 protein content, and phosphorylation

of AS160 and c-Cbl, two downstream mediators of insulin-induced glucose uptake. However, insulin-induced translocation of GLUT-4 to the plasma membrane analysed by immunodetection of GLUT-4 in plasma membrane fraction was inhibited by AICAR. Treatment of adipocytes with metformin increased basal ($226 \pm 21\%$ of control ($P < 0.01$)) and insulin-induced glucose uptake ($155 \pm 19\%$ of insulin alone ($P < 0.01$)). Metformin-induced glucose uptake was inhibited by phloretin, an inhibitor of glucose transporters. Metformin increased GLUT-4 protein content, GLUT-4 translocation to the plasma membrane and induced glucose-uptake even in the presence of wortmannin, an inhibitor of the classical "PI3K/Akt"-insulin signalling pathway.

Conclusion: AICAR inhibits insulin-induced GLUT-4 translocation and thus prevents the increase in insulin-induced glucose uptake. In contrast, metformin appears to induce GLUT-4-dependent glucose uptake independently of the classical "PI3K/Akt"-insulin signalling pathway. In addition to the insulin signalling pathway, activation of AMPK by metformin may represent an alternative mechanism to improve glucose uptake in adipocytes.

AMP-activated protein kinase and transcriptional control of gluconeogenic gene expression

J.K. Rundle¹, E.R. Pearson², C. Sutherland¹

¹Department of Pathology and Neuroscience, ²Department of Medicine and Therapeutics, University of Dundee, Dundee, United Kingdom

Background and aims: AMP-activated protein kinase (AMPK) is activated by stimuli that raise intracellular AMP concentrations. Once activated, AMPK antagonises cellular processes which consume ATP and initiates processes that generate ATP, thereby restoring energy homeostasis. AMPK has been identified as a target of metformin, the most widely prescribed anti-diabetic agent. Indeed, animals lacking AMPK in the liver fail to respond to metformin. Previous work has suggested that AMPK activation in liver reduces the transcription of PEPCK and G6Pase genes, two rate-controlling enzymes of gluconeogenesis. A number of small molecules activate AMPK, for example 5-aminoimidazole-4-carboxamide-1- β -D-ribofuranoside (AICAR) activates AMPK indirectly as it is metabolised to the AMP mimic molecule, ZMP. More recently, thienopyridone compound, A-769662, has been developed to directly target and activate AMPK. In this study, we compare AICAR and A-769662 activation of AMPK and subsequent effects on gluconeogenic gene expression.

Materials and methods: Rat hepatoma cell line HL1C was incubated with the AMPK activators AICAR or compound A-769662 for 30 min, 4h, or 16h and changes in AMPK, ACC, and ERK 1/2 phosphorylation were measured by Western blot as surrogates for activation of AMPK and ERK. PEPCK and G6Pase gene transcription were measured by real-time PCR. HL1C cells are stably transfected with a chloramphenicol acetyltransferase (CAT) reporter gene construct under the control of the PEPCK promoter. Therefore, PEPCK promoter activity was also assessed by a CAT enzyme activity assay in response to hormones and AMPK activators.

Results: AICAR transiently activates AMPK whereas activation by A-769662 appears to be chronic. Activation of AMPK by A-769662 could still be detected 16h after initial exposure.

PEPCK and G6Pase gene transcription is induced by the application of dexamethasone (synthetic glucocorticoid) and 8CPT-cAMP (mimics glucagon) to liver cells. This induction is completely inhibited by the presence of insulin. G6Pase gene expression was efficiently inhibited by AICAR (80%) and partially by A-769662 (40%); however, PEPCK gene expression was only repressed by AICAR (~50%). This result was confirmed by the PEPCK-CAT promoter activity assay. This suggested that AMPK activation was not sufficient to inhibit PEPCK gene transcription. AICAR has been shown to activate the ERK pathway in human muscle. ERK 1/2 phosphorylation was significantly increased when HL1C cells were stimulated with AICAR at all time points. A specific inhibitor of ERK 1/2 activation, PD184352, did not alter the repression of these genes by AICAR, suggesting this pathway is not required for the regulation of PEPCK by AICAR.

Conclusion: Our data suggests that the repression of PEPCK gene transcription by AICAR is AMPK-independent. We also show that this repression by AICAR is independent of ERK 1/2 activation, despite AICAR efficiently activating ERK at all time points studied. Direct activation of AMPK by A-769662 is sufficient to reduce G6Pase transcription, albeit much less potently than insulin, but this compound has no effect on PEPCK gene expression. Taken together, these data show that PEPCK and G6Pase are regulated differently from one another in response to AMPK activation, and therefore metformin. Repression of PEPCK must be independent of AMPK.

Infusion of a lipid emulsion modulates AMP-activated protein kinase (AMPK) and related proteins in rat liver, muscle and adipose tissues

S. Anavi, E. Ilan, O. Tirosh, Z. Madar

Faculty of Agriculture, The Hebrew University Of Jerusalem, Rehovot, Israel

Background and aims: It has been shown that fat accumulation in liver, muscle and adipose tissue may play an important role in the development of the metabolic syndrome, but the precise mechanisms are not fully known. AMPK, a serine/threonine protein kinase, has been proposed to function as a 'fuel gauge' to monitor cellular energy status in response to nutritional variation. There is also compelling evidence that adipose tissue is an endocrine organ through secretion of "adipokines" which may mediate AMPK action. Recent studies indicate alteration/defects in AMPK signaling at the onset of the metabolic syndrome. The primary objective of this study was to examine the effects of exposure to a lipid emulsion (LE) on AMPK expression in rat liver, muscle and adipose tissues. Other proteins involved in AMPK pathway were also examined.

Materials and methods: Wistar rats were infused via the jugular vein with 10 ml of LE or PBS for 4h per day (2 ml/h) for 6 days. Liver, muscle and adipose tissues were removed and mRNA (RT-PCR), protein (Western blot) and protein phosphatase 2C (PP2C) activity analyses were performed.

Results: Following rat treatment with LE for 6 days AMPK and acetyl-coA carboxylase (ACC) phosphorylation were significantly ($p < 0.007$ -0.02) decreased by 64% and 62% respectively and a significant increase ($p = 0.007$) in PP2C activity of 1.5-fold were observed. Hepatic mRNA levels of AMPK α 2, ACC α , adiponectin receptor 1 (AdipoR1), AdipoR2 and PEPCK were also significantly ($p < 0.004$ -0.05) reduced by approximately 2-3-fold. No significant changes in AMPK α 1, peroxisome-proliferator-activated receptor- γ coactivator1 α (PGC1 α), PGC1 β and PP2C expression were detected. In contrast, muscles exhibited significantly increased AMPK and ACC phosphorylation of 148% and 150% respectively ($p < 0.01$ -0.02). Muscle mRNA levels of AMPK α 2, ACC β , AdipoR1, PGC1 α and PGC1 β mRNA were also increased by 3-50-folds ($p < 0.001$ -0.05). No significant effect of LE on AdipoR2 mRNA levels or PP2C activity was found. In adipose tissue there was no significant alteration in AMPK or ACC phosphorylation but AMPK α 1 and AMPK α 2 mRNA levels were significantly ($p < 0.04$) increased by 12.8 and 6.2 respectively. Adipose mRNA levels of ACC α , PGC1 α , PGC1 β , AdipoR1 and AdipoR2 remained unchanged.

Conclusion: These results demonstrate that LE suppresses the AMPK signaling pathway and key proteins involved in fat oxidation, mitochondrial function and biogenesis in the liver. Therefore we speculate that alterations in the liver rather than in skeletal muscle and even less in adipose tissue may be associated with the onset of the metabolic syndrome.

Improved glucose tolerance after long-term exercise and 5-Aminoimidazole-4-carboxamide-1- β -D-ribofuranoside (AICAR) treatment in Goto-Kakizaki rats despite reduced beta cell mass

R. Pold¹, C. Godfredsen², L. Solskov¹, O. Schmitz¹, A. Flyvbjerg³, S. Lund³

¹Pharmacology, Aarhus University, Denmark, Novo Nordisk A/S, Måløv, Denmark, ³Aarhus University Hospital, Aarhus Sygehus (NBG). Medical Department M (Diabetes and Endocrinology), and Medical Research Laboratories, Aarhus, Denmark

Background and aims: Type 2 diabetes is characterized by insulin resistance and a compromised β -cell function. Accordingly compensatory retrieval in β -cell mass and the preservation of the β -cell function are essential in prevention of diabetes. Recent studies on an obese rat model for type 2 diabetes (ZDF-rats), characterized by severe insulin resistance combined with a β -cell defect, have shown that long-term aerobic training or 5-Aminoimidazole-4-carboxamide-1- β -D-ribofuranoside (AICAR) administration can preserve islet morphology in the pancreas. To clarify if the changes are secondary to the improvements in insulin sensitivity or due to a direct effect on the β -cell the present study was undertaken to determine the β -cell morphology and the β -cell mass after 6 weeks of aerobic exercise and AICAR treatment in a lean animal model of type 2 diabetes (GK-rats) characterized primarily by a β -cell defect.

Materials and methods: Five weeks old GK-rats were allocated into 3 groups: an exercise, an AICAR treated and an untreated group. Wistar rats were used as non-diabetic controls. The exercise treated GK-group was allocated to treadmill running for one hour five days a week. AICAR treated

animals received a daily subcutaneous injection every morning of 0.5 mg AICAR/g body weight. After 6 weeks of treatment an oral glucose tolerance test (OGTT) was performed. After the intervention period pancreas was removed for further studies

Results: The OGTT revealed significant improvements in the glucose tolerance in the treated groups. Consistently the insulin resistance index was increased in the untreated GK-rats after the intervention period. In contrast the β -cell mass was significantly lower in exercise treated and AICAR treated animals when compared to the untreated GK-rats (AICAR; 2.5 ± 0.3 mg, Exercise; 2.7 ± 0.4 mg Untreated; 4.9 ± 0.8 mg, Wistar; 7.4 ± 1.2 mg). No differences in β -cell morphology between the treated and untreated GK-rats were observed

Conclusion: In conclusion, both exercise and AICAR treated GK-rats had improved glucose tolerance despite diminished β -cell mass. This improvement can contribute to the preservation of the β -cell which is essential for delaying or preventing the onset of diabetes

789

SCD1 knockdown in the beta cell protects against apoptosis and improves ER folding capacity

K. Thörn, M. Hovsepian, P. Bergsten

Medical Cellbiology, Uppsala Universitet, Sweden

Background and aims: Stearoyl-CoA desaturase 1 (SCD1) is an endoplasmic reticulum (ER) resident protein involved in the synthesis of mono-unsaturated fatty acids. Although it has been shown that high levels of SCD1 have a protective effect in vitro, mice lacking SCD1 have protection from diet-induced obesity. The lack of SCD1 results in higher energy expenditure, reduced fatty acid de novo synthesis, decreased expression of lipogenic genes and increased insulin sensitivity. However, these results have been obtained in insulin target tissue and no studies have so far addressed the potential beneficial effects of SCD1 disruption or reduction in the pancreatic β -cell. The aim of the present study was to investigate the molecular changes in the β -cell caused by decreasing the levels of SCD1.

Materials and methods: Insulin-producing MIN6 cells with reduced levels of SCD1 were obtained by transfecting the cells with siRNA against SCD1. Cells with normal or reduced SCD1 were cultured for 72 hours after which apoptosis was measured. Also, cells were lysed and proteins separated by two-dimensional (2D) gel electrophoresis. Subsequently, differentially expressed proteins were identified by peptide mass fingerprinting employing MALDI-TOF MS. Proteins of cell lysates were also separated by SDS-PAGE and immunoblotted with antibodies directed towards ER resident proteins.

Results: In MIN6 cells transfected with siRNA against SCD1 the protein level of the enzyme was reduced by 70%. This knockdown of SCD1 in MIN6 cells resulted in reduced apoptosis 72 hours post transfection. Analysis of differentially regulated protein by 2D gel electrophoresis indicated regulation of proteins mainly involved in protein folding and degradation. Protein disulfide isomerase, prolyl 4-hydroxylase and glucose regulated protein 94 (GRP94), chaperones involved in protein folding in the ER, were all up-regulated by more than 50%. Indications of increased function of the proteasome was also found as two of its components, proteasome subunit α type 3 and proteasome 26S subunit, were up-regulated by more than 50%. To investigate if the lower apoptosis and increased levels of chaperones seen after knockdown of SCD1 were caused by altering activity of the regulatory proteins in the unfolded protein response (UPR), phosphorylation of PERK and cleavage of ATF6 was investigated. Phosphorylation of PERK was decreased and cleavage of ATF6 was increased in β -cells with lowered SCD1 levels.

Conclusion: The beneficial phenotype of SCD1 knockdown in the β -cell may be caused by enhanced capacity of the ER as evidenced by increased cleavage of ATF6 and up-regulation of chaperones involved in protein folding and proteins involved in degradation. Furthermore, decreased apoptosis may in part be mediated by lower activity of the PERK pathway of the UPR.

Obesity is associated with activation of innate immune pathway and ER stress in human abdominal subcutaneous adipose tissue

G. Tripathi, C.M. Kusminski, A.L. Harte, K.C. McGee, P.J. O'Hare, P.G. McTernan, S. Kumar

Warwick Medical School, University of Warwick, United Kingdom

Background and aims: Obesity and type 2 diabetes mellitus (T2DM) are closely associated with chronic inflammation characterised by abnormal cytokine production and activation of inflammatory signalling pathways, but the mechanisms underlying the pathogenesis of obesity induced inflammation remain unclear. Recent findings in rodent models indicate that endoplasmic reticulum (ER) stress is critical to the initiation and integration of pathways of inflammation and insulin action in obesity and T2DM. The ER represents a fundamental site for protein folding, maturation, storage and transport. Recent studies have highlighted that ER stress is caused by the accumulation of unfolded/misfolded proteins. This leads to the subsequent activation of the unfolded protein response (UPR) to restore functional integrity which, in turn, leads to upregulation of genes such as PERK-like ER kinase (PERK) and activating transcription factor 6 (ATF6). Both PERK and ATF6 have been implicated to influence JNK and NF κ B pathways. However, to date, no study has examined the potential relationship between ER stress and JNK/NF κ B in human adipose tissue. Therefore our aims were to 1) examine the impact of increasing adipose tissue mass on ER stress activated genes 2) and the influence of obesity on the NF κ B and JNK signalling pathways in human adipose tissue.

Materials and methods: Abdominal subcutaneous adipose tissue (AbSc AT) was collected from patients undergoing elective liposuction surgery. Samples were divided into lean (n=20) and obese (n=20) sub-groups (lean: age, 45 ± 3.3 yrs; BMI, 21.9 ± 2.4 kg/m²; obese: 47 ± 4.1 yrs; 29.6 ± 4.2 kg/m²). Real-time PCR and western blotting was utilised to examine ATF6, eIF2 α and PERK expression and also the NF- κ B and JNK pathway.

Results: ATF6, eIF2 α and PERK mRNA levels were 7.3-fold, 9.1-fold and 8.2-fold higher in obese AbSc AT when compared with lean (ATF6: Lean Δ Ct: 10.22 ± 0.96 ; Obese Δ Ct: 7.36 ± 1.49 ; $p < 0.001$; eIF2 α : Lean Δ Ct: 10.84 ± 1.36 ; Obese Δ Ct: 7.65 ± 1.82 ; $p < 0.001$; PERK: Lean Δ Ct: 10.36 ± 0.43 ; Obese Δ Ct: 7.42 ± 0.95 ; $p < 0.001$). In parallel, expression of key components of the NF κ B pathways were markedly unregulated in obese AT in comparison with lean (MyD88: 1.94-fold \uparrow , $p < 0.001$, n=6; TRAF-6: 1.13-fold \uparrow , $p < 0.05$, n=6; NF κ B: 1.23-fold \uparrow , $p < 0.05$, n=6). JNK1 and JNK2 expression were also analysed by RT-PCR in lean (n=12) and obese cohorts (n=12). No significant difference was observed with JNK1 gene expression in relation to adiposity status (Lean: JNK1, Δ Ct 13.39 ± 0.55 ; JNK1, Obese Δ Ct 14.17 ± 0.68). However, JNK2 expression was significantly higher in the obese cohort (Lean: JNK2, Δ Ct 10.39 ± 0.17 ; JNK2, Obese: Δ Ct 9.6 ± 0.23 ; $p < 0.05$). We also examined the effect of adiposity for total and phosphorylated JNK1 expression. Phosphorylated JNK1 was significantly higher in obese (Lean: 1.1 ± 0.3 , Obese: 3.2 ± 0.3 ; $p < 0.001$).

Conclusion: Our findings confirm, for the first time, ER stress in human AbSc AT from obese subjects as compared with lean subjects. Our data also demonstrate upregulation of key factors of the innate immune signalling pathway; suggesting ER stress and inflammation in adipose tissue may underlie sub-clinical inflammation that may potentially contribute to pathogenesis of obesity associated T2DM. Further mechanistic studies are underway to show that ER stress may be one of the factors that induces pro-inflammatory cytokine response in human adipose tissue.

Endoplasmic reticulum stress prevention improves hepatic steatosis of ob/ob mice through an inhibition of SREBP-1c proteolytic cleavage

H. Kammoun, H. Chabanon, I. Hainault, P. Ferré, F. Foufelle

Metabolic and nutritional pathologies : obesity and type 2 diabetes, INSERM UMR872, Paris, France

Background and aims: Hepatic steatosis is strongly associated with the metabolic syndrome, including type 2 diabetes and obesity. In rodents, lipogenesis has been shown to be one of the major pathway implicated in the set up of steatosis. The transcription factor SREBP-1c has a central role in the transcriptional control of lipogenic enzymes. SREBP-1c is regulated by insulin both at the transcriptional and post-translational level (activation of the proteolytic cleavage). Interestingly, high level of nuclear SREBP-1c are detected

in the fatty liver of rodents characterized by a severe hepatic insulin resistance suggesting that another mechanism than insulin can trigger the activation of SREBP-1c. Endoplasmic reticulum (ER) stress has been shown to be induced in the liver of obese rodents. We hypothesized that ER stress activation in obese animals can activate SREBP-1c proteolysis leading to a stimulation of lipogenesis and finally to the development of hepatic steatosis.

Materials and methods: ob/ob mice were used as a model of fatty liver. ER stress was inhibited using an adenoviral vector allowing the overexpression of the BiP/GRP78 chaperone. The consequences of ER stress inhibition were analysed on nuclear and microsomal SREBP-1c and on SREBP-1c target genes as well as liver and serum triglycerides content.

Results: As described previously, several ER stress protein markers (ATF6 and XBP1) are induced in the liver of ob/ob mice compared to their lean control. Nuclear content of SREBP-1c as well as the expression of lipogenic enzymes are also greatly induced in the liver of ob/ob mice. Hepatic overexpression of protein BiP/GRP78 results in (1) a decrease of ER stress markers, (2) a decrease in precursor and nuclear content of SREBP-1c, (3) a decrease in lipogenic enzyme gene expression (4) a reduction in hepatic and serum triglycerides concentrations. This leads to an improvement of liver insulin sensitivity as shown by the fact that the insulin/glucose ratio and the expression of gluconeogenic enzymes are strongly decreased.

Conclusion: The ER stress pathway can contribute to the development of hepatic steatosis in obese mice by activating the transcription factor SREBP-1c and hepatic de novo lipogenesis. This pathway could then be a pharmacological target to reduce hepatic steatosis.

Rimonabant reduces body weight and adiposity independent of changes in resting metabolic rate and food intake

O.O. Woolcott, D. Stefanovski, L.N. Harrison, V. Mooradian, D. Zheng, M. Lottati, J. Dittmann, C.M. Kolka, S.P. Kim, I.R. Hsu, K.J. Catalano, V. Ionut, S. Yae, R.N. Bergman, J.M. Richey
Physiology & Biophysics, Keck School of Medicine, University of Southern California, Los Angeles, United States

Background and aims: Rimonabant (RIM), a drug used to treat obesity, is believed to reduce body weight (BW) mainly by decreasing appetite. Recently, it has been shown that RIM acutely increases energy expenditure in rodents. In this study, we longitudinally monitored fat distribution, food intake and resting metabolic rate (RMR) in dogs fed a high-fat diet and chronically treated with RIM to determine the mechanism by which RIM reduces BW.

Materials and methods: Twelve male dogs fed a hypercaloric high-fat diet (HHFD) consisted of ~5400 kcal/day (fat: 53%), starting at week -6. After 6 weeks of HHFD (baseline: week 0), dogs were divided in two groups: 7 dogs started RIM treatment (1.25 mg/kg/d, P.O.), and 5 dogs received placebo (PBO) during 16 weeks. HHFD was maintained until the end of the study. Fat and non-fat content changes (Δ) in the abdominal trunk were monitored by magnetic resonance imaging (MRI) at weeks: -6, 0, 2, and 16. Body composition in the trunk was divided in 5 categories: visceral adipose tissue (VAT), subcutaneous adipose tissue (SAT), total fat (TF=VAT+SAT), non-fat tissue (NFT) and total tissue (TT=TF+NFT). At week -6, BW and body composition were not significantly different between groups. RIM and PBO groups had similar baseline BW (32.5 ± 1.2 and 32.3 ± 1.3 kg, respectively, mean \pm SEM). RMR was measured by indirect calorimetry.

Results: After 16 weeks of treatment, concomitant with a HHFD, RIM dogs lost weight by 4.3% ($P=0.005$), while PBO dogs increased their BW by 5.9% ($P=0.01$). RIM reduced food intake by 26.3% (79.8 ± 5.4 vs. 58.8 ± 5.6 kcal/kg/d, $P=0.019$) only in the first two weeks of the study. Food intake in the PBO group remained unchanged. RIM consistently decreased TF and SAT contents by 18.2% ($P=0.018$) and 24.4% ($P=0.011$), respectively. In contrast, PBO group showed an average increase in SAT by 37% ($P=0.002$) and TF by 24.2%, though not significant ($P=0.075$). In the RIM group, compared with PBO, the Δ of TF and SAT was significantly different (81.2 ± 5.2 vs. $123.9 \pm 10.4\%$ [$P=0.002$], and 76.1 ± 4.4 vs. $136.6 \pm 3.4\%$ [$P<0.001$], respectively). NFT and VAT remained unchanged in both groups. TT was correlated with BW in the RIM and PBO group ($r^2=0.67$ [$P=0.025$] and $r^2=0.77$ [$P=0.049$], respectively). Surprisingly, compared with baseline, RIM group showed a decrease in RMR at week 16 (1414.1 ± 85.5 vs. 1618.8 ± 76 kcal/d, $P=0.047$) while PBO group showed no changes (1628.5 ± 139.9 vs. 1632.9 ± 63.7 kcal/d). However, there

was no correlation between RMR and BW, TF, VAT or SAT in any group, at any week. Moreover, there was no difference in RMR between groups.

Conclusion: Chronic treatment with RIM resulted in reduction of BW and fat content in the abdominal trunk. However, these findings are not explained by either changes in food intake or RMR. Together, these results suggest that weight loss and fat reduction induced by RIM may be due to an effect on physical activity.

Weight loss improves platelet sensitivity to thiol antioxidant N-acetyl-L-cysteine in obese insulin-resistant subjects: relationships with improvement of insulin sensitivity

G. Anfossi, I. Russo, M. Viretto, P. Del Mese, G. Doronzo, K. Bonomo, C. Giordanino, L. Mattiello, M. Trovati
Diabetes Unit, Department of Clinical and Biological Sciences, University of Turin, San Luigi Gonzaga Hospital, Italy

Background and aims: N-acetyl-L-cysteine (NAC) is a thiol compound with both extra- and intracellular antioxidative properties, able to reduce platelet responses to agonists by enhancing the inhibitory effects of nitric oxide (NO) via an increase of the anti-aggregating nucleotide cyclic guanosine monophosphate (cGMP). We previously observed that in central obesity platelets are resistant to the anti-aggregating effects of NAC, as a piece of a multifaceted resistance to anti-aggregating substances, deeply involved in the increased atherothrombotic risk. Lifestyle changes prevent the occurrence of cardiovascular events in obese subjects: few studies, however, evaluated so far whether weight loss reduces the obesity-related platelet dysfunction. Aim of this study is to clarify whether a diet intervention to obtain a body weight reduction of at least 10% of baseline improves platelet sensitivity to NAC.

Materials and methods: 10 subjects affected by central obesity [M/F: 5/5; age: 38.4 ± 3.4 years; BMI 35 ± 1.5 kg/m²; waist circumference (WC): 102.7 ± 3.5 cm] were investigated at baseline and after a 6-month diet intervention program, by measuring: i) insulin resistance by Homeostasis Model Assessment (HOMA-IR) Index; ii) circulating markers of endothelial dysfunction (such as sVCAM) and of platelet activation (such as sCD40 Ligand); iii) platelet concentrations of cGMP in response to a 3-min incubation with 10 μ mol/l of the NO donor Sodium Nitroprusside (SNP), with or without a 30-min pre-incubation with 3 mmol/l of NAC. The effect of NAC on the synthesis of cGMP induced by SNP was calculated also as the ratio between the cGMP levels elicited by NAC+SNP and the cGMP levels elicited by SNP alone. Data are expressed as mean \pm SEM.

Results: At the end of diet intervention, obese subjects showed: i) significant reductions of body weight ($-13.5 \pm 1.4\%$), BMI ($-12.8 \pm 1.5\%$) and WC ($-9.0 \pm 1.3\%$); ii) a decrease of HOMA IR from 7.7 ± 1.2 to 3.3 ± 0.4 ($p<0.002$); iii) a decrease of sVCAM from 1093.8 ± 77.8 to 685.1 ± 54.9 (ng/ml) ($p<0.0001$) and of sCD40L from 5.9 ± 0.5 to 2.1 ± 0.5 ng/ml ($p<0.0001$); iv) an increase of platelet cGMP concentrations (pmol/10⁹ plts) in response to NAC from 7.57 ± 0.54 to 15.32 ± 1.01 ($p<0.0001$), in response to SNP from 9.73 ± 0.70 to 33.36 ± 4.23 ($p<0.0001$), in response to NAC+SNP from 26.22 ± 2.60 to 188.80 ± 6.73 ($p<0.0001$); v) an increase of the ratio between platelet cGMP in response to NAC+SNP and platelet cGMP in response to SNP alone, from 3.02 ± 0.56 to 7.06 ± 1.46 ($p<0.019$). By the simple regression analysis, cGMP levels measured in the presence of NAC+SNP inversely correlated with BMI ($r=-0.538$, $p<0.014$), WC ($r=-0.528$, $p<0.017$), HOMA IR ($r=-0.805$, $p<0.007$), sVCAM ($r=-0.709$, $p<0.0001$) and CD40L ($r=-0.718$, $p<0.0001$). In multiple regression analysis, HOMA-IR was the only parameter significantly correlated with the cGMP response to NAC+SNP ($p=0.0001$).

Conclusions: Diet-induced weight loss in subjects affected by central obesity improves platelet sensitivity to NAC, with a significant relationship with the improvement of insulin sensitivity. This phenomenon could be involved in the decrease of the atherothrombotic risk induced by weight loss related to the correction of insulin resistance.

Mechanism of improvement of glucose tolerance in obese subjects with type 2 diabetes following gastric bypass surgeryM. Anselmino¹, M. Nannipieri², A. Mari³, E. Mancini², E. Barsotti², E. Ferrannini²¹Bariatric Surgery, Azienda Ospedaliera Universitaria di Pisa, ²Internal Medicine, University of Pisa, ³Bio-Engineering, CNR of Padua, Italy

Background and aims: β -cell dysfunction and insulin resistance are the main pathophysiological defects responsible for the development of hyperglycaemia. In morbidly obese patients with type 2 diabetes (T2DM), bilio-pancreatic-diversion (a predominantly malabsorptive surgical approach) restores euglycaemia and the acute insulin response to glucose. Aim of this study was to analyse the mechanisms underlying the improvement in glucose tolerance in morbidly obese T2DM patients undergoing Roux-en-Y gastric bypass (GBP, a predominantly restrictive operation).

Materials and methods: We evaluated glucose tolerance by a standard 75-g OGTT, insulin sensitivity by the OGTT-derived OGIS index, β -cell function by modelling analysis of the C-peptide response to oral glucose in 9 non-diabetic subjects (NGT) and 12 T2DM subjects before and 45 days after surgery.

Results: At 45 days post-GBP, body mass index (BMI) decreased to the same extent in NGT and T2DM subjects (from 43.7 ± 4.9 to 36.9 ± 4.4 kg m⁻² in NGT and from 47.5 ± 7.2 to 40.4 ± 7.2 in T2DM, mean \pm SD, $p < 0.0001$). GBP improved glucose tolerance in all subjects ($p < 0.0001$) but especially in T2DM ($p < 0.01$ for the interaction) (mean glucose during the OGTT: from 7.2 ± 0.6 to 6.3 ± 0.7 in NGT and from 11.6 ± 2.5 to 9.0 ± 2.6 mM in T2DM). At baseline, insulin sensitivity was reduced in T2DM as compared to NGT (279 ± 33 vs 368 ± 43 , $p < 0.0001$) despite a similar degree of obesity. Following surgery, insulin sensitivity improved significantly in all subjects (to 332 ± 54 ml min⁻¹ m⁻² in NGT and to 412 ± 54 , in T2DM, $p < 0.0001$). At baseline, β -cell glucose sensitivity (*i.e.*, the slope of the dose-response curve of insulin secretion rates and plasma glucose concentrations) was severely impaired in T2DM (41 ± 23 pmol min⁻¹ m⁻² mM⁻¹ vs 80 ± 33 of NGT subjects, $p < 0.01$). After GBP, β -cell glucose sensitivity improved in all subjects (to 67 ± 43 pmol min⁻¹ m⁻² mM⁻¹ in T2DM and to 131 ± 55 in NGT, $p = 0.0005$), although it remained impaired in T2DM vs NGT ($p < 0.01$). The surgery-induced percent changes in β -cell glucose sensitivity were positively related to the corresponding changes in BMI ($r = 0.58$, $p < 0.01$).

Conclusion: Following gastric bypass surgery, glucose tolerance improves as a result of an increase in both insulin sensitivity and β -cell glucose sensitivity. These changes are of rapid onset and roughly proportional to the weight loss regardless of initial glucose tolerance.

Supported by: grant from the Italian Ministry of Research and Education

Effect of weight loss on the mRNA expression of high-mobility group box 1 (HMGB1) protein in subjects with impaired glucose metabolism and the metabolic syndrome - the GENOBIN studyV.D.F. Mello^{1,2}, M. Kolehmainen¹, L. Pulkkinen¹, U. Schwab^{1,3}, U. Mager¹, D.E. Laaksonen³, H. Gylling^{1,3}, M. Uusitupa¹¹School of Public Health and Clinical Nutrition/Food and Health Research Centre, University of Kuopio, Finland, ²Internal Medicine, Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil, ³Institute of Clinical Medicine, Internal Medicine, Kuopio University Hospital, Finland

Background and aims: HMGB1 is a protein that can act as an immune marker and a proinflammatory cytokine, participating in the induction of cytokine production. Previously we have shown that weight loss altered gene expression of selected cytokines and receptors of the NF κ B pathway in peripheral blood mononuclear cells (PBMCs) of overweight subjects with abnormal glucose metabolism and the metabolic syndrome (MS). In this study we sought to evaluate how weight loss and the associated improvement in insulin sensitivity affected mRNA expression of HMGB1 in PBMCs in overweight individuals with the MS.

Materials and methods: Altogether 34 overweight or obese (BMI: 32.6 ± 3.1 kg/m²) subjects with the MS randomized to either a weight reduction (WR) or a control group for 33 weeks were studied. Subjects in the WR group had an intensive 12-wk weight loss period followed by a 21-wk period where the minimum aim was weight maintenance. The mRNA expression was studied using real-time PCR and TaqMan[®] chemistry at baseline and wk 33. Intra-

venous and oral glucose tolerance tests and body composition were also assessed in the beginning and at the end of the study.

Results: In the WR group, body weight, BMI and waist circumference decreased ($p < 0.01$), and the insulin sensitivity index (S_i) improved ($p < 0.05$). In the WR group a decrease in mRNA expression of HMGB1 occurred (median -18% [interquartile range: -25.0 - 2.0%], $p < 0.001$). The decrease in HMGB1 mRNA expression correlated with an increase in the S_i after adjustment for changes in waist circumference ($r = -0.46$, $p = 0.03$) or BMI ($r = -0.46$, $p = 0.06$). Only the changes in HMGB1 expression ($\beta = -0.46$, $p = 0.04$) and waist circumference ($\beta = -0.58$, $p = 0.01$) had an independent effect on the improvement in S_i in multiple regression analysis. Adjustment for changes in physical activity frequency, energy adjusted intake of total fat, saturated fat, monounsaturated fat, polyunsaturated fat or total fiber did not attenuate these independent effects. The decrease in HMGB1 expression also correlated with the change in TNF mRNA expression ($r = 0.46$, $p = 0.04$). Moreover, baseline levels of mRNA HMGB1 expression correlated with baseline fasting insulin concentration ($r = 0.44$, $p < 0.01$). Adjustments for baseline BMI and gender did not alter this result.

Conclusion: Weight loss downregulates the mRNA expression of HMGB1 in PBMCs. HMGB1 expression after WR in turn was associated with the improvement in S_i independently of confounding factors. These results suggest, along with the association between HMGB1 expression and fasting insulin concentration, that mRNA expression of HMGB1 in obese subjects with the MS is involved in the regulation of insulin sensitivity and might reflect the local inflammatory response in the PBMCs.

Dapagliflozin-induced glucosuria is accompanied by weight loss in type 2 diabetes patientsV. Woo¹, J.F. List², E. Morales³, W. Tang², F.T. Fiedorek²¹Diabetes Research & Treatment Centre, Health Sciences Centre, Winnipeg, Canada, Bristol-Myers Squibb, Princeton, United States, ³Cardiometabólica, Centro de Investigación Cardiometabólica, Aguascalientes, Mexico

Background and aims: Dapagliflozin, a novel oral antidiabetic agent that potently and selectively inhibits the renal sodium-glucose co-transporter 2, is being developed for the treatment of patients with type 2 diabetes (T2DM). By inhibiting glucose reabsorption, and with it the urinary loss of calories, the novel mechanism of dapagliflozin has the potential to drive weight loss. The effect of dapagliflozin on weight was evaluated in treatment-naïve T2DM patients.

Material and methods: In this 12-wk, double-blind, parallel-group, dose-ranging, placebo (PBO)-controlled trial, 389 treatment-naïve T2DM patients with inadequate blood glycemic control and low mean glucosuria at baseline were randomized in equal ratios to once-daily dapagliflozin 2.5, 5, 10, 20, or 50 mg, metformin (Met) XR 750 mg titrated to 1500 mg or PBO.

Results: Dapagliflozin treatment led to consistent and sustained increases in urinary glucose excretion, rising to mean glucosuria values between 51.8 to 85.0 grams per day (g/d) at wk 12 in the dapagliflozin study arms from baseline means between 5.8 to 10.9 g/d. Mean glucosuria with PBO and Met both remained low (5.7 and 5.6 g/d, respectively, at wk 12). Mean percent reductions for body weight and absolute changes in body mass index (BMI) over 12 wks are shown below. A higher proportion of patients in each of the dapagliflozin groups achieved a 5 % weight reduction than PBO. Mean daily 24-hour urine volumes at baseline were between 1.9 and 2.2 L per day; small dose-related increases in 24-hour urine volumes were observed at wk 12 from +107 mL (2.5-mg dose) to +470 mL (50-mg dose) compared with -112 mL for PBO and -96 mL for Met. There was no apparent effect of dapagliflozin treatment on appetite, as assessed by a visual analogue scale. Adverse events of polyuria/pollakiuria were reported by 4 (1.4%) subjects in the dapagliflozin groups and there were no reports of nocturia.

Conclusion: Overall, dapagliflozin treatment led to greater degrees of weight loss than PBO in patients with T2DM.

Table. Mean Changes from Baseline at Wk 12.

	Dapagliflozin dose (mg)						
	2.5 n=59	5 n=58	10 n=47	20 n=59	50 n=56	PBO n=54	Met n=56

The reduction of body weight with liraglutide, a once-daily human GLP-1 analogue for type 2 diabetes, primarily comes from fat tissue and the fat tissue lost is predominantly visceral fat

J. Jendle¹, M.A. Nauck², D. Matthews³, A. Frid⁴, K. Hermansen⁵, M. Düring⁶, M. Zdravkovic⁶, B. Strauss⁷, A. Garber⁸¹Clinical Medicine, University of Örebro, Örebro, Sweden,²Diabeteszentrum, Bad Lauterberg im Harz, Germany, ³OCDEM, University of Oxford, United Kingdom, ⁴Oresund Diabetes Team, University Hospital, Lund, Sweden, ⁵Endocrinology and Metabolism, Aarhus University Hospital, Aarhus, Denmark, ⁶Novo Nordisk A/S, Bagsvaerd, Denmark, ⁷Endocrinology, Monash University, Clayton, Australia, ⁸Baylor College of Medicine, Methodist Hospital, Houston, United States

Background and aims: The majority of subjects with type 2 diabetes are overweight and most antidiabetes medications exacerbate weight gain. Therefore, therapies that minimise weight gain while improving glycaemic control are desirable.

Materials and methods: Two trials recruited subjects with type 2 diabetes [LEAD 2, baseline body weight (BW) 92.1±14.0 kg; LEAD 3, baseline body weight (BW) 92.7±19.6 kg]: LEAD 2 was a 26-week double-blind, double-dummy, randomised, active control, parallel group trial; LEAD 3 was 52 weeks long, with treatments for both trials as indicated in the table. Measurements were taken at baseline and week 26 for LEAD 2, and baseline and week 52 for LEAD 3. Dual-energy X-ray absorptiometry (DEXA) was used to measure changes in total lean body tissue and fat as well as fat percentage in a subgroup of subjects from both studies. Visceral and sc adipose tissue in the central region of the body was measured using computerised tomography (CT) in LEAD 2 only.

Results: A 13–17% reduction from baseline in central body visceral adipose tissue in liraglutide + metformin was demonstrated by CT. Central body sc adipose tissue was reduced by 5–9% with liraglutide + metformin, which was significantly different from glimepiride + metformin (3% increase) but not from placebo + metformin (4% reduction). An increase in liver-spleen attenuation ratio (indicating reduced hepatic steatosis) was seen in liraglutide 1.8 mg + metformin, which was significantly different from glimepiride + metformin. The reduction in percentage of body fat (fat%) with liraglutide 1.2 mg + metformin and liraglutide 1.8 mg + metformin was significantly different from the increase in fat% with glimepiride + metformin. Reduction in fat% did not differ significantly between liraglutide + metformin and placebo

+ metformin. With liraglutide monotherapy, the reductions in fat mass and percentage with both doses of liraglutide were significantly different to the increases associated with glimepiride.

Conclusion: Liraglutide either as monotherapy or added to metformin significantly reduced body weight, fat mass, and fat percentage compared with glimepiride in subjects with type 2 diabetes.

798

Enhanced weight loss following co-administration of pramlintide with sibutramine or phentermine in obese subjects

A. Halseth¹, L. Aronne², C. Burns¹, L. Porter¹, L. Shen¹¹Amylin Pharmaceuticals, Inc., San Diego, ²Medicine, Weill-Cornell Medical College, New York, United States

Background and aims: In diet-induced obese rats, monotherapy with the anorexigenic small molecules sibutramine or phentermine or the neurohormone amylin elicited significant vehicle-corrected weight loss of up to ~8%, while combination treatment with amylin and sibutramine or phentermine elicited 12–13% weight loss. Similar results were seen with sibutramine, phentermine or the amylinomimetic pramlintide monotherapy in obese humans.

Materials and methods: This randomised trial was designed to assess the safety and efficacy of sibutramine or phentermine with pramlintide. Following a 1-wk placebo lead-in, 244 overweight or obese subjects (ITT, 88% female, 41±11 y, BMI 37.7±5.4 kg/m², mean±SD) received placebo or pramlintide (120 µg TID) alone via SC injection or pramlintide in combination with sibutramine (10 mg QAM) or phentermine (37.5 mg QAM) for 24 wks along with diet and lifestyle intervention.

Results: At 24 wks (Evaluable), weight loss with pramlintide+sibutramine (11.3±1.2 kg; mean±SE) and pramlintide+phentermine (11.3±0.9 kg) was significantly greater than with pramlintide (3.6±0.7 kg) or placebo (2.1±0.9 kg) (P<0.0001 combination arms vs. pramlintide or placebo). More subjects achieved ≥5% weight loss and ≥10% weight loss in the pramlintide+sibutramine (78% and 49%, respectively) and pramlintide+phentermine (82% and 56%) than pramlintide (36% and 11%) or placebo treatment groups (28% and 3%) (P<0.001 combination arms vs. pramlintide or placebo). The safety profiles of the combinations were generally consistent with those previously established for the individual agents.

Conclusion: These results are consistent with previous findings in DIO rats and suggest that targeting multiple pathways through the combination of the amylin agonist pramlintide and other centrally acting anorectic agents may result in robust weight loss.

Effect of weight loss by very-low-calorie-diet on free fatty acid uptake in liver, pancreas, femoral adipose tissue and femoral muscle

A.C. Karmi, A. Viljanen, K. Virtanen, P. Iozzo, P. Nuutila
Turku PET Centre, University of Turku, Finland

Background and aims: The importance of free fatty acids (FFAs) in the pathogenesis of metabolic syndrome is very well known. The aim of this study was to evaluate FFA uptake in obese subjects having metabolic syndrome (MBO) in liver, pancreas, femoral adipose tissue and femoral muscle, and whether weight reduction modifies this uptake.

Materials and methods: Study population included 22 obese subjects with MBO (age 43 ± 8 year, BMI 33.5 ± 4.1 kg/m²) who were studied during fasting condition using PET with [¹⁸F]fluoro-6-thia-heptadecanoic acid (FTHA) and with [¹¹C]-palmitate. In mitochondria, [¹⁸F]-FTHA is trapped after initial steps of oxidation and represents the total uptake of FFAs while [¹¹C]-palmitate represents the non-oxidative residual. After baseline measurements, subjects were started on a very-low-calorie-diet for 6 weeks and were restudied after 1-week recover with eucaloric diet. Fatty acid uptake rates were measured using fractional uptake rates for liver, pancreas, femoral adipose tissue and muscle.

Results: Body weight decreased 11.0 ± 2.5 kg. Serum lipids and glycemic control improved, but fasting FFA levels were not changed. There was reduction in FFA uptake in all organs. Liver FFA uptake decreased from 10.1 ± 3.1 to 8.6 ± 2.5 $\mu\text{mol}/(100\text{g tissue} \cdot \text{min})$ ($p < 0.05$) mostly due to the decreased non-oxidative FFA retention ($p < 0.06$). Simultaneously with improved pancreatic beta-cell response to glucose, total uptake of FFA decreased from 1.78 ± 0.82 to 1.40 ± 0.66 $\mu\text{mol}/(100\text{g tissue} \cdot \text{min})$ ($p < 0.04$). Femoral subcutaneous adipose FFA uptake decreased from 0.20 ± 0.07 to 0.15 ± 0.04 $\mu\text{mol}/(100\text{g tissue} \cdot \text{min})$ ($p < 0.006$), but no change was observed in femoral muscle FFA uptake.

Conclusion: Weight loss decreases effectively FFA retention in the key organs involved in metabolic syndrome in the fasting state.

Liraglutide, the once daily human GLP-1 analogue in combination with the CB-1 antagonist rimonabant reduces body weight in obese rats in a synergistic manner

K. Raun, K. Dahl, L.B. Knudsen
Novo Nordisk A/S, Maaloev, Denmark

Background and aims: Obesity has reached epidemic proportions throughout most of the world and continues to increase at an alarming rate, giving rise to serious health consequences especially risk of developing type 2 diabetes. At present drug efficacy, in terms of weight loss, is modest with a relative high level of side effects. The ultimate goal for obesity drugs should be to have the effectiveness of bariatric surgery, with the safety of lifestyle intervention. A potential approach for obtaining this goal could be by combining different drugs in lower doses and that way get the advantage of reduced side effects together with elimination of the strong counter regulatory response when using single drug approach. The once-daily human GLP-1 analogue liraglutide has completed phase 3 clinical development for treatment of type 2 diabetes, and is currently in development also for the treatment of obesity. Beyond superior improvement of glycaemic control, liraglutide also reduces body weight with a mechanism that in animals has been shown to include lowering of food intake, altered food choice and maintained energy expenditure. The most recent obesity drug is the anorexigenic cannabinoid receptor-1 antagonist rimonabant which is available in Europe. In the current study, we have investigated the effect on body weight loss in diet induced obese (DIO) rats after treatment with combinations treatment of liraglutide and rimonabant.

Materials and methods: 5 groups ($n=8$) of DIO rats were used for the study. Sub maximal efficacy doses were chosen in order to get a window for investigating combination effects. The rats were treated with either vehicle (s.c.+ p.o.), liraglutide (30 $\mu\text{g}/\text{kg}$, s.c.), rimonabant (1 or 3 mg/kg p.o.) or lira+rimo combinations (30 $\mu\text{g}/\text{kg}$ + 1 mg/kg or 30 $\mu\text{g}/\text{kg}$ + 3 mg/kg for 3 weeks. Body weight was monitored daily.

Results: All data are presented as mean \pm SEM. The rats lost from 4.8 to 10.4 % bodyweight over the entire treatment period with least weight loss in the vehicle treated group and the highest in the lira 30 + rimo 3 treated group. Tachyphylaxia in body weight loss occurred in all groups over time as the bodyweight came closer to that of normal weight rats. This leads to a decline in differences between groups over time, meaning that the differences

are more obvious at a time point where the slopes of the weight loss curves are still declining. After two weeks treatment the vehicle subtracted weight loss for 30 $\mu\text{g}/\text{kg}$ liraglutide was $-13.5 \text{ g} \pm 5.2 \text{ g}$ and for 1 and 3 mg/kg rimonabant $-5.6 \text{ g} \pm 5.0 \text{ g}$ and $-14.0 \text{ g} \pm 4.5 \text{ g}$ respectively. The weight loss observed for the liraglutide+rimonabant combinations was $-29.5 \text{ g} \pm 4.4 \text{ g}$ for lira 30 + rimo 1 and -39.0 ± 3.0 for the lira 30 + rimo 3. This is a significantly greater weight loss than would be expected from adding the effects of the individual doses. A one-sample t-test resulted in $p < 0.05$ (compared to 19.1 g, the added value for lira 30 and rimo 1) and $p < 0.01$ (compared to 27.5 g the added value for lira 30 and rimo 3). At the end of the study when the bodyweight of the combination groups were approaching that of normal weight rats the synergy obtained by combinations became non significant.

Conclusion: Liraglutide can induce weight loss in combination with other anti-obesity agents in diet induced obese rats. Liraglutide lowered body weight in a synergistic manner when combined with rimonabant.

The involvement of protein S-nitrosylation in adipose tissue dysfunction

H. Ovadia, N. Bashan, A. Rudich

Clinical Biochemistry, Ben Gurion University, Beer Sheva, Israel

Background and aims: Oxidative and Nitrosative stress occurs systemically in diabetes, and was suggested to be involved in the development of muscle insulin resistance in various experimental systems. S-nitrosylation of protein cysteinyl residues has been suggested to be an important nitric oxide-dependent post-translational modification. While increased oxidative stress is well established in fat tissue, it is unknown whether increased nitrosative stress occurs in fat tissue in obesity, and if so, what is its role in the induction of adipose tissue dysfunction. Aims: i. To evaluate protein S-nitrosylation in omental fat tissue of High Fat fed (HFD) and ob/ob mice. ii. To compare the level of protein S-nitrosylation in human omental fat in obesity iii. To assess in 3T3-L1 adipocytes the ability of S-nitrosoglutathion (GSNO) to induce insulin resistance.

Materials and methods: For studying in-vivo proteins S-nitrosylation in obesity we utilized 2 animal models (male C57BL/6J mice after 20 weeks of high fat feeding, and ob/ob mice at the age of 16 weeks), and human omental fat biopsies. S-nitrosylation was evaluated in fat tissue by the Biotin switch technique. For studying the effect of nitrosylation in 3T3-L1 adipocytes the cells were exposed to 1mM GSNO for up to 8h.

Results: Total S-nitrosylation of adipose tissue proteins obtained for HFD and ob/ob mice was elevated compared to lean mice. A significant increased (2.5–11.8-fold of control) of S-nitrosylated proteins was documented in bands corresponding to Mw of: ~60kDa, ~50kDa, ~40kDa and ~37kDa. In accordance, human omental fat tissues obtained from obese women demonstrate 2–17-fold increased S-nitrosylation in proteins with similar molecular weights. In order to evaluate the role of S-nitrosylation on insulin signaling, 3T3-L1 adipocytes were exposed to GSNO, conditions which enhanced proteins S-nitrosylation. In association with the increased S-nitrosylation, insulin stimulated PKB/Akt phosphorylation and the serine phosphorylation of various PKB substrates were reduced by 10–47% in the treated cells compared to control.

Conclusion: Obesity is associated with increased S-nitrosylation of adipose tissue proteins, which may contribute to the induction of adipocyte insulin resistance.

Myeloperoxidase deficiency diminishes hepatic steatosis without affecting plasma glucose levels in mice

S. Rensen¹, E. Loyens², V. Bieghs², K. Wouters², R. Shiri-Sverdlov², W. Buurman¹

¹Surgery, Maastricht University, ²Molecular Genetics, Netherlands

Background and aims: Type 2 diabetes is associated with non-alcoholic steatohepatitis (NASH). In both conditions, inflammatory processes are thought to play a defining role in pathogenesis and progression. We have investigated the role of myeloperoxidase (MPO), an important neutrophil enzyme at the crossroad of inflammation and oxidative stress, in the development of NASH and insulin resistance.

Materials and methods: Male LDLR knockout mice received bone marrow from wild-type (WT) or MPO knockout (KO) mice (n=9 in each group). After 10 weeks recovery, mice were fed a high fat diet (HFD) for 8 weeks. Bodyweight, lipid profile and glucose and insulin levels were monitored during the experiment. After 8 weeks, mice were sacrificed and liver and adipose tissue were analyzed using biochemical assays, immunohistochemistry and Q-PCR analyses.

Results: Bodyweight increased from 20.0 g in both groups to 21.8 g (WT) and 21.3 g (KO), respectively (p=0.03 for both groups, difference between groups not significant). The number of leukocytes and the relative proportion of neutrophils, macrophages, B-lymphocytes and T-lymphocytes was comparable between the groups both at baseline and at 8 weeks HFD. Interestingly, glucose levels increased from 7.5 mmol/l at baseline to 8.5 mmol/l in the WT group at 4 weeks HFD (p=0.07), whereas KOs only displayed an increase from 7.6 to 8.0 mmol/l (p=0.33). However, glucose levels dropped again towards comparable levels in both groups at 8 weeks HFD (7.6 vs. 7.5 mmol/l for WT

vs. KO, respectively). Liver triglyceride accumulation was similar in the KO group compared to the WT group (0.31 vs 0.35 µg/µg protein; p=0.24). In contrast, hepatic accumulation of cholesterol was significantly higher in the WT group (0.090 vs. 0.072 µg/µg protein; p=0.01).

Conclusion: Our preliminary results indicate that reduced inflammation caused by MPO deficiency results in attenuated hepatic steatosis without affecting plasma glucose levels.

Inhibition of oxygen consumption in adipocytes by reactive oxygen species

Y. Si¹, T. Wang¹, O.S. Shiriha², V. Schultz¹, H. Si¹, R.F. Corkey¹, L. Hu¹, J.T. Deeney¹, W. Guo¹, B.E. Corkey¹

¹Obesity Research Center, Boston University School of Medicine,

²Department of Pharmacology and Experimental Therapeutics, Tufts University School of Medicine, Boston, United States

Background and aims: The main fate of fuels (glucose and fatty acids) entering white adipocytes is utilization for storage (in the form of triglyceride, TG). Shifting the fuel distribution toward less storage and more burning could provide a strategy to reduce adiposity. To this end, it is critical to understand the regulatory mechanisms by which respiration is modulated in adipocytes. Adipose tissue is subject to inflammatory infiltration, and existing evidence supports a role for reactive oxygen species (ROS) in intracellular signaling, inflammatory processes and insulin resistance. This study was designed to test the hypothesis that adipocyte respiration is inhibited by ROS, and the removal of ROS stimulates respiration and reduces TG stores.

Material and methods: Basal and uncoupled maximal respiration, mitochondrial membrane potential, ATP/ADP ratio, and intracellular levels of ROS were measured in rat primary adipocytes treated with the ROS scavengers, pyruvate or N-acetylcysteine (NAC). Mice provided with NAC in their drinking water (3 mg/ml) were imaged by NMR and their rates of respiration were assessed using indirect calorimetry.

Results: We demonstrated a persistent basal rate of adipocyte oxygen consumption (4.3 ± 0.3 nmol/min/mg-protein, n = 65) despite addition of fuels or FCCP (carbonyl cyanide 4- (trifluoromethoxy) phenylhydrazone), a chemical uncoupler of oxidative phosphorylation. Combination of FCCP with pyruvate uniquely stimulated adipocyte oxygen consumption up to 5-fold. The stimulatory effect of pyruvate could not be replaced by other fuels, and was completely inhibited by a mitochondrial pyruvate transport inhibitor. Additionally, NAC also stimulated adipocyte oxygen consumption. Both NAC and pyruvate decreased intracellular ROS levels. *In vivo*, NAC-treated mice showed increased oxygen consumption (by 23%, P < 0.05) and decreased body fat (by 35%, P < 0.05).

Conclusion: This study suggests for the first time that oxygen consumption in the adipocyte is inhibited by ROS. ROS inhibition of oxygen consumption may explain the difficulty in identifying effective strategies to increase fat burning and subsequent fat loss in adipocytes. Stimulating fuel oxidation in adipocytes by decreasing ROS may provide a novel means to shift the balance from fuel storage to fuel burning.

The effect of combined treatment of α-lipoic acid and insulin on skeletal muscle in OLETF rats

S.-J. Yoo¹, O.-K. Hong², H.-S. Kwon², S.-S. Lee¹, S.-R. Kim¹, D.-S. Kim³, D.-M. Kim⁴, K.-H. Yoon², M.-I. Kang², B.-Y. Cha², S.-W. Kim⁵, K.-W. Lee², H.-Y. Son², S.-K. Kang¹

¹Endocrinology and Metabolism, The Catholic University of Korea Holy Family Hospital, Bucheon, Kyunggi-do, ²Endocrinology and Metabolism, The Catholic University of Korea, Seoul, ³Endocrinology and Metabolism, The Hanyang University, Seoul, ⁴Endocrinology and Metabolism, The Hallym University Kangdong Sacred Heart Hospital, Seoul, ⁵Endocrinology and Metabolism, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea

Background and aims: α-lipoic acid (ALA) is a naturally occurring short chain fatty acid with sulfhydryl groups. It is a powerful antioxidant and is associated with improvements in skeletal muscle glucose transport activity and whole-body glucose tolerance in insulin-resistant animals and type 2 diabetic

human. It has been reported that ALA prevents the development of diabetes in diabetes-prone obese rats by reducing triglyceride accumulation in non-adipose tissues. To investigate the basic mechanism of ALA on preventing diabetes through skeletal muscle metabolism, we evaluated the effect of ALA on growth regulation and composition of skeletal muscle.

Materials and methods: Male Otsuka Long-Evans Tokushima Fatty (OLETF) and their diabetes-resistance counterpart Long-Evans Tokushima Otsuka (LETO) rats which served as normal controls, aged 24 weeks, were treated with or without ALA (100 mg/Kg body weight/day in drinking water) and / or insulin (insulin glargine, 2U/Kg body weight/day; subcutaneous injection) for 12 weeks. Total RNA was isolated and purified from skeletal muscle using the Rneasy Fibrous Tissue Mini Kit (Qiagen Inc., Valencia, CA). RNA samples were quantified on UV spectrophotometer (NanoDrop Technologies Inc., Wilmington, DE). Quantitative real-time PCR analysis of myostatin, TGF- β 1, connective tissue growth factor (CTGF) and MHC isoform (MHC I, IIa, IIb, IIc/x) mRNA expression was performed using a Bio-Rad iCycler and each mRNA expression normalized to 18S ribosomal RNA expression for each sample.

Results: The treatment of ALA with or without insulin reduce body weight significantly and save relatively larger amount of skeletal muscle mass from lower leg (gastrocnemius) compared with insulin-alone treated group and control group of OLETF rats. Myostatin gene expression in skeletal muscle was increased in ALA-alone and insulin-alone treated group and decreased significantly in combined treatment group of ALA and insulin compared with control group of OLETF and LETO rats. TGF- β 1 and CTGF gene expression in skeletal muscle was decreased in combined treatment group of ALA and insulin compared with control group of OLETF rats. The isoform profile of MHC was significantly increased in MHC I, MHC IIa and MHC IIc/x in ALA-alone treated group whereas decreased in MHC I, MHC IIa, MHC IIb and MHC IIc/x in combined treatment group of ALA and insulin compared with the control group of OLETF and LETO rats.

Conclusion: The effect of ALA in preventing weight gain was not affected by combined insulin treatment. However the effect on growth regulation and composition of skeletal muscle was totally depend on the presense of insulin treatment. With appropriate glycemic control with insulin, it may cause less amount of glycolytic MHC fiber composition and has an important role in preserving skeletal muscle mass by decreasing myostatin gene expression in animal model of obesity and diabetes.

Adaptive responses of human endothelial cells and T-lymphocytes to oxidative stress of high concentrations of glucose and palmitate, and reversal with linolenate

A.E. Kitabchi, F. Stentz, A.B. Warren, A. Aluoch, L. Razavi
Division of Endocrinology, University of Tennessee Health Science Center, Memphis, United States

Background and aims: Incubation of human T-lymphocytes (T-cells) and aortic endothelial cells (E-cells) in 15 and 30 mM glucose (but not 5mM) - results in their activation, characterized by de novo emergence of growth factor receptors for insulin (IR), IGF1 (IGFR), IL2 (IL2R), and Glut 4, with simultaneous production of lipid peroxide, as detected by thiobarbituric acid (TBA)-reacting material (MDA) and reactive oxygen species (ROS), using dichlorofluorescein-DCF as marker. These cells then metabolize glucose and become insulin sensitive tissues. Hyperglycemia and hyperlipidemia are prevalent in uncontrolled diabetes with production of MDA and ROS. As incubation of the E or T- cells with palmitate (but not linolenate) in 1, 50, and 500 μ M resulted in activation of these cells, we proposed that such activation might be associated with the development of fatty acid receptors, (GPR40) and transporters (FAT/CD36). Herein we report the results of our studies and responses of these cells to palmitate and linolenate.

Materials and methods: We incubated E and T-cells in various concentrations of palmitate and linolenate (1, 50, and 300 μ M) alone and together from 0-72 hours and measured DCF, MDA, IR, Glut4, E-selectin, as well as GPR40 and FAT/CD36. These compounds were assayed by the use of specific antibodies and quantitated by Western blot analysis.

Results and conclusion: Addition of palmitate to these cells resulted in their time and concentration-dependent activation by increased levels of E-selectin, DCF, MDA, and emergence of IR, Glut4, FAT/CD36, and GPR40 with peak levels at 300 μ M of palmitate, which were 2-fold or greater above the baseline values. Linolenate up to 300 μ M resulted in no detectable changes in values from the baseline for the above parameters. Addition of linolenate to palmitate, however, reduced the palmitate-induced changes in all the above

parameters in a dose-dependent fashion by 50-70%. We conclude that the affluent environment of high palmitate and hyperglycemia in T2DM activate these cells and triggers early complications, which could be attenuated with linolenate. However, orderly development of appropriate receptors for dissipation of excess glucose (Glut4 and IR) and palmitate (GPR40 and FAT/CD36) may prevent deleterious and toxic acute effects of high glucose and palmitate as adaptive responses. The implication that unsaturated fatty acids (i.e. omega 3) can act as protective substrates may be of nutritional significance.

Insulin glargine reduces carotid intimal hyperplasia after balloon catheter injury in Zucker fatty rats potentially by IGF-1 suppression of oxidative stress

P.J. Kadowitz¹, S.N. Murthy², S. Chandra¹, S. Sukhanov³, J. McGee⁴, P. Delafontaine³, D.B. McNamara¹, V.A. Fonseca²
¹Pharmacology, ²Medicine, ³Cardiology, ⁴Surgery, Tulane University Health Sciences Center, New Orleans, United States

Background and aims: Impaired glucose tolerance and type 2 diabetes are associated with increased cardiovascular disease morbidity and mortality particularly after vascular injury. Very little is known about the effect of insulin on the vasculature early in the course of the disease. Therefore we tested the effect of 2 insulins: glulisine (a short acting insulin) and glargine (long acting and known to increase IGF-1 levels and action) in Zucker fatty rat (insulin resistant but non-diabetic) carotid artery following balloon catheter injury. We have previously shown that IGF-1's atheroprotective effect correlates with a reduction in oxidative stress and eNOS upregulation.

Materials and methods: Zucker fatty rats were sc injected a daily dose 0.45 mg/kg of glargine (once) or glulisine (twice) before meal (given twice for glulisine rats) for one week before and three weeks after balloon catheter mediated injury of the carotid artery. Fasting and postprandial glucose was measured in the tail vein blood twice weekly. Injured and the contra lateral arteries, liver, aorta and blood were harvested on day 22 after injury. In H & E stained carotid artery sections the intima/media (I/M) ratio, an index of intimal hyperplasia was measured by microscopy in a blinded manner. The unstained sections were used for immunohistochemistry of nitro-tyrosine as a measure of oxidative stress. The serum was analyzed for IGF-1, and the aortic protein for 8-isoprostane. The aortic eNOS was measured by Westernblot methods.

Results: Both fasting and postprandial glucose did not vary significantly between the control and insulin groups. As against controls, the I/M was reduced in the insulin treated groups, but was statistically significant in the glargine group [0.9 ± 0.1 -control; 0.6 ± 0.1 -glulisine; 0.4 ± 0.1 -glargine, $p < 0.05$]. A trend for increased eNOS was observed in both insulin treated groups. Compared to control rats IGF-1 levels were higher in both insulin groups; however, it was significantly higher only in the glargine treated rats [567 ± 121 (ng/ml)-control; 763 ± 161 (ng/ml)-glulisine; 1059 ± 150 (ng/ml)-glargine, $p < 0.05$]. Immunopositivity for nitrotyrosine was lower than control in the insulin treated groups and lowest in the arteries from the glargine treated animals. Aortic 8-isoprostane was significantly reduced in the glargine group (921 ± 419 pg/mg protein vs. 2566 ± 399 pg/mg protein in control; $p < 0.05$).

Conclusion: We conclude that insulin glargine (or to a lesser extent glulisine) reduces intimal hyperplasia following balloon catheter injury in obese non diabetic rats with an increase in IGF-1 and eNOS and a concomitant reduction in oxidative stress. These data support the concept of a beneficial effect of insulin in general and glargine in particular in vascular disease.

807

Activation of Nrf2-ARE pathway by simvastatin

P.G. Ziros¹, D.V. Chartoumpekis¹, A. Psyrogiannis¹, V. Kyriazopoulou¹, A.G. Papavassiliou², I.G. Habeos¹

¹Medicine, University of Patras, Rio, Patras, Greece, ²Biochemistry, University of Athens, Greece

Background and aims: Statins inhibit the activity of the rate-limiting enzyme in cholesterol biosynthesis, HMGCoA reductase and are widely used in the treatment of cardiovascular diseases. Beyond their cholesterol reducing effect, they have also been reported to have antioxidant activities. On the

other hand, Nrf2 is a broadly expressed transcription factor that lies central to the antioxidant defense cellular system. Nrf2 controls the expression of a number of protective genes in response to oxidative stress and electrophiles, through binding to antioxidant response elements (AREs) located on target genes. Although, the effect of statins on endogenous antioxidants, has not been systematically studied. Taking these into account, we wanted to investigate the potential role of Nrf2 in mediating the reported antioxidant effects of statins.

Material and methods: Subjects were male wistar rats (100–200 g) were randomized into two groups fed a standard 4% rat diet. One group was given simvastatin dissolved in methylcellulose by gavage at a dose 120 mg/kg while the other was given the same amount of methylcellulose. ST2 cells stably expressing a luciferase reporter plasmid with an ARE response element (ST2-ARE) which binds Nrf2, was used to study the effect of simvastatin in vitro. Experiments with ST2-ARE cells and primary hepatocytes were performed in lipid free serum. Nuclear and total protein extracts were prepared from liver as well as primary hepatocytes Renonuclease protection assay was used to quantitate mRNA expression

Results: Wistar rats were treated with simvastatins (120 mg/kg) or vehicle for 5 days and total as well as nuclear liver extracts were prepared. Western blot experiments showed that Simvastatin induces nuclear translocation of Nrf2 in rat liver. This was confirmed in primary hepatocytes treated with simvastatin 5 μ M for 24 hours. Furthermore, the effect of simvastatin on primary hepatocytes was mevalonate dependent and cholesterol independent. The DNA binding activity of Nrf2 was also increased in the same nuclear extracts from the liver and primary hepatocytes treated with simvastatin. The above findings were further supported from in vitro studies using as a model the stably transfected st2 cell line (st2-ARE). Treating these cells with simvastatin enhances Nrf2 mediated transcriptional activity in a dose dependent way up to 5 μ M, by a factor of 3, while sulforaphane, a known inducer of Nrf2 enhances the activity by a factor of 7. Moreover pretreatment of these cells with mevalonate abolished the above result, while cholesterol had no effect. Finally two of the known targets of Nrf2 (HO-1 and GPX2) were found to be increased, when they were quantitated by RPA in rat liver RNA, after simvastatin treatment.

Conclusion: Overall our results provide in vitro as well as in vivo evidence that the antioxidant effects of simvastatin might be, at least partly, mediated by the transcription factor Nrf2.

Comparison of the effects of rosuvastatin and colestimide on metabolic parameters, adipokines and oxidative stress in type 2 diabetes patients complicated by hyperlipidaemia

K. Takebayashi, M. Suetsugu, S. Matsumoto, Y. Aso, T. Inukai
Internal Medicine, Dokkyo Medical University Koshigaya Hospital,
Koshigaya, Japan

Background and aims: Rosuvastatin, a strong statin, and colestimide, a new anion exchange resin, are both clinically useful drugs for treatment of hypercholesterolemia. This study was designed to compare the effects of rosuvastatin and colestimide on metabolic parameters including circulating lipids and glucose levels, adipokines, and markers of oxidative stress and diabetic nephropathy in patients with type 2 diabetes complicated by hyperlipidemia.

Materials and methods: Design: A total of 40 patients with type 2 diabetes complicated by hyperlipidemia were prospectively recruited. The patients were assigned randomly in equal numbers to rosuvastatin (2.5 mg/day) and colestimide (3.0 g/day) groups. Blood and urine were measured at the beginning of the study and after 12 weeks.

Results: Rosuvastatin significantly decreased the level of serum retinol binding protein-4 (RBP4: an insulin-resistant adipokine) in a subgroup of patients with poor glycemic control (HbA1c more than 8.0%), in addition to exerting a strong low-density lipoprotein (LDL-C)-lowering effect. Colestimide significantly decreased HbA1c, even in patients treated with a sulfonylurea at a more than a moderate dose (more than glibenclamide 2.5 mg/day or glimepiride 3.0 mg/day), without influencing insulin resistance or adiponectin (an insulin-sensitive adipokine) and RBP4 levels. Colestimide (but not rosuvastatin) significantly decreased the levels of urinary 8-iso-prostaglandin (PG) F2 α (a marker of oxidative stress) and urinary monocyte chemoattractant protein-1 (MCP-1) (a marker of diabetic nephropathy).

Conclusion: Our results suggest that rosuvastatin and colestimide exert different beneficial effects in type 2 diabetic patients complicated by hyperlipidemia. Accordingly, concomitant use of these drugs may be useful for prevention of progression of diabetic complications.

N^ε-(Carboxymethyl)lysine accumulates in adipose tissue of obese patients and alters the expression of adipocytokines

K.H.J. Gaens^{1,2}, M.P.H. van de Waarenburg^{1,2}, J. Scheijen³, J. Nijhuis⁴, M.C.G. Brouwers^{1,2}, C.D.A. Stehouwer^{1,2}, C.G. Schalkwijk^{1,2}

¹Department of Internal Medicine, Maastricht University, ²Cardiovascular Research Institute Maastricht, Maastricht University, ³Department of Clinical Genetics, Maastricht University, ⁴Department of General Surgery, Maastricht University, Netherlands

Background and aims: Obesity is closely linked to a wide variety of patho-physiologic conditions. Dysregulated production of adipocytokines is associated with obesity, providing a link between obesity and inflammation, changes in glucose homeostasis and lipid metabolism. Factors by which obesity leads to a dysregulated production of adipocytokines remain largely unknown. Because of local conditions in adipose tissue of obese patients, such as increased levels of polyunsaturated fatty acids, high rate of lipid peroxidation and oxidative stress, we speculate an increased formation of the lipoxidation endproduct N^ε-(Carboxymethyl)lysine (CML) in adipose tissue and we hypothesize that CML contributes to the altered expression of adipocytokines.

Materials and methods: Accumulation and localization of CML in human adipose tissue was assessed by immunohistochemistry using a monoclonal antibody against CML. Colocalisation studies of CML with macrophages and endothelial cell were done using antibodies against CD68 and CD31, resp. Plasma concentrations of protein-bound CML were determined in control subjects (n=77), familial combined hyperlipidemia (FCH) patients (n=42) and obese patients (n=44) by UPLC tandem MS. To examine the biological effects of CML, human preadipocytes were incubated with CML-modified albumin and changes in gene expression of plasminogen activator inhibitor-1 (PAI-1), interleukin-6 (IL-6) and the receptor for AGE (RAGE) were analyzed by Real Time PCR.

Results: Immunohistochemistry demonstrated the presence of CML in adipocytes, macrophages and endothelial cells of adipose tissue of obese patients. Plasma CML concentrations were surprisingly lower in obese (1.27 \pm 0.21 μ M, p<0.001) and FCH patients (1.31 \pm 0.28 μ M, p<0.001) as compared with control subjects (1.94 \pm 0.52 μ M). A negative correlation was observed between CML plasma concentrations and BMI (r=-0.475, p<0.001), visceral adipose tissue (r=-0.548, p<0.001), but not with subcutaneous adipose tissue (r=-0.148, p=0.238). Incubation of human preadipocytes with CML-albumin during 24h and 48h had no effect on PAI-1, IL-6 and RAGE expression, while an incubation of 72h with minimally-modified CML-albumin increased the expression of IL-6, PAI-1 and RAGE 2.1-fold, 1.7-fold and 3.4-fold, resp. Incubation with highly-modified CML-albumin increased the IL-6, PAI-1 and RAGE mRNA expression by 2.4-fold, 1.8-fold and 4.9-fold, resp.

Conclusion: We demonstrated for the first time that CML is found in adipose tissue, namely in adipocytes, macrophages and endothelial cells of obese patients. This accumulation is a local process, since plasma CML levels are decreased in obese patients as compared to control subjects. In addition, the inverse relationship with plasma levels of CML-modified proteins and visceral adipose tissue also suggests an uptake of CML in visceral adipose tissue. A dysregulated production of adipocytokines by CML-albumin, as shown in human preadipocytes, supports our hypothesis that CML has important biological effects regarding the dysregulation of adipocytokines.

The effect of PKC δ on the IL-6 signalling and action in adipose cells

E. Wallerstedt, C.X. Andersson, U. Smith
Department of molecular and clinical medicine/Diabetes, Medicine,
Gothenburg, Sweden

Background and aims: We have recently shown in differentiated 3T3-L1 cells that insulin antagonizes interleukin-6 (IL-6) signaling and exerts anti-inflammatory effects by significantly reducing the tyrosine phosphorylation of the intracellular signaling molecule STAT3. Treatment with the MEK inhibitor PD98059 in these cells reduced both the serine phosphorylation of STAT3 and the anti-inflammatory effect of insulin on IL-6 signaling. It has

previously been described that serine phosphorylation of STAT3 is important for the transcriptional activity of STAT3 and that PKC δ is involved in this phosphorylation. To study the involvement of PKC δ on IL-6 signaling and the anti-inflammatory properties of insulin, we analyzed differentiated 3T3-L1 cells treated with the PKC-activating phorbol ester PMA or the specific PKC δ inhibitor rottlerin. In addition, wt MEFs and cells expressing a dominant negative PKC δ (PKC δ dn) were also used.

Materials and methods: Differentiated 3T3-L1 cells were cultured and preincubated with or without rottlerin (6 μ M) and PMA (100 nM) for 30 minutes before stimulation with insulin (100 nM) and/or IL-6 (20 ng/ml) for 30 minutes up to 24 hours. Wt MEFs and PKC δ dn MEFs were incubated with IL-6 (30 ng/ml) and soluble IL-6 receptor (30 ng/ml) for 60 minutes and 24 hours. RNA was extracted and the gene expression was analyzed with real-time RT-PCR (TaqMan) while the proteins were analyzed by immunoblotting.

Results: Both insulin and PMA, but not IL-6, increased the Tyr-311 phosphorylation of PKC δ in differentiated 3T3-L1 cells while all ligands increased the Ser-727 phosphorylation of STAT3. Cells treated with rottlerin showed a reduced IL-6-induced Ser-727 phosphorylation of STAT3 whereas the insulin-induced activation of STAT3 was not effected. IL-6-induced gene expression of the negative feedback inhibitor of IL-6 signaling, SOCS3, as well as the inflammatory markers SAA3 and haptoglobin were significantly reduced in the presence of rottlerin. The importance of PKC δ for the effect of IL-6 through the STAT3 pathway was further supported by studies in PKC δ dn MEFs which showed a significantly reduced IL-6-induced gene expression of SOCS3, haptoglobin and SAA3 compared to wt MEFs.

Conclusion: These data support the concept that PKC δ is important for the pro-inflammatory effect of IL-6 and involves Ser-727 phosphorylation of STAT3. However, PKC δ does not seem to be involved in the insulin-induced and PMA-induced Ser-727 phosphorylation of STAT3, which mainly seems to be dependent on the MAPK pathway.

PTEN downregulation in adipocytes promotes inflammation of adipose tissue

M. Foti¹, C. Veyrat-Durebex², C. Juge-Aubry², C. Darimont³, V. Giusti⁴, C.A. Meier², F. Rohner-Jeanrenaud², M. Vinciguerra¹

¹Dept. of Cellular Physiology and Metabolism, Faculty of Medicine, University of Geneva, Switzerland, ²Dept. of Internal Medicine, University Hospital, Geneva, Switzerland, ³Nestec, Nestle Research Center, Lausanne, Switzerland, ⁴Dept. of Medicine, University Hospital, Lausanne, Switzerland

Background and aims: The phosphoinositide phosphatase PTEN is a potent tumor suppressor and a regulator of insulin sensitivity in peripheral tissues. In adipocytes, experimental alterations of PTEN expression modulate the sensitivity of these cells to insulin. However, virtually nothing is known about the pathophysiological regulation of endogenous PTEN in adipose tissue. Herein, we investigated in vivo and in vitro whether alterations of PTEN expression in adipocytes are associated with the metabolic syndrome and what are the functional outcomes of dysregulated PTEN expression/activity.

Materials and methods: PTEN expression was examined in vivo in adipose tissue of rats and human with the metabolic syndrome. Metabolic factors mediating dysregulation of PTEN expression in adipocytes and the subsequent effects on the physiology of these cells were investigated in vitro using human CHUB-S7 preadipocytes.

Results: We demonstrated that PTEN is downregulated, both at the mRNA and protein levels, in adipose tissue of diabetic/obese ZDF rats and in subcutaneous adipose tissue of obese human patients. PTEN downregulation

correlated with degradation of I κ B α and hyperactivation of NF- κ B, a transcription factor previously described to modulate PTEN expression. The expression of SHIP2, another PtdIns(3,4,5)P3 phosphatase involved in the control of insulin sensitivity and the development of obesity, was not altered. In vitro analyses using differentiated human CHUB-S7 preadipocytes showed that PTEN downregulation is not triggered by high concentrations of glucose or fatty acids. In contrast, the pro-inflammatory cytokines IL-1 α and TNF α , significantly downregulate PTEN expression. Consistent with the IL1 α -dependent PTEN downregulation, long-term incubation of CHUB-S7 cells with IL-1 α potentiates insulin-induced Akt and ERK1/2 signaling. We finally showed that PTEN downregulation in CHUB-S7 preadipocytes by PTEN siRNAs induced an increased secretion of the pro-inflammatory cytokines IL-1 β , IL-6 and TNF α .

Conclusion: Taken together, these data indicate that PTEN expression is downregulated in adipose tissue of obese/diabetic subjects, potentially via cytokine-mediated activation of the NF- κ B pathway. PTEN downregulation in adipocytes might in turn worsen adipose tissue inflammation through a vicious circle by further stimulating the secretion of pro-inflammatory cytokines.

Effect of 24-hour hypertriglyceridaemia on tumor necrosis factor alpha and resistin in type 2 diabetes and healthy subjects

J. Kopecky jr.¹, E. Krusinova¹, P. Wohl¹, L. Kazdova¹, P. Mlejnek², M. Hill³, T. Pelikanova¹

¹Diabetes Center, Institute for Clinical and Experimental Medicine,

²Institute of Physiology, Academy of Sciences of the Czech Republic,

³Obesity Management Centre, Institute of Endocrinology, Prague, Czech Republic

Background and aims: Tumor necrosis factor alpha (TNF) and resistin are implicated in the pathogenesis of insulin resistance (IR). Its regulation during experimental lipid infusion which is known to cause IR has not been thoroughly investigated so far.

Materials and methods: The aim of the study was to assess plasma concentrations of TNF and resistin during prolonged hypertriglyceridemia in type 2 diabetes and healthy subjects. 11 patients with type 2 diabetes (D) and 11 age-matched healthy control subjects (C) underwent 24-hour infusion of lipid emulsion (Intralipid 20%; 3 g of fat/kg/day; HTG). Plasma concentrations of TNF and resistin were measured before (0 min), at 30 min, 240 min and 24 hours of HTG. Needle biopsy of abdominal subcutaneous adipose tissue was performed before, at 240 min and 24 hours of infusion to assess the expression of selected cytokines by real-time PCR (expression of adipokine mRNA relative to cyclophilin mRNA).

Results: Plasma concentrations of TNF were significantly higher in D compared to C ($p < 0.001$). During HTG, plasma levels of TNF showed in D no dynamic changes, whereas in C significant increase at 24 hours of the infusion was detected ($p < 0.001$; ANOVA). Expressions of TNF in subcutaneous adipose tissue were significantly greater in D than in C ($p < 0.001$, ANOVA), changes in time throughout the HTG were not significant. Plasma concentrations of resistin significantly rose during the HTG ($p < 0.05$; ANOVA) and the difference between the two groups was not statistically significant. Differences in expressions in adipose tissue were not significant.

Conclusion: In D, plasma concentrations of TNF and its expression in abdominal subcutaneous adipose tissue are increased. Mainly in C, prolonged lipid infusion is associated with increase in plasma TNF and resistin. Our results are in accordance with the hypothesis that TNF and resistin are implicated in lipid induced IR.

Table: Plasma concentrations (plasma; pg/mL) and expressions in abdominal subcutaneous adipose tissue (expressions; TNF mRNA relative to cyclophilin mRNA) of Tumor necrosis factor alpha (TNF) and Resistin. Data expressed as mean \pm SEM. (D, type 2. diabetes; C, healthy controls) IR.

Group	Time				Expressions		
	Plasma						
	0 min	30 min	240 min	24 h	0 min	240 min	24 h

The changes of PPAR γ , ATGL and adipocytokines in TNF- α induced insulin resistance in miceS. Shi^{1,2}, L. Li^{1,2}, G. Yang³, K. Li³¹The Key Laboratory of Laboratory Medical Diagnostics in Ministry of Education, ²Department of Clinical Biochemistry, ³Department of Endocrinology, the Second Affiliated Hospital, Chongqing Medical University, Chongqing, China

Background and aims: Tumor necrosis factor- α (TNF- α) has been linked to obesity-related insulin resistance and metabolic disorder, but the molecular mechanisms have not been elucidated. We undertook the present study to further investigate the *in vivo* molecule mechanisms that TNF- α contributes to the pathogenesis of insulin resistance (IR) on the related gene of lipid metabolism in mice.

Materials and methods: C57BL/6J mice were treated by TNF- α for 7 days. After 7 days, we examined the *in vivo* effects of TNF- α on glucose-lipid glucose metabolism and insulin sensitivity by intravenous glucose tolerance tests (IVGTT) and euglycemic - hyperinsulinemic clamp. In addition, we also analyzed the *in vivo* role of TNF- α on some metabolism-related genes and adipocytokines in the development of insulin resistance.

Results: Plasma FFA, insulin and fasting blood glucose levels were significantly higher in TNF- α treatment animals than in controls (7.86 ± 0.40 vs. 5.58 ± 0.33 mmol/L, $P < 0.01$; 32.4 ± 1.9 vs. 12.4 ± 1.12 mU/L, $P < 0.05$; 1.78 ± 0.05 vs. 1.54 ± 0.11 mmol/L, $P < 0.05$). Insulin responses to IV glucose in IVGTT were drastically reduced in TNF- α treatment mice compared to controls. During euglycemic - hyperinsulinemic clamp, The rate of glucose infusion needed to maintain euglycemia (GIR) in TNF- α treatment mice was markedly lower than in the controls (39.1 ± 2.3 vs. 54.2 ± 2.2 mg·kg⁻¹·min⁻¹, $P < 0.01$), and insulin-stimulated whole body glucose uptake and skeletal muscle glucose uptake were significantly decreased by 11% and 24%, respectively. Insulin's ability to suppress HGP during clamps was significantly impaired in TNF- α mice (%), indicating severe insulin resistance in these mice. The mRNA expression of PPAR γ in adipose tissue was significantly down-regulated in mice with TNF- α treatment compared with controls (0.83 ± 0.06 vs. 1.07 ± 0.07 arbitrary units, $P < 0.05$). Adipose ATGL mRNA expression and plasma protein level were significantly lower in mice with TNF- α treatment compared with controls (0.85 ± 0.09 vs. 1.37 ± 0.12 and 0.53 ± 0.03 vs. 0.65 ± 0.05 arbitrary units, $P < 0.01$ and $P < 0.05$). Adiponectin mRNA content in adipose tissues and plasma protein levels were lower in the TNF- α treatment rats than in the controls (0.48 ± 0.04 vs. 0.95 ± 0.12 arbitrary units, $P < 0.01$ and 16.43 ± 0.35 vs. 21.94 ± 0.59 μ g/ml, $P < 0.01$). In treated rats with TNF- α , plasma visfatin was significantly lower than in the controls (0.90 ± 0.05 vs. 1.14 ± 0.13 arbitrary units, $P < 0.05$), and mRNA expression of visfatin in adipose tissue was significantly down-regulated (0.74 ± 0.03 vs. 0.92 ± 0.06 arbitrary units, $P < 0.01$).

Conclusion: This is the first report that chronic TNF- α treatment *in vivo* not only downregulated adipose tissue PPAR γ and ATGL mRNA expression, and ATGL plasma protein levels but also reduced adipose tissue adiponectin and visfatin mRNA expression and their plasma protein levels. These alterations may contribute to TNF- α -mediated elevated FFA levels and insulin resistance.

Inflammatory role of the cytokine TWEAK and its receptor Fn14 on human adipocytes. Relationship of the soluble fraction with systemic inflammatory markers in obese and type 2 diabetic patientsJ.J. Vendrell¹, M.R. Chacón¹, M. Miranda¹, V. Ceperuelo-Mallafra¹, J. Fernández-Real², A. Megia¹¹Endocrinology and Diabetes Unit, CIBERDEM. University Hospital of Tarragona Joan XXIII. Rovira i Virgili University, Tarragona,²Endocrinology and Diabetes Unit, CIBEROBN. Josep Trueta Hospital, Girona, Spain

Background and aims: Tumor necrosis factor-like weak inducer of apoptosis (TWEAK) is a member of the tumor necrosis factor superfamily of cytokines. Soluble TWEAK can be found as biologically active form circulating in human plasma and interacting with a receptor named fibroblast growth factor-inducible 14 (Fn14). This binding activates the NF- κ B signalling pathway, known to play an important role in the inflammatory processes. Type 2 diabetes and obesity are both subjected to a chronic inflammatory "low

degree" condition driven by a combination of a pro-inflammatory adipose tissue expression profile with an increase in some inflammatory cytokines at bloodstream. In previous studies, we have shown that mRNA of TWEAK and Fn14 are highly expressed in human subcutaneous fat from obese and type 2 diabetes patients. Therefore, our interest is focused on investigating whether TWEAK/Fn14 has a pro-inflammatory role on human adipocytes *in vitro* and to determine if its circulating levels are related to human obesity and type 2 diabetes contributing to the inflammatory environment.

Research design and methods: 71 non-diabetic subjects (n=26 with BMI<25 and n= 45 with 30 \geq BMI<40, matched for age and gender) and 28 type 2 diabetic subjects (age: 65.4 ± 8.4 years, BMI: 29.8 ± 3.4) were included in the study. Plasma levels of sTWEAK, sMCP-1, sTNFR1, sTNFR2 and sIL-6 were measured by ELISA. Glycerol levels were measured by a colorimetric assay. TWEAK/Fn14 expression was analysed by RT-PCR during SGBS preadipocyte cell line differentiation to mature adipocytes. The dose effect of TWEAK protein on human preadipocyte and differentiated adipocytes cell line was studied and compared to TNF α stimulus (from 1 to 50 ng/mL for both cytokines). The expression of MCP-1, IL-6, TNF α , APM1, and Lep was analysed by RT-PCR.

Results: Non diabetic cohort: sTWEAK in serum was found to be positively correlated with plasma glycerol and sTNFR2 ($r=0.419$, $p<0.001$ and $r=0.275$, $p=0.026$). Type 2 diabetes cohort: sTWEAK showed a strong association with plasma glycerol levels ($r=0.426$ $p<0.006$). Multiple regression analysis showed that sTWEAK was only positively determined by glycerol levels ($B=608.75$, 95%CI(402.7/814.7) $p<0.001$). TWEAK and Fn14 mRNA were found to decrease during adipocyte differentiation. *In vitro* effect of TWEAK on differentiated adipocytes up-regulated the expression of TNF α , MCP-1, IL-6 and down regulates expression of APM1. This cytokine up-regulation was less powerful than the observed for TNF α . TWEAK also up-regulated cytokines expression on preadipocytes in culture.

Conclusion: The circulating levels of this cytokine may be related with the lipolytic activity in adipose tissue. TWEAK is expressed by adipocytes and may have a paracrine effect over structures and cell types responsible for the inflammatory component found in the adipose tissue by increasing expression on IL-6 and TNF α mainly.

Effect of acute hyperinsulinaemia and angiotensin receptor blockade on plasma concentrations and expressions of tumor necrosis factor α and resistin in diabetes mellitusE. Krušinová¹, J. Kopecký jr.¹, P. Mlejnek², P. Wohl¹, L. Kazdová¹, M. Pravenec², T. Pelikánová¹¹Diabetes Center, Institute for Clinical and Experimental Medicine,²Institute of Physiology, Academy of Sciences of the Czech Republic, Prague, Czech Republic

Background and aims: Angiotensin II type 1 receptor blockade (ARB) has been suggested to have distinct antidiabetic and insulin-sensitizing properties, however the underlying mechanisms are not clear. The effect of ARB on tumor necrosis factor α (TNF) and resistin that are implicated in insulin resistance, is not fully understood. We aimed to assess plasma concentrations of resistin and TNF and their expressions in subcutaneous adipose tissue in response to acute hyperinsulinaemia and acute ARB in subjects with type 2 diabetes (D) and control healthy subjects (C).

Materials and methods: Plasma concentrations of resistin and TNF were measured: 1) at 0 min, 30 min and 240 min of hyperinsulinaemic (1 mU·kg⁻¹·min⁻¹) euglycaemic (5 mmol·l⁻¹) clamp (HEC), and 2) during HEC after acute ARB (following administration of losartan 200 mg) (AT-HEC) using the same protocol, in 11D and 12 age-matched C. Needle biopsy of abdominal subcutaneous adipose tissue was performed at 0 min, 30 min and 240 min of both clamps to assess the relative expressions of TNF and resistin using the real-time PCR method (expression of adipokine mRNA relative to cyclophilin mRNA).

Results: Insulin sensitivity, expressed as metabolic clearance rate of glucose, was significantly higher in C compared to D ($p<0.001$), without any changes during AT-HEC in both groups. TNF plasma concentrations and adipose tissue expressions were significantly higher in D compared to C ($p<0.001$; ANOVA). While plasma TNF did not change during hyperinsulinaemia or after ARB in both groups, its expressions increased during HEC but remained stable during AT-HEC ($p<0.05$; ANOVA) in both groups. Plasma concentrations, as well as relative expressions of resistin were also significantly higher

Plasma concentrations and expressions of TNF and resistin. Data expressed as mean±SEM.

in D ($p<0.05$ for plasma; $p<0.01$ for expression levels). We have observed an increase in plasma resistin during both clamps ($p<0.001$; ANOVA), that was comparable also between groups. On the contrary, the changes in resistin expression were only modest - a trend towards increase during HEC was detected in both groups.

Conclusion: TNF and resistin are associated with insulin resistance and type 2 diabetes, as it is documented by increased plasma concentrations and expressions in adipose tissue. In type 2 diabetes and healthy subjects, acute hyperinsulinaemia stimulates the expression of TNF, while ARB ameliorates this effect. Acute hyperinsulinaemia is associated with increase in plasma resistin in both type 2 diabetes and healthy subjects, independently on ARB. This effect can not be explained by stimulated expression in subcutaneous adipose tissue, which implies the involvement of other sources of circulating resistin. Our results suggest, that changes in TNF expression might be involved in the improvement of insulin sensitivity connected with ARB treatment.

The cytokines levels in subcutaneous adipose tissue in situ and in plasma; the effect of weight reduction

M. Vitkova^{1,2}, J. Vrzalova³, E. Klimcakova^{1,2}, M. Kovacikova^{1,2}, Z. Kováčová^{1,2}, J. Polak^{1,2}, M. Bajzova^{1,2}, L. Rossmeislova², Z. Hněvkovská^{1,2}, V. Stich^{1,2}

¹Department of Sport Medicine, 3rd Faculty of Medicine, Charles University in Prague, Czech Republic, ²Franco Czech Laboratory for the Clinical Research on Obesity, INSERM Toulouse and 3rd Faculty of Medicine, Prague, Czech Republic, ³Department of Immunology, Faculty of Medicine in Pilsen, Czech Republic

Background and aims: Cytokines (adipokines) produced by adipose tissue have been implicated in the development of insulin resistance (IR) and other metabolic disturbances linked to obesity. It has been shown that circulating adipokines are elevated in obese and diabetic subjects. The aim of our study was to investigate the levels of cytokines/adipokines in plasma and especially in situ in subcutaneous adipose tissue during the dietary intervention.

Materials and methods: 18 obese pre-menopausal women (BMI 35.8 ± 4.8 kg/m²) followed 6-months weight reduction program consisting of 3 phases: a 4 week 800 kcal/d very low-caloric diet (VLCD), a 2-month low-caloric diet (LCD) with 600 kcal less than the calculated daily energy requirements and a 3 to 4 months weight maintenance phase (WM). Anthropometric and biochemical parameters were determined before and at the end of each dietary phase. To evaluate insulin sensitivity, euglycemic-hyperinsulinemic clamp was done at each phase. Microdialysis of cytokines was performed in 8 women using 100 kDa cut-off catheter. Interstitial concentration of cytokines was determined according to its recovery evaluated by “zero-flow” method. Adipokines, IL-6, IL-1 β , IL-8, IL-10, MCP-1, TNF α , leptin and PAI-1, were analyzed in plasma and dialysate using multiplex immunoassay at Luminex 100.

Results: The diet intervention resulted in the weight loss (99.0 ± 16.1 kg vs. 88.3 ± 15.4 kg), most prominent in the VLCD and the LCD phases. Body weight decrease was accompanied by reduction of insulin, triglycerides and leptin and significant improvement of insulin sensitivity. The levels of circulating cytokines remained unchanged during whole diet intervention except for TNF α and IL-8, which were increased after VLCD ($p<0.001$) and decreased subsequently in LCD and WM ($p<0.01$). Moreover, the relative changes of TNF α correlated with IL-8 changes ($p=0.003$). The interstitial levels of cytokines in adipose tissue were 10-1000 times higher than in plasma. Most of the observed factors had trend to increase during VLCD, and decreased to baseline levels during subsequent phases of the diet. Recovery of

individual proteins in microdialysis measured by “zero flow” method ranged between 10-55 %.

Conclusion: During the long-term weight reducing dietary intervention in obese females, the time-course of levels of cytokines in plasma and in adipose tissue were not associated with indices of IR or body fatness. The results do not support hypothesis that insulin sensitivity is directly associated to cytokines production locally in adipose tissue or systematically in whole body.

Changes of inflammation markers and the effects of different hypoglycaemic agents in newly diagnosed type 2 diabetics

S.X. Lin, X.M. Tong, Z. Li, Y. Li, C. Hua

Department of Endocrinology, The Second Affiliated Hospital of SUN Yat-Sen University, Guangzhou, China

Background and aims: In recent years chronic low-grade inflammation has been shown to be closely associated with obesity, type 2 diabetes and accelerated atherosclerosis. Recently many studies showed that insulin and metformin may have potential effort on anti-inflammation, but the evidence is not enough. To investigate the changes of serum inflammation marker levels including hs-CRP, TNF- α and IL-6 and NF- κ B activity in peripheral blood mononuclear cell (PBMC) and the effects of different hypoglycaemic agents in patients with newly diagnosed Type 2 diabetes (T2DM).

Materials and methods: 67 normal individuals and 100 newly diagnosed T2DM patients were selected. The diabetic patients were divided into group A (with 7.0mmol/L<FPG<11.1mmol/L) and group B (with FPG \geq 11.1mmol/L, insulin). The patients of group A were randomised to group A1 [insulin] and group A2 (oral hypoglycemic agents). Group A2 were further divided into group A2a [25kg/m²<BMI \leq 35kg/m², metformin] and group A2b [20kg/m²<BMI \leq 25kg/m², glizalide]. Serum hs-CRP, TNF- α , IL-6 were assayed by ELISA. Phosphorylation status of NF- κ B p65 in PBMC was determined by immunoblotting with phosphor-specific antibodies to NF- κ B p65(Ser536). Inflammation makers were assayed before treatment and at 12 weeks after glycemic control.

Results: Levels of serum hs-CRP, TNF- α and IL-6 were higher in diabetics than that in control subjects ($P<0.01$). The levels of phosphorylation NF- κ B P65 in PBMC was increased in diabetics compared with control subjects ($P<0.05$). In whole group, the serum levels of hs-CRP, IL-6 and the levels of phosphorylation NF- κ B P65 in PBMC were decreased, TNF- α level did not change significantly after glycemic control comparing with baseline levels. In insulin group, the serum levels of hs-CRP, IL-6, and the levels of phosphorylation NF- κ B P65 in PBMC were decreased, TNF- α level did not change significantly after glycemic control. In metformin group, the serum levels of hs-CRP, IL-6, TNF- α and the levels of phosphorylation NF- κ B P65 in PBMC were decreased after glycemic control. In glizalide group, there were no significant changes of these inflammation markers.

Conclusion: The levels of serum hs-CRP, IL-6 and TNF- α and the levels of phosphorylation NF- κ B P65 in PBMC were increased in newly diagnosed T2DM patients, and the patients treated with insulin and metformin was associated with improvement of inflammation markers.

***FTO* gene is associated not only with obesity-related quantitative traits but also with higher OGTT stimulated glycaemia and leptin levels**

J. Vcelak, P. Lukasova, M. Vankova, D. Vejrazkova, H. Kvasnickova, J. Vrbikova, K. Vondra, B. Bendlova
Institute of Endocrinology, Prague, Czech Republic

Background and aims: In 2007 several independent laboratories identified from broad genome-wide association scans the genetic variants in *FTO* (*Fat mass and obesity associated*) gene that are associated with obesity-related quantitative traits. Found associations were so strong, that they encouraged the genetic studies of polygenic diseases. *FTO* (16q12.2) is a member of one form of the non-heme dioxygenase superfamily. But physiological function of *FTO* in the organism is still not fully understood. The aim of the present study is to compare the frequencies of four polymorphisms in the sets of DM2, polycystic ovary syndrome (PCOS) patients, gestational diabetics, offspring of DM2 and healthy controls without the family history of DM2 and to evaluate anthropometrical data, beta-cell secretion, insulin resistance and hormonal and lipid levels of the study subjects in relationship to the described polymorphisms.

Materials and methods: The study involved 1388 Czech Caucasian people: 383 patients with DM2 (M/F 134/249; age 61.0±7.7/58.6±9.3 years; BMI 29.7±4.4/31.7±6.2 kg/m²); 286 women with PCOS defined according to ESHRE consensus (age 27.2±6.6 years; BMI 26.8±6.5 kg/m²); 199 gestational diabetics (age 32.7±5.0 years; BMI 23.9±4.3 kg/m²); 165 offspring of DM2 (M/F 62/103; age 39.6±10.5/36.6±12.8 years; BMI 26.8±4.5/24.9±4.2 kg/m²) and 355 controls (M/F 115/240; age 29.1±8.1/30.0±10.7 years; BMI 23.9±3.0/23.5±4.6 kg/m²) were collected. Oral glucose tolerance test (oGTT) with sampling for blood glucose, insulin, C-peptide and proinsulin was done (except of DM2 patients). Moreover, 16 anthropometrics parameters, 29 biochemical parameters and hormones, 42 oGTT-derived indices were evaluated. The SNPs: rs1121980; rs17817449; rs1421085; rs9393609 in the *FTO* gene were assessed by ABI TaqMan SNP Genotyping Assays. Statistics was done using NCSS 2004 and Statgraphics software.

Results: The genotypic distribution of alleles was not significantly different among groups and is independent on sex (chi-square test). These four SNPs are in strong Linkage Disequilibrium (pairwise $r^2 > 0.97$). The homozygote carriers of risk and non-risk allele did not differ in age and body height within these groups. The association of *FTO* variants with BMI was apparent in all groups. Only the strongest associations with rs1421085 are presented (ANOVA).

Obesity-related quantitative traits in all subjects: (risk allele first)

Homozygotes CC vs. TT: BMI ($p < 0.0000001$; $power = 0.9994$), weight ($p = 0.000045$; $power = 0.98$), abdomen circumference ($p = 0.000197$; $power = 0.96$).

Biochemical parameters in female controls:

Homozygotes CC vs. TT: Leptin (15.44±1.28 vs. 10.56±0.96 ng/ml $p = 0.003$; $power = 0.84$), Glycemia(oGTT) 60min (6.71±0.21 vs. 5.81±0.18 mmol/l $p < 0.005$; $power > 0.80$), Glycemia(oGTT) 90min (5.59±4.98 vs. 4.98±0.14 mmol/l $p < 0.005$; $power > 0.80$), Glycemia(oGTT) 120min (4.99±0.15 vs. 4.59±0.12 mmol/l $p < 0.005$; $power > 0.80$), Glycemia(oGTT) AUC (690±16 vs. 622±13 $p = 0.0011$; $power = 0.912$).

Conclusion: Our study suggests that *FTO* gene is associated not only with obesity-related quantitative traits (particularly BMI, weight and abdomen circumference) but also with higher oGTT stimulated glycaemia and leptin levels, especially in female controls.

Association of macronutrient intake with overweight and obesity among Bangladeshi population: a hospital based study

U.S. Munni, S. Shahid, S. Hossain, T. Khan, K. Fatema
Dept of Epidemiology and Biostatistics, BIHS, Dhaka, Bangladesh

Background and aims: Obesity is one of the most important risk factors for diabetes and other disorders of metabolic syndrome. Nutritional intake is a major determinant of obesity and it needs to be studied in various population groups based on their racial, socio-economic and cultural context. The information is highly required for designing evidence-based strategies to improve nutritional habits. In the present study we have investigated the nutritional

intake of a group of Bangladeshi nondiabetic and diabetic subjects in relation to their demographic and anthropometric status.

Materials and methods: It was an observational exploratory study with 4063 subjects (1571 male and 2492 female; 1552 nondiabetic and 2511 diabetic) attending the health care centres and hospitals run by the Diabetic Association of Bangladesh in the capital and in northern Bangladesh. A pre-structured interviewer administered questionnaire was used to collect data. Anthropometric measurements (height, weight, waist and hip) were done by standard techniques. BMI and waist-hip ratio were calculated using appropriate formula. A BMI of 23 was taken as the cut-off point for overweight as defined by WHO for this population.

Results: The number of patients coming from rural, semi-urban and urban areas were 67, 699 and 3297 respectively. Fifty one percent subjects were illiterate and 27.7% and 21.2% had education up to secondary and graduate levels respectively. The mean (\pm SD, years) age of the subjects was 46±14; BMI 24.71±5.24 and Waist-Hip ratio was 0.91±0.57. The proportion of subjects with lower, middle and upper socioeconomic classes were 20.6%, 51% and 28.4% respectively. The proportion of calorie contributed by the three principal macronutrients was as follows: carbohydrate 58%, fat 25%, and protein 17%. On group comparison between overweight plus obese (BMI>23) and normal weight individuals the intake of carbohydrate and protein did not vary between the groups, but fat intake was paradoxically lower in the overweight group. On logistic regression with normal weight and over weight (plus obesity) as dependent variables carbohydrate and protein intake was found to be associated with overweight when other confounders (age, waist-hip ratio and diabetic state) were adjusted.

Conclusion: Weight gain in Bangladeshi subjects (both nondiabetic and diabetic) is associated with higher carbohydrate intake and a targeted approach to modify this nutritional behavior need to be taken in nondiabetic as well as diabetic population.

Supported by: World Diabetes Foundation and Diabetic Institute of Bangladesh

Association between the vitamin D-binding protein gene (*DBP*) and visceral obesity in obese children and adolescents

L.M. Johansson¹, L.E. Johansson¹, P. Danielsson², S. Norgren², C. Marcus², M. Ridderstråle¹

¹Clinical sciences Malmö, Lund University, Malmö, ²Clinical science, Karolinska Institute, Stockholm, Sweden

Background and aims: A previous study has indicated that variants in the vitamin D-binding protein gene (*DBP*) are associated with obesity and insulin resistance. Here we investigated if the *DBP* single nucleotide polymorphism (SNP) rs17467825 has any impact on the development of obesity and/or obesity related traits in children and adolescents.

Materials and methods: rs17467825 was genotyped in 448 obese (age: 12.7 \pm 3.2 years, BMI: 34.3 kg/m² [30.9–38.3]) and 468 normal weight (age: 17.0 \pm 0.82 years, BMI: 20.7 kg/m² [19.5–22.3]) Swedish Caucasian children and adolescents, using the Sequenom platform (Matrix-Assisted Laser Desorption/Ionization Time-of-Flight Mass Spectrometry - MALDI-TOF MS). Detailed phenotypic information including insulin sensitivity and body composition (DXA scan) was available for the obese subjects.

Results: We found no association between *DBP* rs17467825 and obesity (minor allele frequencies were 4.0% and 5.8% for cases and controls, respectively, $p = 0.37$). However, obese carriers of the minor allele (AA vs. AG+GG; $n = 280$ and 168, respectively) showed significantly decreased percent visceral fat mass (AA: 47.8% [42.5–50.7], AG+GG: 45.9% [40.0–49.7]; $p = 0.013$), fasting plasma glucose (AA: 5.0 mmol/l [4.7–5.3], AG+GG: 4.8 mmol/l [4.5–5.1], $p = 0.001$) and insulin resistance (homeostasis model assessment index of insulin resistance - HOMA-IR; AA: 3.5 [2.6–4.8], AG+GG: 2.7 [2.0–4.5], $p = 0.052$); all comparisons adjusted for age, gender, and BMI where appropriate. The difference in HOMA-IR was significant after adjusting for percent visceral fat mass ($p = 0.045$).

Conclusion: The *DBP* SNP rs17467825 has no major impact on the development of obesity in our cohort of Caucasian children and adolescents when expressed as BMI. It may be involved in the regulation of visceral fat mass and in addition seems to have an independent effect on insulin sensitivity.

Evaluation of the 6-minute walk test as a tool to estimate functional capacity in obese patients during weight loss

M. Ahlén, M. Klintonberg, U. Björck, F. Norström, M. Ridderstråle
Department of Clinical Sciences - Clinical obesity, Lund University, Malmö, Sweden

Background and aims: Obesity is associated with increased risk of several somatic conditions as well as decreased quality of life. However, physically fit obese subjects do not show excess mortality. Here we characterized obese patients before and after weight loss and evaluated the 6-minute walk test (6MWT) as a tool to estimate the functional capacity of obese subjects. In healthy subjects, the result of 6MWT is influenced by age, gender, height and weight.

Materials and methods: Subjects were recruited from the Obesity outpatient unit at the Department of Endocrinology, University Hospital MAS, Sweden. Weight loss was achieved by 14 group counseling sessions over the course of six to eight months preceded by 10 weeks on low calorie diet. For the 6MWT they were instructed to walk in their own maximal walking speed for 6 minutes. Heart rate was recorded before and after and maximal heart rate was estimated (220-age). Degree of pain (1-10) and localization as well as degree of effort (1-10) were reported. Differences between groups and correlations between variables were tested using standard non-parametric tests. Data are reported as median and interquartile range.

Results: 174 patients (46 men and 128 women, age 43 years [35-53], BMI 40.4 kg/m² [37.6-44.6]) participated in the study. Walking distance (534 m [485-568]) correlated negatively to age ($r=-0.15$; $p=0.04$) and BMI ($r=-0.34$; $p=0.00003$). No correlation to height and no difference between genders were observed. Neither was there a correlation between distance and reported degree of effort. There was no correlation between heart rate before the test (78 bpm [70-88]) and measures of obesity. Heart rate after the test (130 bpm [119-141]) correlated to walking distance ($r=0.48$; $p<0.00001$). 53 % of the patients reported pain (graded 4 [3-5]) during the test (tibia 21.8 %, knee joint 7.5 % and lower back 6.9 %). Reported pain did not significantly affect the walking distance but correlated to reported degree of effort ($r=0.22$, $p=0.0037$). 76 patients repeated the test after treatment (median weight loss being 19 kg [10-30]). Walking distance increased significantly (51.5 m [18.5-79], $p<0.0001$), whereas heart rate before (-8.5 bpm [-16-0.75], $p<0.0001$) and after the test decreased (-4 bpm [-14-4], $p=0.002$). The increase in walking distance correlated to the weight loss ($r=0.39$; $p=0.00059$). The degree of reported effort ($p=0.0003$) and pain ($p=0.00003$) during the test decreased and fewer subjects reported associated pain (26 %).

Conclusion: The 6MWT is able to estimate physical capacity in obese patients based on walking distance and shows an improvement after weight loss. The test is easy and inexpensive and allows for self-evaluation and appreciation of treatment success beyond kilogram body weight loss. Activity-related pain was seen in more than half of the patients but responded promptly to weight loss. Further tests to validate these data are needed.

822

A genetic variant in Zn- α_2 -glycoprotein is associated with obesity in Swedish men

E.-C. Långberg¹, D. Lagarde², H.F. Gu¹, L. Essioux², G. Duchateau Nguyen², R.G. Clerc², C.-G. Östenson¹

¹Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden, ²F. Hoffmann-La Roche Ltd, Basel, Switzerland

Background and aims: In several animal studies Zn- α_2 -glycoprotein (ZAG) has been demonstrated to be a novel adipokine involved in regulation of obesity. Our study hypothesis was to evaluate whether polymorphisms in this

gene influences the development of obesity and/or type 2 diabetes (T2D) in humans.

Materials and methods: Genotyping of four SNPs was performed by dynamic allele specific hybridization (DASH) and TaqMan allelic discrimination in a total of 816 Swedish Caucasians including 290 non obese subjects with normal glucose tolerance (NGT), 199 obese subjects with NGT, 86 obese subjects with IGT and 241 patients with T2D.

Results: SNP rs2525554 showed significant allelic association with IGT obese subjects, where the minor allele T was present at a higher frequency in IGT obese subjects compared to non obese NGT controls (0.558 versus 0.465, $P=0.032$; OR=1.453; 95% CI=1.03-2.05). Quantitative trait analysis revealed a significant association for waist circumference (WC) within the obese NGT group; the subjects carrying TT and TC genotypes had an increased WC compared to the CC genotype carriers (105.6 \pm 0.6 versus 102.6 \pm 1.0; $P=0.008$). Association with WC also showed significance when pooling the obese NGT and obese IGT groups together, comparing the same genotypes (106.9 \pm 0.5 versus 103.9 \pm 0.9; $P=0.004$). When analyzing the two NGT groups together there was also a significant difference in WC with regard to genotype (94.4 \pm 0.6 versus 91.6 \pm 1.0; $P=0.014$). The same trends were also seen in non obese NGT subjects. Among obese subjects and non obese NGT controls significant associations with increased BMI, WC, WHR, 2h glucose and systolic BP ($P=0.017$; 0.003; 0.007; 0.038; 0.028 respectively) was found in the carriers with T/T genotype. This effect was abolished when including the T2D patients.

Conclusions: This study provides evidence for association of genetic variation in the ZAG gene with obesity and suggests that SNP rs2525554 confers an increased risk for the development of abdominal obesity in Swedish men. *Supported by: F. Hoffman-La Roche, Swedish Research Council, Swedish Diabetes Association, Novo Nordisk Scandinavia, GlaxoSmithKline, and Loo and Hans Osterman foundation*

The association between depressive symptoms in childhood and overweight in adolescence. The TRAILS study

E.T. Liem^{1,2}, P.J.J. Sauer¹, A.J. Oldehinkel^{3,4}, R.P. Stolk²

¹Department of Pediatrics, University Medical Center Groningen,

²Department of Epidemiology, University Medical Center Groningen,

³Department of Psychiatry and Graduate School of Behavioral and Cognitive Neurosciences, University Medical Center Groningen,

⁴Department of Child and Adolescent Psychiatry, Erasmus Medical Center – Sophia Children's Hospital, Rotterdam, Netherlands.

Background and aims: Prevention of overweight is a major public health concern. Targeted and tailored preventive strategies that take cost-effectiveness into account need to be developed and therefore, important predictors of overweight in childhood and adolescence need to be determined. Depressive symptoms have been described both as a predictor and as a complication of overweight. The aim of this study is to assess the association between depressive symptoms in childhood and overweight in adolescence.

Materials and methods: The TRacking Adolescents Individual Lives Survey (TRAILS) is a population-based cohort study among 2000 adolescents, presently aged 14-16 years. These adolescents have been assessed biennially from the age of 11 years to evaluate the development of psychosocial and somatic health from pre-adolescence into adulthood. At ages 11 and 15, we have assessed weight, height, skinfold thicknesses, and depressive symptoms through Youth Self Report and Child Behavior Checklist questionnaires. Body fat percentage and waist circumference have been obtained at age 15.

Results: Results regarding the first 1037 participants showed that, at age 11 clinical depressive symptoms were present in 10.9% of girls and in 9.9% of boys. Mean BMI at age 15 was 21.28 kg/m² in girls and 20.18 kg/m² in boys. Results from linear regression analyses showed no significant results in boys.

Association between depressive symptoms at age 11 and BMI, skinfolds, BIA, and waist in girls.

Dependent variable	Continuous predictor: B depressive symptoms at age 11 (95% CI), P-value*	Dichotomous predictor: Adjusted difference between depressed and non-depressed (at age 11) children (95% CI), P-value*
BMI at age 15 (kg/m ²)	0.18 (-0.06 - 0.41), P = 0.14	0.83 (0.24 - 1.42), P = 0.01
Sum of four skinfolds at age 15 (mm)	2.01 (-0.21 - 4.23), P = 0.08	4.81 (-0.94 - 10.55), P = 0.10
Body fat at age 15 (%)	0.44 (0.05 - 0.83), P = 0.03	1.27 (0.28 - 2.25), P = 0.01
Waist circumference at age 15 (cm)	0.72 (0.01 - 1.42), P = 0.05	2.06 (0.27 - 3.84), P = 0.02

* Adjusted for BMI at age 11.

The results regarding girls are listed in the table. After adjusting for body mass index (BMI) at age 11, depressive symptoms at age 11 are associated with higher body fat percentage and larger waist circumference at age 15 in girls. Dichotomizing depressive symptoms using a clinically relevant cut-off value, resulted in stronger associations.

Conclusion: In girls, clinically relevant depressive symptoms at age 11 are associated with an increased BMI, body fat percentage, and waist circumference at age 15.

Expression of thyrotropin receptors in adipose tissue of obese subjects with type 2 diabetes

M. Nannipieri¹, F. Cecchetti¹, M. Anselmino², E. Mancini¹, F. Santini³, A. Pinchera³, E. Ferrannini¹

¹Internal Medicine, University of Pisa, ²Bariatric Surgery, Azienda Ospedaliera Universitaria di Pisa, ³Endocrinology, University of Pisa, Italy

Background and aims: Morbidly obese subjects may present abnormal thyroid function tests, probably as a result of a central reset of thyroid function. Information on the expression of TSH receptors (TSHR) in extra-thyroidal tissues in humans is scarce and conflicting. Whether TSHR and thyroid hormone receptors (ROTa1 and ROTa2 subunits) are expressed in subcutaneous (SAT) or visceral adipose tissue (VAT) is unknown.

Materials and methods: Total RNA was extracted from SAT and VAT tissue specimens obtained during abdominal surgery from 12 lean non-diabetic subjects (C) (BMI=24.1±2.9 kg m⁻²), 27 obese subjects with type 2 diabetes (T2DM-Ob) (BMI=44.9±6.2 kg m⁻²), 17 obese subjects with impaired glucose tolerance (IGT-Ob) (BMI=47.2±7.1 kg m⁻²) and 50 obese subjects with normal glucose tolerance (Ob) (BMI=47.5±9.6 kg m⁻²). Relative quantification of TSHR, ROTa1 and ROTa2 mRNA (target gene) was performed by Real-Time PCR. Results were expressed as the target/reference (Hypoxanthine phosphoribosyl-transferase) ratio for each sample.

Results: In SAT, TSHR expression was significantly higher in control than obese subjects regardless of glucose tolerance (C=0.68±0.4 vs Ob=0.36±3 vs IGT-Ob=0.46±0.5 vs T2DM-Ob=0.30±0.3, p=0.005 by Kruskal Wallis test), whereas no differences were found in ROTa1 or ROTa2 expression among groups. Similarly, in VAT TSHR was significantly more expressed in controls as compared to the other groups (C=0.65±0.5 vs Ob=0.21±0.2 vs IGT-Ob=0.19±0.2 vs T2DM-Ob=0.25±0.28, p=0.01); again, no differences were found in ROTa1 and ROTa2 among groups. TSHR in SAT and VAT were positively related to each other (ρ =0.45, p<0.0001). TSHR in both SAT and VAT were reciprocally associated with BMI (ρ =−0.20 and −0.36, respectively, p≤0.05 for both); this association persisted after adjusting for sex, age and fasting glucose levels. While circulating thyroid hormones levels did not differ significantly across groups, plasma TSH levels were lower in C than in the other groups (0.7±0.4 µU/ml vs 1.9±0.9, 2.1±1.6, 2.0±1.5, C vs Ob vs IGT-Ob vs DM2-Ob, p=0.0002) and were directly related to BMI (ρ =0.35, p=0.0002) and inversely related to VAT TSHR (ρ =−0.28, p=0.01).

Conclusion: TSHR gene is expressed in adipose tissue, to a similar extent in subcutaneous and visceral depots. In both depots, TSHR - but not thyroid hormone receptors - are reduced in obesity (and in proportion to the degree of obesity) regardless of the glucose tolerance status. The inverse association of TSHR in VAT and circulating TSH levels suggests that visceral fat may be the site of a feedback regulation.

Is the favorable effect of type 2 diabetes mellitus on bone mineral density associated to increased body fat?

D.J. Hadjidakis, A. Mylonakis, I.I. Androulakis, M. Peppas, A.E. Raptis, A. Papaefstathiou, T. Economopoulos, S.A. Raptis

2nd Department of Internal Medicine-Propaedeutic, Research Institute and Diabetes Centre, «Attikon» and «Evgenidion» University Hospitals, Athens University, Greece

Background and aims: In type 2 diabetes mellitus, insulin resistance has been associated with the presence of excessive fat mass and obesity. On the other hand, the observed positive effect of the disease on bone mineral density

(BMD) has mostly been attributed to hyperinsulinemia. The present study investigates whether this positive effect is directly associated to excessive fat mass.

Materials and methods: In 117 postmenopausal women (age 63.1±5.7 yrs, mean ± 1 SD, range 51-70) suffering from diabetes mellitus type 2 for more than 5 years, never on insulin or glitazone treatment, whole body (WB) composition and BMD [L1-L4 vertebrae, total hip (TH) and femoral neck (FN)] measurements were performed by DXA. Somatometric parameters, such as Body Mass Index (BMI, kg/m²), “Fat Mass Index” (“FMI”, fat mass in kg/m²), the proportion of whole body fat mass (WBFM%) as well as the proportion of the trunk fat mass (TRFM%) were evaluated. Diabetic women were twice separated in 2 subgroups according to the median value [(+) above the median, (-) below the median] of either the “FMI” [FMI(-) and FMI(+)] or the BMI [BMI(-) and BMI(+)].

Results: Within the whole group of diabetic postmenopausal women only BMI but not “FMI” was significantly positively correlated to the BMD values of all anatomic sites (all p<0.01, Pearson’s correlation). Between the FMI(-) and FMI(+) subgroups, no significant differences were observed in the BMD values of any anatomic site (all p>0.6, t-test). Conversely, BMI (+) subgroup presented significantly higher BMD values in L1-L4 vertebrae and TH compared to BMI (-) (p<0.01). In all subgroups only BMI but not “FMI” was significantly positively correlated with the BMD values of all anatomic sites (p<0.01 for BMI and >0.4 for “FMI” always). No significant correlation was observed in any subgroup between the WBFM% or TRFM% and any BMD value.

Conclusion: Mechanical loading due to increased whole body mass rather than the presence of excessive fat mass seems to be responsible for the observed positive effect of type 2 diabetes mellitus on bone mineral density of postmenopausal women. Adiposity, general or central, does not seem to be directly associated to bone density.

Depot specific activity of the 15-lipoxygenase pathway in adipose tissue: the inflammatory response and metabolic disease

A.L. Harte¹, M.J. Hill¹, N.F. da Silva², K.C. McGee¹, A.R. Baker¹, J.C. Clapham², S. Kumar¹, P.G. McTernan¹

¹Clinical Sciences Research Institute, University of Warwick Medical School, Coventry, United Kingdom, ²AstraZeneca, Alderley Park, United Kingdom

Background and aims: 15-Lipoxygenase (15-LO) is a key, highly regulated enzyme catalysing the oxygenation of arachidonic acid (AA) forming a variety of lipid metabolites that exert diverse pro- and anti-inflammatory properties. To date, no study has addressed the role of 15-LO in human adipose tissue (AT), whilst sub-clinical inflammation is known to represent a key player in the pathogenesis of obesity-mediated type 2 diabetes mellitus (T2DM). Therefore the aims of this study were to (1) investigate the mRNA expression profile of major pathways involved in AA metabolism in human abdominal subcutaneous (AbSc) and omental (Om) AT depots (2) assess the relative depot specific changes in mRNA and protein expression of the 15-LO pathway in inflammatory models (3) examine the role of adiposity.

Materials and methods: Paired AbSc and Om AT were collected from patients undergoing elective liposuction surgery (Age: 45.81±1.73 yrs; lean BMI: 22.67±0.40 kg/m²; obese BMI: 33.05±0.72kg/m²; n=36) for gene expression analysis by microarray and real time polymerase chain reaction (PCR). Protein expression and secretion were determined by Western blot and ELISA analysis.

Results: Microarray data showed that Om AT had significantly higher expression of 15-LO than paired AbSc AT, independent of BMI (p=0.00016). In addition, other key elements of AA metabolism; prostaglandin D2 synthase (p=0.000008), leukotriene A4 hydrolase (p=0.00036), prostaglandin endoperoxide synthase 1 (p=0.000001) and cytochrome p450 (p=0.000075) showed significantly higher expression in Om AT. PCR data further corroborated the 15-LO expression profile (AbSc AT: ΔCt 17.10 ± 0.86 and Om AT: ΔCt 6.48 ± 0.37 (p<0.001)) independent of BMI. Western blotting confirmed depot specific expression of 15-LO was still present at the protein level and continued to be independent of BMI. Lipoxin A₄ secretion was observed by ELISA in isolated adipocytes.

Conclusion: These studies highlight, for the first time, that 15-LO is clearly differentially expressed in human AT and that the pathway metabolite lipoxin A₄ is secreted from adipocytes. Furthermore that omental AT, which is associated with increased inflammatory response, also has increased mRNA expression of the 15-LO pathway. Taken together, these findings suggest a previously undefined mechanism within human fat that may exacerbate the inflammatory response in obesity mediated T2DM.

Neutrophils transiently infiltrate intra-abdominal fat early in the course of high fat feeding

V. Elgazar-Carmon, A. Rudich, N. Hadad, R. Levy

Clinical Biochemistry, Ben-Gurion University, Beer-Sheva, Israel

Background and aims: It has been established that obesity is characterized by chronic inflammation of adipose tissue manifested by secretion of proinflammatory cytokines and macrophage infiltration. Yet, the initiating event(s) in adipose inflammation is still unknown. In various infectious and non-infectious inflammatory processes, chronic inflammatory infiltrate is characterized by predominant mononuclear cells and is usually preceded by acute infiltration of the tissue by circulating neutrophils. We aimed to study whether neutrophils infiltrate adipose tissue prior to macrophages, and to characterize adipocyte-neutrophil adherence in molecular terms.

Materials and methods: *In-vivo:* Male C57BL/6J mice were subjected to high fat feeding for 3 days to 16 weeks, after which subcutaneous and peri-epididymal fat tissues were analyzed by immunoblotting and immunohistochemistry. *In-vitro:* we determined the role of CD11b-ICAM-1 complex formation in mediating adherence between 3T3-L1 adipocytes and isolated mouse neutrophils using surface integrin exposure analyses by FACS, neutralizing antibodies and co-immunoprecipitation approaches.

Results: Early (3 and 7 days) after initiating high fat feeding of C57BL/6J mice, neutrophils transiently infiltrate the parenchyma of intra-abdominal, but not subcutaneous, adipose tissue. Mean periepididymal fat myeloperoxidase ex-

pression (representing neutrophils) was significantly increased 3.5-fold (p<0.01) and 2.9-fold (p<0.03), at days 3 and 7 compared to day 0. Immunohistochemistry analysis demonstrated physical binding between neutrophils and adipocytes. In an *in-vitro* adherence assay, mouse peritoneal neutrophils physically adhered to a monolayer of 3T3-L1 mouse adipocytes. The degree of adherence depended on neutrophils' activation state, being 41.9±3.7% or 29.5±2%, when neutrophils were stimulated with PMA or the IL-8 analog KC, respectively, compared with 24.8±1.5% in unstimulated neutrophils. Activation-dependent adherence required Ca²⁺ and could be mimicked by Mn²⁺, suggesting the involvement of integrins, and corresponded to the degree of surface exposure of CD11b (Mac-1). The adherence was prevented by pre-incubating neutrophils or adipocytes, respectively, with neutralizing anti-CD11b or anti-ICAM-1 antibodies. Furthermore, immunoprecipitation of CD11b from lysates of a mixed neutrophil-adipocyte cell population resulted in co-immunoprecipitation of ICAM-1, indicating that the interaction is mediated by neutrophil CD11b and adipocyte ICAM-1.

Conclusion: The early and transient infiltration of neutrophils to intra-abdominal (but not subcutaneous) adipose tissue and the binding to adipocytes may provide a novel insight on the initiating events of the inflammatory process occurring in adipose tissue during development of obesity.

Glucose-dependent insulinotropic polypeptide (GIP) modulates inflammatory markers and regulates proliferation in subcutaneous adipose tissue

Ö. Gögebakan¹, S. Mosig², I. Middelbeck¹, M.A. Osterhoff³, N. Rudovich³, D. Groth⁴, A.F.H. Pfeiffer^{1,3}

¹Clinical Nutrition, DIfE, Rehbrücke, ²Institute for Vaskular Medicine, Friedrich-Schiller-University Medicine, Jena, ³Endocrinology, Diabetes and Nutrition, Charité-University Medicine, Berlin, ⁴Bioinformatics, Max-Planck-Institute, Potsdam Golm, Germany

Background and aims: Glucose-dependent insulinotropic polypeptide (GIP) is a gastrointestinal hormone that is secreted in response to food intake and modulates β-cell function. GIP acts on various tissues, including pancreatic β-cells, via interaction with its G-protein-coupled receptor. Some studies in rodents suggested that GIP directly links overnutrition to obesity. GIP exerts a physiological role on lipid uptake into adipocytes. Insulin release by GIP is contingent upon elevated blood glucose similar to the other important incretin hormone, glucagon like peptide 1 (GLP-1). This assures that insulin release is not stimulated under hypoglycaemic conditions. GIP loses its insulinomimetic effect in the presence of chronic hyperglycaemia and thus appears to be ineffective in poorly controlled T2DM at least with regard to insulin release. The mechanism by which this occurs is not clear and it is not known whether this loss of function is restricted to insulin release. To analyse the effect of GIP-Infusions on changes in adipose tissue gene expression at different blood-glucose levels in obese men and also detect different biomarkers and hormone interactions caused by GIP.

Materials and methods: Seventeen healthy overweight men (BMI: 28-40 kg/m²; age: 30-65 years) with normal glucose tolerance underwent a single-blind intervention study at four different time points with euglycaemic or hyperglycaemic clamps in combination with GIP or saline infusions. Each solution was applied at physiological concentrations for four hours. Before and after the infusions biopsies from subcutaneous adipose tissue were taken. We isolated total RNA from all fat biopsies and hybridized the RNA to Agilent Whole Human Genome Microarrays (total 100 arrays). The results were verified by RT-PCR.

Results: Using Agilent Genespring Software and the MetaCore platform we identified several genes being involved in inflammatory and proliferative cell signalling. Under euglycaemic hyperinsulinaemic clamp conditions in combinations with a GIP-Infusion we find a significant upregulation of chemokine ligand 2 (CCL-2/MCP-1), interleukin-1β (IL-1β), interleukin-6 (IL-6), fibroblast growth factor receptor 1 (FGFR-1) and oncostatin M (OSM). We also see an activation of cell proliferation by members of the wnt signalling in adipose tissue after exposure with GIP mediated by cyclin D1 and several zinc finger proteins like ZNF 397 and ZNF 629.

Conclusion: GIP may play a role in inflammation and cell proliferation in adipose tissue of obese men. Depending on blood glucose levels GIP, is also able to upregulate lipid and glucose metabolism in adipose tissue.

Regulatory effects of heat shock protein 60 on inflammatory adipocyte functions

V. Burkart, E. Gülden, S. Möller, J. Brüggemann, C. Habich
Institute for Clinical Diabetes Research, German Diabetes Center,
Düsseldorf, Germany

Background and aims: Adipose tissue has been characterized for a long time mainly by its energy storing capacity. Recent studies identified adipocytes as an important source of numerous inflammatory mediators including interleukin-6 (IL-6), IL-8 and monocyte chemoattractant protein-1 (MCP-1). Further investigations now provide increasing evidence that adipocyte-derived cytokines and chemokines sustain systemic low grade inflammation thereby promoting the development of metabolic disorders such as type 2 diabetes, and diabetes-specific complications. However, the physiological signals triggering the formation of inflammatory mediators in adipocytes are largely unknown. Analyses of the functional activities of adipocytes showed that this cell type shares essential features with innate immune cells. The stress protein heat shock protein (Hsp) 60, a putative beta-cell autoantigen, has been identified as a potent stimulator of pro-inflammatory activities of innate immune cells. These findings qualify Hsp60 as potential signal for the induction of pro-inflammatory mediators from adipocytes. Therefore, the present study was designed to analyse the regulatory effects of Hsp60 on adipocytes.

Materials and methods: Preadipocytes and mature adipocytes of the murine line 3T3-L1 were incubated with recombinant Hsp60 and the release of IL-6, KC and MCP-1 from these cells was determined by ELISA. The maturation state of the cells was determined by FACS, analysing the expression of the differentiation marker preadipocyte factor 1 (Pref-1). Binding of Hsp60 to the (pre-)adipocytes was studied by FACS analyses with fluorescent-labelled Hsp60.

Results: Analyses of the adipocyte maturation state by FACS confirmed a high expression level of Pref-1 in 3T3-L1 preadipocyte cultures (>90%), whereas the expression in mature adipocyte cultures was strongly reduced (<20%). Exposure of 3T3-L1 preadipocytes to increasing concentrations of Hsp60 (1, 10 and 20 µg/ml) dose-dependently induced a significant release of the cytokine IL-6 (from 113±1 to 459±45 pg/ml) and the chemokines KC (from 2±1 to 31±2 ng/ml) and MCP-1 (from 16±1 to 39±7 ng/ml). Incubation of mature 3T3-L1 adipocytes with Hsp60 increased the levels of the inflammatory mediators IL-6 (from 259±13 to 2208±202 pg/ml), KC (from 11±1 to 43±6 ng/ml) and MCP-1 (from 37±2 to 78±8 ng/ml). Comparative analyses of mature 3T3-L1 adipocytes after different cultivation periods (14 versus 23 days) revealed no significant differences in the Hsp60-stimulated formation of IL-6 and KC, whereas the Hsp60-induced release of MCP-1 decreased from 78±8 to 35±1 ng/ml. FACS analyses demonstrate specific Hsp60 binding to adipocytes with the characteristics of a receptor-ligand interaction. These findings implicate that Hsp60-stimulated formation of pro-inflammatory mediators in adipocytes is triggered by a receptor-mediated binding of the stress-protein.

Conclusion: Our results identified Hsp60 as important regulator of adipocyte functions supposed to contribute to the development of chronic, diabetes-associated inflammatory processes.

Toll-like receptor 4 controls the inflammatory activity and maturation of adipocytes

E. Gülden, C. Habich, V. Burkart
Institute for Clinical Diabetes Research, German Diabetes-Center,
Düsseldorf, Germany

Background and aims: Adipocytes have been identified as important cellular source of mediators which control a variety of metabolic and inflammatory processes. Recent findings show that adipocytes and their mediators do not only contribute to the development of type 2 diabetes and diabetes-associated complications but may also affect the autoimmune processes involved in the pathogenesis of type 1 diabetes. Depending on the maturation state of the adipocytes, their inflammatory activities share many features with innate immune cells. Innate immune cell functions are efficiently controlled by Toll-like receptors (TLR), in particular TLR4, the mammalian receptor for bacterial lipopolysaccharide (LPS). We therefore investigated whether TLR4 is able

to control the release of inflammatory adipocyte mediators and to affect the differentiation of adipocytes to mature cells.

Materials and methods: Our studies were performed with adipocytes of the murine line 3T3-L1 and adipocytes of TLR4 deficient C57BL/10ScCr (TLR4^{-/-}) and TLR4 expressing C57BL/10ScSn (TLR4^{+/+}) mice. Mature adipocytes were generated by cultivating preadipocytes in a defined differentiation medium. The purity and maturation state of the adipocytes were analysed with the lipid specific dye Oil Red O and by FACS-based determination of the macrophage specific marker CD11b and the differentiation marker Pref-1. The induction of inflammatory mediators by the TLR4 ligand LPS was quantified by ELISA.

Results: The purity of the isolated murine preadipocytes typically reached >99.2 % as determined by Oil Red O staining and CD11b expression. Analyses of the maturation state confirmed the presence of Pref-1 in more than 95 % of preadipocytes and in about 20 % of mature adipocytes. LPS exposure (24 h) resulted in a dose-dependent increase of inflammatory mediators from preadipocytes of TLR4^{+/+} but not of TLR4^{-/-} mice. LPS (1 ng/ml) induced a significant increase of IL-8 release (1.5 ± 0.1 ng/ml, p < 0.001) in TLR4^{+/+} preadipocytes but failed to induce IL-8 release from TLR4^{-/-} cells. Studies on the impact of the maturation state on LPS-responsiveness showed that mature TLR4^{+/+} adipocytes exhibit an increased inducibility of inflammatory mediators which was most pronounced for the chemokine MCP-1. At 1 ng/ml LPS preadipocytes released 17.7 ± 5.2 ng/ml MCP-1 whereas mature adipocytes released 55.3 ± 5.9 ng/ml MCP-1 (p < 0.01). Complementary studies on the potential effect of chronic TLR4 activation during adipocyte maturation showed that differentiation of 3T3-L1 cells in the presence of LPS had neither an effect on TLR4- and Pref-1-expression nor on the Oil Red O staining pattern. The presence of LPS during differentiation also did not affect spontaneous MCP-1 release (14.1 ± 1.4 ng/ml) by mature adipocytes; however, it significantly reduced LPS-inducible MCP-1 release. Mature adipocytes differentiated in the absence of LPS released 54.7 ± 13.7 ng/ml MCP-1 in response to 1 ng/ml LPS. In contrast, adipocytes differentiated in the presence of 1 or 100 ng/ml LPS released 35.7 ± 6.7 ng/ml (p < 0.05) or 18.8 ± 3.9 ng/ml MCP-1 (p < 0.01) after LPS stimulation.

Conclusion: Our results point to important roles of TLR4 in the regulation of inflammatory adipocyte-activities and in the development of LPS-responsiveness during the maturation of adipocytes. Our findings further implicate that TLR4-dependent adipocyte functions may contribute to the inflammatory processes involved in the pathogenesis of diabetes and diabetes-associated complications.

Adipose tissue derived SPARC and obesity related inflammation in healthy adults

K. Kos¹, S. Wong¹, D. Kerrigan², J.P.H. Wilding¹, J.H. Pinkney³
¹Obesity Research Group, Clinical Sciences, Liverpool, ²Department of Surgery, University Hospital Aintree, Liverpool, ³Unit for Diabetes, Peninsula Medical School and Royal Cornwall Hospital, Truro, United Kingdom

Background and aims: The extracellular matrix-associated- glycoprotein Secreted Protein Acidic and Rich in Cysteine (SPARC, osteonectin) is an adipokine with as yet poorly defined function. We have previously confirmed that adipose tissue (AT) expression of SPARC is upregulated in obesity and that its expression is associated leptin expression. However, little is known about a potential role of SPARC in inflammation and its contribution to cardiovascular risk.

Materials and methods: Morbidly obese non-diabetic subjects undergoing bariatric surgery (age=44.5±1.4years (mean±SE), BMI=46.8±1.9kg/m², n=37) and age-matched lean controls undergoing elective surgery (age=42.3±4.1years, BMI=23.6±0.8kg/m², n=18) were recruited and consented. A blood sample, visceral-AT (VAT) and subcutaneous-abdominal-AT (SCAT) biopsy were taken from each subject. Plasma cytokine levels were measured by ELISA and their AT-derived mRNA expression by real time-PCR using QuantiTect® Multiplex PCR (Qiagen, Crawley, UK), with prevalidated primers and Quantiprobe®, on a ROTORGENE-2000 analyser (Corbett Research, Cambridge, UK).

Results: SPARC expression was higher in SCAT than VAT (1.18±0.02 Signal Units (SU) versus 0.073±0.001SU, p<0.001, n=47). VAT and SCAT expression were highly correlated (r=0.44, p<0.01) and associated with increased

fat mass. SCAT-SPARC was strongly correlated with hsCRP ($r=0.44$, $p<0.01$); SCAT-retinol binding protein-4 (RBP-4; $r=0.36$; $p<0.01$), SCAT-adiponectin ($r=-0.3$, $p<0.05$) and SCAT-IL6 ($r=-0.3$, $p<0.05$) and SCAT- macrophage migration inhibitory factor (MMIF; $r=0.3$, $p<0.05$), but not TNF α , SCAT-macrophage inflammatory protein-1 (MIP-1), SCAT-monocyte chemoattractant protein-1 (MCP-1) or RANTES. VAT-SPARC was also correlated with VAT-RBP-4 ($r=0.47$, $p<0.001$). After correction for fat mass, age, gender, HOMA-IR and GLUT-4, only the correlation with RBP-4 remained significant and this in both AT-depots. Stepwise multiple regression revealed RBP-4 as a key predictor of SPARC expression. In addition, SCAT- and VAT-SPARC mRNA was positively correlated with HOMA-IR ($r=0.3$, $p<0.05$ and $r=0.36$, $p<0.05$ respectively).

Conclusion: SPARC does not appear to have a marked role as proinflammatory adipokine when correcting for fat mass. However, SPARC- AT-depot expression appears to have a marked correlation with local RBP-4 AT expression independent of fat mass and inflammation. RBP-4 and SPARC have been linked with lipid storage. A indirect influence on the pathogenesis of these two proteins on cardiovascular disease other than by inflammation cannot be excluded. Whilst AT-derived SPARC expression appears to be increased with insulin resistance, the close correlation of SPARC and RBP4 expression may suggest a disturbance of glucose metabolism by a common pathway.

The role of hyperglycaemia and hyperlipidaemia on inflammation in human abdominal subcutaneous adipose tissue and isolated adipocyte

E.M.Y. Yousef¹, A.L. Harte¹, C.M. Kusminski¹, N. da Silva¹, E.A. Wahba², A.A. Huseen³, A. Cerello¹, P. O'Hare¹, S. Kumar¹, P.G. McTernan¹

¹Diabetes and Metabolism Unit, Clinical Science Research Institute, Warwick, United Kingdom, ²Biochemistry Department, National Research Center, Cairo, Egypt, ³Clinical Pathology Department, National Institute of Diabetes and Endocrinology, Cairo, Egypt

Background and aims: Obesity-associated inflammation plays a major role in the pathogenesis of type 2 diabetes mellitus; however whether hyperglycaemia and hyperlipidaemia directly induce insulin resistance through inflammatory-based mechanisms is unclear. Therefore the key aims of this study were (1) to investigate the influence of chronic high-glucose concentration (H-Glc) and free fatty acids (FFAs) on the inflammatory pathways in human abdominal subcutaneous (AbSc) adipose tissue (AT) and AbSc adipocytes, and (2) to determine whether the effects induced by glucose and FFAs are mediated through NF- κ B pathways

Materials and methods: AT was collected from patients undergoing elective liposuction surgery (age, 45 ± 3.3 yrs; BMI, 21.9 ± 2.4 kg/m²; $n=4$). AbSc AT explants and adipocytes were treated with low-glucose (L-Glc): 5.6mM and H-Glc: 17.5mM, with low (0.2mM) and high (2mM) doses of a palmitate: stearic mix for 48 hours. Conditioned media were collected and pro-inflammatory cytokine secretions were assessed by ELISA. Components of the NF- κ B pathway were examined by Western blot analysis.

Results: Both L-Glc and high FFAs, H-Glc and high FFAs up-regulated key factors of the NF- κ B pathway in both AbSc AT explants (NF- κ B, $p<0.05$; IKK β , $p<0.05$, $n=5$) and isolated adipocytes (NF- κ B, $p<0.05$; IKK β , $p<0.05$, $n=5$). Downstream both TNF- α and IL-6 secretion was markedly increased from AbSc AT explants and isolated adipocytes treated with chronic L-Glc combined with high FFAs and H-Glc in combination with high FFAs, compared to controls (L-Glc alone). (AbSc AT explants: TNF- α : Control 0.41 ± 0.163 pg/mL; L-Glc & FFA (2mM) 4.1 ± 0.73 pg /mL; H-Glc & FFA(2mM), 4.7 ± 2.06 pg/mL; $p<0.05$; IL-6: Control, 1275 ± 352.5 pg/mL; L-Glc & FFA(2mM), 32389 ± 19972 pg/mL; H-Glc&FFA (2mM), 48741 ± 23151 pg/mL, $p<0.05$, $n=4$). Isolated adipocytes:TNF- α : Control, 0.9 ± 0.23 pg/mL; L-Glc & FFA(2mM), 8.51 ± 1.545 pg/mL; H-Glc & FFA(2mM), 5.9 ± 1.64 pg/mL; $p<0.05$; IL-6:Control, 8734 ± 2856.5 pg/mL; L-Glc & FFA(2mM), 39726 ± 8345 pg/mL; H-Glc & FFA(2mM), 42500 ± 8277 pg/mL, $p<0.05$, $n=4$).

Conclusion: Principally, irrespective of hyperglycaemic conditions, hyperlipidaemia has a profound effect on the increased production of the inflammatory cytokines, ranging from a 10-25 fold increase in TNF α and IL-6 production, respectively, with consistent upregulation of NF- κ B components in human AbSc AT explants and adipocytes. This study implicates elevated FFAs as a key instigator of the inflammatory response in both AT and adipocytes via NF- κ B with clear implications for the metabolic disease pathogenesis.

Does macrophage migration inhibitory factor precipitates obesity-associated type 2 diabetes development - an animal study

T. Cvjetanin, S. Stosic-Grubic, I. Stojanovic

Immunology, Institute for Biological Research "Sinisa Stankovic", Belgrade, Serbia

Background and aims: Hyperglycemia during type 2 diabetes (T2D) is a consequence of inappropriate insulin action. However, the final stage of this disease is characterized by β cell apoptosis leading to actual insulin deficiency. Recently, T2D has been characterized as a state of persistent, low-grade inflammation, and various pro-inflammatory mediators along with fatty acids are implicated in β cell apoptosis. Since some human studies discovered increased circulating levels of macrophage migration inhibitory factor (MIF) in patients with T2D and high MIF levels were associated with higher incidence of T2D, our aim was to further delineate the role of MIF in T2D.

Materials and methods: An animal model of obesity-associated T2D induced by high-fat (HF) food intake was used and applied on mice with MIF gene deletion (MIF-KO) and their wt counterparts C57BL/6 mice. Low-fat (LF) food was used as a control diet for both groups of mice. MIF secretion from pancreatic lymph node cells was determined by ELISA 5 weeks after the beginning of the experiment. Weight and basal non-fasting blood glucose levels were measured weekly. Intraperitoneal glucose tolerance test was performed every two weeks.

Results: The intake of HF diet increased body weight and impaired glucose tolerance in wt mice, while their blood glucose levels started to rise around week 9. Our preliminary data indicate that MIF secretion from pancreatic lymph node cells accompanied the weight gain in mice fed with HF diet in comparison to wt mice fed with low fat (LF) diet. Interestingly, MIF-KO animals on LF diet gained considerably more weight than wt (21.3% and 6.0%, respectively) after 4 weeks of feeding. At the same time MIF-KO on HF diet gained 30.2% of their original weight, while wt mice gained only 9.8%. By the end of 8th week, wt mice progressively gained weight and the difference between LF and HF group became significant, while MIF-KO mice stagnated. Although MIF-KO on HF diet mice became obese very early, they normally responded to glucose overload throughout the examination period and preserved normoglycemia.

Conclusion: Our results indicate that high levels of MIF are associated with development of obesity-associated T2D in C57BL/6 mice. Moreover, MIF is probably involved in the impairment of glucose homeostasis in mice on HF diet since its deletion lead to improved regulation of glycemia. Also, MIF inhibitors could be a valuable therapeutic approach in blocking β cell failure, having in mind the normal response of obese MIF-KO mice to glucose overload. Our goal is to further investigate the precise mechanism of MIF action in T2D.

Co-culture of adipocytes with macrophages inhibits insulin action and promotes a pro inflammatory state in adipocytes which is modulated by long chain n-3 polyunsaturated fatty acids

E. Oliver^{1,2}, C. Phillips¹, S. Toomey¹, H.M. Roche¹

¹Nutrigenomics, University College Dublin, Ireland, ²Department of Clinical Medicine, Trinity College Dublin, Institute of Molecular Medicine, Ireland

Background and aims: Obesity is the key aetiology factor that predisposes individuals to insulin resistance. Recent studies have shown that obese adipose tissue is characterised by increased infiltration of macrophages. These macrophages may release pro-inflammatory stressors, which may alter insulin sensitivity in adipocytes by modifying the insulin-signalling pathway, leading to type 2 diabetes mellitus (T2DM). There is strong evidence to suggest that long chain n-3 polyunsaturated fatty acids (LC n-3 PUFA) have anti-inflammatory as well as protective effects on T2DM risk. Cell culture studies have shown that pre-incubation with eicosapentaenoic (EPA) & docosahexaenoic (DHA) can attenuate pro-inflammatory cytokine production and down-regulate NF- κ B activation in macrophages. This study investigated the molecular interactions between macrophages & adipocytes and determined the effects on molecular markers of insulin sensitivity (GLUT4, IRS-1 & adiponectin) & inflammation (IL-6, TNF- α & IL-1 β) in adipocytes and to determine the therapeutic effects of anti-inflammatory n-3 LC-PUFA EPA & DHA on these markers.

Materials and methods: A co-culture of differentiated 3T3-L1 adipocytes and J774.2 macrophages was used as a model for obesity. In the contact system 3T3-L1 cells were cultured with unstimulated and LPS stimulated J774.2 cells (0.1 µg LPS/ml) for 24 hours followed by EPA or DHA (50 µmol/L) treatment for a further 24 hours. The transwell system was identical except inserts kept cell types separate but allowed exchange of soluble molecules. Cultured cells and supernatants were harvested for RT-PCR, western blot, confocal and ELISA analysis.

Results: The presence of macrophages significantly reduced adipocyte GLUT4 ($p < 0.05$) and IRS-1 ($p < 0.05$) mRNA expression, classical markers of insulin sensitivity. In contrast, IL-6 ($p < 0.05$) and TNF- α mRNA levels were up-regulated by the presence of macrophages. Also cell supernatant TNF α ($p < 0.05$), IL-6 ($p < 0.05$) and IL-1 β ($p < 0.05$) concentrations were increased while adiponectin levels were reduced ($p < 0.05$) on exposure to macrophages in both the contact and transwell systems. Adipocyte co-culture with LPS stimulated macrophages expressed significantly less GLUT4 protein ($p < 0.05$). Interestingly, EPA and DHA modify these effects within the adipocytes, reducing the expression of pro-inflammatory mediators (TNF- α , IL-6 and IL-1 β) and increasing markers of insulin sensitivity (GLUT4 and IRS-1).

Conclusion: These results suggest that obesity is associated with the generation of macrophage-derived soluble factors that promote a pro-inflammatory insulin-resistant adipocyte function. This work shows that pre-culturing macrophages with EPA and DHA can attenuate this effect. A longer pre-treatment of the macrophages with n-3 LC PUFA (Chronic pre-treatment) may be necessary to see a more defined attenuating effect. Further work is continuing to elucidate the molecular interactions between adipocytes, macrophages and dietary fatty acids.

Metformin significantly improves immune activity of natural killer (nk) cells of type 2 diabetic patients by regulating the expression of glucotransporter 4 (glut4)

A. Czech¹, P. Piatkiewicz¹, M. Kniotek², M. Nowaczyk²

¹Chair and Department of Internal Medicine and Diabetology, ²Department of Clinical Immunology, Warsaw Medical University, Warsaw, Poland

Background and aims: Abnormal metabolic conditions (hyperglycemia) may influence the function of peripheral blood NK cells which represent the first line defense in the immune system. This relationship can be particularly expressed by glucose transporter proteins in these cells. The earlier obtained results revealed significant differences in glucose transport between NK cells of healthy subjects and diabetic patients. The aim of this study was to evaluate the number and activity of NK cells obtained from Type 2 diabetic patients (T2DP) before and after the administration of metformin in comparison with healthy subjects and to determine the quantitative expression of insulin-dependent GLUT4 in these cells.

Materials and methods: Incubation tests were performed at baseline in 8 newly-diagnosed T2DP, naive to any hypoglycaemic drugs and 10 carefully matched control subjects; in the diabetic patients, the tests were repeated after 6 months of therapy with metformin accordingly to clinical indications. Peripheral blood mononuclear cells (PBMC) were isolated by Ficoll gradient centrifugation. The K562 human erythroleukemia cell line was used as the standard target for human NK cytotoxicity assay. K562 were labelled with DIO(3,3-diiododecylloxycarbocyanine perchlorate). Target and effector cells were added to reach effector/target ratios: 50:1, 12:1. Dead target cells were stained with PI (propidium iodide). After 4 hours of incubation data were collected for analysis on the Becton-Dickinson FACScalibur flow cytometer. Immunofluorescent phenotyping of NK (CD16⁺) cells in PBMC was performed using specific murine anti-human CD16 PE-conjugated monoclonal antibodies. The expression of GLUT4 was investigated by flow cytometry. Cells were stained by using anti-human GLUT4 antibody and FITC-conjugated immunoglobulin. The data was analyzed using Cell Quest software.

Results: The T2DP at baseline in comparison to healthy subjects had an increased number (13,35±6,0% vs 9,63±4,7%) but decreased activity (3,1±2,2% vs 9,2±3,7%) of NK cells. These differences were statistically significant ($P < 0.01$). Above abnormalities were associated with the higher level of GLUT4 protein in NK cells of T2DP versus control group (43±4,8% vs 12,5±2,4%), as shown in flow cytometry. Treatment with metformin resulted in a statistically significant reduction in fasting plasma glucose of 1.65 mmol/

L ($P < 0.001$) and in HbA_{1c} of 0.82% ($P < 0.001$) and also a significant decrease from 43% to 15.7% ($P = 0.002$) in the level of GLUT4 protein presented by NK cells of type 2 diabetics. The T2DP after 6 month of metformin administration demonstrated substantially decreased number and increased activity of NK cells when compared to the baseline conditions (10,83±4,6% and 5,7±2,8% respectively vs 13,35±6,0% and 3,1±2,2%).

Conclusion: The high expression of GLUT4 in NK cells may be the cause of impaired immune response in T2DP. Increased number and decreased activity of NK cells may reflect incorrect metabolic conditions of the T2DP. Metformin therapy improves immune activity of NK cells in Type 2 diabetes. The influence of metformin on NK cells function constitutes a new pleiotropic action of this drug, and underlines the importance of immune response as a potential target of pharmacotherapy in type 2 diabetes mellitus.

Insulin resistance caused by thiazide diuretics can be explained by adipose tissue alterations - visceral redistribution, inflammation and altered gene expression

J. Palmberg¹, P.-A. Jansson¹, F. Renström², I. Nagaev¹, L. Johansson^{3,4}, C. Karlsson⁴, L. Lind⁵, J.W. Eriksson^{1,4}

¹Department of Molecular and Clinical Medicine, Lundberg Laboratory for Diabetes Research, University of Gothenburg, ²Department of Public Health and Clinical Medicine, Umeå University, ³Department of Radiology, Uppsala University Hospital, ⁴AstraZeneca R&D, Mölndal, ⁵Department of Medicine, Uppsala University Hospital, Sweden

Background and aims: Angiotensin II receptor blockers (ARBs) are associated with lower risk of developing T2DM compared to beta blockers and thiazide diuretics. The aim was to compare the effects of treatment with the ARB candesartan (C), hydrochlorothiazide (H) and placebo (P) in adipose tissue and on adipokine levels.

Materials and methods: In a multicenter double-blind, cross-over trial, 26 non-diabetic, hypertensive patients with abdominal obesity (waist >102 cm, M; >88 cm, F) were randomized to three 12 week treatment periods with C (16–32 mg), H (25–50 mg) and P, respectively. Of the 22 patients (10 M, 12 W) who completed the study was the mean age 54.8±10.4 years and mean BMI 30.2±3.0 kg/m². After 8 weeks of each treatment period, subcutaneous adipose tissue biopsies were taken for analyzing the glucose uptake capacity and insulin signaling in adipocytes, adipocyte size and to isolate RNA. ¹⁴C-glucose uptake was measured after adipocyte incubation with insulin (50 µU/ml, 1000 µU/ml). Immunoblotting was used to analyze the insulin signaling in adipocytes after incubation with insulin (50 µU/ml, 1000 µU/ml). Gene expression was analyzed using real-time PCR. The insulin sensitivity was measured with euglycemic clamp. Abdominal subcutaneous and visceral adipose tissue (SAT and VAT, respectively) as well as liver fat content were measured using MRI and ¹H-MRS.

Results: The SAT/VAT ratio was reduced after treatment with H compared to C and P (p<0.01). The three different treatments did not influence the adipocyte cell size or the basal or insulin stimulated glucose uptake capacity. Insulin stimulated phosphorylation of the insulin receptor, insulin receptor substrate 1 and protein kinase B in adipocytes displayed a similar pattern during the three treatment periods. In addition, the cellular content of these signaling proteins did not differ between the treatments. The serum level of the inflammation marker C reactive protein (hsCRP) were higher following H compared to the C and the P treatments (p<0.01 for both). The serum levels of two other inflammation markers serum amyloid A (SAA) and E-selectin (SELE) were higher following H compared to the C treatment (p<0.05, p<0.01, respectively). The SAA mRNA expression in adipose tissue was increased after both the H (p=0.016) and the C (p=0.05) treatments compared to P. As previously reported, the H treatment was followed by lower insulin sensitivity (p<0.01) and by increased liver fat content (p<0.05).

Conclusion: The thiazide H caused visceral fat redistribution and signs of low-grade inflammation with elevated serum levels of SAA, hsCRP and SELE compared to the C and the P treatments. In contrast, the ARB C had less pronounced adipocyte effects. Increased gene expression and secretion of inflammatory mediators from adipose tissue, e.g SAA, could contribute to the metabolic alterations exerted by thiazide treatment.

Cross-talk between interferon-gamma and hedgehog signalling restores adipogenesis in 3T3-L1 cells

J. Todoric, O. Wagner, H. Esterbauer

Department of Medical and Chemical Laboratory Diagnostics, Medical University Vienna, Vienna, Austria

Background and aims: Hedgehog (Hh) signalling has been shown recently to inhibit adipocyte differentiation by preventing the induction of the pro-adipogenic master regulator PPARγ. INFγ, a cytokine synthesized and secreted by T-lymphocytes, which production is increased in obesity, has also

been demonstrated to inhibit the differentiation of adipocytes and to play a role in the development of insulin resistance. In this study we aimed to clarify the potential interaction between Hh signalling and INFγ in adipocyte differentiation.

Materials and methods: A synthetic hedgehog pathway activator (SAG) and recombinant INFγ were used to stimulate Hh- and INFγ-signalling, respectively. Luciferase and β-gal activity was measured in hedgehog reporter cell lines Shh-light II and Ptc1-/- LacZ to screen for potential pathway interactions. Relative mRNA levels of selected genes were analyzed by real-time PCR. 3T3-L1 cells were used to study adipocyte differentiation. Morphology of 3T3-L1 cells was judged by light microscopy and Oil-Red-O (OrO) staining. A two-tailed Student's *t*-test was performed to test for statistical differences.

Results: Luciferase activity of the Hh-target gene Gli1 was induced >20 fold by 100 ng/ml SAG in Shh-light II cells. This induction was strongly inhibited in a dose dependent manner by simultaneous INFγ treatment (up to 7 fold reduction, p<0.01). In Ptc1-/- cells, which exhibit constitutive Gli1 expression, Gli1 expression was reduced up to 2.5 fold in response to increasing concentrations of INFγ (p<0.05). Next, 3T3-L1 cells were induced to form adipocytes and stimulated during 10 days of differentiation with 10 ng/ml of SAG and/or 50 ng/ml INFγ. As expected, RNA levels of Hh-pathway target genes (Gli1, Gli2, Ptc1, Ptc2 and Hhip) were significantly increased after SAG-treatment relative to untreated cells (up to 3200 fold; p<0.001). INFγ alone did not affect expression of Hh-target genes tested. However, co-stimulation (SAG plus INFγ) of 3T3-L1 cells blunted the increase and resulted in decreased levels of this group of Hh-target genes (up to 60 fold inhibition; p<0.001). As published previously, SAG treatment also prevented induction of markers of adipocyte differentiation (Cebpa, Pparg, aP2/Fabp4, adiponectin, adipisin, Glut4, Lpl). Adipocytes incubated with SAG only showed an up to 20 fold decrease in mRNA levels of these genes as compared to untreated cells (p<0.001). Expression of adipocyte-marker genes was also inhibited by INFγ treatment, albeit to a lesser extent (up to 5 fold inhibition; p<0.001). Interestingly, combined treatment (SAG plus INFγ) efficiently abrogated inhibition of marker gene expression mediated by each of these stimuli and reverted RNA levels back up to 65% of those of untreated cells (SAG vs. SAG+INFγ, p<0.001). This was associated with the reappearance of typical morphological changes associated with normal adipocyte differentiation (lipid droplets) that were completely blocked by SAG and partially inhibited by INFγ. This re-entry in the adipocyte differentiation program was also reflected by marked increase in OrO lipid-staining.

Conclusion: Co-activation of Hedgehog and Interferon-gamma signalling cascades in 3T3-L1 cells diminishes the pathways' individual anti-adipogenic actions, thus allowing precursor cells to re-enter the full adipocyte differentiation program.

838

Insulin resistance of cultured human preadipocytes is related to estimates of obesity of the donors

C.J.H. van der Kallen, M.M.J. van Greevenbroek, C.G. Schalkwijk, C.D.A. Stehouwer

Dept of Internal Medicine/Cardiovascular Research Institute Maastricht (CARIM), University Maastricht, Netherlands

Background: Obesity is a driving force behind the increasing prevalence of the metabolic syndrome and type 2 Diabetes Mellitus. Adipose tissue expands to accommodate increased lipid through hypertrophy of existing adipocytes and also by initiating differentiation of preadipocytes. It was suggested that it is not the absolute amount of adipose tissue but rather the capacity/flexibility of adipose tissue to expand that affects metabolic homeostasis. An important factor involved in these processes may be cellular insulin resistance of (pre)adipocytes since insulin plays an important role in adipocyte function e.g. lipid synthesis and lipolysis.

Aims: To identify whether insulin sensitivity of cultured human preadipocytes is related to measures of obesity in the original cell donors.

Methods: Preadipocytes were isolated from human volunteers via periumbilical liposuction biopsies (n=20). Preadipocytes were cultured in DMEM medium containing 10% fetal calf serum and 1% glutamine/streptomycin/penicillin (GSP). After 4–6 weeks in culture (between passage 4–8), uptake of palmitate by the preadipocytes was measured by addition of [¹⁴C]-palmitate (0.3 µCi, final concentration, 0.6 mM). The reaction was carried out at 37°C for 7 hours in absence or presence of 100 nM insulin. Samples were applied to HP-TLC to separate triglycerides and phospholipids. Radioactivity was

measured after exposure to an imaging screen with the Personal Molecular Imager FX (Bio-Rad).

Results: Insulin sensitivity of fatty acid incorporation into triglycerides was defined as; the difference between the insulin stimulated and the basal incorporation divided by the basal incorporation. A significant correlation was found between the insulin sensitivity of fatty acids incorporated into triglycerides and measures of obesity (waist circumference ($r = -0.567$, $P: 0.009$) and waist-to-hip ratio (WHR, $r = -0.539$, $P: 0.006$)). These results remain significant after correction for age and sex. A more general measure of whole body obesity (BMI) did not reach significance ($r = -0.415$, $p = 0.069$).

Conclusion: In this study we show that metabolic characteristics of primary cultured preadipocytes associate with obesity of the cell donor. More specifically, we show in primary cultured human preadipocytes that a larger waist circumference (or WHR) is associated with lower insulin sensitivity for fatty acid incorporation into cellular triglycerides. This suggests that adipose tissue of lean subjects has better metabolic flexibility than adipose tissue of obese individuals. The fact that these results were obtained with primary preadipocytes in culture suggests that this is either a direct consequence of a genetic defects or may result from environmental influences during life causing epigenetic imprinting. Environmental adversity may produce persistent epigenetic alterations that set the stage for insulin resistance, metabolic obesity and Type II diabetes. The observed data offer a possible explanation for mechanisms underlying clinical observations in obesity and insulin resistance.

Rates of glucose uptake in the adipose tissue *in vivo* after a mixed meal in morbid obesity

P. Mitrou¹, G. Dimitriadis¹, V. Lambadiari¹, E. Maratou², E. Boutati¹, A. Papakonstantinou³, V. Komesidou⁴, N. Katsilambros⁵, T. Economopoulos¹, S.A. Raptis^{1,2}

¹2nd Department of Internal Medicine and Research Institute, Athens University Medical School, Attikon University Hospital, ²Hellenic National, Diabetes Center, ³1st Department of Surgery, Evangelismos Hospital, ⁴Department of Nutrition, Evangelismos Hospital, ⁵Eugenidion Hospital, University of Athens, Greece

Background and aims: In obese subjects, hepatic glucose production is increased, and there is a defect in insulin-stimulated glucose uptake into muscle. This raises the question as to which tissue clears the abnormally large amounts of glucose entering the circulation in obese, non-diabetic subjects. This study was undertaken in subjects with morbid obesity to investigate insulin action on glucose disposal in adipose tissue (AD) after the ingestion of a mixed meal.

Materials and methods: A mixed meal was given to 30 obese (OB, age 34 ± 1 yrs, BMI 47 ± 1 kg/m², percentage of fat $49.4 \pm 1.5\%$) and 10 non-obese subjects (NOB, age 39 ± 4 yrs, BMI 23 ± 1 kg/m², percentage of fat $25.3 \pm 3\%$). Plasma samples for measurements of glucose (G) and insulin (I), were taken for 360 min from a vein (V) draining the anterior abdominal subcutaneous AD depot and from the radial artery (A). With each sample AD blood flow (BF) was measured with ¹³³Xe. Calculations: Glucose flux: $[G_{(A-V)}] \times [BF]$; Glucose fractional extraction: $[G_{(A-V)}] / [G_{(A)}]$.

Results: Postprandial changes (area under curve 0–360 min) in OB vs NOB: (1) Arterial G was not different (2173 ± 73 vs 2040 ± 40 mM/min), but I was increased (23578 ± 2372 vs 10331 ± 608 mU/L/min, $p < 0.05$). (2) BF was decreased (657 ± 48 vs 1345 ± 102 ml/100 ml tissue, $p < 0.05$). (3) Although AD glucose flux (per 100 ml tissue) was decreased (164 ± 45 vs 320 ± 91 μmol/100 ml tissue, $p < 0.05$), fractional glucose uptake (which is independent of BF) was not different (12 ± 3 vs $13 \pm 5\%$ per min). (4) Total AD glucose flux was increased (125767 ± 32056 vs 51016 ± 11998 μmol, $p < 0.05$).

Conclusion: (1) In obesity, the sensitivity of glucose metabolism to insulin is impaired in the adipose tissue mainly due to a decrease in blood flow rates, (2) increased total fat mass compensates for insulin resistance.

840

Circulating lactoferrin is associated to insulin sensitivity *in vivo* and *in vitro*

J. Moreno-Navarrete¹, J. Bassols¹, F. Ortega¹, J. Vendrell², W. Ricart¹, J. Fernandez-Real¹

¹Endocrinology, Hospital of Girona, ²Endocrinology, Hospital of Tarragona, Spain

Background and aims: There is a chronic low level inflammation associated with insulin resistance. Lactoferrin is a pleiotropic glycoprotein with anti-inflammatory activity. We aimed to investigate 1) the cross-sectional relationship between circulating lactoferrin, insulin resistance and innate immune system; and 2) the effects of LPS, interleukin-6 (IL-6) and rosiglitazone on lactoferrin secretion according to glucose tolerance status; 3) the effects of lactoferrin in insulin sensitivity under inflammatory conditions.

Materials and methods: Circulating non-stressed lactoferrin (ELISA), metabolic variables and inflammatory markers were measured in 229 men, 94 with normal (NGT) and 135 with altered glucose tolerance (AGT). Lactoferrin secretion and action were investigated in whole blood culture, and in the cell lines HepG2 and THP-1 (pAKT/AKT ratio after 100 nM insulin).

Results: Circulating lactoferrin concentration was significantly higher in subjects with normal than in those with altered glucose tolerance ($p < 0.001$), and was positively associated with insulin sensitivity ($r = 0.24$, $p = 0.002$) and negatively with age ($r = -0.15$, $p = 0.02$), body mass index ($r = -0.15$, $p = 0.02$), waist to hip ratio ($r = -0.25$, $p = 0.001$), fasting glucose ($r = -0.20$, $p = 0.005$), HbA_{1c} ($r = -0.26$, $p = 0.001$), HOMA value ($r = -0.31$, $p = 0.001$) and LBP ($r = -0.43$, $p < 0.001$) in the whole group of subjects (even after controlling for neutrophil count). In control subjects, lipopolysaccharide binding protein (LBP) contributed independently to 25 % of circulating lactoferrin variance ($p = 0.01$), after controlling for the effects of age, waist to hip ratio, HbA_{1c}, and HOMA in multiple linear regression analysis. In subjects with altered glucose tolerance, age ($p = 0.03$), waist to hip ratio ($p = 0.025$) and HOMA value ($p = 0.01$) contributed independently to 43 % of circulating lactoferrin variance. LPS-induced lactoferrin secretion was higher in control men than in patients with type 2 diabetes (4.92 ± 1.3 vs. 3.24 ± 0.27 , $p = 0.04$). In the presence of IL-6, LPS-induced lactoferrin release decreased in non-diabetic subjects ($p = 0.001$). Rosiglitazone treatment led to increased lactoferrin secretion in all subjects (398.5 ± 193.8 vs. 314.6 ± 140.3 , $p < 0.0001$). Lactoferrin treatment (0.01, 0.1, 1, 10 μM) increased insulin action dose-dependently in HepG2 under normal glucose conditions (1.1, 1.2, 1.6 and 2.2-fold). Lactoferrin (0.01 and 0.1 μM) rescued insulin resistance of HepG2 cells incubated in conditioned media from LPS stimulated THP-1 cells and increased insulin sensitivity by 2.9 and 1.6-fold.

Conclusion: The association between insulin action and lactoferrin is bi-directional. Insulin sensitizers led to increased lactoferrin concentration and lactoferrin rescued inflammation induced insulin resistance *in vitro*.

Small heterodimer partner (SHP) modulates the transcriptional expression of LGK by LXR and PPAR

T.-H. Kim^{1,2}, J.-M. Park^{1,2}, M.-Y. Kim^{2,3}, J.-S. Bae^{2,3}, Y.-S. Park^{1,2}, Y.-H. Ahn^{1,2}

¹Brain Korea 21 Project for Medical Sciences, ²Center for Chronic Metabolic Disease Research, ³Dept. of Biochemistry and Molecular Biology, Yonsei University College of Medicine, Seoul, Republic of Korea

Background and aims: Small heterodimer partner (SHP) is an atypical nuclear receptor that lacks a conventional DNA binding domain. It is known to repress the transcriptional activity by either competing with coactivator in binding to transcriptional factor or recruiting corepressor directly to the transcriptional repression domain of SHP. SHP also inhibits the transcriptional activity of LXRα and RXRα by direct interaction. In contrast to repressive role of SHP, the molecule is reported to augment PPARγ transcriptional activity by competing with the binding of other corepressors. Recently, we identified functional LXRE in the LGK promoter. LXRα directly increases LGK expression through the LXRE. These led us to explore the role of SHP in transcriptional regulation of LGK by LXRα and PPARγ.

Materials and methods: pRGL-1448, LGK promoter into pGL3basic, was transfected into human hepatoma Alexander cells and the effect of SHP on LXRα or PPARγ dependent activation of LGK promoter was measured. To observe the inhibitory effect of SHP on PPARγ or LXRα dependent activa-

tion of LGK, adenovirus expressing SHP was transduced into the primary cultured hepatocytes and measured mRNA level by real time PCR. To elucidate the repressive mechanism of SHP on LXR α or PPAR γ , we performed the mammalian two hybrid assay in Alexander cells and GST-pull down assay.

Results: LXR α or PPAR γ dependent activation of LGK promoter was decreased by SHP expression vector in a dose dependent manner in the Alexander cell lines. Adenoviral expression of SHP dramatically decreased LGK expression in the primary cultured hepatocytes. We observed that SHP directly interacts with RXR α rather than PPAR γ or LXR α .

Conclusion: In this study, we demonstrated that LGK gene expression is down-regulated by SHP. The transcriptional activation of LGK by PPAR γ and LXR α is controlled by SHP. The mechanism of LGK gene repression by SHP may occur through binding of RXR α , which is a common partner for PPAR γ and LXR α .

Abdominal obesity in type 1 and type 2 diabetes patients

R. Lichiardopol, L.D. Popescu, I. Ionescu, D. Dovan, C. Pencea
Clinic of Diabetes, Nutrition and Metabolic Diseases,
“N.C. Paulescu” Institute, Bucharest, Romania

Background and aims: Abdominal obesity is frequently associated with type 2 diabetes and is intensively investigated in this context. There are a few data on its prevalence and impact in type 1 diabetes. The aim of this study is to evaluate the prevalence of abdominal obesity and its possible relationships with macro and microvascular complications in type 1 and type 2 diabetes patients.

Materials and methods: Medical records data from 270 type 1 (136 M and 134 W, median age of 42; range: 20–84 yrs) and 1159 type 2 diabetes patients (518 M and 641 W, median age 59; range: 22–97 yrs), successively admitted to Diabetes Department during an entire year (1 Jan 2007–31 Dec 2007), were analyzed. We used waist circumference (WC) measurements and considered abdominal obesity at values exceeding 912 mm in women and 948 mm in men as these values were above the maximal level for the lower tertile of the distribution in this group. The same criterion was used to define „increased levels” of some risk factors: Systolic Blood Pressure (SBP), HbA1c, Triglyceride/HDL-cholesterol (TG/HDL) ratio.

Results: Sixty eight patients (25%; 40 men, 28 women) with type 1 diabetes had abdominal obesity (AO). The group with AO had greater mean (SD) age [49.3(12.4) vs 40.3(14.3) yrs; $p < 0.0001$] and increased prevalence of coronary (CHD) heart disease (OR 2.80; 95% CI: 1.49–5.27), diabetic (DR) retinopathy (OR 2.36; 95% CI: 1.35–4.14) and diabetic peripheral (DPN) neuropathy (OR 2.89; 95% CI: 1.62–5.16) as compared to the group without AO. In type 1 patients, at similar levels of TG/HDL ratio [≥ 2.21] OR 5.25; 95% CI: 1.93–14.25], HbA1c [$> 8.5\%$] OR 3.34; 95% CI: 1.65–6.74] and SBP [> 120 mm Hg] OR 2.28; 95% CI: 1.23–6.75] the prevalence of CHD was greater in those with AO. The prevalence of DPN was increased, at each level of TG/HDL ratio [< 2.21 OR 4.64; 95% CI: 1.57–13.69 or ≥ 2.21 OR 2.76; 95% CI: 1.16–6.60], SBP [< 120 mm Hg OR 6.26; 95% CI: 2.16–18.17 or ≥ 120 mm Hg OR 2.66; 95% CI: 1.45–4.86] and at HbA1c $> 8.5\%$ OR 2.85; 95% CI: 1.33–6.12 in people with AO. At similar increased HbA1c ($> 8.5\%$) levels, in patients with and without AO, the prevalence of DR was greater (OR 4.15; 95% CI: 1.65–10.44) in patients with AO. In logistic regression analysis, CHD ($p = 0.0001$), DR ($p = 0.026$) and DPN ($p = 0.0018$) were each significantly correlated with WC. Eight hundred and eighty (76%) type 2 diabetes patients (407 M, 473 W) had abdominal obesity. As compared to AO group, the group of type 2 patients without AO had greater mean values for age [62.2(11.4) vs 59.5(10.1)], but there were no significant differences in prevalence of CHD, DR and DPN between groups. An increased TG/HDL ratio above 2.21 in people with (OR 1.53; 95% CI: 1.09–2.14) and without (OR 1.83; 95% CI: 1.08–3.12) and HbA1c levels above 8.5% in people with (OR 1.37; 95% CI: 1.04–1.81) and without (OR 2.09 95% CI: 1.24–3.53) AO were all associated with an increase in CHD prevalence. An increase in SBP above 120 mm Hg was not associated to variations in CHD prevalence. In logistic regression analysis CHD and DPN were correlated with HbA1c and with disease duration, while DR was correlated with SBP and disease duration. In simple linear regression analysis, the WC was directly correlated with age ($r = 0.316$; $n = 269$; $p = 0.000$) in type 1, while in type 2 diabetes patients an inverse correlation between WC and age ($r = -0.141$; $n = 1158$; $p = 0.000$) was found.

Conclusion: Our data suggest that abdominal obesity may have different comorbid associations and may reflect different physiopathogenic mechanisms in type 1 and type 2 diabetes.

Effect of fat distribution on several cardio-metabolic parameters in a healthy European population

E. Bobbioni-Harsch, V. Makoundou, V. Barthassat, Z. Pataky, A. Carpentier, F. Habicht, A. Golay
Service of Therapeutical Education for Chronic Diseases, Geneva University Hospital, Switzerland

Background and aims: Waist circumference and/or waist-to-hip ratio are used as indicators of fat distribution, but they depend on the extent of fat mass (FM). It is difficult to discriminate the effects of a preferential FM depo-

sition from those due to FM enlargement. Furthermore, the specific influence of hip circumference is underestimated. Therefore, we evaluated the influence of waist and/or hip circumferences, after their adjustment for FM, on several cardio-metabolic parameters in a healthy European population (677 males, 829 females) participating in the RISC study.

Materials and methods: The population was recruited in 14 clinical centres of 9 European Countries. The effects of waist and hip circumferences were separately evaluated. For that, in a first analysis, we subdivided the participants into two sub-groups: subjects showing a waist circumference larger or smaller than that predicted from FM (respectively W+ or W-). In a second, independent analysis, the participants were subdivided into two sub-groups: subjects showing a hip circumference larger or smaller than that predicted by FM (respectively H+ or H-). Factorial ANOVA was used to evaluate the differences between the groups.

Results: In men, the W+ in comparison to the W- group showed lower insulin sensitivity ($p=0.0004$), higher insulinemia ($p=0.002$), total ($p=0.0008$) and LDL cholesterol ($p=0.002$). W+ was not significantly associated with blood pressure, heart rate or carotid intima-media thickness (IMT). The H- group had a lower Fat Free Mass than the H+ group ($p<0.0001$). In women, the W+ group showed higher insulinemia ($p=0.01$), total and LDL cholesterol ($p=0.002$) as well as a lower HDL cholesterol ($p=0.005$) than the W- group. The H+ group had a smaller IMT ($p=0.01$) and lower circulating Free Fatty Acid ($p=0.002$) as well as a lower LDL cholesterol ($p=0.005$).

Conclusion: Hip circumference exerts a protective effect on cardiometabolic risk factors. In women. Therefore, when evaluating risk factors in normal body weight or in moderately obese women, the effects of waist and hip circumference should be evaluated separately and after adjustment for the fat mass.

The TCF7L2 expression in subcutaneous and visceral fat tissues in women with gestational diabetes

N. Wawrusiewicz-Kurylonek, M. Kuzmicki, J. Szamatowicz, M. Gorska, A.J. Kretowski

of Endocrinology, Diabetology and Internal Medicine, Medical University of Białystok, Poland

Background and aims: Recent data have shown a strong association between the *TCF7L2* gene variants and risk of type 2 diabetes. The *TCF7L2* is a transcription factor which was found to play a role in glucose homeostasis and adipogenesis. In our study we aimed to examine if the expression of *TCF7L2* mRNA in subcutaneous and visceral fat tissues in women with gestational diabetes mellitus (GDM) is different when compared to the healthy pregnant women.

Materials and methods: The subcutaneous (SAT), visceral (VAT) adipose tissues and placental tissue were obtained from 27 pregnant women (12 with normal glucose tolerance and 13 with GDM), during caesarian section. The mRNA levels of *TCF7L2*, adiponectin and PPAR γ were quantified by Real-Time PCR.

Results: *TCF7L2* mRNA levels were 1.5 times lower in VAT and 2.4 times lower in SAT in women with GDM when compared to healthy pregnant controls. There were no significant differences in the placental *TCF7L2* mRNA levels between the studied groups. We have observed a strong positive correlation between *TCF7L2* gene expression and PPAR γ or adiponectin mRNA levels in subcutaneous ($R=0.57$, $p=0.004$; $R=0.85$, $p=0.000000$ respectively) and visceral adipose tissue ($R=0.7$, $p=0.01$; $R=0.79$, $p=0.002$ respectively). There was also a negative correlation between the *TCF7L2* expression in VAT and BMI ($R=-0.79$, $p=0.001$).

Conclusion: Our results show that *TCF7L2* mRNA levels are decreased in fat tissues in women with GDM and may suggest the role of *TCF7L2* in adipogenesis and pathogenesis of insulin resistance.

Lower cut-off point of waist circumference for central obesity and the metabolic syndrome in Korean

H.-K. Kim¹, J.-Y. Park², K.-U. Lee², J.-H. Kim¹, C.-H. Kim³

¹Health Promotion Center, Asan Medical Center, Seoul, ²Internal Medicine, University of Ulsan College of Medicine, Seoul, ³Internal Medicine, Soonchunhyang University College of Medicine, Bucheon, Republic of Korea

Background and aims: The waist circumference criterion for defining central obesity and the metabolic syndrome in Asian populations is still not fully established because there are ethnic differences in obesity prevalence and body fat distribution. We analyzed the cutoff value of waist circumference for Korean population in relation to ischemic ECG and compared it with that in relation to diabetes, hypertension, and multiple factors for metabolic syndrome.

Materials and methods: We examined the clinical and laboratory data of 31,399 subjects (age, 47.8 ± 10.2 , range 20–89 years; 18,717 men and 12,682 women) who underwent medical check-ups in 2006. We plotted the receiver operating characteristic (ROC) curve to determine the cutoff value of waist circumference in relation to ischemic ECG (signs suggesting myocardial infarction or ischemia). We also determined the cutoff values of waist circumference in relation to hypertension, diabetes, and multiple factors for metabolic syndrome other than central obesity using the 2005 revised NCEP-ATP III criteria.

Results: According to the ROC analyses, the cutoff values yielding the optimal sensitivity and specificity for predicting the presence of ischemic ECG were 87 cm for men (sensitivity 39%, specificity 74%) and 74 cm for women (sensitivity 66%, specificity 55%). The cutoff points of waist circumference in relation to hypertension, diabetes, and multiple factors for metabolic syndrome were 84, 85, 83 cm for men and 77, 77, 76 cm for women, respectively. The cutoff levels of waist circumference discriminating increased percent body fat ($> 15\%$, which was associated with the presence of ischemic ECG) were 84.5 cm for men (sensitivity 85%, specificity 71%) and 74.5 cm for women (sensitivity 82%, specificity 79%).

Conclusion: The waist circumference cutoff values in relation to the cardio-metabolic diseases or risk factors were below 87 cm for men and 77 cm for women, which were lower than previously recommended Asian values of 90 cm for men and 80 cm for women. These results suggested that waist circumference criteria for defining central obesity and metabolic syndrome should be lowered in Korean population.

846

Abdominal adiposity is associated with increased plasma concentration of C reactive protein independent of body weight

E. Lapice, S. Maione, L. Patti, P. Cipriani, A.A. Rivellese, G. Riccardi, O. Vaccaro

Dipartimento di Clinica e Medicina Sperimentale, University of Naples Federico II, Naples, Italy

Background and aims: Abdominal adiposity provides additional information beyond overall adiposity in predicting cardiovascular (CV) risk. One likely mechanism linking visceral adiposity to CV disease is subclinical inflammation. C reactive protein (CRP) is an easily measured marker of systemic inflammation and has proved to be a strong predictor of CVD. Aim of the study is the evaluation of the relative importance of overall adiposity and abdominal obesity as correlates of plasma C reactive protein concentrations.

Materials and methods: The design of the study is observational case-control. Participants were selected from a population of 3500 employees of a telephone company aged 35–65 years undergoing a health screening. We studied 350 people with abdominal adiposity (waist/hip ratio ≥ 0.9 in males and ≥ 0.85 in females) and 199 controls without abdominal obesity (waist/hip ratio < 0.9 in males and < 0.85 in females) matched on BMI, gender and age. Anthropometry, blood pressure, fasting lipids, glucose, insulin, fibrinogen and CRP (high sensitivity method) were measured.

Results: As a result of the selection criteria and successful matching waist/hip ratio and waist girth were significantly and substantially higher in cases than control (1.07 ± 0.08 vs 0.85 ± 0.05 ; $p<0.001$; 96.4 ± 6.03 vs 83.27 ± 6.7 cm; $p<0.01$) whereas no differences were observed in BMI (24.81 ± 2.46 vs 24.75 ± 2.16 kg/m²), age (44.74 ± 6.17 vs 44.91 ± 6.46 years) and gender. CRP levels and the proportion of people with elevated CRP values (> 3 mg/dl) was significantly higher in cases than controls (1.96 ± 2.6 vs 1.53 ± 1.74 mg/

dl, $p < 0.01$; and 21.4% vs 10.1%, $p < 0.05$). In addition people with abdominal adiposity had significantly higher BP, triglycerides, insulin, HOMA-IR, and lower HDL cholesterol independent of BMI. The proportion of smokers was similar in the two groups. Multivariate analysis confirmed a significant, positive association of W/H ratio with PCR values independent of BMI

Conclusion: In healthy, non obese people abdominal adiposity is associated with subclinical inflammation beyond the effect of BMI, this may partly explain the excess CVD risk conferred by abdominal adiposity.

Relation of abdominal visceral and subcutaneous adipose tissue to markers of inflammation in type 2 diabetes

T. Mazzone¹, S. Haffner², M.H. Davidson³, R.B. D'Agostino⁴, S. Feinstein⁵, G. Kondo⁶, A. Perez⁷, S. Sam¹

¹Department of Medicine, Section of Endocrinology, Diabetes & Metabolism, University of Illinois, Chicago, ²Division of Clinical Epidemiology, University of Texas Health Science Center, San Antonio, ³Clinical Development, Radiant Research, Chicago, ⁴CAS Mathematics And Statistics, Boston University, Boston, ⁵Section of Cardiology, Rush University Medical Center, Chicago, ⁶Section of Cardiology, University of Illinois, Chicago, ⁷Clinical Research, Takeda Global Research & Development Center, Inc., Deerfield, , United States

Background and aims: Inflammatory markers are increased in obesity and have been implicated in insulin resistance and linked with type 2 diabetes (DM2) and cardiovascular disease. Different fat depots may contribute differently to the increase in inflammatory markers. We investigated the relationship between visceral or subcutaneous fat depots to inflammatory markers in DM2.

Materials and methods: Three hundred eighty two subjects with DM2 underwent abdominal computed tomography to determine subcutaneous (SAT) and visceral (VAT) adipose tissue distribution. Fasting blood was obtained for inflammatory markers for all subjects. Each inflammatory marker was examined in relation to body mass index (BMI), SAT, and VAT areas using multivariable regression models adjusted for age, sex, duration of diabetes, smoking, statin use, and hemoglobin A1c levels; additional models included BMI or VAT and SAT.

Results: VAT was positively related to CRP, MCP, and PAI-1 antigen before adjustment for BMI. After adjustment for BMI, the relationship to CRP was lost, but significant positive associations with MCP, PAI-1 antigen, ICAM-1, and VCAM were evident (Table 1). BMI was positively related to CRP ($R^2=0.18$, $P=0.000002$) and remained related after adjustment for VAT and SAT. BMI was also positively related to fibrinogen ($R^2=0.1$, $P=0.002$) and PAI-1 antigen ($R^2=0.1$, $P=0.01$), but the significance for both was lost after adjustment for SAT and VAT. The only relation for SAT was a negative association with MMP9 after adjustment for BMI ($R^2=0.1$, $P=0.01$).

Conclusion: These results indicate that 1) VAT correlates positively with systemic inflammatory markers and some of these associations are independent of BMI, 2) BMI but not VAT strongly correlates with CRP independent of VAT and SAT, 3) SAT is negatively correlated with MMP9. Our results demonstrate a positive association between VAT and inflammatory markers in DM2. In contrast to previous studies, done predominantly on nondiabetic subjects, our results do not demonstrate an independent association between VAT and CRP or a positive association between SAT and any inflammatory marker.

Relation between VAT and Inflammatory Biomarkers

Parameter	Multivariable Model		Multivariable Model Plus BMI	
	Mean change [CI] in biomarker per 10 cm ³ increase in VAT	P-value	Mean change [CI] in biomarker per 10 cm ³ increase in VAT	P-value
CRP, mg/L	2.84 [1.39, 5.79]	0.004	1.29 [-1.76, 2.92]	0.54
ICAM-1, pmol/L	1.65 [1.19, 2.30]	0.08	1.74 [1.18, 2.58]	0.005
MCP, ng/L	1.71 [1.13, 2.61]	0.01	1.82 [1.10, 2.98]	0.02
VCAM-1, pmol/L	1.10 [-1.17, 1.42]	0.45	1.41 [1.05, 1.89]	0.02
Fibrinogen, g/L	1.22 [-1.02, 1.50]	0.07	1.06 [-1.21, 1.36]	0.65
MMP9, ng/mL	1.35 [-1.07, 1.95]	0.11	1.12 [-1.38, 1.72]	0.62
PAI-1 antigen, µg/L	2.90 [1.94, 4.36]	<0.0001	2.79 [1.73, 4.50]	<0.0001

BMI=body mass index; VAT=visceral adipose tissue; CRP=C-reactive protein; ICAM-1= intercellular adhesion molecule 1; MCP=monocyte chemoattractant protein; VCAM-1=vascular cell adhesion molecule 1; MMP9=matrix metalloproteinase 9; PAI-1 antigen=plasminogen activator inhibitor 1 antigen.

Neck circumference is a powerful predictor of visceral adiposity and insulin resistance in morbid (WHO grade III) obesity

L.Y. Yang¹, Y.P. Samarasinghe², Y. Al-Zaman¹, S.A. Amiel², S.J.B. Aylwin¹

¹Department of Endocrinology, ²Diabetes Research Unit, King's College London, London, United Kingdom

Background and aims: There is large body of evidence suggesting that visceral adiposity (VA) is strongly implicated in the development of insulin resistance (IR), the metabolic syndrome and type 2 diabetes. There is however sparse data on the relationship between VA and IR in WHO grade III morbid obesity (BMI > 40 kg/m²). Many studies investigating VA have used indirect measures of visceral adipose tissue (VAT) rather than gold standard imaging techniques. Waist circumference is widely used as one such measure. Although measuring waist circumference is a practical and transferable technique, anatomical landmarks required to obtain accurate readings are often difficult to locate in obese people, leading to high measurement variability. In addition there is little data on the value of waist circumference at BMIs beyond 34 kg/m². A small number of studies have shown that neck circumference is positively correlated with BMI, waist circumference and other factors associated with the metabolic syndrome in overweight and obese individuals with BMI 25–35 kg/m². The aims of this study were to assess the relationship between VA and IR in a WHO grade III obese cohort and ascertain whether correlations still exist between anthropometric measurements and CT quantified adipose tissue areas in these subjects.

Materials and methods: 13 non-diabetic patients with BMI > 40 kg/m² were recruited from King's College Hospital obesity clinic (10F; 3M, 7 Caucasian; 6 Afro-Caribbean, mean(±SD) age 47.8 (± 11.4) years, weight 145.3 (± 22.1) kg, BMI 51.4 (± 5.9) kg/m². IR was calculated using HOMA-IR and a 2 hour 75g OGTT was conducted. Measurements of BMI, waist, hip and neck circumference were taken at the same visit. A 2-slice CT scan at the L4 vertebral level and the greater trochanter was carried out. "Sliceomatic" (Tomovision, Montreal, Canada) image analysis software was used to measure VAT, abdominal subcutaneous adipose tissue (ASAT) and gluteal subcutaneous adipose tissue (GSAT) areas.

Results: Statistically significant correlations were demonstrated between VAT area and IR ($R^2 = 0.54$, $P = 0.004$). No relationships were established between ASAT, GSAT and IR. Neck circumference was the only anthropometric measurement to correlate significantly with VAT area ($R^2 = 0.57$, $P = 0.003$) and IR ($R^2 = 0.45$, $P = 0.013$). Waist circumference failed to show significant associations with VAT area ($R^2 = 0.15$, $P = 0.19$) or IR ($R^2 = 0.21$, $P = 0.12$).

Conclusion: VA remains a strong and significant determinant of IR whilst subcutaneous fat shows no relationship with IR in WHO grade III obesity. Neck circumference surpasses all other anthropometric measurements as a powerful predictor of both VA and IR in this obese cohort. The ease of measurement and smaller likelihood for user errors make neck circumference a potentially useful adjunct to waist circumference in future.

849

Gene expression profiling of the epicardial adipose tissue demonstrate a significant overexpression of the secretory phospholipase A(2)A. Dutour¹, C. Henegar², A. Silaghi¹, N. Naour², B. Gaborit¹, V. Achard¹, K. Clement²¹Endocrinology, INSERM U626, Marseille, ²Les Cordeliers, INSERM UMR-S 872, Paris, F-75006, France.

Background and aims: The epicardial adipose tissue (EAT) is a relatively neglected component of the heart in close contact with coronary vessels. This proximity suggests a potential pathophysiological role of the EAT in relation to the coronary disease. The objective of our study was to compare gene expression profile of paired biopsies of subcutaneous adipose tissue (SAT) and EAT, obtained from patients with coronary artery disease (CAD) or without CAD (NCAD), to identify target genes and functional pathways characterizing the transcriptomic signature of the EAT in CAD patients.

Materials and methods: We analyzed the transcriptomic signature of paired biopsies of SAT and EAT obtained from a series of 8 CAD and 8 NCAD patients. An integrative functional genomics approach was applied to identify relevant structural and functional themes annotating differentially expressed genes. Afterwards a co-expression networks analysis was performed to quantify relationships and relate co-regulated themes into a comprehensive map of transcriptional interactions characterizing the EAT. RT-PCR was used to confirm expression changes of some gene targets.

Results: Our analysis identified 2500 genes significantly overexpressed in EAT as compared to SAT of CAD subjects. The functional themes annotating these genes were mainly related to the cell cycle and the RNA processing and splicing. Surprisingly, themes related to the immune response and cell adhesion molecules were significantly overrepresented among those annotating genes up-related in the SAT, but not the EAT, of CAD patients. Among the genes annotated by significantly overrepresented functional themes, the secretory type II phospholipase A(2) (PLA2G2A) mRNA was highly increased in EAT as compared to SAT in both CAD (X13) and NCAD(X8) samples. RT-PCR confirmed the significant overexpression of PLA2G2A mRNA in EAT ($p=0.01$) of both CAD and NCAD patients (SAT = 10.8 ± 4.6 , EAT = 76.7 ± 17). Regarding a set of inflammatory genes, RT-PCR showed no difference in the expression levels of several pro-inflammatory cytokines (MCP 1, IL6, IL1 β) between SAT and EAT in each group, mostly confirming microarray results. However, they were increased in EAT of CAD compared to NCAD patients.

Conclusion: Our results demonstrate a significant over-expression of PLA2G2A in EAT, a phospholipase that was shown to be expressed in atherosclerotic lesions and in inflammatory conditions. These findings suggest a potentially important pathophysiological role of EAT in coronary atherogenesis.

Specific metabolic effects of insulin detemir in human visceral adipocytes differentiated *in vitro* from precursor stromal cellsS. Perrini¹, A. Cignarelli¹, L. Laviola¹, M. Barbaro¹, A. Conserva¹, A. Pescechera¹, A. Natalicchio¹, A. Quagliara¹, F. De Stefano¹, M. Melchiorre¹, M. De Fazio², V. Memeo², R. Giorgino¹, F. Giorgino¹
¹D.E.T.O., Internal Medicine, Endocrinology and Metabolic Diseases, University of Bari, ²D.E.T.O., General Surgery, University of Bari, Italy

Background and aims: Clinical use of the acylated insulin analog detemir is associated with the stabilization of body weight, particularly in individuals with high BMI values. However, whether insulin detemir is able to directly modulate adipocyte metabolism, and if this insulin analog may exert peculiar metabolic effects on adipose tissue from different fat depots has not been determined. Therefore, the aim of this study was to evaluate metabolic responses induced by detemir, compared with regular human insulin, in human subcutaneous (SC) and visceral (V) adipocytes differentiated *in vitro* from precursor stromal cells.

Materials and methods: Paired biopsies from SC and V fat were obtained from 7 subjects (3F/4M, age 63 ± 1 years, BMI 25.9 ± 1.4) with normal glucose tolerance and preserved insulin sensitivity (HOMA-IR = 5.4 ± 1.6). Preadipocytes were isolated from the stromal fraction of SC and V fat biopsies, respectively, and differentiated *in vitro* with dexamethasone, IBMX, insulin and rosiglitazone. Terminal differentiation of the adipocyte cultures was verified through morphological evaluation, Oil-O-Red staining, and assessment of gene expression of fat-specific molecules (PPAR γ , adiponectin, GLUT4). Glucose uptake was assessed through evaluation of [³H]1,2-deoxy-D-glucose uptake rates.

Results: Under basal conditions, glucose uptake was 65% higher in V- as compared to SC-derived adipocytes (165 ± 13 vs 99 ± 12 pmol/mcg/min, $p < 0.05$). In SC adipocytes the incubation with regular insulin induced a limited increase in glucose uptake (+50% with regular insulin 100 nM, $p = 0.05$ vs. basal), while insulin detemir did not significantly modify glucose uptake rates ($p = 0.40$ vs. basal). In V adipocytes, 100 nM regular insulin induced a 3-fold increase in glucose transport ($p < 0.05$). However, insulin detemir appeared to be much more efficient, inducing 8-fold and 5-fold increases in glucose uptake at 100 nM and 10 nM, respectively ($p < 0.05$). The correlation of insulin-stimulated glucose uptake with clinical characteristics of the patients was then analyzed by regression analysis. Glucose uptake induced by insulin detemir was found to be inversely correlated with BMI ($\beta = -20.7$, $R^2 = 0.87$, $p < 0.05$) and HOMA-IR ($\beta = -70.7$, $R^2 = 0.92$, $p < 0.05$), whereas no correlation was found with regular insulin (BMI, $\beta = -3.6$, $R^2 = 0.029$, $p = \text{n.s.}$; HOMA-IR, $\beta = -20.6$, $R^2 = 0.08$, $p = \text{n.s.}$).

Conclusion: In conclusion, insulin detemir stimulates glucose uptake more efficiently than regular insulin in human visceral adipocytes, indicating that visceral adipose tissue is more important for insulin detemir than for regular insulin as a determinant of the effects on glucose metabolism. However, the inverse correlation between the effects on glucose uptake and the degree of adiposity/insulin resistance, which occurs for insulin detemir but not for regular insulin, suggests that the action of insulin detemir on visceral adipocytes is more prominently influenced by changes in total body fat, and this could be relevant to the weight-sparing effects of this insulin analog in obese type 2 diabetic patients.

Resistance training combined with a weight loss diet improves the lipid profile in adult hypercholesterolaemic obese women despite a significant decrease in circulating adiponectinL. Forga¹, F.J. Basterra-Gortari¹, M. Izquierdo², C. Martínez-Labari², M. García-Unciti³, M.J. Goñi¹, E.M. Gorostiaga²¹Endocrinology, Hospital of Navarra, Pamplona, ²Research and Sports Medicine Center, Government of Navarra, Pamplona, ³Dietetic and Dietotherapy, University of Navarra, Pamplona, Spain

Background and aims: It has been shown that circulating adiponectin is positively associated with plasma HDL-C and negatively correlated with LDL-C and triglycerides. However, at present, both the physiological role of adiponectin on the improvement of lipid profile with body or fat mass loss and

the effect of a progressive resistance training (RT) on circulating adiponectin are yet incompletely understood. The present study aimed to examine the relationships of plasma adiponectin and different body composition variables with lipid profile when a RT was applied to a group of adult hypercholesterolemic obese women with a concomitant weight-loss diet.

Materials and methods: The design was a 16 week randomized controlled trial. Thirty three women were assigned to 3 groups: a Control group (C; n=8); a Diet group (WL; n=12), with a caloric restriction of 500 Kcal/day; and a Diet plus Resistance Training (WL+RT; n=13), with the same caloric restriction as WL group and a supervised resistance training program of 2 sessions/ week. Weight, energy intake, energy expenditure (accelerometry), volumes of different adipose tissue compartments and the muscle mass of thigh measured by magnetic resonance, and serum levels of estradiol, progesterone, adiponectin, total cholesterol (TC), HDL-cholesterol (HDL-C), measured LDL-cholesterol (LDL-C), VLDL-cholesterol (VLDL-C) and triglycerides (TG) were measured baseline and at week 16. ANOVA was used to determine differences among the three groups; Bonferroni was the post hoc procedure.

Results: Baseline characteristics were similar in the 3 groups. By week 16, no significant difference between WL and WL+RT groups was observed neither in body mass, nor in abdominal fat or thigh fat. Compared to control group, body mass was significantly diminished in WL and WL+RT groups by -6.3% and -7.7% ($p<0.001$), respectively; whereas abdominal subcutaneous adipose tissue decreased by -18.3% and -21.4% ($p<0.001$), and thigh subcutaneous fat by -16.4% and -18.9% ($p<0.001$), respectively. Likewise, visceral fat mass was reduced in WL and WL+RT groups by -19.9% and -20.5% ($p<0.001$), respectively. As expected, WL led to a significant lost in thigh muscle mass (-3.5%); however, in the WL+RT group, thigh muscle mass was maintained. Moreover, in the WL group no variation neither in lipid profile nor in adiponectin was observed. In turn, in WL+RT group we observed a decrease in: adiponectin (-8.3%, $P<0.05$), LDL-C (-8.6%, $P<0.01$), CT (-13.6%, $P<0.01$) and HDL-C (-11.7%, $P<0.001$), whereas TC/ HDL-C ratio was maintained unaltered. In a multiple linear regression analysis, the most significant factor impacting on total cholesterol in this WL+RT group (95% of its variance) was LDL-cholesterol, even after accounting for the effects of age, BMI, and adiponectin.

Conclusion: In adult hypercholesterolemic obese women, resistance training (2 sessions/ week) seems to play an essential role in the improvement of the lipid profile, in spite of a significant decrease in circulating adiponectin.

Amelioration of glucotoxicity with insulin detemir alone or combined with premeal insulin aspart improves plasma lipoproteins, insulin secretion and hepatic steatosis in poorly controlled T2DM patients

K. Cusi¹, S. Wang¹, P. Kumar¹, B. Balas¹, R. Ali¹, C. Darland¹, A. Gastaldelli¹, V. Kochunova², Q. Peng², J. Hardies², M. Mathew¹

¹Medicine, UTHSCSA, ²Radiology, UTHSCSA, San Antonio, United States

Background and aims: Basal insulin therapy alone is commonly used in primary care although the addition of pre-meal insulin allows optimal control of pts with type 2 diabetes mellitus (T2DM). We examined the effects on glycemic and lipid control, insulin secretion, intramyocellular lipid and hepatic fat content, and subcutaneous and visceral fat of basal/premeal insulin therapy in poorly controlled pts with T2DM.

Materials and methods: 24 patients with T2DM (59±3 yr, BMI: 31.4±1.4 kg/m²; reporting 17) were treated with a bedtime dose of insulin detemir for 3 months, followed by pre-meal insulin aspart for another 3 months. The insulin dose was adjusted every 3 to 5 days to target a fasting plasma glucose (FPG) of 70–100 mg/dl and 2-hour postprandial glucose ≤160 mg/dl. Patients were admitted 3 times: before treatment, after 3 months of bedtime detemir insulin only, and after another 3 months of adding insulin aspart to the detemir insulin regimen. On each admission they had the following tests: 1) FPG, A_{1c}, fructosamine and day-long plasma glucose, FFA, C-peptide and insulin profile (Day 1); 2) Lipoprotein particle number/size by NMR; 3) Glucose-stimulated insulin secretion (GSIS) during a hyperglycemic clamp (Day 2); 4) Total body fat by DXA; 5) Liver (LFAT) and muscle (IMCL) fat content by MRS, and abdominal fat by MRI.

Results: Insulin detemir significantly reduced FPG (from 178±18 to 111±13mg/dl), fructosamine (from 325±10 to 243±11μmol/l), A_{1c} (from 8.9±0.3% to 7.4±0.2%), day-long glucose (from 240±2 to 161±4 mg/dl, all $p<0.01$) and FFA (from 394±54 to 328±29 nmol/l). Detemir had a favora-

ble impact on the lipid profile as it reduced VLDL and LDL particle number (both $p<0.02$) and increased LDL and HDL size (both $p<0.05$). Insulin secretion improved as evidenced by a ~2 fold increase in day-long C-peptide and ~2-fold higher 2nd phase GSIS (both $p<0.01$). The combination of insulin detemir and aspart further improved glycemic control (FPG: 100±7 mg/dl, A_{1c}: 6.9±0.2% and fructosamine: 226±6 μmol/l; all $p<0.01$ vs. insulin detemir alone), increased 2nd phase GSIS by 50% and HDL particle size ($p<0.02$). Total body fat (DXA) did not increase significantly with either insulin regimen (27.0±2.2%, 27.0±2.1%, 27.6±2.2%, respectively, NS), nor did visceral fat. LFAT showed a trend to decrease at 3 and 6 months (from 17.9±7.1% to 7.2±2.1% and 10.5±3.8%, $p=0.13$ and 0.19 vs. pretreatment, respectively) while IMCL was unchanged (from 0.77±0.38% to 0.41±0.11% and 0.83±0.20%, both NS vs. pretreatment, respectively). Insulin sensitivity was unchanged. Intensified insulin therapy was not associated with severe hypoglycemia or any other adverse event.

Conclusion: In poorly controlled patients with T2DM, basal insulin detemir therapy aiming at a normal fasting plasma glucose concentration is a safe and effective way to achieve good glycemic control. Amelioration of glucotoxicity is associated with better glucose-stimulated insulin secretion, a less atherogenic apolipoprotein profile and a reduction in hepatic steatosis. Additional pre-meal rapid-acting insulin aspart allows to further optimize metabolic control.

Effect of ezetimibe/simvastatin (E/S) versus atorvastatin (A) on lipoprotein subclasses in type 2 diabetes (T2DM) patients with hypercholesterolaemia (HC)

J.E. Tomassini¹, T. Mazzone², R.B. Goldberg³, J.R. Guyton⁴, R.S. Weinstock⁵, A. Polis¹, A.M. Tershakovec¹

¹Merck & Co., Inc., N. Wales, ²Departments of Medicine and Pharmacology, University of Illinois at Chicago, ³Diabetes Research Institute, Miller School of Medicine, Univ. of Miami, ⁴Medical Center, Duke Univ., Durham, ⁵Division of Endocrinology, Diabetes and Metabolism, SUNY Upstate Medical University and VA Medical Center, Syracuse, United States

Background and aims: Patients with T2DM are at increased risk for cardiovascular disease, attributed partly to dyslipidemia characterized by elevated triglycerides (TG) levels and TG-rich proteins (VLDL, IDL), low HDL-C levels, and a predominance of small, dense, LDL particles. This analysis assessed the effect of the usual, recommended starting doses and next higher doses of E/S and A on the cholesterol content of lipoprotein subclasses in patients with T2DM and HC.

Materials and methods: A post-hoc analysis of the data obtained from a multicenter, double-blind, randomized, 6 wk trial which demonstrated the lipid-altering efficacy and safety of the usual, recommended starting doses of E/S (10/20mg) vs A (10 and 20 mg) and next higher doses of E/S (10/40 mg) vs A (40 mg). The effect of E/S and A on the % change from baseline in cholesterol content of lipoprotein subclasses was assessed by Vertical Auto Profile II (VAP II) and LDL subclass pattern by segmented gradient gel electrophoresis (S₂GGE) in 1013 patients with T2DM and HC in the modified Intent-To-Treat population (ANCOVA model).

Results: E/S (10/20mg) vs A (10 and 20 mg) and E/S (10/40 mg) vs A (40 mg), provided significantly greater reductions from baseline at 6 wks in the cholesterol content of lipoprotein subfractions including LDL₁, LDL₂, LDL₃, LDL_C, total IDL, and total VLDL (see table) and in IDL₁, IDL₂ and VLDL₃. Greater improvements were also observed in HDL₃ at E/S 20 mg vs A 20 mg, in VLDL₁₊₂ at E/S 20 mg vs A10 mg, and in VLDL₁₊₂ and HDL₃ at E/S 40 mg vs A 40 mg. Changes in LDL₄ and R-LDL subclass pattern (A, B, I) were comparable for both treatments.

Conclusion: At 6 weeks, the usual, recommended, starting doses and next highest doses of E/S reduced the cholesterol content associated with most atherogenic lipoprotein subfractions significantly more than A in T2DM patients with HC at all dose comparisons. In addition to more effective reduction in true LDL-C level, our results demonstrate that E/S reduces TG-rich lipoprotein fractions IDL and VLDL more than A. This suggests that the combination E/S may provide benefit by improving both cholesterol-rich and triglyceride-rich atherogenic lipoprotein subfractions in these patients. The clinical significance of such effects awaits further assessment.

Effect of ezetimibe/simvastatin (E/S) plus extended-release niacin (N) in type IIa and IIb hyperlipidaemia (HL) patients with diabetes (DM) or metabolic syndrome (MS)

J.R. Guyton¹, B.G. Brown², S. Fazio³, J. Lin⁴, A. Polis⁴, J.E. Tomassini⁴, A. Shah⁴, A.M. Tershakovec⁴

¹Department of Medicine, Duke University Medical Center, Durham,

²Division of Cardiology, University of Washington, Seattle, ³Vanderbilt Lipid Laboratory, Vanderbilt University Medical Center, Nashville, ⁴Merck & Co., Inc., N. Wales, United States

Background and aims: Patients with DM and MS are at increased risk for CVD attributed to high plasma triglycerides (TG), low HDL, and small, dense LDL. When LDL-C is also elevated, combination drug treatment should be considered. Combination E/S + N has been shown to substantially improve

the lipid profile of patients with type IIa or IIb hyperlipidemia vs E/S and vs N alone. Here we assessed the effect of these treatments on lipid parameters in subgroups of patients with DM, MS without DM (MS/nonDM), or without either condition (nonDM/nonMS).

Materials and methods: In a double-blind, randomized 24 wk study (pre-defined initial phase of a 64 wk study), 1220 HL patients were treated with E/S (10/20mg) + N (0.5-2g) vs E/S (10/20 mg) or N (0.5-2g). The effect of these treatments on various lipid parameters (LDL-C, TG, HDL-C, non-HDL-C, total cholesterol, Apo B, Apo A-I), lipid ratios (TC/HDL-C, LDL-C/HDL-C, Apo B/Apo A-I, non-HDL-C/HDL-C) and hsCRP were assessed within subgroups of patients with DM, MS/nonDM, or nonDM/nonMS by ANCOVA in the completers (n=765) population. Clinical and laboratory adverse events (AEs) including fasting glucose (FG) increases were monitored in the modified Intent-To-Treat (mITT, n=757) population for these subgroups.

TG % difference (95% CI) ‡	-16.6 (-27.7, -6.0)	-21.2 (-30.2, -10.5)	-4.9 (-11.0, 1.5)	-18.0 (-24.0, -12.1)	-16.2 (-23.5, -9.1)	-19.2 (-25.9, -12.9)
FG % difference§¶ (95% CI)	-0.2 (-6.7, 6.2)	2.9 (-3.2, 8.9)	-2.2 (-6.3, 1.9)	3.7 (0.2, 7.2)	-0.1 (-3.6, 3.4)	2.1 (-1.4, 5.5)

E/S = ezetimibe/simvastatin (10/20 mg); N = extended-release niacin (0.5-2 g), DM = diabetes, MS = metabolic syndrome; FG = fasting glucose

*Completers include all patients with a baseline value who received at least 24 wk of active study therapy and had an on-treatment value at the maximum titrated dose [i.e. 2 g of niacin (ER) for both E/S + N and N treatment groups]; n represents the number of patients in the analysis of the primary endpoint (percent change from baseline to wk 24 in LDL-C).

†LS means of treatment difference based on ANCOVA model with terms for treatment, DM/MS category, baseline LDL-C, baseline TG, gender, and treatment by DM/MS category interaction.

‡Hodges-Lehmann estimate of the median difference between treatments with a corresponding distributions free CI based on Wilcoxon's rank sum test.

§Analysis based on mITT population (all randomized patients with a baseline value and at least one post-baseline value with A Last Observation Carried Forward [LOCF] approach to impute any missing data for the wk 24 assessment), and included n= 112, 299, 346 patients respectively in the DM, MS without DM and neither DM nor MS subgroups.

¶LS means of treatment difference based on ANCOVA model with terms for treatment, DM/MS category, baseline fasting glucose, and treatment by DM/MS category interaction.

Results: E/S+N decreased LDL-C and non-HDL-C significantly more than N in all subgroups and compared to E/S in the nonDM/nonMS group (see table). Moreover, E/S+N treatment decreased non-HDL-C significantly compared to E/S in the MS group. HDL-C increases were greater with E/S+N vs E/S and similar vs N for all subgroups. E/S+N treatment reduced TG more than N and E/S treatments in all subgroups, except for E/S+N vs N in MS patients. Mean FG trended higher in the N treatment groups vs E/S group, peaking at 8–12 wks and declining by 24 wks. New onset DM was identified as 2 consecutive FG ≥ 126 mg/dL or initiation of antidiabetic medication. Among MS patients, 8.8% met this criterion for E/S+N, 1.7% for E/S and 5.1% for N groups. Among nonDM/nonMS patients the proportions were 1.2% (E/S+ N), 0% (E/S) and 0% (N).

Conclusion: The effects of E/S+N on lipid/lipoprotein profiles in subgroups of patients with or without DM or MS are consistent with the results obtained in the full HL cohort of the study. FG levels worsened more commonly with MS and with N-containing therapy. Triple combination E/S+N is a treatment option for dyslipidemia in patients with DM and MS, but requires monitoring and possibly treating glucose changes as per the Niaspan label.

Rosuvastatin 20 mg restores normal HDL apoA-I kinetics in type 2 diabetes

B. Vergès^{1,2}, E. Florentin², S. Baillot-Rudoni¹, S. Monier², J. Petit^{1,2}, P. Gambert², L. Duvillard²

¹Endocrinology, Diabetology, Hôpital du Bocage, CHU, ²Biochemistry, INSERM CRI 866, Dijon, France

Background and aims: Patients with type 2 diabetes show an accelerated catabolism of HDL particles leading to a significant reduction of their plasma residence time, which may be detrimental. Rosuvastatin is the most powerful statin to reduce plasma LDL-cholesterol but its effects on the metabolism of HDL remain unknown, in type 2 diabetes.

Materials and methods: This prompted us to perform a randomised double blind cross-over trial of six-week treatment period with placebo or rosuvastatin 20 mg/d in 8 patients with type 2 diabetes treated with oral glucose lowering agents. In each patient, an in vivo kinetic study of HDL apoA-I with ¹³C leucine was performed at the end of each treatment period. Moreover, a similar kinetic study was performed in 8 non-diabetic normolipidemic controls.

Results: Rosuvastatin 20 mg significantly reduced plasma LDL-cholesterol, triglycerides (TG) and HDL-TG. HDL apoA-I FCR was significantly reduced by rosuvastatin (0.25 ± 0.06 vs 0.32 ± 0.07 pool/day, $p=0.011$) leading to a significant increase in plasma HDL apoA-I residence time (4.21 ± 1.07 vs 3.30 ± 0.73 day, $p=0.011$). Treatment with rosuvastatin was associated with a concomitant reduction in HDL apoA-I production rate (PR) (12.79 ± 3.98 vs 16.19 ± 4.31 mg/kg.day, $p=0.011$). The decrease in HDL apoA-I FCR, induced by rosuvastatin 20 mg was correlated with the reduction in plasma TG ($r=0.75$, $p=0.031$) and in HDL-TG ($r=0.84$, $p=0.009$). Treatment with rosuvastatin 20 mg/d restored, in patients with type 2 diabetes, HDL apoA-I FCR and PR values which were not significantly different from controls (apoA-I FCR: 0.25 ± 0.06 vs 0.20 ± 0.06 pool/day, $p=0.16$ and apoA-I PR: 12.79 ± 3.98 vs 12.19 ± 1.74 mg/kg.day, $p=0.75$).

Conclusion: Rosuvastatin induces significant modification of HDL apoA-I kinetics in patients with type 2 diabetes. Rosuvastatin 20 mg is responsible for a 22% reduction in HDL apoA-I catabolism. Rosuvastatin restore to normal the increased HDL turn-over observed in type 2 diabetes. These kinetic modifications induced by rosuvastatin may have beneficial effects by increasing HDL plasma residence time.

A molecular basis for the cell-specific activation of the peroxisome proliferator activator receptor PPAR gamma

P.C. Lefebvre¹, B. Lefebvre¹, A. Guédin¹, N. Hennuyer¹, C. DACQUET², A. Ktorza², B. Staels¹

¹Inserm U545, Atherosclerosis Dept- Pasteur Institute of Lille, ²SERVIER, Division of Metabolic Diseases, Suresnes, France

Background and aims: Thiazolidinediones (TZDs) are PPARgamma ligands highly efficient in gaining stable glycaemic control, in maintaining pancreatic beta cell functions and in improving insulin sensitivity of peripheral organs. Their clinical use is however hampered by side-effects such as oedema, os-

teoporosis and decreased hemoglobin levels, the origin of which being supposedly linked to renal, bone and vascular PPARgamma-mediated effects. These unwanted effects may thus potentially be circumvented through the design of tissue-selective PPARgamma activators or SPPARms. PPARgamma transcriptional activity is known to be regulated, as that of all other nuclear receptors, through protein-protein interactions, and most especially through the orchestrated dismissal and recruitment of transcriptional corepressors and coactivators respectively. We have therefore designed an experimental strategy aiming at identifying factor(s) that may regulate PPARgamma transcriptional activity in a cell-selective manner.

Materials and methods: Using PPARgamma as a bait, we have characterized its interaction with several cofactors in preadipocytes and adipocyte cell lines. We modulated the level of expression of these cofactors by RNA interference or by overexpression in these cell lines and studied the functional consequences of these altered expression levels on the transcriptional activity of PPARgamma-regulated chimaeric and endogenous genes. The interaction of these cofactors with PPARgamma was also monitored in intact cells using the one- and the two-hybrid technologies, as well as chromatin immunoprecipitation assays.

Results: We observed that the transcriptional corepressor SMRT is a major regulator of the transcriptional response of PPARgamma-containing heterodimers to agonist treatment. The ability of a reference PPARgamma agonist (Rosiglitazone) to trigger SMRT dismissal from the PPAR-containing heterodimer was strictly conditioned by the nature of the RXR isotype integrated into the heterodimer. The integration of a given RXR isotype in the heterodimer yielded either "SMRT-releasing" or "SMRT-tethered" heterodimers. In cellular backgrounds exhibiting an equivalent expression of RXR isotypes, we found that PPARgamma responsiveness to agonist stimulation was blunted compared to that observed in cells expressing preferentially the "SMRT-releasing" isotype. Similar results were obtained when manipulating RXR isotype expression levels through overexpression or RNA interference.

Conclusion: Our data show that PPARgamma transcriptional activity can be modulated in a tissue-specific manner through the variation of expression of RXR isotypes, opening new perspectives for the search of novel ligands which, upon the specific modulation of this interaction, will restrict or increase the transcriptional activity of PPARgamma.

CB1- receptor blockade induces trans-differentiation towards an insulin-sensitive brown fat phenotype in white adipocytes

N. Perwitz¹, J. Wenzel¹, I. Wagner¹, J. Buening¹, M. Drenckhan¹, M. Ristow², J. Klein¹

¹Department of Internal Medicine 1, University of Luebeck, ²Department of Human Nutrition, University of Jena, Germany

Background and aims: The endocannabinoid (EC) system is emerging as a key player in the control of energy homeostasis. It stimulates a positive energy balance via both central and peripheral pathways. CB1 cannabinoid receptor knockout mice are resistant to diet-induced obesity, and blockade of the CB1 receptor with the specific CB1 receptor antagonist rimonabant induces weight reduction and improves cardiovascular risk factors in overweight patients. The mechanisms responsible for these effects remain only partially elucidated. Here, we demonstrate a direct role of cannabinoid on thermogenesis and trans-differentiation in white adipocytes.

Results: Acute and chronic treatment of murine white adipocytes with rimonabant induced CB1 Receptor expression in a dose- and time dependent manner. Lipid accumulation and cell morphology were not effected by chronic CB1 Receptor inhibition as assessed by oil red O staining. As compared to control cells, pre-treatment with 100nM rimonabant for 5 days, increased insulin-induced glucose uptake significantly by 10%. Furthermore, chronic treatment of white adipocytes with rimonabant strongly induced the thermogenic protein-1 (UCP-1) mRNA and protein expression by 125% and 300% ($p<0.05$) in fully differentiated cells. This effect was dose dependent and peaked with a concentration at 1μM. Moreover, we measured a 30% ($p<0.02$) highly significant increase of the trans-differentiation factor PGC1 alpha after 1μM rimonabant treatment for 10 days. To verify these findings of a trans-differentiation process in white adipocytes during rimonabant stimulation we measured mitochondrial biogenesis and function. Indeed, we found that white adipocytes exposed to rimonabant during adipogenesis increased mitochondrial numbers compared to non-treated cells by 60% shown with electron microscopy images and FACS analyses using a mitochondrial specific

MitoTracker Green Staining. Furthermore, pre-treatment with 1 μ M rimona-bant for 10 days raised the cytochrom c oxidase activity by 30% ($p<0.05$) and enhanced the oxygen consumption by 40% ($p<0.02$).

Conclusion: Taken together, our data provide evidence for a trans-differen-tiation towards an insulin-sensitive brown fat phenotype in white adipocytes during CB1 receptor blockade. Thus, thermogenesis might be one mecha-nism responsible for the weight loss seen under rimonabant treatment in overweight patients.

Saxagliptin added to a sulfonylurea is safe and more efficacious than up-titrating a sulfonylurea in patients with type 2 diabetes

S. Ravichandran¹, A.R. Chacra², G.H. Tan³, A. Apanovitch¹, R. Chen¹

¹Bristol-Myers Squibb, Princeton, United States, ²Department of Endocrinology, Universidade Federal de Sao Paulo, Brazil, ³Endocrinology, Cebu Doctor's University Hospital, Cebu City, Philippines

Background and aims: Saxagliptin (SAXA) is a potent modulator of key hormones that regulate glucose homeostasis, specifically designed to provide selective, durable inhibition of the dipeptidyl peptidase-4 (DPP-4) enzyme. This 24-wk study (CV181-040) assessed the safety and efficacy of SAXA added to an intermediate dose of glyburide (GLY) versus up-titration of intermediate dose GLY monotherapy in patients with type 2 diabetes (T2D) and inadequate glycemic control ($HbA_{1c} \geq 7.5\% \leq 10\%$) after ≥ 2 mo of treatment with an intermediate dose of a sulfonylurea at enrollment.

Materials and methods: All patients received open-label GLY 7.5 mg for a 4-wk lead-in period. Then, 768 patients were randomized to receive blinded SAXA 2.5 or 5 mg or GLY 2.5 mg, once daily, in addition to the open-label GLY. During the 24-wk study period, blinded up-titration of GLY was allowed in the GLY-only arm to a maximum total daily GLY dose of 15 mg based on pre-defined protocol criteria. The primary end point was change from baseline in HbA_{1c} . Decreases in fasting plasma glucose (FPG) and postprandial glucose (PPG) were also evaluated. Efficacy analyses were performed using an ANCOVA model utilizing LOCF methodology on randomized patients.

Results: Treatment groups were well balanced at baseline (mean HbA_{1c} 8.4%; mean age, 55 y; mean FPG, 173.3 mg/dL). Approximately 92% of patients in the UP-GLY group had been up-titrated to a total GLY dose of 15 mg per day by wk 24. SAXA 2.5 and 5 mg demonstrated significant adjusted mean decreases from baseline to wk 24 compared with adjusted mean increases with UP-GLY, respectively, in HbA_{1c} (-0.54%, -0.64% vs 0.08%; both $P<0.0001$) FPG (-7.1, -9.7 mg/dL vs 0.7 mg/dL; $P=.0218$ and $P=.002$, respectively), and PPG at 120 min during an OGTT (-30.9, -34.2 mg/dL vs 7.6 mg/dL; both $P<0.0001$). A greater proportion of patients in the UP-GLY treatment group were discontinued due to lack of glycemic control or rescued for failing to achieve glycemic targets (29.6%) vs patients in the SAXA 2.5- and 5-mg groups (18.1% and 16.6%, respectively). SAXA was well tolerated; the proportion of patients receiving SAXA 2.5, SAXA 5 mg, and UP-GLY who had adverse events (AEs) were 75%, 72%, and 77%, respectively, despite longer exposure to study medication in the SAXA groups (151, 150 vs 140 d, respectively). The most common AEs with occurrence rates $\geq 5\%$ (in all patients receiving SAXA vs UP-GLY) were urinary tract infection (8.0% vs 8.2%), headache (7.6% vs 5.6%), nasopharyngitis (5.8% vs 6.7%), upper respiratory tract infection (5.4% vs 6.7%), back pain (5.4% vs 4.5%), hypertension (5.0% vs 2.2%), diarrhea (4.8% vs 5.2%), influenza (4.6% vs 6.0%), and pain in the extremity (4.0% vs 5.6%). Reported hypoglycemic events were similar in patients treated with SAXA 2.5 and 5 mg (13.3% [33/248] and 14.6% [37/253]) vs UP-GLY (10.1% [27/267]) ($P=NS$ for both).

Conclusion: For patients with T2D inadequately controlled with an intermediate dose of sulfonylurea, the combination of saxagliptin and glyburide provided improved glycemic control (HbA_{1c} , FPG, PPG) without additional safety and tolerability concerns compared with up-titration of glyburide monotherapy. This improvement in glycemic control was achieved without any significant increase in hypoglycemia.

Background and aims: Saxagliptin is a potent modulator of key hormones that regulate glucose homeostasis, specifically designed to provide selective, durable inhibition of the dipeptidyl peptidase-4 (DPP-4) enzyme. Saxagliptin was added to ongoing thiazolidinedione (TZD) therapy to assess the safety

and efficacy of this combination in patients with type 2 diabetes (T2D) and inadequate glycemic control on TZD alone.

Materials and methods: A multinational, randomized, placebo-controlled, parallel-group, double-blind study (CV181-013) was initiated among patients with T2D inadequately controlled ($HbA_{1c} \geq 7.0\%$ and $\leq 10.5\%$), aged 18–77 y, receiving stable TZD monotherapy (pioglitazone 30 or 45 mg, or rosiglitazone 4 or 8 mg) for ≥ 12 wk prior to screening. Following a 2-wk dietary and exercise, placebo (PBO) and TZD lead-in period, 565 patients were randomized to receive saxagliptin 2.5 mg, saxagliptin 5 mg, or PBO, once daily, in addition to their stable TZD dose for 24 wks. Efficacy analyses for continuous variables were performed using an ANCOVA model with last observation carried forward (LOCF) methodology.

Results: Demographic and baseline diabetes characteristics were well balanced across treatment groups: mean age 54 y; mean duration of diabetes 5.2 y; mean HbA_{1c} 8.3%; mean fasting plasma glucose (FPG) 161.8 mg/dL. Relative to PBO, patients randomized to saxagliptin 2.5 and 5 mg demonstrated significant adjusted mean change from baseline in HbA_{1c} (PBO -0.30% vs saxagliptin 2.5 mg -0.66%, $P=.0007$, and saxagliptin 5 mg -0.94%, $P<.0001$); FPG (PBO -2.8 mg/dL vs saxagliptin 2.5 mg -14.3 mg/dL, $P=.0053$, and saxagliptin 5 mg -17.3 mg/dL, $P=.0005$); and postprandial glucose (PPG) AUC (PBO -2690 mg*min/dL vs saxagliptin 2.5 mg -7849 mg*min/dL, $P<.0001$, and saxagliptin 5 mg -9269 mg*min/dL, $P<.0001$). Compared with PBO (25.6%), a greater proportion of patients achieved target $HbA_{1c} < 7\%$ at wk 24 in the saxagliptin groups: saxagliptin 2.5 mg (42.2%, $P=.001$) and saxagliptin 5 mg (41.8%, $P=.0013$). The adjusted mean change from baseline PPG at 120 min during an OGTT was also significantly greater in patients treated with saxagliptin 2.5 mg (-54.7 mg/dL, $P<.0001$) and saxagliptin 5 mg (-64.6 mg/dL, $P<.0001$), as compared with PBO (-14.6 mg/dL). Saxagliptin treatment increased postprandial insulin and C-peptide AUC compared with PBO during OGTT. β -Cell function, as assessed using HOMA-2 β , improved in the saxagliptin 5-mg group compared with PBO ($P<.05$). Overall, the rates of reported adverse events (AEs) and discontinuations due to AEs in the saxagliptin treatment groups were similar to PBO. All reported hypoglycemic events were similar to PBO (saxagliptin 2.5 mg, 4.1%; saxagliptin 5 mg, 2.7%; PBO, 3.8%).

Conclusion: In patients with T2D inadequately controlled on TZD monotherapy, the addition of saxagliptin was safe and well tolerated. The addition of saxagliptin to ongoing TZD therapy led to clinically meaningful and statistically significant improvements in glycemic control without increasing the risk of hypoglycemia.

Alogliptin added to pioglitazone therapy improves glycaemic control in patients with type 2 diabetes without increasing weight gain or hypoglycaemia

R. Pratley¹, J. Reusch², P. Fleck³, C. Wilson³, Q. Mekki³

¹Medicine, University of Vermont, Burlington, ²Medicine, University of Colorado Denver and Health Sciences Center and Denver VAMC, Denver,

³Takeda Global Research & Development Center Inc., Deerfield, United States

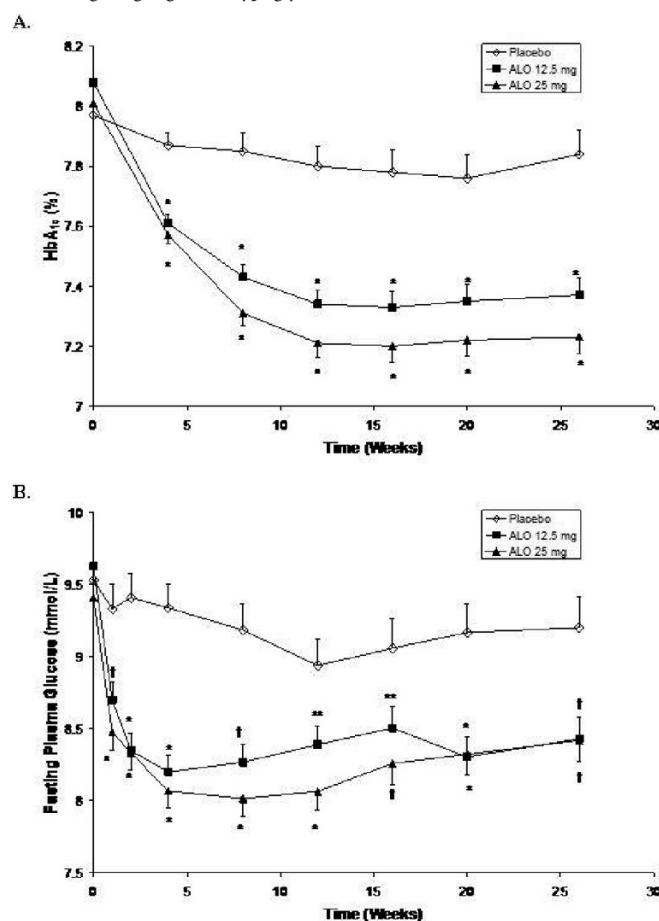

Background and aims: Alogliptin (ALO) is a potent and highly selective DPP-4 inhibitor being developed for the treatment of type 2 diabetes mellitus (T2DM). T2DM is a progressive disease and combination therapy is often required to adequately achieve and maintain glycemic control. This randomized, double-blind, placebo (PBO)-controlled study assessed the efficacy and safety of ALO added to pioglitazone (PIO) in patients with T2DM inadequately controlled on a thiazolidinedione alone or on a thiazolidinedione with metformin (MET) or a sulfonylurea (SU).

Materials and methods: Patients (N=493; mean age=55 years; 74% white; 58% men; mean baseline HbA_{1c} =8.0%; mean duration of T2DM=8 years) were assigned to receive ALO 12.5 mg (n=197), ALO 25 mg (n=199), or PBO (n=97) once daily in addition to their ongoing PIO regimen (mean dose=35 mg/day) for 26 weeks after a 4-week single-blind PBO run-in/stabilization period. Those patients already taking MET (56%) or an SU (21%) continued this therapy at a stable dose throughout the study. The primary endpoint was change from baseline in HbA_{1c} at week 26 (or last observation) in the intent-to-treat population.

Results: A total of 372 patients completed the study (ALO 12.5 mg, 77.7%; ALO 25 mg 80.4%; PBO, 73.2%). At week 26, least-squares (LS) mean changes from baseline in HbA_{1c} were significantly ($P<.001$) greater for ALO 12.5 mg (-0.66%) and ALO 25 mg (-0.80%) vs PBO (-0.19%) (Figure). The

changes from baseline in HbA_{1c} were similar regardless of age (<65 or ≥ 65 years), BMI (<30 or ≥ 30 mg/kg²), ethnicity (Hispanic or non-Hispanic), or background therapy (MET, SU, or none), and were greater in patients with higher baseline HbA_{1c} . At week 26, LS mean changes from baseline in fasting plasma glucose were significantly ($P=.003$) greater for ALO 12.5 mg (-1.09 mmol/L) and ALO 25 mg (-1.10 mmol/L) vs PBO (-0.32 mmol/L) (Figure). No significant differences from PBO in LS mean changes from baseline in weight and lipids were observed for either ALO dose at week 26. The proportions of patients who experienced ≥ 1 adverse event (ALO 12.5 mg, 69.7%; ALO 25 mg, 72.4%; PBO, 64.9%) or ≥ 1 serious adverse event (ALO 12.5 mg, 2.5%; ALO 25 mg, 6.5%; PBO, 4.1%) or who discontinued due to an adverse event (ALO 12.5 mg, 3.0%; ALO 25 mg, 3.0%; PBO, 3.1%) were similar across groups. The proportion of patients who experienced hypoglycemia (ALO 12.5 mg, 5.1%; ALO 25 mg, 7.0%; PBO, 5.2%) or edema (ALO 12.5 mg, 6.1%; ALO 25 mg, 5.5%; PBO, 7.2%) were also similar across groups.

Conclusion: ALO added to ongoing PIO therapy (with or without MET or an SU) significantly improved glycemic control in patients with T2DM, without increasing weight gain or hypoglycemia.

Alogliptin added to metformin therapy in patients with type 2 diabetes reduces HbA_{1c} without changing weight or increasing gastrointestinal symptoms or hypoglycaemia

G. Ellis¹, P. Fleck², C. Wilson³, Q. Mekki², M. Nauck³

¹Medicine, Helderberg Diabetes and Medical Centre, Cape Town, South Africa, ²Takeda Global Research & Development Center Inc., Deerfield, IL, United States, ³Diabetes Clinic, Diabetes Center Bad Lauterberg, Germany

Background and aims: Alogliptin (ALO) is a potent and highly selective DPP-4 inhibitor being developed for the treatment of type 2 diabetes mellitus (T2DM). T2DM is a progressive disease and combination therapy is often

required to adequately achieve and maintain glycemic control. This randomized, double-blind, placebo (PBO)-controlled study assessed the efficacy and safety of ALO in combination with metformin (MET) in patients with T2DM inadequately controlled on MET monotherapy.

Materials and methods: Patients (N=527; mean age=55 years; mean BMI=32 kg/m²; 77% white; 50% men; mean baseline HbA1c=7.9%; mean duration of T2DM=6 years) were assigned to receive ALO 12.5 mg (n=213), ALO 25 mg (n=210), or PBO (n=104) once daily in addition to their ongoing MET regimen (mean dose=1847 mg/day) for 26 weeks after a 4-week single-blind PBO run-in/stabilization period. The primary endpoint was change from baseline in HbA1c at week 26 (or last observation) in the intent-to-treat population.

Results: A total of 413 patients completed the study (ALO 12.5 mg, 82.6%; ALO 25 mg 78.6%; PBO, 69.2%). Least-squares (LS) mean changes from baseline in HbA1c were significantly ($P<.001$) greater for ALO 12.5 mg (-0.6%) and ALO 25 mg (-0.6%) vs PBO (-0.1%) at week 26 (Figure). The changes from baseline in HbA1c were similar regardless of age (<65 or ≥65 years), BMI (<30 or ≥30 kg/m²), or ethnicity (Hispanic or non-Hispanic) and were greater in patients with higher baseline HbA1c. At week 26, significantly ($P<.001$) greater proportions of patients achieved a ≥1% decrease from baseline for HbA1c levels (ALO 12.5 mg, 28.6% and ALO 25 mg, 30.0% vs PBO, 8.7%). LS mean changes from baseline in fasting plasma glucose were significantly ($P<.001$) greater for ALO 12.5 mg (-1.0 mmol/L) and ALO 25 mg (-1.0 mmol/L) vs PBO (0 mmol/L) at week 26 (Figure). LS mean changes from baseline in weight and lipids at week 26 were not clinically meaningful. The proportions of patients who experienced ≥1 adverse event (ALO 12.5 mg, 62.9%; ALO 25 mg, 57.0%; PBO, 66.3%) or ≥1 serious adverse event (ALO 12.5 mg, 2.8%; ALO 25 mg, 3.9%; PBO, 3.8%) or who discontinued the study due to an adverse event (ALO 12.5 mg, 3.3%; ALO 25 mg, 1.9%; PBO, 1.0%) were similar across groups. The proportion of patients with ≥1 gastrointestinal symptom was also similar across groups (ALO 12.5 mg, 10.3%; ALO 25 mg, 12.6%; PBO, 15.4%). The incidence of hypoglycemia was low (ALO 12.5 mg, 2 patients; ALO 25 mg, 0 patients; PBO, 3 patients).

Conclusion: ALO added to ongoing MET monotherapy improved glycemic control in patients with T2DM without changing weight or increasing the incidence of gastrointestinal symptoms or hypoglycemia.

Efficacy and safety of alogliptin monotherapy in patients with type 2 diabetes inadequately controlled with diet and exercise

Q. Mekki¹, P. Fleck¹, C. Wilson¹, R. DeFronzo²

¹Takeda Global Research & Development Center Inc., Deerfield, ²Medicine-Diabetes, University of Texas Health Science Center, San Antonio, United States

Background and aims: Alogliptin (ALO) is a potent and highly selective DPP-4 inhibitor being developed for the treatment of type 2 diabetes mellitus (T2DM). DPP-4 inhibitors represent a new class of oral antihyperglycemic agents that improve glycemic control by preventing the degradation of the incretin hormones glucagon-like peptide-1 and glucose-dependent insulinotropic polypeptide. This randomized, double-blind, placebo (PBO)-controlled study was conducted to assess the efficacy and safety of ALO monotherapy in patients with T2DM inadequately controlled on diet and exercise alone.

Materials and methods: Patients (N=329; mean age=53 years; 53% men; 67% White; mean baseline HbA1c=7.9%) were assigned to receive ALO 12.5 mg (n=133), ALO 25 mg (n=131), or PBO (n=65) once daily for 26 weeks. The primary endpoint was change from baseline in HbA1c at week 26 (or last observation) in the intent-to-treat population.

Results: A total of 252 patients completed the study (ALO 12.5 mg, 78.9%; ALO 25 mg 81.7%; PBO, 61.5%). At week 26, the least-squares (LS) mean changes from baseline in HbA1c were significantly ($P<.001$) greater for ALO 12.5 mg (-0.56%) and ALO 25 mg (-0.59%) vs PBO (-0.02%) (Figure). The changes from baseline in HbA1c were similar regardless of age (<65 or ≥65 years), BMI (<30 or ≥30 kg/m²), or ethnicity (Hispanic or non-Hispanic), and were greater in patients with higher baseline HbA1c (Figure). A greater proportion of patients achieved HbA1c ≤7.0% for ALO 12.5 mg (47%; $P=.001$) and ALO 25 mg (44%; $P=.008$) vs PBO (23%) at week 26. The LS mean changes from baseline in fasting plasma glucose were significantly ($P<.001$) greater for ALO 12.5 mg (-0.57 mmol/L) and ALO 25 mg (-0.91 mmol/L) vs PBO (+0.63 mmol/L) at week 26. No significant differences from PBO in LS mean changes from baseline in weight were observed for either ALO dose at week 26. The proportions of patients who experienced ≥1 adverse event (ALO 12.5 mg, 68.4%; ALO 25 mg, 67.4%; PBO, 70.3%), who discontinued the study due to an adverse event (ALO 12.5 mg, 1.5%; ALO 25 mg, 1.5%; PBO, 1.6%), or experienced ≥1 severe adverse event (ALO 12.5 mg, 3.8%; ALO 25 mg, 0.8%; PBO, 3.1%) were similar across groups. The most common adverse events were nasopharyngitis (ALO 12.5 mg, 9.0%; ALO 25 mg, 7.6%; PBO, 7.8%), headache (ALO 12.5 mg, 7.5%; ALO 25 mg, 6.8%; PBO, 4.7%), and upper respiratory tract infection (ALO 12.5 mg, 3.8%; ALO 25 mg, 4.5%; PBO, 9.4%). The incidence of hypoglycemia was low and similar across groups (ALO 12.5 mg, 3.0%; ALO 25 mg, 1.5%; PBO, 1.6%).

Conclusion: ALO monotherapy significantly improved glycemic control and was generally well tolerated in patients with T2DM inadequately controlled with diet and exercise.

Exenatide improves acute phase insulin response to a meal in patients with type 2 diabetesJ. Han¹, H. Dong¹, L. Nielsen¹, Y. Qu², L. Glass², D. Bhole¹, D. Maggs¹¹Amylin Pharmaceuticals, Inc., San Diego, ²Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, United States

Background and aims: The incretin mimetic exenatide can markedly lower postprandial glucose. However, conventional interpretations of insulin secretion during exenatide treatment can be confounded by small postprandial plasma glucose excursions, as well as difficulty in accounting for the accompanying glucoregulatory effects of glucagon suppression and slowed gastric emptying. To address this issue, we utilised an insulinogenic index of insulin secretion that calculates the insulin:glucose ratio (IGR) using peak postprandial glucose concentration, and corresponding insulin concentration, during a meal tolerance test:

$$\text{IGR} = \frac{\text{Insulin } (\mu\text{U/mL}) \text{ at peak glucose} - \text{Insulin at } t = 0}{\text{Glucose (mg/dL) at peak} - \text{Glucose at } t = 0}$$

Materials and methods: Data were log-transformed and examined in an Analysis of Covariance (ANCOVA) model. Calculations were conducted in two separate cohort datasets where meal tolerance tests were performed in patients with type 2 diabetes at baseline and study end: (1) a pooled clinical database from three 30 wk PBO-controlled trials (75M, 51F; age 55.1±9.7y; BMI 33.4±5.8kg/m²; HbA_{1c} 8.3±1.1%; duration of diabetes 7.7±5.7y; mean±SD); (2) a 26-wk insulin glargine comparator trial (41M, 21F; age 56.5±8.3y; BMI 32.0±5.0kg/m²; HbA_{1c} 8.3±0.9%; duration of diabetes 9.9±5.4y; mean±SD). **Results:** For cohort 1, IGR was significantly greater for the 5-μg (n=40) and 10-μg (n=43) exenatide-treated cohorts compared with the PBO (n=43) cohort (geometric LS mean ratio of Wk 30 to baseline: 1.60±0.21, 1.55±0.20, and 0.75±0.09, respectively; p<0.0001 exenatide vs. PBO). For cohort 2, IGR was significantly greater for the exenatide cohort (n=28) compared with the insulin glargine cohort (n=34; geometric LS mean ratio of Wk 26 to baseline: 1.74±0.24 vs. 1.13±0.14, respectively; p=0.0274 exenatide vs. glargine).

Conclusion: Exenatide treatment increases the acute phase insulin secretion response to a caloric challenge compared to PBO-controlled patients and patients receiving insulin glargine, an effect that likely contributes to the improvement in postprandial glycaemia observed with exenatide treatment.

864

Exenatide sensitises insulin-mediated glucose uptake at liver and skeletal muscle, an effect amplified by hyperglycaemia

D. Zheng, V. Ionut, V. Mooradian, D. Stefanovski, R.N. Bergman

Physiology and Biophysics, University of Southern California, Los Angeles, United States

Background and aims: Exenatide (EX) is a long-acting mimetic of glucagon-like peptide-1 (GLP-1), which in addition to its currently recognized actions (enhancing glucose-dependent insulin secretion, suppressing glucagon secretion and GI motility), may have a glucose-lowering effect independent of an increased beta-cell response. The aim of our study was to elucidate whether exenatide stimulates insulin-independent glucose uptake directly or if it potentiates insulin-mediated glucose uptake.

Materials and methods: Protocol I: modified hyperinsulinemic euglycemic clamps in awake dogs (n = 6), with EX (20 μg, sc) or saline (SAL). Plasma insulin was raised to ~250 pM (postprandial levels). Exogenous glucose was infused intraportally to maintain systemic euglycemia and simultaneously stimulate the putative portal GLP-1/glucose sensor together with exenatide. The rate of peripheral glucose disappearance (Rd) was calculated using Steele's equation. Net hepatic glucose balance (NHGB), the difference between endogenous glucose production (EGP) and 1st-pass hepatic glucose uptake (HGU), was calculated by subtracting intraportal glucose infusion (PoGinf) from the rate of glucose appearance (Ra); NHGB = EGP - HGU = Ra - PoGinf (positive values = net production [NHGP], negative values = net uptake [NHGU]). To test the hypothesis that the potential enhancement of glucose disposal by exenatide is amplified at higher glycemia we performed Protocol II.

Protocol II: hyperinsulinemic hyperglycemic clamps (n = 8), was identical to Protocol I except that systemic glucose was raised to 150 mg/dL (postprandial levels). To investigate whether a rise in plasma insulin levels is necessary for exenatide's effect, we performed Protocol III.

Protocol III: euinsulinemic hyperglycemic clamps (n = 6) was identical to protocol II, except that plasma insulin was maintained at basal levels

Results: During the hyperinsulinemic euglycemic clamps with EX PoGinf was 18% higher than in SAL (13.2 ± 1.9 SAL vs. 15.6 ± 2.1 EX mg/kg/min, p = 0.01), due to an 11% increase in Rd (13.0 ± 2.4 SAL vs. 14.5 ± 2.4 EX mg/kg/min, p = 0.02) and a 46% increase in NHGU (-1.1 ± 0.1 SAL vs. -1.6 ± 0.5 EX mg/kg/min, p = 0.3). When systemic glucose was elevated, EX enhanced PoGinf by 29% (15.9 ± 1.6 SAL vs. 20.4 ± 2.1 EX mg/kg/min, p < 0.001), Rd increased by 19% (15.5 ± 1.5 SAL vs. 18.4 ± 2.1 EX mg/kg/min, p = 0.01) and NHGU rose by 91% (-1.2 ± 0.2 SAL vs. -2.3 ± 0.3 EX mg/kg/min, p = 0.03). However, in the absence of hyperinsulinemia, despite elevated glucose, EX did not cause greater PoGinf (2.7 ± 0.7 SAL vs. 2.3 ± 0.4 EX mg/kg/min). Rd increased slightly and similarly with or without exenatide (4.1 ± 0.5 SAL vs. 4.0 ± 0.3 EX mg/kg/min) and NHGP was similarly suppressed (to 51% of basal SAL vs. 57% of basal EX).

Conclusion: We conclude that there exists a systemic glucose-lowering effect of exenatide as a result of the sensitization of insulin-mediated glucose uptake at liver and the periphery (presumably skeletal muscle). Therefore, along with its other known actions, exenatide represents an acute insulin sensitizer, acting effectively in postprandial conditions (high insulin and glucose levels) and possibly rescuing the impaired insulin sensitivity in type 2 diabetes.

Relative contribution of splanchnic glucose metabolism and gastric emptying in exenatide attenuation of post-meal hyperglycaemia in T2DM subjects

E. Cersosimo, A. Cervera, E. Wajsborg, C. Triplitt, J. Joya, P. Zuo, R. DeFronzo

Medicine/Diabetes, University of Texas, San Antonio, United States

Background and aims: Exenatide markedly attenuates postprandial and reduces fasting glucose, but the prevalent mechanisms of action during acute vs. chronic exposure are unknown.

Materials and methods: We examined 26 T2DM subjects (45±10y; 7F/19M; BMI=33±6 kg/m², FPG=126-188 mg/dl range, HbA_{1c}=9.3±1.9%) treated with diet (n=6), metformin (n=6), sulfonylurea (n=5) or both (n=9). Subjects received: i) 6-h meal tolerance test (MTT) with iv saline or iv exenatide (n=13) (ACUTE) or ii) 6-h MTT before and after (n=13) 2 weeks of exenatide (10 ug sc bid) (CHRONIC) with no exenatide on the study day. The meal had 600 cal of fat/protein/glucose (75g) with 100 μCi of [1-¹⁴C]-glucose, and 1 g acetaminophen to monitor gastric emptying. Endogenous glucose production (EGP), rate of oral glucose appearance (RaO) and splanchnic glucose uptake [SGU=75 g - RaO₍₀₋₃₆₀₎] were measured with dual isotope technique.

Results: IV Exenatide completely prevented the post-meal rise in glucose (126 [fasting] to 123 mg% [mean postprandial]), increased insulin (by 11±4 μIU/ml, p<0.01) and decreased glucagon ((by 4±1 pg/ml, p<0.05) vs. iv saline. Two weeks exenatide sc decreased fasting glucose (by 43 mg%, p<0.05), reduced mean post-prandial glucose (by 45 mg%, p<0.05), increased insulin (by 12 μIU/ml, p<0.01) and reduced glucagon (by 6 pg/ml, p<0.05) vs. the pre-exenatide MTT. Both iv (ACUTE) and sc (CHRONIC) exenatide similarly suppressed EGP (by 15-20%, p<0.05), decreased RaO of glucose (129 to 82 vs. 101 to 63 mg/min, respectively) and increased SGU (33±2 to 56±4 g vs. 33±4 to 52±5 g, respectively) during the MMT. However, acetaminophen_(AUC) decreased by 47% (1761 to 831 μg/ml.360 min, p<0.05) with iv exenatide, indicating delayed gastric emptying was responsible for the increase in splanchnic glucose retention. In contrast, acetaminophen_(AUC) was identical before and after 2 weeks of sc exenatide (1481±44 vs. 1487±83 μg/ml.360 min). Thus, increase in splanchnic (hepatic) glucose uptake, not delayed gastric emptying, was responsible for decreased RaO following sc exenatide. Plasma exenatide concentration during iv infusion was 96±17 pg/ml (therapeutic range) vs. undetectable levels during sc exenatide.

Conclusion: Acute elevation in plasma exenatide to clinical practice levels reduces post-meal glucose by slowing gastric emptying and inhibiting EGP, while chronic exenatide markedly augments hepatic glucose uptake and modestly reduces EGP.

Intranasal administration of exenatide in patients with type 2 diabetes: pharmacokinetics, pharmacodynamics, safety and tolerability

E. Blase, W. Deng, B. Walsh, M. Fineman, C. Rhodes
Amylin Pharmaceuticals, Inc., San Diego, United States

Background and aims: Exenatide, an incretin mimetic administered twice daily (BID) via subcutaneous (SC) injection, has been demonstrated to improve glycaemic control with associated weight reduction. The present study examined the pharmacokinetic and pharmacodynamic effects of intranasal (IN) exenatide administration in patients with type 2 diabetes using at least one oral antidiabetic agent (13 M, 7 F; age 55 ± 9 y; BMI 31.3 ± 3.2 kg/m²; HbA_{1c} $8.13 \pm 1.28\%$; FPG 8.68 ± 1.92 mmol/L; mean \pm SD).

Materials and methods: Exenatide IN and placebo IN were proprietary formulations containing an absorption enhancer. Saline IN consisted of a 0.65% aqueous solution of sodium chloride. All IN administrations consisted of one to three 100- μ L nasal sprays. Each patient received exenatide 5 μ g SC 30 min after saline IN, and on a separate day, placebo IN. Thereafter, patients received on separate days either 60, 200, and 600 μ g exenatide IN (n=11); or 600, 800, 1200, and 1800 μ g exenatide IN (n=6). A standardised meal was given immediately after exenatide IN. Blood samples were collected prior to and during the 8 hours following study medication.

Results: Plasma exenatide concentration peaked at 15–30 min with exenatide IN compared to 2 hours with SC. Exenatide exposure (AUC, C_{max}) increased in a dose-related manner from 60 μ g to 1800 μ g, and therapeutic plasma concentrations (>50 pg/mL) were maintained for 3 to 5 hours with exenatide IN doses greater than 600 μ g. Near-maximal improvements in postprandial glucose were observed at 600 μ g (incremental AUC_{0–240 min} -148.8 ± 105.2 mmol-min/L vs. $+656.6 \pm 66.8$ mmol-min/L with placebo; mean \pm SE), and these improvements were maintained at all higher doses. The most frequent adverse events (AEs) with exenatide IN were nausea (6 patients), vomiting (5 patients), and sneezing (2 patients); these AEs occurred only at doses of 600 μ g and above. Nausea and sneezing also occurred with placebo IN (1 patient for each AE). There were no serious AEs or hypoglycaemic events.

Conclusion: In this study, intranasal administration of exenatide in patients with type 2 diabetes resulted in therapeutic plasma exenatide concentrations and improved PPG control.

867

Pulmonary administration of GLP-1 (GLP-1 Technosphere powder) I: Kinetics

J. Cassidy¹, R. Baughman¹, D. Costello², B. Levy³, A. van Vliet⁴, M. Diaz¹, C. Damico⁵, P. Richardson⁶

¹Experimental Pharmacology, MannKind Corporation, Paramus, United States, ²Clinical Research, MannKind Corporation, Paramus, United States, ³Metabolic Diseases, Johnson & Johnson Pharmaceutical Services, LLC, Raritan, United States, ⁴PRA Group BV, PRA International, Zuidlaren, Netherlands, ⁵Program Management, MannKind Corporation, Paramus, United States, ⁶Research and Development, MannKind Corporation, Paramus, United States

Background and aims: GLP-1 enhances insulin release and regulates both glucagon release and gastrointestinal motility. MKC253 is GLP-1 (15% by weight) adsorbed to Technosphere microparticles for administration using the MedTone Inhaler. Technosphere microparticles dissolve rapidly in the lung, providing a drug delivery platform for pulmonary administration of protein and peptide drugs.

Materials and methods: The safety, tolerability, pharmacokinetics, and pharmacodynamics of MKC253 were evaluated in a first-in-human, single-dose, open-label, dose-escalation trial in 26 healthy adult males. Five doses of MKC253 were tested in fasted subjects: 4 subjects received 0.05 and 0.45 mg GLP-1 and 6 subjects received 0.75, 1.05, and 1.5 mg of GLP-1.

Results: All doses of MKC253 were well tolerated. No nausea or vomiting was reported. GLP-1 was rapidly absorbed; peak concentrations were achieved at the first post-dose sampling time (3 minutes). Mean peak concentrations of active GLP-1 were >300 pmol/L at the 1.5 mg dose, and 2 subjects achieved concentrations above the quantitation limit of the assay (500 pmol/L). The

half-life of GLP-1 was about 2 minutes. Maximal plasma concentrations of active GLP-1 at the 1.5 mg dose were approximately 2/3 those of total GLP-1. Despite high levels of DPP-IV in the lungs, the levels of GLP-1 following MKC253 inhalation were equivalent to those achieved with intravenous bolus administration of 50 μ g and are more than 10X those reached following physiological postprandial release. GLP-1 plasma concentrations increased dramatically at doses above 0.75 mg, suggesting that DPP-IV degradation has been mitigated.

Conclusion: Pulmonary administration of MKC253 produces high circulating GLP-1 concentrations without nausea and vomiting.

868

Pulmonary administration of GLP-1 (GLP-1 Technosphere powder) II: Dynamics

D. Costello¹, R. Baughman², B. Levy³, A. van Vliet⁴, A. Price², M. Diaz², C. Damico⁵, P. Richardson⁶

¹Clinical Research, MannKind Corporation, Paramus, United States, ²Experimental Pharmacology, MannKind Corporation, Paramus, United States, ³Metabolic Diseases, Johnson & Johnson Pharmaceutical Services, LLC, Raritan, United States, ⁴PRA Group BV, PRA International, Zuidlaren, Netherlands, ⁵Program Management, MannKind Corporation, Paramus, United States, ⁶Research and Development, MannKind Corporation, Paramus, United States

Background and aims: GLP-1 enhances insulin release and regulates both glucagon release and gastrointestinal motility. MKC253 is GLP-1 (15% by weight) adsorbed to Technosphere microparticles for administration using the MedTone Inhaler. Technosphere microparticles dissolve rapidly in the lung, providing a drug delivery platform for pulmonary administration of protein and peptide drugs.

Materials and methods: The safety, tolerability, pharmacokinetics, and pharmacodynamics of MKC253 were evaluated in a first-in-human, single-dose, open-label, dose-escalation trial in 26 healthy adult males. Five doses of MKC253 were tested in fasted subjects: 4 subjects received 0.05 and 0.45 mg GLP-1 and 6 subjects received 0.75, 1.05, and 1.5 mg of GLP-1.

Results: Mean peak concentrations of active GLP-1 were >300 pmol/L at the 1.5 mg dose. MKC253 was well tolerated at all doses tested. The most frequent adverse events were cough and headache. No subject vomited or reported nausea or profuse sweating, although the literature reports >50% of subjects with GLP-1 concentrations >100 pmol/L have these adverse events. Inhalation of MKC253 led to rapid increases in plasma insulin in fasting subjects. Maximum insulin concentrations were measured at 6 minutes after dosing, the first time point sampled. The insulin increase was dose dependent; the highest mean insulin level of 375 pmol/L was achieved with the 1.5 mg dose of MKC253. The plasma C-peptide concentration profile matched the plasma insulin curve. Inhalation of MKC253 reduced plasma glucose; 20 minutes after the 1.5 mg dose, mean fasting plasma glucose was reduced from 85 to 70 mg/dL.

Conclusion: Pulmonary administration of GLP-1 releases endogenous insulin and reduces plasma glucose in fasting subjects without nausea and vomiting.

869

Pharmacodynamics of oral encapsulated analogues of GLP-1 in domestic pigs

R.R.C. New, T.P. Broke-Smith

Diabetology Limited, Cobham, United Kingdom

Background and aims: The pharmacodynamics of encapsulated analogues of GLP-1 (G001 and G002) using proprietary Axxess™ oral formulations were investigated in relation to subcutaneous injected delivery of the same GLP-1 analogues in juvenile domestic pigs. The Axxess formulation has already been tried and tested in humans and proved successful in phase II studies with insulin.

Materials and methods: Six study arms used 5–8 juvenile domestic pigs each. The dosing groups were: placebo capsule (Axxess excipients only), no treatment, 0.4 mg s.c. injected G001, 0.4 mg s.c. injected G002, 4 mg capsule Axxess-formulated G001, 4 mg capsule Axxess-formulated G002. The Axxess-formulated capsules were delivered via intrajejunal stoma. Treatments took place on days 1, 3, 7, 9, 11, 14, 16 and 18. Blood samples were taken at t+0, 10, 15, 30, 60, 120, 180, 240, 300, 360 and 480 minutes. As this was the first test of these peptides in this model and using this oral delivery formulation, doses used were comparatively large in order to ensure that there were data generated for analysis.

Results: Falls in blood glucose were observed for all treatment arms which were greater than the controls. The oral formulations of each analogue generated glucose falls that were similar to those produced by the s.c. injection treatments. No advantage was gained by incorporating a protease inhibitor in the formulation (data not shown).

Treatment Arm		Mean AUC ₄₈₀ of % change in plasma glucose (st.dev.)
No treatment		–42.9 (108.5)
Subcutaneous injection	G001	–61.3 (49.1)
	G002	–81.1 (41)
Capsule i.j. delivered	Placebo	–40.4 (69.9)
	G001	–51.4 (49.4)
	G002	–70.2 (74.2)

Mean AUC₄₈₀ of % change in plasma glucose

Conclusion: This proof of concept study has confirmed that, using a standard pharmaceutical capsule, the Axxess delivery technology is capable of delivering oral encapsulated GLP-1 analogues via the jejunum. This supports the development of Axxess-formulated GLP-1 and/or its analogues as an oral alternative to the subcutaneous injections of these peptides for the treatment of type 2 diabetes in man.

870

Albiglutide, a long-acting GLP-1 mimetic: pharmacodynamics, pharmacokinetics, safety and tolerability in subjects with type 2 diabetes

M.W. Stewart¹, J. Matthews², E.H. De Boever³, R.L. Dobbins², R.J. Hodge⁴, S.E. Walker⁵, C.H. Holland⁶, M.A. Bush⁷¹Alternative Development Program, GlaxoSmithKline, King of Prussia,²Clinical Pharmacology Discovery Medicine, GlaxoSmithKline, ResearchTriangle Park, ³BioPharm Drug Discovery, GlaxoSmithKline, King ofPrussia, ⁴CSSO, GlaxoSmithKline, Research Triangle Park, ⁵DiscoveryBiometrics, GlaxoSmithKline, Research Triangle Park, ⁶ClinicalImmunology, GlaxoSmithKline, King of Prussia, ⁷Clinical Pharmacokinetics,

GlaxoSmithKline, Research Triangle Park, United States

Background and aims: Native GLP-1 is rapidly degraded, so a long-acting GLP-1 mimetic might be of greater benefit for the management of type 2 diabetes (T2D). Albiglutide (ALB) is a GLP-1 mimetic generated by genetic fusion of a DPP-IV-resistant GLP-1 dimer to human serum albumin. The pharmacodynamics (PD), pharmacokinetics (PK), safety and tolerability of ALB were assessed in subjects with T2D in two clinical studies.

Materials and methods: Study 1 evaluated fasting plasma glucose (FPG), 24h glucose profiles and PK of ALB vs placebo (PBO) in subjects with T2D. Subjects were diet-controlled or withdrawn from metformin (MET), a sulfonylurea (SU), or MET+SU for 2 weeks prior to the first dose. Subcutaneous (sc) injections of PBO or ALB (9, 16, or 32 mg) were administered on days 1 and 8.

Study 2 was non-PBO controlled and evaluated PD and PK of single doses (16 and 64 mg) of ALB after sc injection in the arm, thigh, or abdomen. Subjects with T2D were diet-controlled or remained on MET or a thiazolidinedione. On day 3 post-dose (T_{max}), FPG was assessed prior to breakfast and post-prandial glucose (PPG) profiles were assessed after breakfast.

Results: In study 1, baseline-adjusted FPG and mean 24h glucose (on day 9) were reduced relative to PBO (FPG: 1.32–2.81 mmol/l; AUC(0–24): 1.72–3.13 mmol/l) over the dose range evaluated.

In study 2, glucose reductions were consistent across injection sites. Mean FPG was reduced by 0.23–1.17 mmol/l and 1.19–1.94 mmol/l at the 16 and 64 mg doses, respectively, and mean PPG by 0.34–0.89 mmol/l and 2.29–2.93 mmol/l at the 16 and 64 mg doses, respectively. The PK of ALB was comparable across different sites following sc administration. Exposure was moderately greater than dose proportional for AUC(0–∞) and C_{max} . $T_{1/2}$ ranged from 4–6d; T_{max} ranged from 3–4d.

In both studies, the majority of adverse events (AEs) were mild in intensity. No dose-related trends in the frequency of AEs or significant lab changes were reported for subjects receiving ALB.

Conclusion: ALB was well tolerated with a favorable safety profile and improved FPG and PPG with the potential for at least weekly dosing in subjects with T2D.

871

8 weeks treatment with R1583, a novel long-acting, human GLP-1 analogue improves beta cell function in metformin-treated diabetic subjects: a double-blind, placebo-controlled phase 2 study

R. Berria¹, A. Gastaldelli², M. Nauck³, M. Boldrin¹, V. Asnaghi⁴, R. Balena⁴¹Roche Labs Inc, Nutley, United States, ²CNR, Institute of ClinicalPhysiology, Pisa, Italy, ³Fachklinik F. Diabetes und Stoffwechselkrankheiten,Diabeteszentrum, Bad Lauterberg im Harz, Germany, ⁴Hoffmann-La Roche,

Basel, Switzerland

Background and aims: R1583 is a novel, long-acting 10% formulation of [Aib^{8–35}] human GLP-1 (7–36 amide). We sought to evaluate the effects of R1583 on several parameters of β -cell function in patients with type 2 diabetes mellitus (T2DM), inadequately controlled with metformin, after 8 weeks of treatment with R1583 compared to placebo.

Materials and methods: As part of a larger, randomized, double-blind phase 2 trial, a subset of 118 T2DM subjects (age: 56±8 yrs; BMI: 33.3±5.1 kg/m²; HbA1c: 7.9±0.6 %; duration of T2DM: 5±4 yrs), inadequately controlled with metformin ≥ 1500 mg/daily, were studied to assess the response to a mixed meal test (MMT). Volunteers were randomized to 8 weeks of treatment with placebo (PLO) or R1583, given either as 5, 10, 20 mg weekly (QW), or 10 or 20 mg once every two weeks (Q2W). Patients underwent a 240-min MMT, performed under post-absorptive conditions at baseline (PRE) and at week 9 (POST, one week after the last injection of active drug or PLO). PRE and POST treatment insulin secretion rate (ISR) was calculated by C-peptide de-

convolution analysis, and beta cell glucose sensitivity (β -GS) as the slope of the dose-response curve of ISR vs. glucose concentration. Changes in plasma glucose parameters are reported as % changes from baseline.

Results: After 8 weeks of treatment with R1583, fasting plasma glucose (FPG) decreased by 21%, 24% and 26% vs. PRE in the 5, 10 and 20 mg QW groups respectively, compared to -8% in the PLO arm. In the Q2W arm FPG declined by 12% and 16% in the 10 and 20 mg groups respectively. R1583 also decreased two-hour postprandial plasma glucose (2h-PPG) by 17%, 25% and 22% in the 5, 10 and 20 mg groups respectively (vs. -9% in PLO), as well as glucose-AUC, which decreased by 21%, 26% and 23% in the 5, 10 and 20 mg groups respectively (vs. -8% in PLO). In the Q2W arm, 2h-PPG decreased by 13% and 16%, while glucose-AUC declined by 11% and 15% in the 10 and 20 mg groups respectively. ISR improved significantly during fasting (average in the weekly regimen: +11 pmol/min m², $p=0.03$ vs. PLO), as well as total insulin response during the 240 min after the meal (average: +9 nmol/m², $p=0.003$ vs. PLO). Both changes were directly proportional to the drug dose ($r^2=0.91$ and 0.93 respectively, $p<0.001$). The Δ AUC-ISR/ Δ AUC-glucose calculated during the first 2 hours after the meal, clearly improved in all weekly regimens (Figure 1). Moreover, β -GS was enhanced in all weekly regimens ($p<0.001$ vs. PRE; $p=0.06$ vs. PLO).

Conclusion: These data suggest that R1583 significantly improves β -cell function in patients with T2DM treated with metformin, and is a promising long-acting, human GLP-1 analogue for the treatment of T2DM.

PS 076 Exenatide: clinical trials

872

Exenatide resulted in significantly greater improvements in postprandial glycaemic control compared to sitagliptin

L. MacConnell¹, X. Guan¹, T. Okerson¹, J. Holcombe², R. DeFronzo³

¹Amylin Pharmaceuticals, Inc., San Diego, ²Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, ³Medicine, University of Texas Health Science Center, San Antonio, United States

Background and aims: Exenatide (Ex) and sitagliptin (Sita) are incretin-based therapies used to treat T2DM. Ex binds to the GLP-1 receptor, whereas Sita increases circulating levels of endogenous GLP-1.

Materials and methods: This double-blind crossover study compared their effects on postprandial (PP) measures of glucose control and gastric emptying in 61 (evaluable) patients with T2DM treated with MET (54% F; age 54±9 y; BMI 33±5 kg/m²; HbA_{1c} 8.5±1.2%; 2-hr PPG 2-hr PPG 13.6±3.63 mmol/L). The evaluable population consisted of subjects meeting predefined requirements (including detectable Ex and Sita PK within the first 2-hrs of the meal test). Ad libitum food intake was measured in a subset of subjects (N=25). Patients received Ex (5 µg BID for 1 wk followed by 10 µg BID for 1 wk) or Sita (100 mg qAM for 2 wks). After 2 wks, subjects crossed over to the alternate therapy. All values are LS mean±SE, all ratios are Ex to Sita.

Results: After 2 wks of treatment, FPG was similar between Ex (9.1±0.24 mmol/L) and Sita (8.8±0.24 mmol/L) (baseline, 9.9±0.34 mmol/L; $P=0.3234$). In response to a standard meal, 2-hr PPG was significantly lower with Ex vs. Sita in both evaluable (N=61; 7.4±0.34 mmol/L vs. 11.5±0.35 mmol/L, $P<0.0001$) and ITT populations (N=95; 9.2±0.41 mmol/L vs. 11.7±0.42 mmol/L, $P<0.0001$). Ex reduced 2-hr PPG excursion compared with Sita (change from preprandial), -1.7±0.29 mmol/L vs. +2.6±0.30 mmol/L, $P<0.0001$. At crossover, Ex to Sita switch was associated with an increase in 2-hr PPG of +4.05±0.61 mmol/L, whereas switch from Sita to Ex had a further reduction of 2-hr PPG of -4.22±0.56 mmol/L. Ex improved the insulinogenic index relative to Sita (ratio: 1.50±0.26, $P=0.0239$) and reduced PP glucagon and triglyceride concentrations (ratio AUC: 0.88±0.03, $P=0.0011$; 0.90±0.04, $P=0.0118$, respectively). Ex but not Sita reduced gastric emptying (acetaminophen ratio AUC: 0.56±0.05, $P<0.0001$). After 2 wks, Ex reduced body weight compared to Sita (-0.8±0.2 kg vs. -0.3±0.2 kg, $P=0.0056$). During the ad libitum meal, Ex reduced while Sita increased food intake from baseline (-134±97 kcal vs. +130±97 kcal, $P=0.0227$). Nausea (Ex: 34%; Sita: 12%) and/or vomiting (Ex: 24%; Sita: 3%), were the most common adverse events.

Conclusion: This study demonstrates a greater decline in PPG with Ex vs. Sita, which may be due in part to more significant effects of Ex on slowing gastric emptying (Ex only), a more robust PP insulin response, and a greater reduction in PP glucagon. Furthermore, decreased ad libitum food intake was observed only with Ex. These data delineate key differences in the MOAs between exenatide and sitagliptin.

873

Comparison of glucose variability in patients with diabetes treated with exenatide or a biphasic insulin regimen

L.C. Glass¹, Y. Qu¹, M.S. Lewis¹, I.B. Hirsch²

¹Eli Lilly, Indianapolis, United States, ²Metabolism, Endocrinology & Nutrition, University of Washington Medical Center, Seattle, United States

Background and aims: High variability in glucose concentrations is associated with an increased production of reactive oxygen species, which leads to oxidative stress and has been associated with vascular complications in type 2 diabetes (T2D). This post-hoc analysis compared glucose variability in patients with T2D randomized to treatment with either exenatide (EXE) or biphasic insulin aspart (BASP).

Materials and methods: 478 patients with T2D suboptimally controlled on metformin and sulfonylurea, with a baseline and at least one post-baseline measurement for 7-point self monitored blood glucose profile (7-SMBG), were randomized in an open label study to add either EXE (n =239; 5 µg bid for 4 weeks, then 10 µg bid through study end) or BASP bid before morning and evening meals (n =239; titrated to achieve fasting plasma glucose <7 mM and postprandial plasma glucose <10 mM) for a total of 12 months. 7-SMBG measurements were collected before and after the morning, mid-day, and evening meals, and 3AM, on two separate days within one week before each clinic visit. The daily mean, SD, M-value and mean amplitude of

glycemic excursion (MAGE) of glucose for each patient was calculated using the 7 measurements in that day. The between-day standard deviation for each patient was calculated using the matching values of each 7-SMBG time point from two separate days. The mean of the between- and within-day SD, daily mean, M-value and MAGE of glucose were summarized and compared at baseline using ANOVA, and at the end of study using ANCOVA.

Results: Baseline values for age (58.7 years), BMI (30.4 kg/m²), sex (50.8% male), and A1C (8.6%) were similar between EXE and BASP, as were all baseline values for the mean daily plasma glucose, the mean of the between- and within-day SD, M-value, and MAGE. At study end, both treatments significantly reduced A1C to a similar extent (mean \pm SE change: BASP, -0.88 ± 0.07 ; EXE, -1.00 ± 0.07 ; $p < 0.001$ compared to baseline, $p = 0.20$ between treatments). Mean daily plasma glucose or M-value was not statistically significantly different between treatments, however EXE had significantly lower within-day plasma glucose SD (BASP 2.09 mM vs. EXE 1.78 mM, $p < 0.001$) and MAGE (BASP 3.73 mM vs. EXE 3.23 mM, $p < 0.001$). Overall, patients treated with EXE also had significantly lower between-day plasma glucose SD than those on BASP (Table 1). The overall incidence of hypoglycemia for BASP and EXE was not different between groups (17.6% vs. 14.6%, $p = 0.07$), but the incidence of nocturnal hypoglycemia was significantly greater for BASP than for EXE (6.3% vs. 0.8%, $p = 0.002$).

Conclusion: EXE reduced both within- and between-day glucose variability significantly more than BASP, and had a lower incidence of nocturnal hypoglycemia than BASP. Thus, EXE resulted in a more favorable glucose profile, which may lead to less oxidative stress. This last possibility requires further study.

Table 1. Within-patient, between-day BG variability (mean SD from 2 BG reading days)

	Insulin Aspart (mM)		Exenatide (mM)		Between-treatment P-value
	Baseline†	52 weeks	Baseline†	52 weeks

Exenatide and biphasic insulin aspart differentially affect postprandial glucose excursions in patients with type 2 diabetes

J.K. Malone¹, R. Brodows¹, Y. Qu¹, D. Johns¹, B. Calhoun¹, T. Okerson², J. Holcombe¹

¹Eli Lilly and Company, Indianapolis, ²Amylin Pharmaceuticals, San Diego, United States

Background and aims: In patients with type 2 diabetes (T2D) and mild to moderate elevations in HbA_{1c}, evidence suggests that postprandial glucose (PPG) excursion, compared with fasting glucose (FG), has a greater effect on overall glycemic control. Treatment of T2D with exenatide (EXE) or biphasic insulin aspart 30/70 (BASP) results in similar improvements in glycemic control when added to metformin and a sulfonylurea. In the current post hoc analysis we examined the relative contribution of PPG excursions to hyperglycemia in EXE and BASP-treated patients.

Materials and methods: A total of 463 patients [(EXE: 232, BASP: 231) mean \pm SD: age 58.6 ± 8.9 years; HbA_{1c} $8.6 \pm 1.0\%$; BMI 30.4 ± 4.1 kg/m²] with a baseline and at least one post-baseline self-monitored blood glucose (SMBG) (before and 2 hours after each meal) were included in the analysis. PPG area under the curve (AUC_{PPG}) excursions, total glucose area under the curve but above 6.1 mmol/L (AUC_{Total}) and the percentage of hyperglycemia due to PPG excursions ($AUC_{PPG} \div AUC_{Total} \times 100$) were calculated and compared between treatments.

Results: At baseline, AUC_{PPG} , AUC_{Total} and mean FG were similar between the EXE and BASP-treated patients. At 52 weeks, both EXE and BASP treatment significantly reduced overall hyperglycemia [$AUC_{Total} \pm SE$] (-22.1 ± 2.0 mmol/L²h vs. -25.3 ± 2.1 mmol/L²h, $P = 0.70$ between treatments) and FG (-1.6 ± 0.2 mmol/L²h for both groups; $P = 0.54$ between treatments). EXE-treatment reduced PPG excursions significantly more than did treatment with BASP (-8.2 ± 1.0 mmol/L²h vs. -4.7 ± 1.0 mmol/L²h, $P = 0.002$). The greater reduction in PPG excursion with EXE-treatment resulted in significantly lower contribution of PPG to overall hyperglycemia compared to BASP (37% vs. 42%, $P = 0.04$).

Conclusion: Although both EXE- and BASP-treatments significantly improved overall glycemic control, EXE reduces PPG excursions more than BASP. Therefore, EXE should be considered an important treatment option in helping patients with T2D achieve post-prandial, and thus, overall glycemic control.

Change in HbA_{1c}, fasting serum glucose, weight, lipids, and vital signs by baseline BMI in 2 clinical trials of exenatide vs. insulin comparators

M. Trautmann¹, D. Johns¹, J. Burger¹, T. Okerson², R. Brodows¹

¹Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, ²Amylin Pharmaceuticals, Inc., San Diego, United States

Background and aims: Exenatide (EX) treatment is associated with weight reduction. Consequently, we examined the relationship between baseline BMI and change in HbA_{1c}, fasting serum glucose (FSG), weight, lipids, and vital signs in patients with type 2 diabetes treated with metformin (MET)/sulphonylurea (SU) and either EX or an insulin comparator (insulin glargine [IG] or biphasic insulin aspart [IA]).

Materials and methods: Data from 2 clinical trials of patients with type 2 diabetes with suboptimally controlled glycaemia treated with MET/SU were examined. Patients were treated with EX (n=281 vs. IG, n=251 vs. IA), IG (n=267, QD at bedtime for 26 wks), or IA (n=248, BID for 52 wks). Data collected at 28 wks from the EX vs. IA study were pooled with data from the EX vs. IG study at 26 wks. Insulin doses were titrated for optimal glucose control. EX was administered at 5 μ g BID for 4 wks and 10 μ g BID thereafter. All patients continued their pre-study MET/SU treatments. Patients were divided into baseline BMI quartiles (kg/m² [min-max]; exenatide, low [≥ 22.4 – ≤ 27.6], midlow [> 27.6 – ≤ 30.4], midhigh [> 30.5 – ≤ 33.5], high [> 33.5 – ≤ 45.5]; insulin comparators, low [≥ 22.5 – ≤ 27.3], midlow [> 27.3 – ≤ 30.1], midhigh [> 30.1 – ≤ 33.7], high [> 33.7 – ≤ 44.2]). Correlations were determined between baseline BMI and change in HbA_{1c}, FSG, weight, lipids (total cholesterol, HDL, LDL, triglycerides), heart rate, and systolic and diastolic blood pressure. From analysis of covariance, changes within each treatment and baseline BMI quartile and Least Square (LS) mean differences (exenatide minus insulin) and 95% confidence intervals (CI) are presented.

Results: There were no significant between group differences in HbA_{1c} changes in all patients and across all BMI quartiles. Compared with the insulin group, the EX group had a significantly greater reduction in systolic blood pressure in all patients and across low, midlow, and high BMI quartiles and weight in all patients and across all BMI quartiles. Compared with the EX group, the insulin group had a significantly greater reduction in FSG in all patients and across low, midlow, and midhigh BMI quartiles (Table 1). There were no consistent significant between-group differences across BMI quartiles in changes in lipids, heart rate, and diastolic blood pressure. There were no significant correlations between baseline BMI and change in HbA_{1c}, FSG, weight, total cholesterol, HDL, LDL, triglycerides, heart rate, and systolic and diastolic blood pressure in either treatment group (all $|r| < 0.1$, $P \geq 0.114$).

Conclusion: This post-hoc, meta-analysis shows that baseline BMI does not predict improvements in glycaemic control or lipid changes for either EX or insulin treatment. Regardless of initial BMI, there appears to be clinically meaningful effects on systolic blood pressure and weight with EX and larger decreases in FSG with insulin.

Exenatide is superior to insulin in attaining tight glycaemic control (HbA_{1c} ≤6.5%) with a more favourable accompanying metabolic profile

D. Maggs¹, D. Bhole¹, P. Yan¹, A. Stonehouse¹, R. Brodows², T. Okerson¹
¹Amylin Pharmaceuticals, Inc., San Diego, ²Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, United States

Background and aims: Exenatide (Ex) and insulin (Ins) are injectable therapies used in the treatment of type 2 diabetes. In pooled datasets from two studies comparing 10 µg exenatide BID to either Ins glargine or biphasic Ins aspart in patients treated with background therapy of metformin and sulphonylurea for approximately 6 months, we examined metabolic endpoints in those patients who achieved HbA_{1c} of ≤6.5%.

Materials and methods: In this post-hoc analysis, 1015 patients comprised the pooled ITT population with entry HbA_{1c} >6.5% and at least one post-baseline HbA_{1c} value (547 M, 468 F; age 58.8±9.1; BMI 30.8±4.3 kg/m² [mean±SD]; baseline HbA_{1c} 8.4±0.03%; baseline FSG 10.7±0.09 mmol/L [mean±SE]).

Results: HbA_{1c} threshold, body weight change, and blood pressure data were as follows:

	Exenatide		Insulin	
	HbA _{1c} ≤6.5%	HbA _{1c} >6.5%	HbA _{1c} ≤6.5%	HbA _{1c} >6.5%
Dose	10 µg	10 µg	24.2±2.1 U [†]	25.4±1.2 U [†]

Δ Systolic blood pressure (mm Hg)	-7.2±1.5*	-3.6±0.8 [†]	-0.3±1.4	-0.4±0.8
Δ Diastolic blood pressure (mm Hg)	-2.1±0.9 [§]	-1.1±0.5 [§]	-0.9±1.0	-0.5±0.5

(mean±SE); [†]Ins dose at approximately 6 months, *P<0.005,

**P<0.0001, [†]P<0.05, [§]P=NS; Ex vs. Ins

In the patients who achieved HbA_{1c} of ≤6.5%, Ex induced favourable reductions from baseline compared to Ins in total cholesterol (Ex: -0.221±0.050 mmol/L, P<0.0001; Ins: +0.002±0.093 mmol/L, P=NS; ΔP<0.005) and LDL-cholesterol (Ex: -0.162±0.045 mmol/L, P<0.0005; Ins: +0.130±0.075 mmol/L, P=NS; ΔP<0.0005). Both Ex and Ins induced favourable changes compared to baseline in HDL-cholesterol (Ex: +0.058±0.014 mmol/L, P<0.0001; Ins: +0.089±0.018 mmol/L, P<0.0001; ΔP=NS) and triglycerides (Ex: -0.185±0.090 mmol/L, P<0.05; Ins: -0.421±0.164 mmol/L, P<0.05; ΔP=NS). In patients achieving tight glycaemic control (HbA_{1c} of ≤6.5%), hypoglycaemia occurred more frequently with Ins treatment compared to exenatide [overall: Ins 60%, Ex 52% (ΔP=NS); nocturnal: Ins 36%, Ex 20% (ΔP<0.01)].

Conclusion: In summary, patients are more likely to achieve tight glycaemic control (HbA_{1c} of ≤6.5%) with exenatide than with basal or biphasic aspart Ins. The exenatide-treated patients able to achieve tight glycaemic control manifest with a more favourable overall metabolic profile than those treated with insulin. The implications of the differential effects observed with these two therapeutic approaches deserve further study.

Exenatide improved systolic blood pressure compared to insulin or placebo in patients with type 2 diabetes

T. Okerson¹, P. Yan¹, A. Stonehouse¹, R. Brodows², D. Bhole¹

¹Amylin Pharmaceuticals, Inc., San Diego, ²Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, United States

Background and aims: The incretin mimetic exenatide (Ex) is approved as an adjunctive treatment of type 2 diabetes (T2DM). In pooled datasets from clinical studies comparing 10 µg Ex BID to insulin glargine, biphasic insulin aspart, or placebo, we examined the effects on systolic blood pressure (SBP) in patients with T2DM in the normal (<130 mm Hg) or abnormal (≥130 mm Hg) range after approximately 6 months of treatment.

Materials and methods: In this post-hoc analysis, 1050 patients comprised the ITT insulin-comparator (I-C) population (54% M; age 59±0.3; baseline (BL) BMI 31±0.1 kg/m²; HbA_{1c} 8.4±0.03%; BL FPG 10.7±0.09 mmol/L; mean±SE). 1121 patients comprised the ITT PBO-controlled (PBO-C) population (59% M; age 55±0.3; BL BMI 33±0.2 kg/m²; HbA_{1c} 8.4±0.03%; FPG 9.9±0.09 mmol/L; mean±SE).

Results: SBP data were as follows:

For each strata of abnormal SBP (130–139 mm Hg, 140–149 mm Hg, and ≥150 mm Hg) Ex-treated patients experienced greater improvement in SBP compared to insulin or PBO-comparators. For I-C, change from BL for Ex in each strata was -3.3±1.2 mm Hg, P=0.0114; -5.9±1.1 mm Hg, P=0.0275; -16.4±1.5 mm Hg, P=0.0210, respectively, and for PBO-C, change from BL for Ex in each strata was -4.6±1.0 mm Hg, P=0.0288; -8.0±1.3 mm Hg, P=0.1201; -20.0±2.4 mm Hg, P=0.0151, respectively (P value: Ex vs. I-C or PBO-C). Significant changes in overall diastolic blood pressures (DBP) were observed in the I-C (Ex: -1.5±0.4 mm Hg, P<0.0005; PBO: -0.8±0.4 mm Hg, P=0.0481) but not the PBO-C (Ex: -0.6±0.4 mm Hg, P=0.0924; PBO: -0.4±0.4 mm Hg, P=0.3206). However, pulse pressure (PP) effects followed a similar pattern of improvement as SBP. In the abnormal SBP baseline groups, including weight change as a covariate in the analysis of covariance model showed favourable differences when Ex was compared to either insulin (-2.1 mm Hg, P=0.077) or PBO (-3.2 mm Hg, P=0.003). In patients who lost weight in each group and had abnormal SBP, Ex produced greater SBP reductions (I-C: Ex: -3.25±0.15 kg; -10.2±0.9 mm Hg vs. Insulin: -1.96±0.19 kg; -4.5±1.6 mm Hg; SBP, Ex vs. insulin, P=0.0007. PBO-C: Ex: -3.29±0.16 kg; -8.7±1.0 mm Hg vs. PBO: -2.66±0.19 kg; -6.6±1.0 mm Hg; SBP, Ex vs. PBO, P=0.0291). The percentage of patients who changed their anti-hypertensive drug regimen was similar between Ex vs. I-C and Ex vs. PBO-C. Adverse events were as previously reported, and included nausea and vomiting in Ex patients.

Conclusion: Exenatide treatment resulted in greater improvement in SBP and PP compared to insulin or PBO-treated patients. These clinically meaningful blood pressure improvements with Exenatide therapy are only partially explained by weight loss and deserve further investigation.

Netherlands, ³Lundberg Laboratory for Diabetes Research, Sahlgrenska

University Hospital, Goteborg, Sweden, ⁴Amylin Pharmaceuticals, Inc., San

Diego, United States, ⁵Eli Lilly, Nederland, Houten, Netherlands

Background and aims: Traditional blood glucose lowering agents do not sustain adequate glycaemic control in most type 2 diabetic (T2D) patients. Preclinical and clinical studies with exenatide, an incretin mimetic, have shown improvements in beta-cell function.

Materials and methods: This study compared the effect of 1-year exenatide (Ex) vs. insulin glargine (IG) treatment on beta cell function, and following a 12-week wash-out. 69 metformin treated patients with T2D (mean±SD: age 59±8y; HbA1C 7.5±0.8%; BMI 31±4kg/m²; body weight 91.5±13.1kg) were randomised to exenatide (n=36) or insulin glargine (n=33). Beta cell function was measured during a hyperglycaemic (15 mM) clamp with arginine stimulation at week 0, week 52 and after a 4-week wash-out.

Results: Following 1 year treatment both therapies reduced HbA1C similarly: by 0.8±0.1%, and 0.7±0.2% for exenatide and insulin glargine, respectively (P=0.92). After 12 weeks of wash-out, glycaemic control returned to pre-treatment values in both treatment groups. Exenatide significantly reduced body weight compared to insulin glargine (-3.6±0.8kg vs +1.0±0.8kg (P=0.0002) after 1-year intensified treatment. After cessation of exenatide, body weight trended back to pre-treatment values after 12-weeks wash-out, however a significant between group difference remained [-2.4±0.7kg (Ex) and +0.2±0.8kg (IG); P<0.0001]. Combined glucose and arginine stimulated C-peptide secretion increase in the exenatide (n=29) group by 1.46 fold (P<0.0001) greater compared to insulin glargine (n=30) and relative to pre-treatment after 1 year. The mean (±SE) AUC of the C-peptide response showed a 2.19±0.24 vs. 0.31±0.07 fold increase from pre-treatment, respectively (P<0.0001). After the 4-week wash out all clamp derived beta cell function parameters were not significantly different from pre treatment values.

Conclusion: One year of exenatide therapy, compared to insulin glargine improved indices of beta cell function, glycaemic control and body weight. Following wash-out the beneficial effects on beta cell function and glycaemic control were not sustained.

Exenatide improves postprandial hyperglycaemia and dyslipidaemia in metformin treated patients with type 2 diabetes

M.C. Bunck¹, A. Corner², M. Diamant¹, B. Eliasson³, J.L. Malloy⁴, R.M. Shaginan⁵, W. Deng⁴, D.M. Kendall⁴, U. Smith³, H. Yki-Jarvinen², R.J. Heine¹, M.R. Taskinen²

¹Department of Endocrinology / Diabetes Center, VU University Medical Center, Amsterdam, Netherlands, ²Department of Medicine, Helsinki University Hospital, Finland, ³Lundberg Laboratory for Diabetes Research, Sahlgrenska University Hospital, Goteborg, Sweden, ⁴Amylin Pharmaceuticals, Inc., San Diego, United States, ⁵Eli Lilly, Nederland, Houten, Netherlands

Background and aims: Postprandial metabolic derangements may affect cardiovascular disease risk. Current therapies do not adequately correct these disturbances in patients with type 2 diabetes (T2D).

Materials and methods: In this investigator designed study, we compared the long term effects of exenatide vs. insulin glargine treatment on the plasma glucose, insulin and lipid responses to a standardised meal. Sixty-nine metformin treated patients with T2D (age±sd 59±8yr; HbA1c 7.5±0.8%; BMI 31±4kg/m²) were randomised to exenatide (n=36) or insulin glargine (n=33). Before and after 51 weeks on treatment and again after 5 weeks off-treatment, 59 patients (exenatide: n=30; insulin glargine: n=29) received a breakfast and lunch both containing 50g of fat, 75g of carbohydrates, and 35g protein.

Results: At 1 year the incremental postprandial glucose excursion (±SE), compared to pre-treatment areas under the curve, were lower for exenatide (0.43±0.07), and remained similar for insulin glargine (1.06±0.14; P<0.0001). One year treatment with either drug reduced postprandial triglyceride excursions

from pre-treatment (±SE); for exenatide: 15399±7065.34mg*min/dL, and insulin glargine: 521.79±4147.515mg*min/dL (P=0.0155). After 1 year of treatment exenatide reduced the postprandial HDL decline compared to insulin glargine (P=0.0133). No effects on LDL and total cholesterol were observed. After the 5 week off treatment period, all postprandial measures were similar to those at pre treatment.

Conclusion: 1-year of exenatide therapy, compared to insulin glargine, lowered postprandial glucose and triglyceride excursions. These beneficial effects were not sustained 5-weeks following wash-out.

Patient views of diabetes treatment experience comparing once weekly and twice daily exenatide

K.S. Boye¹, T.H. Kim², M. Martin³, M. Wintle²

¹Eli Lilly and Company, Indianapolis, ²Amylin Pharmaceuticals, San Diego,

³Health Outcomes, Health Research Associates, Seattle, United States

Background and aims: Qualitative interviews were conducted on a subset of the population in a 52-week randomized, multicenter, open-label study (DURATION-1) of 295 subjects with Type 2 diabetes who received either a once weekly (QW) formulation of exenatide (2 mg, QW) or exenatide twice daily (10 mcg, BID).

Materials and methods: Exenatide BID subjects were switched to exenatide QW at week 30 through the remainder of their study participation. A subset of 33 subjects was enrolled in each study arm for telephone or face to face interviews. The first interviews were conducted within two weeks of enrollment and final interviews at 52 weeks. Subjects were asked to discuss their feelings about injections, treatment benefits, and treatment satisfaction. Transcript extracts were organized by like responses to compare exenatide QW and exenatide BID groups.

Results: For both the overall study and the interview subgroup, exenatide QW and exenatide BID populations were demographically similar, and the interview subgroup demonstrated comparable changes in clinical parameters as with the overall study results. 51 subjects (24 exenatide BID and 27 exenatide QW) remained in the interview sample at Week 52. When the exenatide BID group (who experienced both treatments) was asked to indicate their most beneficial change during treatment, most of the group (63%; N=15) reported it to be the convenience of a once weekly injection, followed by 25% (N=6) citing control of blood glucose. When the exenatide QW group (on exenatide QW for 52 weeks) was asked to state the most beneficial benefit during treatment, most of the group (48%; N=13) reported it to be lower blood sugar levels and 19% (N=5) reported it to be the convenience of a once weekly injection. At the week 30 interviews, 75% of the exenatide BID group and 90% of the exenatide QW group indicated that the treatment regimen was easy. By the 52 week interviews, 83% of the exenatide BID group who had switched to exenatide QW at week 30 and 96% of the exenatide QW group reported that the treatment regimen was easy. Other benefits expressed by both groups included weight loss, better eating habits, more energy and feeling better.

Conclusion: In conclusion, the majority of exenatide QW group reported their most beneficial change at 52 weeks as having their blood glucose in better control, while the exenatide BID group reported the most beneficial change was the convenience of a once weekly injection.

PS 077 Exenatide: real life clinical practice

881

Real-world six-month outcomes of patients initiating exenatide in a primary care electronic medical record database

M. Wintle¹, R. Fabunmi¹, K. Boye², C. McAdam-Marx³, X. Ye³, D. Brixner³
¹Amylin Pharmaceuticals, Inc., San Diego, ²Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, ³Pharmacotherapy, University of Utah, Salt Lake City, United States

Background and aims: This study evaluated real-world outcomes of HbA_{1c} and weight in patients with type 2 diabetes (T2DM) initiating exenatide therapy.

Materials and methods: Patients extracted from the General Electric (GE) electronic medical record (EMR) research database from January 1, 2000 through June 30, 2007 were ≥18 years old, and T2D defined by ICD-9 codes, ≥2 fasting blood glucose levels ≥7.0 mmol/L, or glycosylated hemoglobin (HbA_{1c}) over 7.0%. Patients had prescription orders in the previous 395 d for metformin (MET), a sulphonylurea (SU), or a thiazolidinedione (TZD) as monotherapy or in combination. Baseline HbA_{1c}, weight and BMI were documented 45 d prior to 15 d post-exenatide initiation and ±45 d at 6 mo post-exenatide initiation.

Results: For the 2086 patients with 6 mo of follow-up data, baseline mean (SD) HbA_{1c} was 8.4% (1.2), weight was 110.6 kg (24.9 kg), and BMI was 38.5 kg/m² (7.9). Upon initiation of exenatide, 363 (17.4%), 147 (7.1%), and 84 (4.0%) were on MET, SU, or TZD monotherapy, respectively; 524 (25.1%) and 257 (12.3%) were on MET with TZD or SU, and 711 (34.1%) were on all three. Overall HbA_{1c} change at 6mo (n=878) was -0.7%. When exenatide was added to MET, SU, or TZD monotherapy, changes were -0.9% (p<0.0001), -1.0% (p<0.0001), and -0.8% (p<0.0032), respectively. HbA_{1c} lowering ranged from -0.5% to -0.8% with multiple oral antidiabetic drugs (OADs) (p<0.0001). Overall weight loss (n=1784) was -2.8 kg (p<0.0001). In the 6 mo following addition of exenatide to prior monotherapy, 14%, 23%, and 45% of patients discontinued MET, SU, and TZD, respectively. Similar discontinuations were seen in the multiple OAD groups.

Conclusion: The average baseline HbA_{1c} (8.4%) and BMI (38.5 kg/m²) is high in this primary care T2DM population, suggesting difficulty in the real world to achieve HbA_{1c} and body weight goals. Exenatide therapy demonstrated significant reductions in HbA_{1c} and weight over 6 mo with decreases in concomitant medications.

882

Exenatide utilisation and effectiveness in a health plan population

B. Schroeder¹, D. Misurski², R. Wade³, R. Quimbo³, L. Nielsen¹, R. Fabunmi¹, M. Wintle¹

¹Amylin Pharmaceuticals, Inc., San Diego, ²Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, ³Consulting and Strategies, HealthCore, Inc., Wilmington, United States

Background and aims: Numerous clinical outcomes trials have demonstrated the benefits of achieving glycaemic goals in patients with type 2 diabetes (T2D). In controlled clinical trials, the incretin mimetic exenatide improved glycaemic control in patients with T2D; 34 to 46% of patients achieved HbA_{1c} ≤7% and mean HbA_{1c} change from baseline was -0.8 to -0.9% (baseline HbA_{1c}: 8.2 to 8.7%). To investigate the effects of exenatide in clinical practice, this retrospective cohort study used a large, US commercial health plan claims database to describe baseline characteristics, comorbidities, concomitant therapies, and clinical effectiveness in patients initiated on exenatide.

Materials and methods: A total of 4936 patients were identified having a new prescription claim for exenatide between May 1, 2005 and June 30, 2006 (first claim = index date), with ≥12 months of pre- and post-index eligibility, and ≥18 years old.

Results: Mean (±SD) age was 54±10 years (10% ≥65y; 51% female). The 12-month mean (SE) medication possession ratio (MPR = days of supply/365 days) in patients with >1 prescription claim was 66±30%. Most patients analysed (94%) were treated with at least one other antidiabetic medication at initiation (100d pre-index to 15d post-index); 23% with 1 drug, 34% with 2 drugs, and 37% with ≥3 drugs. The mean number of antidiabetic drugs (including exenatide) per patient was similar at initiation (3.08) and post-index

(3.05). Clinical effectiveness was measured in all patients with an A1C >7.0% at baseline (≤100d pre-index) and having both baseline and post-index (60-365d) A1C data available (n=201; mean baseline HbA_{1c} = 8.9±1.5%). In this cohort, 30% achieved HbA_{1c} ≤7% in the post-index period and mean HbA_{1c} change from baseline was -0.8%. In patients with an MPR >50% (n=104), 41% achieved HbA_{1c} ≤7%, and mean HbA_{1c} change from baseline was -1.1%.

Conclusion: The mean change in HbA_{1c} and percentage of patients achieving HbA_{1c} ≤7% in this real-world analysis mirrored results of controlled clinical trials. Furthermore, glycaemic improvement was achieved without a further increase in concomitant antidiabetic drugs.

883

Medication compliance and persistency in patients with type 2 diabetes initiating exenatide or insulin glargine

R. Fabunmi¹, L. Nielsen¹, R. Wade², R. Quimbo², B. Schroeder¹, M. Massoudi¹, D. Misurski³, M. Wintle¹

¹Amylin Pharmaceuticals, Inc., San Diego, ²Consulting and Strategies, HealthCore, Inc., Wilmington, ³Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, United States

Background and aims: The incretin mimetic, exenatide (EX), improves glycaemic control in patients with type 2 diabetes (T2D) and was noninferior to insulin glargine or aspart in clinical trials. In this retrospective analysis of a US commercial health plan claims database, we studied T2D patients initiating EX or insulin glargine (IG). Both drugs are injectables frequently used in T2D patients not achieving glycaemic control with oral antidiabetic medications (OAD).

Materials and methods: Patients were ≥18y with a pre-index T2D diagnosis and an initial prescription claim for EX (n=3262) or IG (n=3038) between May 1, 2005 and June 30, 2006; ≥6mo pre-index (1st claim=index date), and ≥12mo post-index data. Baseline diabetes therapies were defined as prescriptions filled 100d pre-index through 15d post-index. The EX cohort had no previous exposure to insulins and vice versa; no other insulin was started.

Results: EX: age (±SD) 53±10y; 54% female. IG: age 56±12y; 41% female. The Deyo-Charlson comorbidity index (DCI) score was 1.45 for EX vs 1.82 for IG (p<0.001). Baseline OAD for EX vs IG, respectively, were 77% vs 69% MET; 47% vs 65% SFU; 50% vs 49% TZD; 56% vs 60% multiple OAD. For patients with >1 prescription fill, 12mo medication possession ratio (MPR=days of supply/365 d) was 68±29% for EX and 58±28%, for IG (p<0.0001). The percentage of this cohort with MPR ≥80% was significantly higher for EX than for IG (47% vs 29%; p<0.0001). More patients discontinued treatment (prescription refill gap >60d) for IG than for EX (75% vs 56%; p<0.0001). The corresponding percentages for a refill gap >90d were 52% and 34%, respectively (p<0.0001).

Conclusion: This study provides the first real-world comparison of T2D patient characteristics newly initiated on EX or IG. Patients initiating EX had fewer comorbidities and fewer were treated with SFU. Compliance and persistency were generally good on both injectable drugs, but significantly better for EX.

884

Exenatide therapy in insulin treated patients with type 2 diabetes and obesity

J.P. Govindan, B. Healey, D.N. Kalupahana, B.M. Singh

The Wolverhampton Diabetes Centre, New Cross Hospital, Wolverhampton, United Kingdom

Background and aims: Those with type 2 diabetes and obesity who are on insulin therapy are a challenging clinical problem, especially so if glycaemic control is poor. This often requires up-titration of insulin doses, resulting in further weight gain. An advantage of exenatide therapy is that it improves glycaemic control with concomitant weight loss. There are very few studies of exenatide and insulin combination therapy in such patients. Our aim was to study efficacy of combined exenatide and insulin in obese type 2 diabetes (ObT2DM) patients with poor glycaemic control.

Materials and methods: The study was undertaken in an outpatient setting. In this prospective study, to date (October 2007 to February 2008), we have initiated exenatide therapy in 40 ObT2DM patients with progressive weight gain and poor glycaemic control. According to a set protocol, the patients were to have regular follow up over a 6 month period; exenatide was initiated at 5 µgm bi daily, maximized to 10 µgm bi daily at four weeks; total insulin

doses were halved at initiation; further dose down-adjustment occurred according to self blood glucose monitoring but every effort was made to not increase insulin doses to the 3 month point so long as glycaemic control was safe. The study evaluated the following parameters: HbA_{1c}, weight, insulin requirement, side effects and tolerability.

Results: We present the results of 27 patients who have completed three months treatment. Three patients were withdrawn from the study due to intolerable gastrointestinal side effects. The 24 patients remaining were aged 54 (41–65) years and 19 (80%) were males. The baseline weight (mean±SD) was 128±15 kg which decreased to 115±14 kg at three months ($P<0.001$), a weight loss of 8.7±4.9 kg (range 2.8–28 kg). Body mass index fell from 43.0±4.7 kg/m² to 39.8±4.5 kg/m² ($P<0.001$). HbA_{1c} at baseline 8.8±1.7% showed no change at three months being 8.5±1.7% ($P=0.23$). Total daily insulin doses at baseline was 170±94 U/day (range 48–420) fell drastically to 36±40 U/day ($P<0.001$). Of the 24 patients, insulin was completely stopped in 10 patients and in the remaining 14 the doses ranged between 10–120 U/day. In addition to the 3 discontinued, 10 patients had mild nausea which improved with time. There were no episodes of significant hypoglycemia.

Conclusion: Exenatide can be used effectively in obese type 2 diabetes patients established on insulin therapy leading to significant weight loss and reduction in insulin dosage requirements but with no improvement in glycaemic control. It is expected that either glycaemic control will improve as weight loss progresses or that insulin will require up titration.

885

The short term effects of exenatide therapy in insulin treated patients with type 2 diabetes mellitus - a new option to achieve weight loss

Y.P. Samarasinghe, A. Shlomowitz, N. Munro, M.D. Feher
Beta Cell Diabetes Centre, Chelsea and Westminster Hospital, London, United Kingdom

Background and aims: Exenatide is the first drug in the class of glucagon like peptide-1 (GLP-1) analogues. Through nutrient mediated release in the small intestine Exenatide induces glucose dependent insulin secretion. It also slows gastric emptying and produces satiety through hypothalamic pathways. Weight loss has been consistently reported with Exenatide in key licensing trials. Exenatide is licensed in the UK for combination therapy with metformin and/or sulphonylurea. It is not yet licensed for treatment with thiazolidinediones or insulin. Weight gain is often seen in insulin treated patients with T2DM. This additional weight may adversely affect other vascular risk factors including hypertension and dyslipidaemia and thus worsen overall cardiovascular risk. We undertook an audit to ascertain the effects of Exenatide therapy in insulin treated T2DM to establish the effects of this treatment on weight and diabetes control.

Materials and methods: This audit was conducted in a central London teaching hospital in a dedicated diabetes centre. All patients commenced on Exenatide in outpatients were entered into a database and over a maximum three month period followed up closely by diabetes specialist nurses and doctors in the clinic. Regular assessments of the patients were made looking for adverse effects of the drug, glycaemic control and changes in weight. All changes were documented on a spreadsheet from which we obtained our analysis.

Results: 71 patients who had been commenced on Exenatide and had at least one follow up visit were analysed. 23 of these patients had been on insulin (mean(SD) dose 69.0(62.1)units) prior to commencing the Exenatide. Median(range) age of this group was 58(41–73)years. Median(range) duration of diabetes was 18.1(4–53)years. 8 of these patients had their insulin withdrawn and 9 had it decreased on starting Exenatide (5 remained on the same dose and 1 increased). In the group that stopped insulin, 6 had to have it restarted (but with a lower mean(SD) starting dose of 55.7(63.5)units), 3 because of poor glycaemic control and 3 due to Exenatide intolerance. Mean(SD) weight and HbA_{1c} at the start of treatment of insulin treated patients who tolerated the Exenatide were 106.6(13.9)kg and 9.2(1.6)%. After a mean of 6 weeks follow up mean(SD) weight reduced by 2.2(2.5)kg and at 3months 1.7(1.1)kg. There was however no change in HbA_{1c} at 3 months (0.0(1.0)%). Duration of diabetes did not predetermine whether Exenatide would be effective as patients above the median duration of diabetes also achieved the same weight reduction without losing glycaemic control at 3months (1.2(0.8)kg and 0.0(0.4)% respectively).

Conclusion: There now appears to be a choice of therapy for weight reduction in insulin treated T2DM patients. Many patients can be safely treated with Exenatide without deterioration in their glycaemic control and with the added benefit of weight loss. In the short term insulin may be withdrawn or have a reduction in dose requirement. Even in those individuals where insulin was recommenced, there was a reduction in the total daily dose which may have lessened the insulin associated weight gain. Intolerance of Exenatide in a clinic based setting does not seem to be any greater than in previous clinical trials. Individuals with a long history of T2DM may also benefit from Exenatide therapy.

886

Metabolic improvement associated with temporal pattern of weight loss in exenatide-treated patients with type 2 diabetes

D. Kendall¹, L. Nielsen¹, J. Han¹, R. Brodows², D. Bhole¹

¹Amylin Pharmaceuticals, Inc., San Diego, ²Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, United States

Background and aims: Exenatide (EX) therapy improves glycaemic control and cardiometabolic risk factors in patients with type 2 diabetes. In clinical trials, EX reduced body weight (BW) in the majority of patients. However, the temporal pattern of weight loss was not fully examined.

Materials and methods: This post hoc analysis studies the specific impact of the pattern of BW change on glycaemic control and other metabolic risk factors during 2y of continuous EX therapy. We analysed a pooled database of patients treated with EX in combination with ±MET±SU±TZD for 2y (n=457). Patients were stratified into 3 cohorts based on the pattern of BW change during treatment: Early (>3% BW loss by Wk12, not regained); Late (>3% BW loss after Wk12); and Neutral (<3% BW loss).

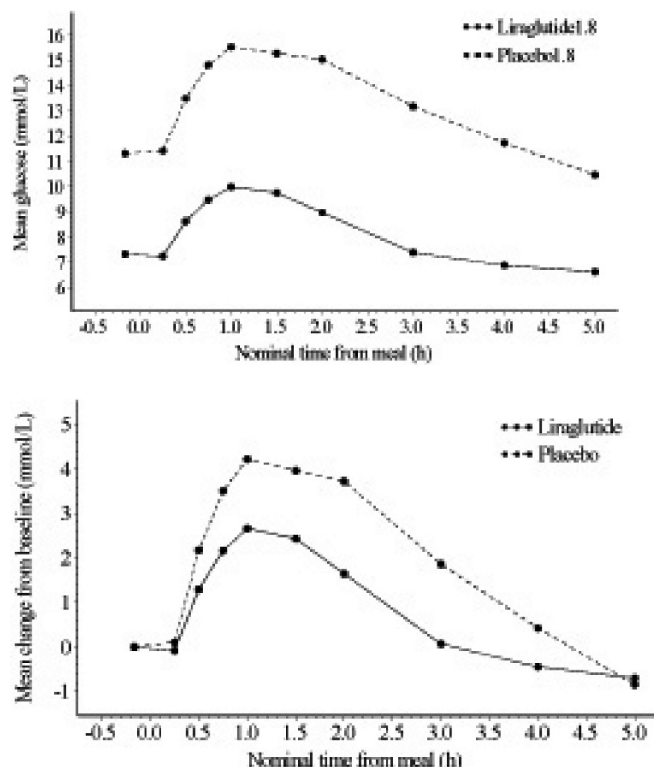

Results: Demographic characteristics were similar across cohorts (age 55–58y; BMI 31–34kg/m²). BW and HbA_{1c} changes are shown below. Similar results were observed when stratifying by 3% or 5% BW loss in patients treated with EX from 1 to 3.5y.

Two Year Completers Stratified by 3% Weight Loss

These data demonstrate that consistent BW loss was observed in a majority (80%) of patients continuously treated with EX for 2y. While one third (34%) of EX-treated patients lost greater than 3% BW during the first 12 wks of therapy, an additional 46% had more gradual BW loss. Yet both groups achieved BW reductions of ~5% over 2y and similar improvements in metabolic control. The neutral cohort also had significant HbA_{1c} reduction. EX therapy was associated with improvements in HDL-C, LDL-C, and triglycerides (TG), with larger reductions in TG in patients who achieved BW loss early.

Conclusion: Either early or later weight loss are observed in the majority of EX-treated patients, and this weight loss further enhances improvements in metabolic control.

PS 078 Liraglutide

The once-daily human GLP-1 analogue liraglutide improves both absolute and baseline corrected postprandial glucose levels

A. Flint¹, C. Kapitza², C. Hindsberger¹, M. Zdravkovic¹

¹Global Development, Novo Nordisk A/S, Bagsvaerd, Denmark, ²Profil Institut für Stoffwechselforschung GmbH, Neuss, Germany

Background and aims: GLP-1 is known to slow gastric emptying and decrease postprandial glucose. This sub-study investigated the effect of the once-daily human GLP-1 analogue, liraglutide, on postprandial glucose, insulin and gastric emptying during a standard meal test.

Materials and methods: The trial was a randomised, placebo controlled, double-blind cross-over trial. Eighteen subjects with type 2 diabetes (diet treated or OAD monotherapy, mean HbA_{1c} 7.8 ± 0.6%) were enrolled. The dose of liraglutide was increased weekly by 0.6 mg to 1.8 mg/day (duration of each treatment period: 3 weeks) and meal tests were performed at each dose level. Before and after an energy fixed meal including 1.5 g paracetamol, blood samples for measurement of plasma glucose, insulin and paracetamol (gastric emptying) were drawn.

Results: At the highest dose tested, there was a significant lowering of fasting and peak postprandial glucose concentrations, together with a significant reduction in the incremental postprandial glycemic levels (on average 1.1 mmol/L, see Figure). In spite of a lower glucose level, this was associated with a higher fasting and total insulin response compared to placebo. At the highest dose tested paracetamol kinetics was compatible with an early delay in gastric emptying (AUC_{0-60min}), but no significant effect on AUC_{0-300min}.

Figure: Mean absolute (left) and baseline corrected (right) postprandial plasma glucose concentrations after 1.8 mg/day of liraglutide

Conclusion: Liraglutide 1.8 mg/day improves not only fasting glucose levels, but also confers improvement in both absolute and incremental postprandial glucose levels. Based on this study, the postprandial effects on glycemic control of liraglutide, are most likely mediated through a combination of increased insulin secretion together with an early delay in gastric emptying.

888

Liraglutide, a human GLP-1 analogue, reduces bodyweight in subjects with type 2 diabetes, irrespective of body mass index at baseline

O. Schmitz¹, D. Russell-Jones², J. Shaw³, M. Brandle⁴, D. Matthews⁵, A. Frid⁶, M. Zdravkovic⁷, A. Garber⁸, B. Zinman⁹

¹Department of Endocrinology and Diabetes, University of Aarhus, Denmark, ²Endocrinology & Metabolism, Royal Surrey County Hospital, Guildford, United Kingdom, ³International Diabetes Institute, Melbourne, Australia, ⁴Endocrinology, Kantonsspital, St Gallen, Switzerland, ⁵OCDEM, University of Oxford, United Kingdom, ⁶Endocrinology, Öresund Diabetes Team AB, Lund, Sweden, ⁷Novo Nordisk A/S, Bagsvaerd, Denmark, ⁸Baylor College of Medicine, Methodist Hospital, Houston, United States, ⁹Sinai Centre for Diabetes, Mount Sinai Hospital, Toronto, Canada

Background and aims: Oral antidiabetic drugs (OADs) prescribed for the treatment of subjects with type 2 diabetes are often associated with weight gain.

Material and methods: This analysis examined the impact of baseline body mass index (BMI) on responses to liraglutide, the investigational once-daily human glucagon-like peptide (GLP)-1 analogue, added to various oral therapies. Mean (SE) changes in bodyweight (BW) from baseline to end-of-trial

	Trial				
	LEAD-1	LEAD-2	LEAD-3	LEAD-4	LEAD-5
Subjects (n)	695	725	746	543	232
Concomitant OADs	glimepiride 2-4 mg	metformin 2 g	–	metformin 2 g + rosiglitazone 8 mg	metformin 2 g + glimepiride 2-4 mg
Baseline HbA _{1c} (% mean)	8.4	8.3	8.3	8.3	8.6
Baseline BW (kg, mean)	81.9	88.1	92.6	96.3	85.5
ΔBW (mean, kg) with liraglutide					
BMI > 35 kg/m ²	–0.7	–4.4	–3.0	–3.0	–2.9
30 ≤ BMI < 35 kg/m ²	–0.5	–3.0	–2.4	–1.9	–1.8
25 ≤ BMI < 30 kg/m ²	–0.4	–2.7	–2.1	–1.9	–1.6
BMI < 25 kg/m ²	–0.1	–1.5	–1.2	–2.5	–1.3

from four 26-week, and one 52-week phase 3 clinical trials (the Liraglutide Effect and Action in Diabetes [LEAD] studies) were divided according to screening BMI (<25, ≥25 to <30, ≥30 to <35, ≥35 kg/m²).

Results: In LEAD-1 approximately one-third of subjects were either slimmer Asians, and/or had previous metformin treatment discontinued at trial entry. Thus lower baseline weight, removal of metformin and addition of sulphonylureas (SU) could explain the absence of weight loss in that trial (Table 1). All BMI sub-groups experienced weight loss with liraglutide, with the greatest decrease in BW occurring in subjects with BMI ≥35 kg/m². In each sub-group, liraglutide + metformin (LEAD-2) produced a greater decrease in BW than liraglutide + glimepiride (LEAD-1), liraglutide monotherapy (LEAD-3), liraglutide + metformin + rosiglitazone (LEAD-4), or liraglutide + metformin + glimepiride (LEAD-5), except for the group with pre-trial BMI <25 kg/m², in which liraglutide + metformin + rosiglitazone had the greatest effect.

Conclusion: Liraglutide added to OADs results in significant weight loss in subjects with type 2 diabetes, especially those with a high baseline BMI.

889

Effects of the once-daily human GLP-1 analogue liraglutide on appetite and energy intake in type 2 diabetes

M. Horowitz¹, A. Flint², S. Doran¹, M.F. Rasmussen², C. Kapitza³, A.H. Andreasen², K.L. Jones¹, M. Zdravkovic², I.M. Chapman¹

¹Discipline of Medicine, University of Adelaide, Australia, ²Novo Nordisk A/S, Bagsvaerd, Denmark, ³Profil Institut für Stoffwechselforschung GmbH, Neuss, Germany

Background and aims: Exogenous GLP-1 decreases appetite and energy intake. The aims of this study were to assess the effect of the once daily GLP-1 analogue, liraglutide, compared with glimepiride and placebo, on appetite, energy intake and meal duration at an *ad libitum* buffet meal and gastric emptying in type 2 diabetes.

Materials and methods: This trial was a double-dummy, randomised, double-blind two-centre study with a balanced, incomplete latin square design. Placebo and glimepiride were used as comparators. Forty-six subjects with type 2 diabetes (mean HbA_{1c} 7.4%) treated by diet or oral antidiabetic drug monotherapy, were enrolled. The dose of liraglutide was increased weekly by 0.6 mg to 1.8 mg/day. Subjects were studied on two test days after two weeks' treatment at the highest liraglutide/glimepiride/placebo dose level. On Day 1 a yoghurt preload (250 kcal ~ 1047 kJ), including 1.0 g paracetamol, was consumed, followed by a buffet meal one hour later. Gastric distension (by antral ultrasonography), gastric emptying (by plasma paracetamol concentrations), energy intake and its macronutrient distribution, duration of eating and sensations of appetite (hunger, fullness and satiety) and nausea (by visual analogue scales) were measured. On Day 2 resting energy expenditure was measured (by indirect calorimetry) before a buffet meal and energy intake, duration of eating and perceptions of appetite and nausea were measured again. Body weight was measured before and after each of the two treatment periods.

Results: The estimated reduction in *ad libitum* energy intake was 9% to 15% after liraglutide treatment compared to both placebo and glimepiride (NS) (meal with preload, estimated ratios: 0.91, 95% CI [0.78; 1.06] and 0.91, 95% CI [0.78; 1.07]; meal without preload, estimated ratios: 0.91 [0.76; 1.09] and 0.85 [0.70; 1.03]). The energy intake was on average 3–4 MJ. At the meal with a preload the duration of eating was 4.3 minutes 95% CI [1.7; 6.9] less after liraglutide compared to placebo (P=0.002). Fasting hunger was lower after liraglutide compared to placebo or glimepiride on both days, however only

significant on Day 2 (Day 1: P=0.117 and Day 2: P<0.001). The AUC_{0–300min} (estimated ratio 0.88, 95% CI [0.80; 0.96]) and C_{max} (estimated ratio 0.80, 95% CI [0.72; 0.89]) for paracetamol were significantly lower after liraglutide compared to placebo. Resting energy expenditure tended to be higher (not significantly) after liraglutide treatment compared to placebo and glimepiride (by 576 kJ and 270 kJ). There were no treatment differences with respect to macronutrient composition, antral area or nausea (low ratings reported throughout). A significant weight loss of 1–2 kg was observed after liraglutide treatment compared to placebo and glimepiride (estimated differences -1.31 kg, 95% CI [-2.06; -0.56] and -2.02 kg, 95% CI [-2.79; -1.24]).

Conclusion: In subjects with type 2 diabetes, four weeks' treatment with liraglutide decreased hunger, slowed gastric emptying and reduced body weight by 1–2 kg. Treatment with liraglutide was also associated with a non-significant reduction in energy intake and a non-significant increase in resting energy expenditure.

890

The effect of liraglutide on the absorption pharmacokinetics of concomitant oral drugs with different solubility and permeability properties in healthy subjects

M. Zdravkovic¹, M. Ekblom¹, L. Brøndsted¹, J. Vouis², H. Lennernäs³, M. Malm-Erjefält¹

¹Novo Nordisk A/S, Bagsvaerd, Denmark, ²Phase 1 Services, Quintiles AB, Uppsala, Sweden, ³Department of Pharmacy, Uppsala University, Sweden

Background and aims: Liraglutide is a once-daily human GLP-1 analogue under development for the treatment of type 2 diabetes. It causes a minor delay in gastric emptying and hence may potentially change the absorption pattern of concomitant oral drugs. In particular, drugs with low solubility may increase their dissolution if retained in the stomach for a prolonged period and thus have the potential to show increased exposure (AUC) and C_{max}, and a delay in t_{max}. In this trial, the effect of liraglutide on the absorption pharmacokinetics of four drugs with different solubility (S) and permeability (P) characteristics was investigated in a randomised, double-blind, two-period crossover trial. The four oral drugs were selected based on the Biopharmaceutical Classification System (BCS).

Materials and methods: This trial was conducted in two parts. In part A, single doses of 40 mg atorvastatin and 500 mg griseofulvin (Class II drugs; high S & low P) were given to healthy subjects (n=42). In part B, separate subjects (n=28) received single doses of 20 mg lisinopril (Class III drug; low S & high P) and 1 mg digoxin (Class IV drug; low S & P). The doses were given in each crossover period, separated by a wash-out period of 9 days, and the dosing times ensured the absorption peaks to correspond with the expected C_{max} of 1.8 mg liraglutide at steady state. Blood was collected up to 60–72 h after dosing and analysed for respective drug. For AUC and C_{max}, equivalence was declared if the 90% CI of the liraglutide/placebo ratio was within [0.80; 1.25].

Results: During liraglutide treatment, the AUCs of griseofulvin and atorvastatin were equivalent to that after placebo treatment while the AUCs of lisinopril and digoxin (AUC_{0–72}) decreased by 15% and 16%, respectively. Moreover, C_{max} for atorvastatin, lisinopril and digoxin were decreased by 38%, 27% and 31% while C_{max} for griseofulvin was increased by 37%. In addition, griseofulvin t_{max} was not affected by liraglutide treatment, while t_{max} for atorvastatin, lisinopril and digoxin were delayed by 1.25 h, 2.00 h and 1.12 h. The unchanged overall exposure of both griseofulvin and atorvastatin support that liraglutide only induced a slight delay in gastric emptying which did not enhance the overall dissolution and absorption of the drugs to any major extent. The decreased C_{max} for atorvastatin was most likely an effect of the delayed gastric emptying since the absorption is normally very rapid from the small intestine. The lower C_{max} and delayed t_{max} for lisinopril and digoxin was in accordance with a slight delay in gastric emptying induced by liraglutide. The minor decrease in plasma AUC for lisinopril and digoxin suggested that the extent of absorption was not affected to any major degree.

Conclusion: The liraglutide-induced shift in the absorption kinetics of the oral drugs followed the expected kinetics according to the individual drugs absorption properties and supported the presence of a slight delay in gastric emptying. However, based on the drugs exposure levels the changes in absorption kinetics were considered minor and with no clinical significance. Further, a similar absorption pattern would be expected for other concomitantly taken BCS Class II, III and IV drugs.

891

Metabolism and excretion of the once-daily human GLP-1 analogue liraglutide in healthy subject and its *in vitro* degradation by dipeptidyl peptidase IV and neutral endopeptidase

I. Bjørnsdottir¹, A. Olsen¹, U. Larsen², H. Helleberg¹, J. Vanggaard¹, B. Oosterhuis³, J. van Lier³, M. Zdravkovic⁴, M. Malm-Erfjelt⁴

¹DMPK, Novo Nordisk A/S, Måløv, Denmark, ²Isotope Chemistry, Novo Nordisk A/S, Måløv, Denmark, ³Clinical Research, PRA Int., Zuidlaren, Netherlands, ⁴GLP-1 Development, Novo Nordisk A/S, Bagsvaerd, Denmark.

Background and aims: Liraglutide is a once-daily human GLP-1 analogue in clinical development for the treatment of type 2 diabetes. The present study investigated the elimination pathways of liraglutide and its metabolite profiles in plasma and excreta in humans. Furthermore, the *in vitro* degradation of liraglutide and GLP-1 by dipeptidyl peptidase IV (DPP-IV) and neutral endopeptidases (NEP) was studied to identify liraglutide metabolites and investigate if these could be related to the metabolites found in human plasma and to those of native GLP-1.

Materials and methods: Seven healthy males received a single dose of [³H]-liraglutide (0.75mg/385μCi). Blood, urine and faeces were sampled up to 14 days post dose and the recovered radioactivity measured by liquid scintillation counting and metabolites profiled by HPLC and radiochromatography. [³H]-liraglutide was incubated *in vitro* for 4, 8 and 24h, and [³H]-GLP-1 for 0.5, 1 and 2h, with DPP-IV and NEP. Liraglutide metabolites were identified by liquid chromatography and mass spectrometry and compared to the GLP-1 metabolites reported in the literature. The *in vitro* liraglutide and GLP-1 metabolite profiles, from incubation with DPP-IV and NEP, were compared to the metabolite profile observed in human plasma.

Results: The cumulative recovery of total radioactivity in urine and faeces was 20% and 6%, respectively. The majority of the radioactivity excreted in urine was suggested to be tritiated water since the total recovered radioactivity in freeze-dried samples was only 6% in urine and 5% in faeces. Three minor liraglutide-related metabolites were excreted in urine and faeces, respectively, during the first 6–8 days post dose but no intact liraglutide was detected. In plasma, intact liraglutide accounted for ≥ 89% of the total radioactivity exposure (AUC_{0–24}). Simultaneously, two minor metabolites were detected (representing ≤9% and ≤5% of total plasma radioactivity). Liraglutide was cleaved by DPP-IV exclusively in the Ala₈-Glu₃ position of the N-terminal of the peptide moiety, while NEP extensively degraded liraglutide into 11 different metabolites. Both DPP-IV and NEP cleaved liraglutide at a much slower rate than observed for GLP-1. The cleavage sites of the observed *in vitro* liraglutide metabolites correlated well with the cleavage sites reported for native GLP-1. Furthermore, the chromatographic retention time of the primary human plasma metabolite correlated well with that of DPP-IV truncated liraglutide. However, both plasma metabolites eluted also very close to metabolites formed by NEP.

Conclusion: Liraglutide is metabolised *in vitro* by DPP-IV and NEP in a similar manner to native GLP-1 although at a much slower rate. The metabolite profiles suggest involvement of DPP-IV, and most likely NEP, also for degradation of liraglutide *in vivo* in human. Further, the low levels of metabolites

in plasma, urine, and faeces and the lack of excreted intact liraglutide support that liraglutide is fully degraded within the body.

892

Liraglutide, a human GLP-1 analogue, significantly improves beta cell function in subjects with type 2 diabetes

D.R. Matthews¹, M. Marre², T.D. Le-Thi³, M. Zdravkovic³, R. Simo⁴, A. Garber⁵, B. Zinman⁶

¹The Oxford Centre for Diabetes Endocrinology & Metabolism, United Kingdom, ²Service d'Endocrinologie-Diabétologie, Groupe Hospitalier Bichat - Claude Bernard, Paris, France, ³Novo Nordisk A/S, Bagsvaerd, Denmark, ⁴Endocrinology, Vall d'Hebron University Hospital, Barcelona, Spain, ⁵Baylor College of Medicine, Methodist Hospital, Houston, United States, ⁶Sinai Centre for Diabetes, Mount Sinai Hospital, Toronto, Canada

Background and aims: Type 2 diabetes is associated with a reduced β-cell function and liraglutide, a once-daily human GLP-1 analogue, has been shown to increase β-cell function. This analysis examined the impact of liraglutide treatment on β-cell function in subjects with type 2 diabetes from four 26-week trials and one 52-week trial from the LEAD (Liraglutide Effect and Action in Diabetes) studies.

Materials and methods: The trials were randomised, double-blind, placebo controlled trials. Baseline data and results are presented in Table 1 for the highest dose of liraglutide (1.8 mg). In the trials, liraglutide was used as monotherapy, or added to OADs, or to metformin (met) 2 g and/or glimepiride 4 mg. The comparators and background therapies are shown in Table 1.

Results: An increase in homeostasis model assessment (HOMA) β-cell function (between 28% and 34% from baseline, vs comparator) was demonstrated with 1.8 mg liraglutide in four of the five trials, and the changes were significant versus either comparator or background. The pro-insulin/insulin ratio decreased with liraglutide in all trials (between 0.05 and 0.12 from baseline) and the difference was significant in all trials versus the comparator (not applicable for LEAD 3), and also when compared to background therapy in LEAD 1.

Conclusion: Based on these data, liraglutide significantly improved β-cell function. However, further studies are needed to evaluate whether this will lead to delay of progression of type 2 diabetes.

pathogenesis of atherosclerosis. Accelerated atherosclerosis is a major contributor to morbidity and mortality in type 2 diabetes. Hyperglycemia induces expression of PAI-1 and vascular adhesion molecules including VCAM-1, ICAM-1 and E-Selectin. Liraglutide is a once daily human glucagon-like peptide-1 (GLP-1) analogue. Liraglutide improves glycaemic control and lowers body weight in subjects with type 2 diabetes.

Our study aimed to explore the *in vitro* effect of liraglutide on vascular endothelial cell (EC) expression of PAI-1, VCAM-1, ICAM-1 and E-Selectin under high glucose conditions in the C11-STH human vascular EC system.

Methods: PAI-1 protein levels were assayed in conditioned medium using ELISA kits (Biopool) whilst Reverse Transcriptase (RT) PCR was used to determine PAI-1, VCAM-1, ICAM-1 and E-Selectin mRNA expression in C11-STH vascular EC.

Results: Exposure to 10mM glucose over 48 hrs resulted in a 60% increase in PAI-1 mRNA expression ($n=3$, $p<0.05$). In addition PAI-1 protein expression was increased 50% when exposed to 10mM glucose over 48 hrs ($n=3$, $p<0.05$). Exposure to 10mM glucose over 48 hrs increased VCAM-1 and ICAM-1 mRNA expression by 80% ($n=3$, $p<0.01$) and 60% ($n=3$, $p<0.05$) respectively. Exposure to 20mM glucose over 48 hrs increased VCAM-1 and ICAM-1 mRNA expression by 90% ($n=3$, $p<0.001$) and 80% ($n=3$, $p<0.001$) respectively. A non-significant trend to induction of E-Selectin mRNA expression was observed in response to 10 or 20mM glucose exposure over 48hrs. Earlier time points demonstrated no significant increase in PAI-1, VCAM-1, ICAM-1 and E-Selectin expression in response to high glucose exposure. Addition of liraglutide (100nM), at 5.5 mM glucose, did not affect basal expression of PAI-1, VCAM-1, ICAM-1 and E-Selectin at any time point. Addition of liraglutide (100nM), at the time of exposure to 10mM glucose, inhibited glucose-mediated induction of PAI-1 mRNA and protein by 90% at 48 hrs ($n=3$, $p<0.05$). Addition of liraglutide (100nM) completely inhibited 10mM or 20mM glucose-mediated induction of VCAM-1 and ICAM-1 mRNA ($n=3$, $p<0.05$) at 48 hrs.

Conclusion: Liraglutide inhibited glucose-mediated induction of PAI-1 and the vascular adhesion molecules VCAM-1 and ICAM-1 in our human cell system. These results indicate a potential role for liraglutide in inhibition of endothelial cell dysfunction in type 2 diabetes.

Patient reported outcomes in subjects with type 2 diabetes treated with monotherapy regimens of once-daily human GLP-1 analogue liraglutide or glimepiride

B.W. Bode¹, P.M. Hale², M. Hammer³, M.A. Testa⁴, A. Garber⁵

¹Endocrinology, Atlanta Diabetes Associates, Atlanta, United States, ²Novo Nordisk Inc, Princeton, United States, ³Novo Nordisk A/S, Bagsvaerd, Denmark, ⁴Biostatistics, Harvard School of Public Health, Boston, United States, ⁵Endocrinology, Baylor College of Medicine, Houston, United States

Background and aims: Improved glycemic control, weight loss and reduced risk of hypoglycemia may improve the Health-Related Quality of Life (HR-QOL) in subjects with T2DM. Liraglutide, a once daily GLP-1 analog, improves glycemic control, has a low risk of hypoglycemia, and can result in weight loss. Patient Reported Outcomes (PRO) were assessed to establish whether treatment with liraglutide has an effect on HRQOL.

Materials and methods: In this 52-week, double dummy, placebo-controlled, blinded trial, 746 subjects were randomized to either once-daily liraglutide monotherapy [1.2 mg ($n=251$) or 1.8 mg ($n=247$)] or glimepiride monotherapy [active control, 8 mg/day ($n=248$)] to investigate changes in glycemic control, weight, body composition and PROs in subjects with T2DM previously treated with lifestyle or oral monotherapy. A self-administered questionnaire (77 items) assessed general perceived health, mental and emotional health, cognitive functioning, overall quality of life (QOL), weight image, weight concern, body size and body distress, and was completed at baseline and weeks 28 and 52. Age and baseline-adjusted treatment means were compared in 732 subjects using linear mixed models. The relationships among baseline to endpoint changes in HbA1c, BMI and PRO scales were assessed using Pearson's correlation coefficient.

Results: Subjects were 50% male, with baseline mean \pm SD HbA1c $8.2\pm1.1\%$ and BMI 33.1 ± 5.8 kg/m². Decreases in HbA1c (mean \pm SE) were greater for 1.2 mg [$-0.73\pm0.09\%$, $P=0.013$] and 1.8 mg [$-1.00\pm0.08\%$, $P<0.001$] liraglutide doses compared to glimepiride [$-0.44\pm0.08\%$]. BMI increased significantly for glimepiride [0.39 ± 0.09 kg/m², $P<0.001$], decreased for 1.2 mg [-0.73 ± 0.09 kg/m², $P<0.001$] and 1.8 mg [-0.85 ± 0.09 kg/m², $P<0.001$] liraglutide doses, and liraglutide changes were different from glimepiride ($P<0.001$).

Pooling all groups, decreases in BMI were associated with improvements in weight image and decreases in weight concern ($r=0.19$ and 0.25 , both $P<0.0001$). Decreases in weight concern were associated with increases in overall QOL ($r=-0.16$, $P<0.0001$), general perceived health ($r=-0.19$, $P<0.0001$) and mental and emotional health ($r=-0.12$, $P=0.002$). Decreases in HbA1c correlated with increases in general perceived health ($r=-0.14$, $P=0.0002$).

Conclusion: Treatment with either 1.2 mg or 1.8 mg liraglutide provided superior glycemic control as compared to glimepiride, and both doses resulted in significant decreases in BMI. For 1.8 mg liraglutide, the superior efficacy and positive impact on weight and weight concern were associated with clinically important improvements in physical and emotional domains of quality of life.

Patient Reported Outcomes Scale ¹	Baseline Covariate Score (N = 732)	Glimepiride 8 mg/day Mean (SE)	Liraglutide 1.2 mg/day Mean (SE) ²	Liraglutide 1.8 mg/day Mean (SE) ²

Liraglutide, a once-daily human GLP-1 analogue, in type 2 diabetes provides similar glycaemic control with reduced body weight compared with glimepiride when added to metformin

K. Hermansen¹, M.A. Nauck², A. Frid³, N.S. Shah⁴, T. Tankova⁵, I.H. Mitha⁶, M. Düring⁷, M. Zdravkovic⁸, D. Matthews⁸

¹Endocrinology and Metabolism, Aarhus University Hospital, Denmark, ²Diabeteszentrum, Bad Lauterberg im Harz, Germany, ³Öresund Diabetes Team AB, Lund, Sweden, ⁴Seth G.S. Medical College and KEM Hospital, Mumbai, India, ⁵Medical University, Clinic of Diabetology, Sofia, Bulgaria, ⁶BenMed Hospital, Benoni, South Africa, ⁷Statistics, Novo Nordisk A/S, Bagsvaerd, Denmark, ⁸OCDEM, University of Oxford, United Kingdom

Background and aims: This placebo-controlled, double-blind, randomised 26-week trial investigated the effect on glycaemic control (HbA_{1c}) of three liraglutide doses (0.6, 1.2 or 1.8 mg, subcutaneous; sc, once daily; OD) added to metformin (met; 1 g twice daily; BD) compared with metformin monotherapy (placebo + metformin) or glimepiride (4 mg OD) added to metformin (glimepiride + metformin).

Materials and methods: The trial included 1091 subjects with type 2 diabetes previously treated with oral antidiabetic drug (OAD) monotherapy (35%) or combination therapy (65%), with mean±SD baseline HbA_{1c} 8.4±1.0% and body weight (BW) 88.6±17.3 kg.

Results: HbA_{1c} was significantly reduced in all liraglutide groups vs placebo + metformin. Reduction in HbA_{1c} was greater in subjects previously treated with OAD mono vs combination therapy. The fraction of subjects achieving HbA_{1c} <7.0% or ≤6.5% was significantly higher in liraglutide + metformin vs placebo + metformin, with no difference between liraglutide + metformin vs glimepiride + metformin. Change in fasting plasma glucose followed the same pattern as for HbA_{1c}. BW decreased significantly in all liraglutide groups vs glimepiride + metformin. Reduction in BW was significantly greater in liraglutide 1.2 mg + metformin and liraglutide 1.8 mg + metformin vs placebo + metformin. Presence of liraglutide antibodies was 0–4% (only subjects not entering the extension phase of the study were included, n=25–32). Minor hypoglycaemia (<3.1 ml/L) occurred in <4% of subjects in liraglutide + met-

formin and placebo + metformin, and in 16.9% in glimepiride + metformin. There was no major hypoglycaemia. The most common adverse events in liraglutide + metformin were gastrointestinal disorders (mainly nausea). Nausea initially occurred in 6–12% of subjects in liraglutide + metformin, declining to placebo + metformin levels (2%) after 8–16 weeks of treatment.

Conclusion: Liraglutide was well tolerated, produced a clinically significant reduction in HbA_{1c}, and in contrast to glimepiride + metformin resulted in few hypoglycaemic episodes and weight loss in subjects with type 2 diabetes. Supported by: Novo Nordisk A/S

896

Significantly better glycaemic control and weight reduction with liraglutide, a once-daily human GLP-1 analogue, compared with glimepiride: all as monotherapy in type 2 diabetes

tide groups reached $HbA_{1c} \leq 6.5$ and $<7.0\%$ ($p < 0.01$ vs. glimepiride). In addition, the decrease in HbA_{1c} with liraglutide 1.8 mg was significantly greater than the decrease with liraglutide 1.2 mg ($p = 0.0046$). At the end of the study, there was significant weight decrease in the liraglutide groups, as compared to weight gain in the glimepiride group. The most common adverse events in the liraglutide groups were gastrointestinal disorders (mainly nausea). Nausea occurred in approximately 29% of subjects in the liraglutide groups, but was transient. The rates of minor hypoglycaemic episodes (<3.1 mmol/L) were significantly lower for the liraglutide groups, vs. glimepiride. No subjects reported major hypoglycaemic events.

Conclusion: Liraglutide monotherapy significantly lowered HbA_{1c} versus glimepiride and, at the same time, resulted in weight loss and lower rates of hypoglycaemia.

Liraglutide added to a sulphonylurea (SU) offers significantly better glycaemic control and favourable weight change compared with rosiglitazone and SU combination therapy in T2D

M. Marre¹, J. Shaw², M. Brandle³, W.M. Wan Bebakar⁴, N.A. Kamaruddin⁵, J. Strand⁶, M. Zdravkovic⁷, T.D. Le-Thi⁸, S. Colagiuri⁹

¹Groupe Hospitalier Bichat - Claude Bernard, Service d'Endocrinologie-Diabetologie, Paris, France, ²International Diabetes Institute, Melbourne, Australia, ³Endocrinology, Kantonsspital St Gallen, Switzerland, ⁴Endocrinology, Universiti Sains Malaysia, Kelantan, Malaysia, ⁵Hospital Universiti Kebangsaan Malaysia, Kuala Lumpur, Malaysia, ⁶Oulun Diakonissalaitos, Oulu, Finland, ⁷Novo Nordisk A/S, Bagsvaerd, Denmark, ⁸Novo Nordisk A/S, Bagsvaerd, Denmark, ⁹Metabolic Health, University of Sydney, Australia

Background and aims: This placebo-controlled 26-week, double-dummy, randomised, parallel group study investigated the effect on glycaemic control (HbA_{1c}) of three doses of the once-daily human GLP-1 analogue liraglutide (0.6, 1.2 or 1.8 mg once daily; OD) added to glimepiride (2–4 mg OD), versus glimepiride alone (placebo), and versus rosiglitazone (4 mg) in combination with glimepiride.

Materials and methods: 1041 subjects (mean (SD) age 56 (10) years, body mass index 30 (5) kg/m², HbA_{1c} 8.4 (0.9)) were stratified based on previous oral antidiabetic drug (OAD) monotherapy (30%) or combination therapy (70%).

Results: All doses of liraglutide + glimepiride resulted in significantly greater reductions from baseline in HbA_{1c} and fasting plasma glucose (FPG) compared with placebo (*) ($p < 0.0001$), and the differences between lira 1.2 and 1.8 mg were also significantly greater vs rosiglitazone + glimepiride for HbA_{1c} (†) ($p < 0.0001$). The HbA_{1c} reduction was about 50% greater in subjects previously on OAD monotherapy. Significantly more subjects achieved $HbA_{1c} < 7\%$ and $\leq 6.5\%$ with liraglutide 1.2 mg + glimepiride and liraglutide 1.8 mg + glimepiride versus placebo and glimepiride + rosiglitazone ($p \leq 0.0003$). Change in body weight was superior for all doses of liraglutide compared with rosiglitazone ($p < 0.0001$). Liraglutide antibodies were found in 9.3–12.7% of liraglutide-treated subjects. Main adverse event with liraglutide was nausea (all $\leq 11\%$); mostly mild and transient in nature. Minor hypoglycaemic episodes (<3.1 mmol/L) occurred in $<10\%$ of subjects with all treatments. One major hypoglycaemic episode occurred with liraglutide 1.8 mg; no medical assistance was required.

Conclusion: Liraglutide added to an SU was well tolerated and provided improved glycaemic control (HbA_{1c} decrease of -1.4% vs placebo + glimepiride) with a favourable weight profile compared with SU and thiazolidinedione combination therapy.

Effect of the GLP-1 analogue liraglutide on glycaemic control and weight reduction in patients on metformin and rosiglitazone: a randomized double-blind placebo-controlled trial

B. Zinman¹, J. Gerich², J. Buse³, A. Lewin⁴, S.L. Schwartz⁵, P. Raskin⁶, P.M. Hale⁷, M. Zdravkovic⁸, L. Blonde⁹

¹Sinai Centre for Diabetes, Mount Sinai Hospital, Toronto, Canada, ²University of Rochester School of Medicine, Rochester, United States, ³University of North Carolina School of Medicine, Chapel Hill, United States, ⁴Clinical Trials, National Research Institute, Los Angeles, United States, ⁵Endocrinology, Diabetes & Glandular Disease Clinic, San Antonio, United States, ⁶University of Texas Southwestern Medical, Dallas, United States, ⁷Novo Nordisk Inc, Princeton, United States, ⁸Novo Nordisk A/S, Bagsvaerd, Denmark, ⁹Endocrinology, Diabetes and Metabolism, Ochsner Diabetes Clinical Research Unit, New Orleans, United States

Background and aims: This 26-week randomized trial compared the efficacy and safety of two doses of liraglutide (1.2 and 1.8 mg, QD) to placebo, all added to metformin 2 g (1 g, BID) and rosiglitazone 8 mg (4 mg, BID).

Materials and methods: Subjects were previously treated with 1 or more OADs. In total, 533 subjects were randomized (mean age 55.1 ± 10.2 years, mean body mass index 33.5 ± 5.2 kg/m², mean HbA_{1c} $8.3 \pm 1.0\%$).

Results: Liraglutide 1.2 + metformin + rosiglitazone and 1.8 + metformin + rosiglitazone reduced HbA_{1c} more than placebo (ANCOVA, $p < 0.0001$) and more of the subjects in the liraglutide groups reached $HbA_{1c} \leq 6.5$ and 7.0% ($p < 0.01$ vs. placebo). Body weight decreased significantly with liraglutide + metformin + rosiglitazone, as compared to placebo + metformin + rosiglitazone. Most common adverse events in the liraglutide groups were gastrointestinal disorders (mainly nausea) and were generally transient. The rates of minor hypoglycemic episodes (<3.1 mmol/L) were 0.38 and 0.64 events/year for liraglutide 1.2 and 1.8 + metformin + rosiglitazone, respectively, vs. 0.17 events/year for placebo + metformin + rosiglitazone ($p = 0.0968$ and 0.0040 , respectively). No subjects reported major hypoglycemic events.

Conclusion: Liraglutide added to metformin + rosiglitazone was generally well tolerated and significantly improved glycaemic control and reduced body weight in comparison placebo + metformin + rosiglitazone therapy with low rates of hypoglycemia.

Liraglutide, a human GLP-1 analogue, reduces systolic blood pressure in subjects with type 2 diabetes

S. Colagiuri¹, A. Frid², M. Zdravkovic³, T.D. Le-Thi³, A. Vaag⁴, A. Garber⁵, B. Zinman⁶

¹Metabolic Health, The University of Sydney, Australia, ²Öresund Diabetes Team AB, Lund, Sweden, ³Novo Nordisk A/S, Bagsvaerd, Denmark,

⁴Steno Diabetes Center, Gentofte, Denmark, ⁵Baylor College of Medicine, Methodist Hospital, Houston, United States, ⁶Sinai Centre for Diabetes, Mount Sinai Hospital, Toronto, Canada

Background and aims: Type 2 diabetes is associated with an increased risk of cardiovascular disease (CVD). Increased blood pressure (BP) is also a risk factor for CVD and prevalent among subjects with type 2 diabetes.

Materials and methods: This analysis examined the impact of treatment with liraglutide, a once-daily human GLP-1 analogue, on systolic and diastolic BP in subjects with type 2 diabetes from four 26-week and one 52-week LEAD [Liraglutide Effect and Action in Diabetes] studies. The studies were randomised, double-blind, placebo-controlled trials.

Results: The baseline and study data are presented in Table 1 for the highest dose of liraglutide (1.8 mg/day). Liraglutide reduced systolic BP in all trials with a statistically significant difference in four of five trials (from -2.7 to -4.5 mmHg vs comparator treatments). The reductions in systolic BP occurred after 2 weeks of treatment and could not be explained by changes in body weight. No statistically significant decrease in diastolic BP was observed. The percentage of subjects reaching a BP target of below 130/80 mmHg in LEAD 5 was 24.3%, 18.4% and 21.6% for liraglutide 1.8 mg, placebo and glargine (NS), respectively. The percentages in LEAD 1 and 2 were similar across all treatments (~25%). There was a trend for pulse to increase slightly, by between 0.9 and 4.5 bpm with liraglutide treatment versus both background and comparator treatments, and these reached statistical significance in LEAD 1, LEAD 4 and LEAD 5.

Conclusion: Liraglutide treatment reduced mean systolic blood pressure by between 2.7 to 4.5 mmHg in subjects with type 2 diabetes. Liraglutide treatment may therefore improve the CV risk profile of subjects with type 2 diabetes by reducing systolic blood pressure.

Action of exendin-4 treatment upon glucose transport in liver and muscle, in normal and type 2 diabetic state

L. Arnés, V. Sancho, I. Valverde, M.L. Villanueva-Peñacarrillo
Metabolism, Nutrition & Hormones, Fundación Jiménez Díaz, Madrid, Spain

Background and aims: It is known that GLP-1 modulates the major glucotransporter expression in liver, muscle and fat, in normal and diabetic conditions. Exendin-4 (Ex-4), 53% structurally GLP-1 homologous peptide, is also antidiabetic and has GLP-1-like effects upon glucose and/or lipid metabolism in extrapancreatic tissues where it is agonist of the GLP-1 specific receptors. We have studied the possible *in vivo* effect of Ex-4 upon glucose transport and Glut4 and Glut2 expression in muscle and liver, respectively, of a type 2 rat diabetic model, compared to normal animals.

Materials and methods: Type 2 diabetic rat model (T2D) was developed by streptozotocin injection (100 µg/g bw) in neonatal Wistar rats. Adult rats, normal (N) and T2D were treated (3 days), through an osmotic pump, with saline solution (control: n=12-19 rats) or 0.1 nmol/kg/h Ex-4 (n=12-14). In fed conditions, blood samples were taken before (basal) and by the end of the treatment, for plasma insulin and glucose measurements; then, the muscle and liver were collected. Glucose transport (GT)–³H-2DOG uptake– was studied in *soleus* muscle, during 60-min at 37°C, in KRB-HEPES containing 0.5 M 2-deoxy-D-[1,2-³H] glucose (Sp. Ac. 40 nCi/µmol) and 2 M [¹⁴C] sorbitol (Sp. Ac. 5 nCi/µmol). Glycogen content in the liver was determined by the anthrone reagent method. Glut2 and Glut4, mRNA and protein, were determined by RT-PCR and Western blot, respectively. Significance of the differences was analyzed by ANOVA or Student *t*-test.

Results: In both, N and T2D rats, after either control or Ex-4 treatment, no significant modifications were detected of their initial value in body weight (279.6±6 g, n=33 and 297±7 g, n=24, N and T2D, respectively), plasma glucose (154±7 mg/dl, n=19 and 170±10 mg/dl, n=17) or insulin (0.75±0.10 ng/ml, n=26, and 0.57±0.10 ng/ml, n=23). In the muscle: GT in T2D-control (0.348±0.008 nmol/mg per min, n=5) was apparently lower than that in N-control rats (0.435±0.046 nmol/mg per min, n=5); Ex-4 treatment did not modify the control level in N, but increased that in T2D to a value (0.578±0.063 nmol/mg per min, n=6, p=0.03) even higher (p<0.05) than that of N-control. Muscle Glut4-mRNA in T2D-control showed to be indistinguishable from that in N-control, while Glut4-protein was lower (86±6% N-control, n=8, p<0.05); Ex-4 in N did not change the Glut4-mRNA, but induced a small but clear stimulation of the protein (124±4% control, n=4, p<0.05); no modification was detected in either Glut4-protein or -mRNA in the T2D group after Ex-4. In the liver: control Glut2-mRNA in T2D was about 2-times higher (p<0.001) than that in N, while the protein was lower (66±8% N-control, p<0.05); Ex-4 induced an increment of Glut2-mRNA in N (6.4±0.7 times control, n=4, p<0.001) and in T2D (2.5±0.2 times control, n=5, p<0.005), and also of the protein (N+Ex-4: 174±18% control, n=5, p<0.05; T2D+Ex-4: 254±56% control, n=5, p<0.05). Liver glycogen content in T2D-control (225±20 ng/µg protein, n=5) was lower (p<0.001) than that in N (386±16 ng/µg protein, n=5); Ex-4 did not altered the value in N (342±26 ng/µg protein, n=5), but induced an increase in T2D (309±22 ng/µg protein, n=5, p<0.02) showing that Ex-4 has a trend to normalize the liver glycogen content (p=0.06 vs N-control).

Conclusion: These data suggest that the antidiabetic action of Ex-4 may occur, at least in part, through its increasing effect upon glucose transport in the muscle and also that upon the glucotransporter expression and glycogen synthesis in the liver.

Exenatide enhanced pancreatic compensation in insulin-resistant diabetic mice

D. Bhole¹, R. Gelling², K. Tatarkiewicz¹, L. Nielsen¹, M. Xiu Steele³, D. Hargrove¹, D. Maggs¹, D. Parkes¹, D. Kendall¹, E. Murphy⁴

¹Clinical, Amylin Pharmaceuticals, Inc., San Diego, ²KineMed, Inc., Emeryville, ³Gladstone Institute, University of California San Francisco, San Francisco, ⁴Medicine, University of California San Francisco, United States

Background and aims: The incretin mimetic, exenatide, improves glycaemic control, reduces weight and improves insulin secretion in patients with type 2 diabetes. To determine pancreatic compensation during exenatide treatment we performed a series of studies using a unique deuterated glucose disposal technique in a mouse model of diabetes. This model is characterised by both insulin-resistance and deficient insulin secretion.

Materials and methods: Four-wk-old male C57Bl6/J mice were fed a high fat (HF) diet (58% fat) for 5 wks, followed by low dose streptozotocin (STZ 100 mg/kg) treatment (IP weekly for 2 wks except in a HF-fed control population). STZ-treated mice with blood glucose >220 mg/dL and <500 mg/dL at wks 7 and 8 were studied. Mice were treated with exenatide (20 µg/kg/day) or vehicle administered by continuous subcutaneous infusion via osmotic minipump for 4 wks. Mice had a 30 min glucose challenge with ²H-glucose as part of the glucose disposal test to measure insulin sensitivity and pancreatic compensation (determined from the absolute rate of whole body glycolysis, i.e., the total production of ²H₂O from ²H-glucose).

Results: Exenatide therapy reduced blood glucose AUC_{0-30 min} by 34% relative to HF-STZ/vehicle-treated mice (p<0.001) and by 24% relative to HF-fed animals not treated with STZ (p<0.01). Insulin concentrations were 52% lower in both HF-STZ-treated groups vs. HF-only animals (p<0.05). Exenatide therapy also increased insulin sensitivity [by 209% vs HF-no STZ /vehicle mice (p<0.01) and by 89% vs HF-STZ-only mice (p<0.05)]. Overall, exenatide therapy significantly increased pancreatic compensation compared with HF-STZ-treatment (31%, p<0.05), and this compensation was comparable to that observed in HF-fed mice not treated with STZ.

Conclusion: Exenatide treatment improved glycaemic control, insulin sensitivity, and pancreatic β-cell response in an animal model of type 2 diabetes characterised by insulin-resistance and deficient insulin secretion.

Exendin-4 restores rapamycin-induced apoptosis in pancreatic betacells by inhibiting JNK and p38 signalling pathways

Y. Kawasaki¹, S.-I. Harashima¹, E. Mukai¹, Y. Nakamura¹, N. Harada¹, K. Toyoda¹, Y. Hamamoto¹, A. Hamasaki¹, Y. Seino², Y. Yamada^{1,3}, N. Inagaki¹

¹Department of Diabetes and Clinical Nutrition, Graduate School of Medicine, Kyoto University, ²Division of Diabetes and Clinical Nutrition, Kansai Electric Power Hospital, Osaka, ³Department of Endocrinology and Diabetes and Geriatric Medicine, Akita University School of Medicine, Japan

Background and aims: Rapamycin is a mTOR inhibitor used to prevent rejection in islet cell transplantation. However, recently, it was reported that rapamycin also impaired glucose-stimulated insulin secretion and decreased viability of islets, or induced fluminate diabetes by increasing insulin resistance and reducing beta cell function and mass. On the other hand, exendin-4, an analog of glucagon-like peptide-1, is known to promote insulin secretion, increases beta cells mass and insulin gene expression. Therefore, our purpose of the current study is to examine whether or not exendin-4 recovers rapamycin-induced beta cell cytotoxicity.

Materials and methods: The mouse beta cell line MIN6 cells were treated with rapamycin and/or exendin-4 for 6 - 48 h in DMEM containing 25 mM glucose. Various inhibitors were added 30 min before the treatment with rapamycin and/or exendin-4. Dead cells were stained with PI and counted by flowcytometry. Apoptosis was detected by Annexin-V-FITC Apoptosis Detection Kit. Phosphorylation of proteins was detected by Western blot.

Results: At first, MIN6 cells were treated with 0.1 nM - 100 nM rapamycin to confirm cytotoxic effect of rapamycin. G1 arrest and cell death were observed in 12 h by the treatment with 10 nM and more rapamycin. 10 nM rapamycin also induced apoptosis in MIN6 cells in 6 h. Contrarily, 10 nM exendin-4 completely restored rapamycin-induced apoptosis and G1 arrest when cells were treated together with both rapamycin and exendin-4. Next, we investigated what signaling pathway is major for exendin-4-blocked apoptosis in-

duced by rapamycin. As PKA, ERK and PI3K are important for exendin-4 signaling in beta cells, we at first examined involvement of these kinases. H89, a PKA inhibitor, partially blocked inhibition of rapamycin-induced apoptosis by exendin-4. By contrast, LY294002, a PI3K inhibitor, and PD98059, an ERK inhibitor, had little effect on exendin-4 reversed phenomena, implying that an alternative signaling pathway is related to the inhibitory effect of exendin-4 against rapamycin. Therefore, we examined JNK signaling pathway because it was recently reported that JNK is a key molecule of beta-cell apoptosis. As expected, SP600125, a JNK inhibitor, blocked rapamycin-induced apoptosis by about 60%. Interestingly, SB203580, a p38 inhibitor, also inhibited rapamycin-induced cell death by about 40%. Western blot analysis further confirmed that rapamycin increased phosphorylation of JNK and p38 in 30 min, while exendin-4 decreased phosphorylation of both JNK and p38 in 30 min. However, exendin-4 did not alter phosphorylation of MKK4 and MKK3, an upper stream kinase of JNK and p38, respectively, indicating that an uncertain signaling pathway of exendin-4 interacts with JNK and p38.

Conclusion: Rapamycin induced apoptosis in beta cells in several hours through direct activation of JNK and p38 signaling pathways, while exendin-4 restored the rapamycin-induced apoptosis via regulating not only PKA but JNK and p38. In the patients who receive islet cell transplantation, exendin-4 might be useful to prevent rapamycin-induced apoptosis in pancreatic beta cells.

Is there a local “incretin system” in human pancreatic islets?

R. Lupi¹, S. Del Guerra¹, V. D'Aleo¹, S. Torri¹, M. Galli¹, M. Bugliani¹, F. Filippini², U. Boggi², F. Mosca², S. Del Prato¹, P. Marchetti¹

¹Endocrinology and Metabolism - Metabolic Unit, ²Department of Oncology, Transplantation and Advanced Technologies in Medicine, University of Pisa, Italy

Background and aims: Incretins are intestinal hormones released in response to nutrient ingestion and which potentiate glucose-stimulated insulin secretion. Glucagon-like peptide-1 (GLP-1) is an important physiological incretin and is secreted from the intestinal L-cells after pro-glucagon cleavage by pro-convertase (PC)-1/3. Recent evidence from cell lines and rodent studies suggests that pancreatic alpha-cells also may secrete GLP-1. We assessed whether a local incretin (GLP-1) system is present in human pancreatic islets and the possible role of type 2 diabetes.

Materials and methods: The expression of glucagon, GLP-1, PC-1/3 and DPP-IV was determined by immunohistochemistry; isolated islets were prepared by enzymatic digestion and gradient separation from the pancreas of non-diabetic (Ctrl) and matched type 2 diabetic (T2DM) multiorgan donors; islets GLP-1, PC-1/3 and DPP-IV gene expression was measured by quantitative RT-PCR; GLP-1 protein expression was assessed by Western-immunoblotting; the active form of GLP-1 in the islets incubation medium was measured by radioimmunoassay.

Results: Immunohistochemistry showed co-localization of glucagon and GLP-1; PC-1/3 was found in most islet cells and scattered DPP-IV positivity was also observed. GLP-1 mRNA and protein expression was found in isolated islets. Gene expression (gene/beta-actin ratio) of DPP-IV and PC-1/3 mRNA differed ($p < 0.01$) between T2DM (respectively 0.60 ± 0.02 and 0.21 ± 0.13) and Ctrl (0.20 ± 0.02 and 0.84 ± 0.01) islets. Active GLP-1 was detected in islets incubation medium, with lower ($p < 0.01$) values with Ctrl (143 ± 84 pmol/l/4h) than T2DM (568 ± 123 pmol/l/4h) islets. In addition, exposure of Ctrl islets for 24h to 1.0 mmol/l FFA (oleic:palmitic, 2:1) determined a significant increase ($p < 0.01$) of GLP-1 release (978 ± 191 pmol/l/4h).

Conclusion: These results suggest the presence of a local GLP-1 system in human islets, which could be altered in type 2 diabetes.

GLP-1 analogue treatment increases beta cell replication and improves metabolic outcome in streptozotocin-diabetic rats transplanted with an insufficient beta cell mass

G. Joanny, N. Téllez, J. Escoriza, J. Soler, E. Montanya

Lab. Diabetes and Experimental Endocrinology, University of Barcelona, Endocrine Unit, Hospital Universitari Bellvitge, IDIBELL, CIBERDEM, L'Hospitalet de Llobregat, Spain

Background and aims: We have previously shown that a new DPPIV stabilized GLP-1 analogue enhanced beta cell regeneration in partially pancreate-

ctomized rats. The treatment increased beta cell replication and neogenesis, and decreased beta cell apoptosis resulting in an increased beta cell mass. Shortage of islets is a major limitation in human islet transplantation and usually determines the transplantation of an insufficient islet mass, and the requirement of two or more transplants to restore normoglycemia. Strategies to increase graft beta cell mass could alleviate the shortage of islets and improve the outcome of islet transplantation. The aim of this study was to determine the effects of this new DPPIV stabilized GLP-1 in rat transplanted islets. In this model, the contribution of neogenesis is negligible due to the almost complete absence of ductal or exocrine tissue in the grafted cells, allowing a direct analysis of the role of enhanced beta cell replication in the outcome of the graft.

Materials and methods: We used a DPPIV stabilized GLP-1 analogue which has been derivatised with a chemical moiety that binds to albumin in a reversible manner thereby extending plasma half-life to at least one day. Streptozotocin-diabetic Lewis rats were syngeneically transplanted with an insufficient beta cell mass of 800 islets and were treated with the GLP-1 analogue (100 µg/kg . day, SC once daily) or with vehicle from the day of transplantation to day 14. An additional control group of non-transplanted STZ-diabetic rats treated with the GLP-1 analogue was studied. Blood glucose and body weight were monitored on days 0, 3, 7, 14 and after graft removal. Beta cell mass was determined by morphometry, beta cell replication by BrdU incorporation and beta cell apoptosis by the TUNEL technique in insulin stained sections of harvested grafts.

Results: Blood glucose levels decreased in transplanted GLP-1-treated animals compared to control non-transplanted GLP-1-treated group at all time points (day14: 285 ± 44 vs 515 ± 52 mg/dl; $p < 0.05$), but were not significantly reduced in transplanted vehicle-treated animals. Furthermore, 30% (3 of 10) of transplanted rats treated with GLP-1 achieved and maintained normoglycemia until the end of the study. In contrast, only 11% (1 of 9) of vehicle treated and none of non-transplanted GLP-1-treated animals achieved normoglycemia. All normoglycemic animals reverted to clear hyperglycemia after graft removal. Beta cell replication in islet grafts of GLP-1-treated group was higher than in grafts of vehicle-treated animals ($1.31 \pm 0.35\%$ vs $0.57 \pm 0.10\%$; $p < 0.01$), and than in normal pancreas ($0.26 \pm 0.02\%$; $p < 0.01$). Beta cell apoptosis was similar in grafts of animals treated with GLP-1 or vehicle, and higher than in control pancreas. Beta cell mass in islet grafts of GLP-1-treated rats was 44% higher than in vehicle-treated animals (1.24 ± 0.32 vs 0.86 ± 0.22 mg) although the difference did not reach statistical significance.

Conclusion: Treatment with this new GLP-1 analogue increased beta cell replication and improved metabolic evolution in diabetic rats transplanted with an insufficient islet mass. These results suggest that the effect of the GLP-1 analogue on replication of transplanted beta cells improved the outcome of the graft.

GLP-1 receptor activation attenuates beta cell damage in Akita mice

S. Yamane¹, Y. Hamamoto¹, N. Harada¹, K. Toyoda¹, Y. Seino², N. Inagaki¹

¹Department of Diabetes and Clinical Nutrition, Kyoto University Graduate School of Medicine, Kyoto, ²Department of Diabetes and Clinical Nutrition, Kansai Electric Power Hospital, Osaka, Japan

Background and aims: Dysfunction of pancreatic β -cells and decreased β -cell mass plays an important role in the development of diabetes mellitus. Recent studies have revealed that the endoplasmic reticulum (ER) stress is one of the causes of β -cell damage in diabetes. On the other hand, a growing body of evidence suggests that incretin hormones, exemplified by glucagon-like peptide-1 (GLP-1), not only increase insulin secretion and upregulate insulin biosynthesis but also enhance resistance to β -cell death. In this study, we examined *in vivo* effects of exendin-4, a potent GLP-1 receptor agonist, on pancreatic β -cell in Akita mice, an animal model of ER stress-mediated diabetes. **Materials and methods:** A point mutation of insulin 2 gene in Akita mice promotes ER stress in β -cells that leads to β -cell apoptosis and hyperglycemia. We examined the changes in blood glucose levels, islet morphology, and the expression of CHOP, a marker of ER stress, histologically in Akita mice treated with vehicle alone or with exendin-4 (24 nmol/kg) that was injected intraperitoneally twice daily for 6 weeks. We also evaluated the effect of exendin-4 treatment on β -cell replication and apoptosis by 5-bromo-2'-deoxyuridine (BrdU) staining and TdT-mediated dUTP-biotin nick-end labeling (TUNEL) staining, respectively.

Results: Exendin-4 treatment significantly reduced blood glucose levels ($p < 0.05$), but there was no significant difference in body weight between ex-

endin-4 treated group and control group. Immunohistochemical examination showed an increase in insulin positive areas in the islets in exendin-4 treated group compared with control group. Furthermore, treatment of Akita mice with exendin-4 resulted in significant decrease in the number of CHOP-positive β -cells even after an adjustment by β -cell area. In BrdU or TUNEL staining evaluated at 6 weeks of exendin-4 treatment, we could not find any differences in proliferation or apoptosis of β -cell between exendin-4 treated group and control group.

Conclusion: Our data suggest that GLP-1 receptor activation can attenuate ER stress-mediated β -cell damage through the reduction of ER stress. Mechanisms responsible for this beneficial effect of exendin-4 are not fully accounted for by these results, therefore, further examination is required in the future.

Expression, storage and rapid regulated secretion of active glucagon like peptide-1 following muscle-targeted gene transfer

A. Mahmoud¹, A. Aldibbiat¹, S.J.M. Niessen², S.C. Campbell¹, G.N. Holliman¹, S. Joshi¹, K.T. Scougall¹, J.A.M. Shaw¹

¹Diabetes, Diabetes Research Group, Institute of Cellular Medicine, Newcastle Upon Tyne, ²Department of Veterinary Clinical Sciences, Royal Veterinary College, Hatfield, United Kingdom

Background and aims: Glucagon-like peptide-1 (GLP-1) is a potent insulinotropic hormone with an important role in enhancing post-prandial glucose-dependent insulin secretion. Short half-life necessitates regular self-injection limiting clinical utility for those with diabetes. Muscle-targeted GLP-1 gene delivery may enable long-term therapeutic efficacy following simple infrequent intramuscular plasmid injection.

The aims of this study were to generate a plasmid construct enabling regulated secretion of GLP-1 and evaluate expression / intracellular localisation in addition to small molecule ligand-mediated post-translational processing / secretion following gene transfer to a murine muscle cell line, and intramuscular injection in mice.

Materials and methods: A novel approach was employed in which GLP-1(7-36) cDNA was expressed downstream of a growth hormone signal peptide sequence as a fusion peptide linked by a consensus furin cleavage sequence to four copies of a mutated FK506 binding protein (4FM) enabling conditional endoplasmic reticulum aggregation and rapid disaggregation / entry into the constitutive secretory pathway in presence of a non-immunosuppressant rapamycin-analogue ligand (AP21998). Following plasmid synthesis and sequence confirmation, transfections were undertaken in the C2C12 mouse muscle cell line employing jetPEI or the constructs were intramuscularly injected in mice preinjected with hyaluronidase and followed by *in situ* electroporation.

Results: GLP-1 expression *in vitro* was confirmed by RT-PCR. GLP1 / 4FM biosynthesis and intracellular co-localisation was demonstrated by immunofluorescence staining / Western blotting. AP21998 ligand-induced secretion of bioactive GLP1 was quantified by specific ELISA (>140 pmol l^{-1} over a 4 hour incubation). Dose responsivity within the range of 0–2 μ M AP21998 was confirmed. GLP1 expression following *in vivo* gene transfer to mouse muscle was evidenced by immunohistochemical staining with systemic secretion confirmed by immunoassay.

Conclusion: GLP-1 biosynthesis and storage following plasmid-mediated gene transfer to muscle has been attained in addition to rapid ligand-induced post-translational processing / secretion of bioactive hormone.

907

Effect of GLP-1 on the bone remodeling in insulin resistant state

B. Nuche-Berenguer¹, P. Moreno¹, S. Dapía², P. Esbrit³, M.L. Villanueva-Peñacarrillo¹

¹Metabolism, Nutrition and Hormones, Fundación Jiménez Díaz, Madrid,

²Trabeculae, S.L., Parque Tecnológico de Galicia, Orense, ³Laboratory of Bone and Mineral Metabolism, Fundación Jiménez Díaz, Madrid, Spain

Background and aims: It is now well documented the insulin-independent antidiabetic action of GLP-1, its insulinotropic effect and positive action upon glucose metabolism in liver, muscle and fat, and its neurotrophic and anorectic among other properties. It has been suggested that hormones with incretin character could participate in the changes in bone turnover occur-

ring after nutrient absorption. Here we have explored the possible *in vivo* modulating effect of GLP-1 on bone remodelling markers in normal and in an insulin-resistant model.

Materials and methods: Insulin resistance (IR) was induced in adult Wistar rats by chronic feeding during 8 weeks with standard chow combined with D-fructose (20% in the drinking water). Groups of normal (N, n=20 rats) and IR (n=20) were 3-days treated, through an osmotic pump, with saline solution (control) or GLP-1 (0.86 nmol/kg/h). In fed conditions, plasma samples were taken before (basal) and by ending the treatment; then, rats were sacrificed and one femur and one tibia from each were collected. In plasma, osteocalcin (OC) and tartrate-resistant acid phosphatase (TRAP) -by ELISA-, insulin -by RIA- and glucose concentrations were measured. In the tibia, after total RNA extraction, the OC, osteoprotegerin (OPG) and RANK ligand (RANKL) gene expression were determined by real time PCR. Femoral bone structure was evaluated -by μ CT- in 3 rats per experimental group.

Results: In plasma: GLP-1 did not change the basal OC value in N rats (407.87 ± 16.1 ng/ml, n=15), but decreased that in IR ($-22.2 \pm 4\%$ Δ of basal, $p < 0.03$), which showed an initial lower ($p < 0.0001$) level than N (289.40 ± 16.64 ng/ml, n=15); N-basal TRAP (2.26 ± 0.20 U/l, n=16) was not modified by GLP-1, while in the IR, with a lower than normal ($p < 0.0001$) basal value (1.14 ± 0.16 U/l, n=15), GLP-1 induced a trend towards a normalization ($48.3 \pm 20.3\%$ Δ basal); in IR, basal insulin and glucose were only slightly higher and lower, respectively, than in N, and neither control or GLP-1 treatment significantly modified the values in any group, N or IR. In the tibia of 7-11 rats: OC mRNA-control in IR was 0.49 ± 0.09 times that in the N group ($p < 0.001$), in which, treatment with GLP-1 increased 4.22 ± 0.83 times its control value ($p < 0.01$), as it did, although in a lower extent ($p < 0.05$ vs N), in IR (1.82 ± 0.18 times control, $p < 0.01$); control OPG mRNA in IR was lower than in N (0.66 ± 0.12 times, $p < 0.02$), and GLP-1 treatment increased the value in N (2.29 ± 0.23 times control, $p < 0.01$) and also in IR (2.84 ± 0.46 times control, $p < 0.01$); control RANKL mRNA was also lower ($p < 0.001$) in IR (0.56 ± 0.09 times N), and GLP-1 induced only a slight increase in N (1.28 ± 0.22 times control) as well as in IR (1.76 ± 0.44 times control). In IR rats, OPG/RANKL mRNA ratio was 1.18-fold of N, and GLP-1 treatment raised the value in an equal magnitude in both groups (1.79- and 1.61-fold, N and IR, respectively). In the femur of IR rats, trabecular thickness and anisotropy were higher and lower, respectively, than those in N group, without any apparent change after GLP-1 treatment; femoral cortical thickness and the momentum of inertia were higher in the IR group than in N rats, and they further increased after GLP-1 treatment.

Conclusion: The insulin-resistance of this experimental model is associated to a low bone remodelling state, and GLP-1 treatment seems to favour both bone formation and bone resistance.

Differential importance of GIP vs. GLP-1 receptor signalling vs. DPP-4 inhibition for beta cell survival and function in mice

A. Maida¹, Y. Seino², D.J. Drucker^{1,3}

¹Samuel Lunenfeld Research Institute, Toronto, Canada, ²Medicine, Kyoto University, Japan, ³Medicine, Banting and Best Diabetes Centre, Toronto, Canada

Background and aims: Glucagon-like peptide-1 (GLP-1) and glucose-dependent insulinotropic polypeptide (GIP) are incretin hormones secreted by gut endocrine cells that act on structurally distinct β -cell receptors to trigger glucose-dependent insulin secretion. Although exogenous GLP-1 receptor (GLP-1R) activation promotes cytoprotection and endogenous GLP-1R signaling is essential for β -cell function, whether the GIP receptor (GIPR) is critically important for β -cell survival remains unclear.

Materials and methods: We administered the β -cell toxin streptozotocin (STZ) to wildtype (WT) mice with or without concomitant treatment with the GIPR agonist [D-Ala²]-GIP, the GLP-1R agonist exendin-4 (Ex-4) or the dipeptidyl peptidase-4 inhibitor sitagliptin. The importance of endogenous GIPR signaling for β -cell survival was assessed in *Gipr*^{-/-} mice. The importance of DPP-4 inhibition for β -cell function and survival was assessed in WT and DIRKO mice.

Results: Exogenous administration of Ex-4 for either 7 or 60 days significantly reduced the extent of STZ-mediated β -cell damage as indicated by improved blood glucose and insulin levels, decreased levels of HbA_{1c}, and increased pancreatic insulin content and β -cell mass. In contrast, comparable administration of the potent GIPR agonist [D-Ala²]-GIP for 7 or 60 days did not improve parameters of β -cell function under identical experimental

conditions. To assess the importance of basal GIPR signaling for β -cell survival we assessed STZ-induced cytotoxicity in *Gipr*^{-/-} mice. Unlike previous results in *Glp1r*^{-/-} mice, *Gipr*^{-/-} mice did not exhibit enhanced sensitivity to STZ-induced diabetes or increased β -cell apoptosis. Potentiation of endogenous incretin action via prolonged continuous administration of the DPP-4 inhibitor sitagliptin reduced HbA_{1c}, and improved levels of plasma and pancreatic insulin after STZ administration. Furthermore sitagliptin reduced the levels of activated caspase-3 in WT mice, but had no effect on caspase-3 activation in dual incretin receptor knockout (DIRKO) mice.

Conclusion: These findings reveal important differences in the endogenous physiological roles and pharmacological importance of murine GIP vs GLP-1 receptors vs DPP-4 inhibition for the preservation of β -cell mass and function in vivo.

PS 081 Sitagliptin and vildagliptin

909

In patients with type 2 diabetes, sitagliptin added to metformin effectively lowers HbA_{1c} regardless of patient age, gender, body mass index, or baseline measure of beta cell function

M. Alba, A.S. Swern, R.B. Langdon, D. Williams-Herman
Merck Research Laboratories, Rahway, United States.

Background and aims: Sitagliptin, a DPP-4 inhibitor, improves glycemic control and is well tolerated when added to ongoing metformin therapy in patients with type 2 diabetes. The purpose of this pooled analysis was to evaluate consistency of glucose-lowering by sitagliptin across subgroups defined by baseline differences in age, gender, body mass index (BMI), HOMA- β , and proinsulin/insulin [P/I] ratio.

Material and methods: Data were pooled from two randomized, placebo-controlled, double-blind, Phase III trials. In these studies, sitagliptin or placebo was added to ongoing treatment with metformin. Changes from baseline in HbA_{1c} (Δ HbA_{1c}, the primary endpoint) and fasting plasma glucose (Δ FPG) were then assessed at 18 or 24 weeks. Overall, 891 patients were randomized to receive either sitagliptin 100 mg once daily (n = 560) or placebo (n = 331) added on to metformin 1500–2550 mg/day. Treatment effects on Δ HbA_{1c} and Δ FPG (differences between sitagliptin and placebo treatments) were evaluated using an ANCOVA model that included terms for treatment, trial, baseline subgroup, and treatment-by-subgroup interaction, with baseline efficacy value included as a covariate. Subgroups were defined as shown in the Table.

Results: At baseline, the two treatment groups had similar demographic, anthropometric and disease characteristics. The overall averages at baseline were: age, 54.6 years; duration of known T2DM, 6.6 years; BMI, 31.0 kg/m²; HbA_{1c}, 8.2%; FPG, 9.9 mmol/L; HOMA- β , 42.8; and P/I ratio, 0.4. Compared with placebo, treatment with sitagliptin reduced LS-mean HbA_{1c} in the overall cohort by -0.7% (95% CI -0.9 to -0.6) and FPG by -1.4 mmol/L (95% CI -1.7 to -1.1). Compared with placebo, sitagliptin treatment lowered HbA_{1c} significantly in all subgroups, with between-group differences in LS-mean Δ HbA_{1c} from -0.5% to -0.9% (Table). Differences in the placebo-subtracted outcome are likely due to differences in Δ HbA_{1c} in the placebo arm, with changes from baseline in the sitagliptin-treated groups ranging from -0.7%

Baseline characteristic	Sitagliptin 100 mg q.d.		Placebo		Between-group difference in LS-mean Δ HbA _{1c} (%) (95% CI)
	N	LS-mean Δ HbA _{1c} (%)	N	LS-mean Δ HbA _{1c} (%)	
Age (p = 0.278)					
< 50 years	168	-0.7	82	0.2	-0.9 (-1.1, -0.7)
≥ 50 and < 65 years	293	-0.8	185	-0.1	-0.7 (-0.8, -0.5)
≥ 65 years	87	-0.7	49	0.0	-0.8 (-1.1, -0.4)
Gender (p = 0.842)					
Female	248	-0.8	144	-0.0	-0.7 (-0.9, -0.6)
Male	300	-0.8	172	-0.0	-0.7 (-0.9, -0.6)
BMI (p = 0.246)					
< 25 kg/m ²	66	-0.7	31	-0.3	-0.5 (-0.8, -0.1)
≥ 25 and < 30 kg/m ²	181	-0.9	96	-0.2	-0.7 (-0.9, -0.5)
≥ 30 kg/m ²	269	-0.7	158	0.1	-0.8 (-1.0, -0.6)
HOMA-β tertiles (p = 0.801)					
Lower (≤ 23.9)	161	-0.8	89	-0.1	-0.7 (-0.9, -0.5)
Middle (> 23.9 and ≤ 45.7)	168	-0.8	84	0.0	-0.8 (-1.0, -0.6)
Upper (> 45.7)	162	-0.7	87	-0.1	-0.7 (-0.9, -0.5)
Proinsulin-to-insulin ratio tertiles (p = 0.967)					
Lower (≤ 0.27)	159	-0.8	72	-0.1	-0.6 (-0.9, -0.4)
Middle (> 0.27 and ≤ 0.45)	159	-0.7	72	-0.1	-0.6 (-0.9, -0.4)
Upper (> 0.45)	148	-0.7	83	-0.1	-0.6 (-0.8, -0.4)
The p-values indicated are for treatment-by-subgroup interactions. BMI = body mass index; CI = confidence interval; LS-mean = least-squares mean					

to -0.9%. Tests for the interaction between baseline characteristics and treatment groups for ΔHbA_{1c} were uniformly non-significant ($p = 0.278\text{--}0.976$). The same was observed for ΔFPG ($p = 0.270\text{--}0.743$).

Conclusion: In patients with type 2 diabetes, sitagliptin provided effective and consistent glycemic control regardless of baseline differences in age, gender, BMI, HOMA- β , and P/I ratio.

Table. By subgroup, change from baseline in least-squares (LS) mean HbA_{1c} (ΔHbA_{1c}) at the predefined study endpoint times (18 or 24 weeks).

Sitagliptin added to ongoing treatment with pioglitazone study up to 52 weeks in Japanese patients with T2DM

H. Maegawa¹, A. Kashiwagi¹, N. Tajima², T. Kadowaki³, K. Nonaka⁴, T. Okamoto⁴, K. Okuyama⁴, M. Nishii⁵, J.M. Amatruda⁶

¹Department of Medicine, Shiga University of Medical Science, Otsu, Japan,

²Department of Internal Medicine, Jikei University School of Medicine,

Tokyo, Japan, ³Graduate School of Medicine, The University of Tokyo, Japan,

⁴Banyu Pharmaceutical Co., Ltd., Tokyo, Japan, ⁵Ono Pharmaceutical Co., Ltd., Osaka, Japan, ⁶Merck & Co., Inc., Rahway, United States

Background and aims: The use of pioglitazone (PIO) for treating type 2 diabetes mellitus (T2DM) has been increasing in Japan. However, its monotherapy may not be sufficient to get patients to current glycemic goals, raising the importance of combination therapy. Sitagliptin (SITA) is an oral, highly selective DPP-4 inhibitor that lowers glucose in a glucose-dependent manner by enhancing the incretin axis. This 12-wk, randomized, double-blind (DB), placebo (PBO)-controlled study with 40-wk open-label extension assessed the efficacy and tolerability of the addition of SITA to ongoing PIO in Japanese patients with T2DM.

Materials and methods: Patients on PIO alone or PIO in combination with other oral antihyperglycemic agents (OHA) entered the screening period. For patients on PIO plus other OHAs, the other OHAs were discontinued and patients entered a wash-out period of ≥ 6 wks. Following this period, eligible patients with an A1C of 6.5–10.0% completed a 2-wk, single blind PBO run-in. Patients on a stable PIO dose ≥ 16 wks and on diet/exercise ≥ 8 wks, were then randomized (1:1) to the addition of once-daily SITA 50 mg or PBO for a 12-wk DB treatment period. The DB period was followed by a 40-wk open-label extension period where patients on PBO were re-allocated to SITA 50 mg and SITA could be titrated from 50 mg to 100 mg. The primary endpoint was A1C change from baseline at Week 12. The efficacy analysis was based on the full analysis set with last observation carried forward.

Results: A total of 134 patients were randomized to SITA 50 mg ($N=66$) or PBO ($N=68$) with mean baseline A1C of 7.7% and 7.6%, respectively. In DB period, SITA significantly ($p<0.001$) reduced A1C from baseline relative to PBO at Week 12 (between-treatment difference in least-squares [LS] mean A1C change from baseline [95% CI] = -0.8% [-1.0, -0.6]; SITA = -0.4% and PBO = 0.4%). Similarly, SITA significantly ($p<0.001$) reduced fasting plasma glucose and 2-hr postprandial glucose, relative to PBO. In addition, β -cell function as assessed by HOMA- β and insulinogenic index significantly improved with SITA relative to PBO ($p<0.001$ for both comparisons). The occurrences of overall adverse experiences (AEs), serious AEs, drug-related AEs, and gastrointestinal AEs were similar between the groups. Hypoglycemia was reported in 2 patients in each group.

In open-label extension period, of 66 patients allocated to SITA, 50 patients completed 52-wk treatment. In the population, excellent durability was observed at Week 52; A1C change from baseline: -0.7%, and the proportions of patients with A1C level $<6.5\%$ ($<7.0\%$): 28.0% (62.0%), without an increase of hypoglycemia. There was an increase from baseline in body weight of 0.76 kg with SITA at Week 52. Similar results of efficacy and safety were also observed in the group where PBO was switched to SITA at Week 12.

Conclusion: In this study, up-to 52-wk treatment with SITA added to ongoing therapy with PIO in Japanese patients with T2DM, provided effective glycemic control and was well tolerated, with a low occurrence of hypoglycemia and without clinically meaningful change in body weight.

Triple combination therapy with sitagliptin, metformin, and rosiglitazone improves glycaemic control in patients with type 2 diabetes

J.C. Arjona Ferreira¹, A. Dobs², B.J. Goldstein³, L. Wiecek³, G. Golm¹, M.J. Davies¹, D. Williams-Herman¹, K.D. Kaufman¹, J.M. Amatruda¹

¹Merck Research Laboratories, Rahway, ²The Johns Hopkins University School of Medicine, Baltimore, ³Medicine, Jefferson Medical College, Philadelphia, United States

Background and aims: Efficacy and safety of sitagliptin, a selective DPP-4 inhibitor, were examined in patients with type 2 diabetes who had inadequate glycemic control (A1C 7.5% to 11%) on the combination of metformin and rosiglitazone.

Materials and methods: After a dose-titration/stabilization period of up to 20 weeks with metformin (≥ 1500 mg/d) and rosiglitazone (≥ 4 mg/d) and a 2-week placebo run-in, 278 patients (mean baseline A1C = 8.8%) were randomized in a 2:1 ratio to the addition of once-daily sitagliptin 100 mg ($n = 181$) or placebo ($n = 97$) for 18 weeks. The primary endpoint was A1C change from baseline at Week 18.

Results: The addition of sitagliptin significantly ($p<0.001$) reduced A1C by 0.7% relative to placebo (change from baseline -0.9% with sitagliptin vs. -0.2% with placebo), with a greater response observed in patients with a baseline A1C $>9\%$ (change from baseline with sitagliptin -1.3%). From the mean baseline A1C of 8.8%, the proportion of patients achieving A1C $<7\%$ was significantly ($p=0.005$) greater with the addition of sitagliptin (22%) compared with placebo (10%). Relative to placebo, sitagliptin significantly ($p<0.001$) reduced fasting plasma glucose by 1.0 mmol/L (change from baseline -1.5 mmol/L with sitagliptin vs. -0.5 mmol/L with placebo) and 2-hr postprandial glucose by 2.2 mmol/L (change from baseline -2.9 mmol/L with sitagliptin vs. -0.8 mmol/L with placebo). Measures related to β -cell function, such as HOMA- β (12.9 vs. 3.5), proinsulin/insulin ratio (-0.12 vs. -0.03), and insulinogenic index (-2.7 vs. -1.1 $\mu\text{IU/mL/mg/dL}$), were significantly ($p\leq 0.05$) improved with sitagliptin compared with placebo, respectively. Sitagliptin was generally well tolerated compared with placebo, with similar incidences of hypoglycemia (2.2% vs. 0%, respectively), gastrointestinal adverse experiences (6.1% vs. 9.3%, respectively), and edema (2.8% vs. 4.1%, respectively). Mean body weight change from baseline was not significantly different between sitagliptin (0.7 kg) and placebo (0.4 kg).

Conclusion: In this study, triple therapy with sitagliptin added to the combination of metformin and rosiglitazone substantially improved glycemic control and was generally well tolerated in patients with type 2 diabetes.

Safety and tolerability of sitagliptin, a selective DPP-4 inhibitor, in patients with type 2 diabetes: pooled analysis of 6139 patients in clinical trials for up to 2 years

D. Williams-Herman, E. Round, A. Swern, B. Musser, M.J. Davies, K.D. Kaufman, J.M. Amatruda

Merck Research Laboratories, Rahway, United States

Background and aims: The safety and tolerability of sitagliptin were assessed by pooling data from 12 large, double-blind, randomized, completed Phase IIb and III studies that included 6139 patients receiving either sitagliptin 100 mg/day ($N = 3415$) or placebo or an active comparator ($N=2724$; non-exposed group).

Materials and methods: The studies were 18 wks to 2 yrs in duration and assessed sitagliptin as monotherapy, initial combination therapy with metformin, or add-on to oral antihyperglycemic agents (metformin, pioglitazone, sulfonylurea, sulfonylurea + metformin, or metformin + rosiglitazone). Patients in the non-exposed group were taking placebo, pioglitazone, metformin, sulfonylurea, sulfonylurea + metformin, or metformin + rosiglitazone. Safety data included evaluation of clinical and laboratory adverse experiences (AEs).

Results: The mean exposure to drug was 307 dosing days in the sitagliptin group and 294 dosing days in the non-exposed group. For clinical AEs, the incidences of AEs overall, serious AEs, and discontinuations due to AEs were similar between groups. The number of deaths was 11 (0.3%) in the sitagliptin group and 16 (0.6%) in the non-exposed group. The incidences of drug-related AEs overall and discontinuations due to drug-related AEs were higher in the non-exposed group, primarily due to events of hypoglycemia in sulfonylurea-treated patients. For specific AEs reported more frequently in a

treatment group (with 95% CI around the between-group difference excluding "0"), 6 AEs were higher in the sitagliptin group and 11 were higher in the non-exposed group. The incidence of gastrointestinal AEs did not meaningfully differ between groups. In an analysis in which the proportion of patients with an ischemia-related AE was assessed, no meaningful difference was found between the sitagliptin (2.0%) and non-exposed (2.3%) groups. Three patients (0.09%) in the sitagliptin group had a fatal ischemic event compared with 7 (0.26%) in the non-exposed group. No meaningful differences in immune-related AEs, including the incidence, severity, and types of infections, were found. The number of incident angioedema-related AEs per 100 patient-years while on an ACE inhibitor was the same (0.9) in both groups. No meaningful differences in laboratory AEs, either summary measures or specific AEs, were observed.

Conclusion: In patients with type 2 diabetes, sitagliptin 100 mg/day was well tolerated in clinical trials up to 2 years in duration.

Improved glycaemic control with vildagliptin 100 mg administered either as a morning or evening dose as add-on therapy to metformin in type 2 diabetes mellitus

M. Goodman¹, H. Thurston², B. Minic³, T. Thuren¹

¹Cardiovascular & Metabolism, Global CD&MA, Novartis Pharmaceuticals Corporation, East Hanover, United States, ²Biostatistics, Global CD&MA, Novartis Pharma AG, Basel, Switzerland, ³Cardiovascular & Metabolism, Global CD&MA, Novartis Pharma AG, Basel, Switzerland

Background and aims: Vildagliptin is a potent and selective dipeptidyl peptidase-IV inhibitor that improves glycemic control in patients with type 2 diabetes mellitus (T2DM) by increasing α - and β -cell responsiveness to glucose. A single 100 mg qd dose given before the PM meal was previously shown to suppress hepatic glucose production throughout the overnight period, suggesting that qd PM dosing would be as effective as qd AM dosing. The present study therefore evaluated the efficacy and safety of vildagliptin 100 mg qd as add-on to ongoing metformin therapy in patients whose T2DM was inadequately controlled with metformin alone, with an exploratory objective of comparing the efficacy of a morning or evening vildagliptin dose regimen.

Materials and methods: This 24-week, multicenter, double-blind, parallel-group, placebo-controlled trial randomized patients whose T2DM ($N=370$) was inadequately controlled (HbA_{1c} 7.5–11.0%) on stable metformin monotherapy (≥ 1500 mg daily) to receive either a morning dose (AM), or an evening dose (PM) of vildagliptin 100 mg or placebo as add-on therapy. The primary efficacy variable was comparison of change in HbA_{1c} from baseline to endpoint between the vildagliptin 100 mg qd AM dose and placebo. Amongst the secondary efficacy variables were comparison of the AM and PM dose in reduction of HbA_{1c} levels and responder rate ($\geq 0.7\%$ absolute reduction in HbA_{1c} level from baseline at endpoint).

Results: The AM dose of vildagliptin 100 mg qd significantly reduced HbA_{1c} from baseline to endpoint compared to placebo (adjusted mean change -0.83% ; 95% CI $[-1.13, -0.54]$; $p<0.001$). A similar efficacy was observed irrespective of administration as an AM or PM dose (difference in adjusted mean change -0.13% ; 95% CI $[-0.42, 0.16]$; $p=0.38$). The responder rate was similar irrespective of whether vildagliptin was administered in the morning (53.8%) or evening (50.4%), and this rate was significantly higher in the pooled vildagliptin 100 mg group (AM + PM) compared to placebo (52.1% vs. 21.7%; $p<0.001$). The incidence of adverse events (34.7% and 34.4%) and serious adverse events (2.8% and 2.5%) was similar in the pooled vildagliptin and placebo groups respectively, with a slightly higher incidence of AEs (39.0%) and SAEs (3.3%) in the PM group than the AM or placebo groups.

Conclusion: In T2DM patients inadequately controlled with metformin monotherapy, the addition of either a morning or evening dose of vildagliptin 100 mg qd significantly improved glycemic control. The safety and tolerability profile of vildagliptin added to metformin was comparable to metformin monotherapy plus placebo.

Vildagliptin is as effective as TZDs in metformin failures: results of GALIANT - a primary care diabetes study

R. Bracer¹, L. Blonde², M. Banerji³, S. Dagogo-Jack⁴, R. Pratley⁵, A. Marcellari¹, D. Purkayastha¹, M. Baron¹

¹Novartis Pharmaceuticals, East Hanover, ²Department of Endocrinology, Diabetes and Metabolic Diseases, Ochsner Medical Center, New Orleans,

³Diabetes Treatment Center, SUNY Downstate Medical Center and

Kings County Hospital, Brooklyn, ⁴Division of Endocrinology, Diabetes & Metabolism, University of Tennessee Health Science Center, Memphis,

⁵Diabetes and Metabolism Translational Medicine Unit, University of Vermont College of Medicine, Burlington, United States

Background: Vildagliptin, a potent and selective dipeptidyl peptidase 4 inhibitor has demonstrated efficacy similar to TZDs without weight gain during phase III clinical trials in patients with type 2 diabetes (T2DM).

Materials and methods: GALIANT tested the hypothesis that the efficacy of vildagliptin would be non-inferior to a TZD as add-on therapy in T2DM patients not reaching goal on metformin monotherapy ($HbA_{1c} > 7\%$ while taking ≥ 1000 mg/day). Patients were recruited from primary care sites to ensure they were representative of the US T2DM patient population. The choice of TZD, the initial dose and titration were all left to the discretion of investigator's to simulate TZD use in actual practice. Patients were randomized (2:1) to open-label vildagliptin (100 mg daily [qd]) or a TZD. The ITT population consisted of 2478 patients (vildagliptin, 1653; TZD, 825). The difference between treatment groups for mean change in HbA_{1c} after 12 weeks was the primary efficacy variable. Non-inferiority would be established if the upper limit of the two-sided 95% confidence interval did not exceed 0.4%. Once non-inferiority was demonstrated, superiority would be tested.

Results: Adjusted mean change in HbA_{1c} is illustrated in Figure 1. Vildagliptin was non-inferior to a TZD for the overall population and for subgroups of race (Caucasian/non-Caucasian), age (<65 , ≥ 65) and BMI (<30 , ≥ 30). The overall incidence of adverse events was similar for vildagliptin and TZDs (39.5% and 36.3% respectively). Body weight decreased with vildagliptin (-0.58 ± 0.09 kg) and increased with TZDs (0.33 ± 0.11 kg) ($P < 0.001$). This relationship was seen in all subsets tested.

Conclusion: These data demonstrated that vildagliptin has similar efficacy to a TZD as add-on therapy in patients not reaching goal on metformin and is associated with beneficial effects on weight regardless of race, BMI and age.

Figure 1. Adjusted mean (SE) change in HbA_{1c} levels from baseline to week 12 vildagliptin and TZD

Cardiovascular safety profile of vildagliptin, a new DPP-4 inhibitor for the treatment of type 2 diabetesW. Kothny¹, C. Gimpelewicz², S. Byiers², D. Mills², M. Fitchet¹¹Novartis Pharmaceuticals Corporation, East Hanover, United States,²Novartis Pharma AG, Basel, Switzerland

Background: Vildagliptin, a potent and selective DPP-4 inhibitor, improves islet function by increasing α - and β -cell responsiveness to glucose. The cardio- and cerebrovascular (CCV) safety profile of oral antidiabetics is currently subject to extensive debate. As diabetes per se is an established risk factor for atherosclerosis and ischemic events, an oral antidiabetic treatment should not increase the risk of these adverse events.

Aim: To characterize the cardio- and cerebrovascular safety profile of vildagliptin in diabetic patients.

Methods: The vildagliptin clinical trials database was analyzed for cardio- and cerebrovascular adverse events defined by preferred terms reflecting atherosclerotic or ischemic disease. Additionally, subcategories of pre-defined cardiovascular, cerebrovascular and peripheral vascular adverse events were analyzed. For these categories, the adverse event incidence rates and corresponding unadjusted odds ratios of each treatment group vs. placebo are presented.

Results: In the treated patients (3784), overall incidences of cardio- and cerebrovascular events for vildagliptin 50mg qd (0.7%) and 50mg bid (0.6%) were less than placebo (1.3%); the corresponding unadjusted odds ratios were less than 1 (0.55 and 0.45 respectively, $p < 0.05$ vildagliptin 50mg bid vs placebo). There were no predefined peripheral vascular adverse events on vildagliptin or placebo. The incidence rates of all cardio- and cerebrovascular serious adverse events observed for vildagliptin 50mg qd and 50mg bid were lower than placebo (0.5% and 0.5% respectively vs. 0.9%); corresponding unadjusted odds ratios were below 1 (0.54 and 0.64 respectively). Analysis of cardio- and cerebrovascular (preferred terms) did not reveal clustering of any specific events.

Conclusion: Adverse event data from vildagliptin clinical trials reveals a favorable cardiovascular safety profile

Dipeptidyl-peptidase 4 inhibition augments postprandial lipid mobilization and oxidation in type 2 diabetic patientsM. Boschmann¹, S. Engeli², P. Budziarek¹, A. Strauss¹, F. Sweep³, F.C. Luft¹, H. Yan-Ling⁴, R. Szabo⁵, J. Jordan²

¹Franz Volhard CRC, University Medicine Berlin, Germany, ²Institute of Clinical Pharmacology, Hannover Medical School, Germany, ³Department of Clinical Endocrinology, Radboud University Medical Center, Nijmegen, Netherlands, ⁴Exploratory Clinical Development, Novartis Institute for Biomedical Research Inc., Cambridge, United States, ⁵Exploratory Clinical Development, Novartis Pharmaceutical Corporation, East Hanover, United States

Background and aims: The metabolic response to dipeptidyl-peptidase-IV (DPP-4) inhibition has been primarily attributed to glucagon like peptide-1 (GLP-1) mediated improvement in glucose-dependent insulin and glucagon secretion. Based on recent studies with the selective DPP-4 inhibitor vildagliptin, we tested the hypothesis that there may be an additional direct effect on tissue metabolism.

Materials and methods: We included 20 patients with type 2 diabetes, body mass index between 28 and 40 kg/m², and an HbA_{1c} of < 9% at screening. Within a randomized, double blind, cross-over study, we compared seven days treatment with 100 mg/day vildagliptin vs. placebo. On the last day of each treatment period, patients underwent a thorough metabolic evaluation before and after ingestion of a mixed meal (5 kcal/ kg body weight) including indirect calorimetry and microdialysis in abdominal subcutaneous adipose tissue and in the vastus lateralis muscle.

Results: Vildagliptin inhibited DPP-4 activity and substantially raised postprandial GLP-1 concentrations. Fasting and postprandial blood pressure, heart rate as well as venous glucose, insulin, glycerol, and free fatty acids were virtually identical with vildagliptin and with placebo. Vildagliptin augmented postprandial plasma norepinephrine ($p < 0.01$). Furthermore, vildagliptin increased dialysate glycerol and lactate concentrations in adipose tissue and attenuated postprandial lactate concentrations in skeletal muscle ($p < 0.0001$ for all). Postprandial carbohydrate oxidation rate was reduced and lipid oxidation rate was increased with vildagliptin ($p < 0.01$ for both).

Conclusion: Augmentation of endogenous GLP-1 through DPP-4 inhibition improves postprandial lipid mobilization and oxidation. The response may have been secondary to GLP-1 mediated sympathetic activation.

917

Inhibition of DPP-4 with vildagliptin improved insulin secretion in response to oral as well as "isoglycaemic" glucose without numerically changing the incretin effect in patients with type 2 diabetesJ.E. Foley¹, L. Becker², L. Köthe³, S. Dejager³, A. Schweizer⁴, M.A. Nauck²

¹ Novartis, East Hanover, United States, ²Diabeteszentrum, Bad Lauterberg im Harz, Germany, ³Novartis, Paris, France, ⁴Novartis, Basel, Switzerland

Background and aims: The incretin effect is the higher insulin secretory response to oral as compared to intravenous glucose caused by gastrointestinal hormones like GIP and GLP-1. Typically, the incretin effect is reduced or lost in patients with Type 2 diabetes (T2DM). DPP-4 inhibitors block the degradation and inactivation of GLP-1 and GIP, thereby increasing nutrient-stimulated plasma concentrations of these incretins. The aim of the present study was to assess insulin secretory responses to oral glucose as well as "isoglycaemic" intravenous glucose infusions in order to quantitatively assess the incretin effect after treatment of patients with T2DM previously on metformin after 12 or 13 days of additional treatment with the DPP-4 inhibitor vildagliptin or placebo.

Materials and methods: 21 patients with type 2 diabetes previously treated with metformin (~2 g/day), including 3 women and 18 men with the mean \pm SE of age (59.0 ± 1.9 years), of BMI (28.7 ± 0.6 kg/m²), of fasting plasma glucose (9.6 ± 0.5 mmol/L), of HbA_{1c} (7.3 ± 0.1 %) and of duration of diabetes (5.9 ± 0.7 years), were studied in a two-period crossover design. They received vildagliptin, 100 mg once daily, or placebo, for 13 days, in randomized order. On day 12, an oral glucose challenge (75 g) was administered in the morning 30 min after the medication. On day 13, an "isoglycaemic" intravenous glucose infusion was guided by measuring capillary glucose every 5 min to match the glycaemic excursion after oral glucose. Blood was drawn over 240 min for the determination of glucose (capillary), insulin, and C-peptide (venous). The incretin effect was calculated as the difference in the insulin secretory responses between oral and "isoglycaemic" intravenous glucose stimulation relative to that after oral glucose (= 100 %). Statistics: Repeated-measures analysis of variance.

Results: Glucose concentrations during "isoglycaemic" intravenous glucose infusions were well matched to those after oral glucose. Starting from similar baseline values, vildagliptin relative to placebo treatment significantly increased insulin secretory responses to both oral glucose and "isoglycaemic" intravenous glucose (e.g., AUC_{C-peptide oral} by 31.4 %, $p = 0.0002$; AUC_{C-peptide iv} by 33.7 %, $p = 0.026$). The incretin effect (IE) was not changed significantly for vildagliptin versus placebo (IE_{C-peptide} 38.5 ± 5.2 vs. 39.7 ± 3.7 %, $p = 0.97$).

Conclusions: DPP-4 inhibition with vildagliptin improved insulin secretory responses after stimulation with both oral and intravenous glucose. As a result and against expectations, the incretin effect was not significantly improved. The vildagliptin effect on insulin secretion stimulated by intravenous glucose may be mediated by increased basal incretin levels, a change in the incretin-related environment of islets with beneficial effects persisting at least overnight, or influences on other, yet identified mediators of DPP-4 inhibition.

Impact of rosiglitazone discontinuation on glycaemic control

P. Weissman¹, B. Arondekar², L. Menditto²¹School of Medicine, University of Miami, ²US Health Outcomes, GSK, Philadelphia, United States

Background and aims: Because of the media controversy in 2007 regarding the association of thiazolidinediones and risk of ischemic cardiovascular events, this study aimed to evaluate the impact of discontinuation of rosiglitazone (RSG) therapy on glycemic control in patients (pts) with type 2 diabetes (T2D). Although, no prospective, randomized clinical trial has conclusively demonstrated a link between TZDs and increase in ischemic cardiovascular events, there is an established link between loss of glycemic control and increased risk of long term microvascular complications.

Materials and methods: Data from the General Electric (GE) Centricity electronic medical records database was used to identify T2D pts with 2 or more prescriptions (Rx's) for RSG (as monotherapy (mono) or combination (combo) therapy) in a 12 month period prior to 5/21/2007 who subsequently discontinued RSG. Discontinuation was defined as no new Rx for RSG (in a follow-up visit post 5/21/2007), or a stop date for RSG recorded in the database, or no new Rx for RSG in a 90 day period following last date of previous Rx for RSG prior to 5/21/2007. Data on these pts were available until 9/30/2007. Outcomes assessed included Rx patterns, FPG levels, HbA1c levels, and percentage of pts at goal post discontinuation. Lab values were assessed in patients irrespective of whether they received no new OAD, a new add-on agent or continued on the second agent (for combo pts.).

Results: A total of 6,871 patients (64% aged 40-69 years, 50% males) who were on RSG mono (41%) or combo therapy (28% RSG+Metformin (MET), 15% RSG+Sulfonylurea (SU), 6.5% RSG+MET+SU, 5% RSG+Insulin (INS), 5% RSG+others) discontinued RSG following 5/21/2007. Among those who discontinued, 33.4% did not receive a subsequent Rx for any OAD or INS, 20% received a Rx for MET mono, 15% for SU mono, 10% INS mono, 9% pioglitazone mono. Patients on RSG mono (and with lab values prior and post discontinuation - last FPG on RSG and first FPG post discontinuation) experienced an increase in FPG levels from 132.5 mg/dL to 140.4 mg/dL ($p=0.14$) with 53% of patients at goal (FPG<130mg/dL) prior to discontinuation compared to 49% post RSG discontinuation. Similarly, pts on combo RSG therapy who discontinued also experience a statistically significant increase in FPG levels post discontinuation (134.5mg/dL to 143.7mg/dL, $p=0.025$) and decrease in number of patients at goal from 43% to 39.8%. There was no change in HbA1c levels, consistent with the short duration of follow-up.

Conclusion: A third of the pts who discontinued RSG post 5/21/2007 did not receive any Rx for an OAD or INS post discontinuation. There was an increase in FPG levels post RSG discontinuation with fewer patients at goal following discontinuation. The follow-up period was short and no difference in HbA1c levels was observed. The loss of glycemic control in the short-term could potentially impact the outcomes of these patients. This data highlights trends which suggest that discontinuation of RSG may be associated with undesirable trends in medication use and glycemic control.

Rosiglitazone treatment in non-alcoholic fatty liver disease

E. Szymanska-Garbacz¹, M. Saryusz-Wolska¹, M. Jablowski²,J. Bialkowska², A. Borkowska¹, A. Omulecka³, J. Loba¹, L. Czupryniak¹¹Diabetology & Metabolic Disease Dept, ²Infectious Diseases Dept,³Pathology Dept, Medical University of Lodz, Poland

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is associated with insulin resistance, subclinical inflammation and increased risk of diabetes development. Glitazones as compounds directly improving insulin sensitivity have been suggested as potential agents for NAFLD treatment. We conducted a prospective study aiming at assessing the efficacy and safety of rosiglitazone (RSG) treatment in a group of individuals with NAFLD and normal glucose tolerance.

Materials and methods: Twenty-seven non-diabetes and otherwise healthy subjects (mean [\pm SD] age 43.9 \pm 10.8 years, BMI 29.2 \pm 3.1 kg/m²) with biopsy-confirmed NAFLD were enrolled into an open-label controlled prospective study and were given RSG 4 mg once daily for 6 months. The control group comprised 13 age-, gender-, and BMI-matched healthy subjects, without any pharmacological treatment. Body weight, oral glucose tolerance test (OGTT) with plasma glucose and insulin measurements extended to 240 min, HbA1c, lipids, aspartate aminotransferase (AST) and alanine aminotransferase (ALT) activity, plasma subclinical inflammation and endothelial dysfunction markers (TNF- α , sVCAM, sICAM, sE-selectin, interleukins IL-1 β , IL-6, thrombomodulin [TM]), adiponectin and hematocrit were assessed at baseline and after the treatment period.

Results: At baseline NAFLD subjects had significantly elevated AST and ALT activities, glucose at 60 min and insulin at all time points of OGTT, HOMA, triglycerides, sE-selectin, IL-6 and TM as well as lower HDL cholesterol and adiponectin as compared to the controls. After 6 months of RSG treatment ALT activity decreased significantly (from 104 \pm 60 to 74 \pm 56 IU/l, $p<0.05$). No change in mean body weight, plasma glucose, HbA1c or lipids was noted. Insulin levels decreased significantly by 30-50% in each point of OGTT as well as HOMA index (from 3.71 \pm 1.95 to 2.05 \pm 1.68, $p<0.001$). Adiponectin increased from 2178 \pm 1904 to 5557 \pm 2164 ng/ml ($p<0.001$), sE-selectin decreased from 75.8 \pm 33.5 to 52.2 \pm 20.5 ng/ml ($p<0.01$) as did IL-6 (from 8.0 \pm 4.1 to 5.0 \pm 1.9 pg/ml, $p<0.01$) and TM (from 1.82 \pm 0.59 to 1.44 \pm 0.48 ng/ml, $p<0.05$). Other assessed parameters remained stable. No adverse events were noted during the study.

Conclusion: RSG treatment in non-diabetes individuals with NAFLD was associated with significant increase in insulin sensitivity. In addition, RSG use resulted in marked improvement of liver and endothelial function as well as decrease in subclinical inflammation, and these effects were apparently unrelated to changes in blood glucose or lipids levels. However, long-term beneficial effects of RSG treatment in NAFLD subjects remain to be confirmed.

Medication adherence to a fixed dose combination (FDC) of glimepiride/rosiglitazone maleate in a managed health care plan

L. Menditto¹, B. Arondekar¹, S. Thayer², C. Harley²¹GlaxoSmithKline, Philadelphia, United States, ²Health Economics and Outcomes, i3 Innovus, Eden Prairie, United States

Background and aims: The purpose of this study was to assess changes in medication adherence rates associated with oral hypoglycemic agents in patients switching from monotherapy (mono) or dual therapy with sulfonylurea (SU) and/or rosiglitazone (RSG) to glimepiride-rosiglitazone FDC therapy. We hypothesized that switching to FDC therapy would lead to increased adherence to prescribed medications.

Materials and methods: This was a retrospective, claims-based analysis using data from a large, US managed care plan. Subjects with ≥ 1 Rx fills for RSG,

Medication Possession Ratio

	Baseline MPRMean (Std Dev)	Baseline MPRMean (Std Dev)	Change in MPRMean (Std Dev)	P-value
Mono/Dual (N=2,518)	0.91 (0.12)	0.81 (0.13)	-0.10 (0.13)	
Mono/FDC (N=543)	0.89 (0.13)	0.87 (0.14)	-0.03 (0.16)	Mono/Dual vs. Mono/FDC $P<0.0001$
Dual/Dual (N=13,145)	0.84 (0.16)	0.89 (0.12)	0.05 (0.14)	
Dual/FDC (N=284)	0.77 (0.18)	0.87 (0.14)	0.10 (0.20)	Dual/Dual vs. Dual/FDC $P<0.0001$

SU, or glimepiride-rosiglitazone (GL-RSG) FDC therapy during the identification period were included. Subjects who received either SU or RSG mono during the pre-index (pre-I) period and switched to dual therapy (SU+RSG) in the post-index (post-I) period (Mono/Dual cohort) were compared with those who switched to FDC therapy (Mono/FDC cohort). Subjects who received dual therapy with SU and RSG during the pre-I period and remained on dual therapy in the post-I period (Dual/Dual cohort) were compared with those who switched to FDC therapy (Dual/FDC cohort). Change in Medication Possession Ratio (MPR) was assessed.

Results: The study sample included 16,490 subjects with mean age of 57 years. 64% of the subjects were male. There was significantly less reduction in the mean MPR between pre-I period and the post-I period for the Mono/FDC cohort compared with the Mono/Dual cohort (-0.03 vs. -0.10 ; $p<0.0001$). There was significantly greater improvement in the MPR change for the Dual/FDC cohort compared with the Dual/Dual cohort (0.10 vs. 0.05 ; $p<0.0001$).

Conclusion: This study identified a relationship between adherence to therapy and Rx drug regimens, namely significantly less reduction in mean MPR when mono users switch to FDC vs. dual therapies and greater improvement in mean MPR when dual therapy users switch to FDC vs. remaining on dual therapies.

921

Achieving glycaemic goal with initial combination therapy versus sequential augmentation therapy using metformin and pioglitazone

B.J. Pandya¹, A. Yu², E. Wu², K. Chen², A. Kaltenboeck², J. Seale², M. Mattson², M. Bron¹, R.W. Baran¹

¹Takeda Global Research & Development Center, Inc., Deerfield,

²Consulting Services, Analysis Group, Inc., Boston, United States

Background and aims: Aggressive control of diabetes is recommended by clinical guidelines. This study aims to determine if early, simultaneous combination of oral antidiabetic (OAD) therapy offers a clinical outcomes benefit over sequential augmentation therapy in treated populations. Thus, we compared glycaemic goal achievement (glycosylated hemoglobin [HbA_{1c}] $<7\%$) in patients with type 2 diabetes mellitus (T2DM) treated with an initial combination of metformin and pioglitazone (fixed-dose or loose-dose) (COMBO) vs those treated sequentially with initial metformin monotherapy and later augmented with pioglitazone (AUG).

Materials and methods: Adult T2DM patients treated with COMBO or AUG therapy were identified from the Integrated Healthcare Information Services (IHGIS) claims database (01/01/00–03/31/07), which includes medical, pharmacy, and lab records. Patients were included with a baseline $HbA_{1c} \geq 7\%$ and a second lab value within 9 months following therapy initiation. The proportion of patients achieving $HbA_{1c} < 7\%$ was examined at months 6, 12, 18, and 24 (± 3 months). Last observation carried forward (LOCF) was applied to impute missing HbA_{1c} values. Goal achievement was studied in subgroups of patients with baseline HbA_{1c} between 7% and 9% and $HbA_{1c} > 9\%$. Baseline differences were adjusted in the logistic regression by controlling for age, gender, baseline HbA_{1c} , comorbidities, prior resource utilization, and prior medications use.

Results: Of the 561 study patients, 213 received COMBO, and 348 received AUG. More patients in the COMBO than AUG groups achieved goal (70.9% vs 49.4%, 68.5% vs 46.6%, 67.1% vs 46.0%, and 67.1% vs 45.7%) at months 6, 12, 18, 24, respectively (all $P<0.0001$). Logistic regression confirmed the findings, as AUG therapy exhibited odds ratios (OR) of 0.26–0.27 across all time points ($P<0.0001$). Further subgroup analysis revealed that the clinical advantage of COMBO therapy is more pronounced among patients with baseline $HbA_{1c} > 9\%$ (OR: 0.13–0.15; all $P<0.001$) than those with baseline HbA_{1c} between 7% and 9% (OR: 0.36–0.43; all $P<0.0025$).

Conclusion: Patients treated with simultaneous combination therapy are more likely to achieve glycaemic goal ($HbA_{1c} < 7\%$) than those treated with sequential augmentation therapy. This benefit is especially more pronounced among those patients with higher baseline HbA_{1c} levels.

Goal Achievement by Group

Month	COMBO Therapy (N=213)		AUG Therapy (N=348)		P-Value
	N	%	N	%	
6	151	70.9	172	49.4	<0.0001
12	146	68.5	162	46.6	<0.0001
18	143	67.1	160	46.0	<0.0001
24	143	67.1	159	45.7	<0.0001

INT131, a non-TZD selective PPAR γ modulator (SPARM), does not cause toxicities typical of TZD full PPAR γ agonists following 6-month high dose treatment of rats or monkeys

A.M. DePaoli, L.S. Higgins

Development, InteKrin Therapeutics, Los Altos, United States

Background and aims: PPAR γ is a validated target for treatment of insulin resistance, but the available thiazolidinedione (TZD) full agonists have significant side effects. INT131 (formerly T0903131, T131, and AMG 131) is a potent non-TZD selective PPAR γ modulator (SPARM) being developed for treatment of type 2 diabetes mellitus (T2DM). INT131 has demonstrated consistent unique properties in functional assays for receptor activation compared with multiple PPAR γ full agonists. Studies with INT131 in rodent models of T2DM have demonstrated similar insulin sensitizing and glucose lowering activity with significantly less fluid retention, weight gain and cardiac hypertrophy than seen with currently available TZDs. A four week clinical study with INT131 in subjects with T2DM has similarly demonstrated significant dose responsive insulin sensitizing and glucose lowering actions, and suggested this efficacy can be separated from typical TZD side effects such as weight gain and fluid retention. Preclinical results for numerous PPAR ligands in rodent and monkey have shown time and dose dependent fluid retention, edema, cardiac hypertrophy, fatty replacement of bone marrow, and in some cases cardiac death. In order to assess the safety profile of INT131, six month safety studies were conducted in cynomolgus monkeys and in rats.

Material and methods: Cynomolgus monkeys were treated with 0, 0.3, 3.0, or 30 mg/kg/d INT131 Besylate by nasogastric gavage once daily for 26 weeks. Groups included 4 animals/sex/dose, with 2 additional animals/sex for 0 and 30 mg/kg/day groups for a 4 week recovery period. Sprague-Dawley rats were treated with 0, 30, 100, or 100 mg/kg/d INT131 Besylate by gavage once daily for 26 weeks. Groups included 15 animals/sex/dose, with 5 additional animals/sex/ group which completed a 4 week recovery period after the dosing period. Measurements for both studies included TK, body weight, clinical observations, hematology, clinical chemistry, urinalysis, organ weight, gross necropsy and microscopic observations. The monkey study also included ECG, ophthalmology exam, echocardiograms, and careful observation for edema.

Results: INT131 was well tolerated with no clinical indications of edema, signs of plasma volume expansion, cardiac hypertrophy, significant weight gain, hepatic toxicity, or fatty replacement of marrow in either rats or monkeys at any dose. The NOAEL was identified in monkey as the high dose (30 mg/kg/d), which translated to exposures of equal or greater than 70 fold the anticipated clinical exposure in the Phase 2b. Greater exposures were attained in the rat, with absence of typical PPAR γ full agonist toxicities at 2–10 fold (males/ females) higher levels than in the high dose monkey group.

Conclusion: INT131 demonstrated no significant fluid retention, weight gain, cardiac hypertrophy, or hepatic toxicity in cynomolgus monkeys or in rats over 6 months at dose exposure multiples of equal or greater than 70 times the anticipated clinical exposure in the highest dose in an ongoing Phase 2b study in subjects with T2DM. These results support in-vitro studies, rodent studies, and the clinical data demonstrating that INT131 is a SPARM with unique PPAR γ activating properties which minimize the commonly recognized side effects seen with full PPAR γ agonists. These data support further study of INT131 as a potent insulin sensitizer for the treatment of T2DM without the significant side effects of the TZDs.

Prevalence of stroke and transient ischaemic attack in diabetic medicare patients treated with oral antidiabetics in the US

F. Shaya¹, C.M. Gbarayor¹, D. Du¹, B. Stuart², T. Shaffer², M. Bron³, B. Pandya³, R.W. Baran³

¹Department of Pharmaceutical Health Services Research, University of Maryland School of Pharmacy, Baltimore, ²Peter Lamy Center for Drug Therapy and Aging, University of Maryland School of Pharmacy, Baltimore,

³Takeda Global Research & Development Center, Inc., Deerfield, United States

Background and aims: Diabetes is a major risk factor for cardiovascular comorbidities. This study aims to determine the prevalence of stroke in elderly diabetic patients based on the Medicare Beneficiary Survey (MCBS) of type 2 diabetic patients in the US. Patients treated with background oral antidiabetic

drugs (OADs), and on metformin (MET), sulfonylureas (SUs), pioglitazone (PIO), and rosiglitazone (ROSI) therapies were examined.

Materials and methods: All MCBS fee-for-service enrollees in 2001–03 with a diagnosis of type 2 diabetes (T2DM) were extracted for a cross-sectional analysis. Patients were included in the analysis if they were aged ≥ 65 years, were residing in the community, were treated with OADs, and reported data in the Cost and Use portion of MCBS Part A and B. An analytic file was constructed for each patient, with demographics, historical diagnosis, drug utilization, comorbidities, and mortality. Regression analysis was used to assess the correlation between MET, SUs, PIO, and ROSI use and stroke, adjusting for age, race, gender, comorbidities, and functional status.

Results: Of 8,348 patients available for analysis in MCBS sample database, 1,826 were diagnosed with T2DM. Demographically, most were Caucasian (74%), lived in urban areas (72%), reported good health (60%), and were not dependent on others for their activities of daily living (60%). Additionally, most T2DM patients were treated with insulin or OADs (60%), and a smaller cohort used at least PIO or ROSI (14%). Of 1,826 Medicare T2DM patients in 2001, the prevalence of stroke with transient ischemic attack (TIA) was 5% (N=98) and 4% (N=67) for stroke without TIA. Similar trends continued in 2002–03. Patient characteristics such as older age, higher comorbidities, and restricted activities of daily living were correlated with a higher prevalence of stroke in the analysis. When data were pooled into datasets with 3 years of follow-up and adjusted for disease severity (diabetic OAD users N=831), the prevalence of stroke without TIA in 617 SU patients was 3.96%, in 416 MET patients was 3.4%, in 92 PIO patients was 3.94%, and in 115 ROSI patients was 5.06%. Prevalence of stroke with TIA in these respective groups was 6.2%, 5.3%, 6.25%, and 7.0%.

Conclusion: This is the first analysis of stroke occurrence and correlation to OAD use in the US type 2 diabetic Medicare population. In a largely Caucasian, urban, healthy, and independent elderly diabetic population with background OAD use, prevalence of stroke without TIA ranged from 3.4% to 5.06%, while stroke with TIA ranged from 5.3% to 7.0%. These results suggest a need for greater awareness of stroke rates in the elderly diabetic population receiving US Medicare benefits.

924

Risk of cardiovascular disease and mortality in type 2 diabetes: a comparison between metformin, sulfonylureas and thiazolidinediones by meta-analysis

J.B. Ruige¹, H. Vanhee¹, D. De Bacquer², J. Kaufman¹, G. T'Sjoen¹

¹Endocrinology, University Hospital Ghent, ²Public Health, Ghent University, Ghent, Belgium

Background and aims: Metformin, sulfonylureas and thiazolidinediones (TZDs) are commonly used for treatment of hyperglycemia in type 2 diabetes mellitus, which is strongly associated with cardiovascular disease (CVD) and mortality. Our purpose was to estimate possible class effects of oral anti-hyperglycemic agents on CVD and mortality.

Materials and methods: Articles were identified by means of a MEDLINE and Embase search and citation tracking. Eligible studies were cohort studies, nested case-control studies and RCTs on the relationship between a single class of agent and CVD or mortality. Data was extracted pertaining to class of oral agent used, type of outcome studied, study design, presence or absence of cardiac morbidity at baseline, sex, mean age of study population, BMI, follow-up period and total number of study subjects. Associations of classes of agents and CVD or mortality were re-expressed in a uniform manner, an estimate of the odds ratio (OR) and 95% CI, to be used in meta-regression analyses.

Results: Eleven out of 13 potentially eligible articles provided sufficient information (total number of events: 43289). The meta-analyses suggested a favourable outcome for metformin; compared to sulfonylureas a summary OR (95%CI) of 0.59 (0.40 to 0.87) was estimated, and, compared to TZDs a summary OR of 0.69 (0.55 to 0.86) was estimated. Sulfonylureas might be preferable to TZDs with an OR of 0.79 (0.59 to 1.06) (all random-effects models; P value of heterogeneity test < 0.05). Meta-regression analysis did not identify study-characteristics modifying the relationship between class of agents and CVD or mortality.

Conclusion: Metformin is associated with a favourable outcome with respect to CVD and mortality, if used as first-line anti-hyperglycemic agent in type 2 diabetes mellitus.

925

Rosiglitazone treatment and cardiovascular disease in the Veterans Affairs Diabetes Trial

H.J. Florez^{1,2}, T. Moritz³, J. Marks^{1,2}, D. Reda³, S. Warren⁴, W. Duckworth⁵, C. Abaira^{1,2}

¹Medicine, University of Miami, ²VADT Research Group, Miami VA Medical Center, Miami, ³VADT Research Group, Hines VA Cooperative Studies Program Coordinating Center, Hines, ⁴VADT Research Group, CSP - Research Pharmacy Coordinating Ctr, Albuquerque, ⁵VADT Research Group, Phoenix VA Medical Center, Phoenix, United States

Background: Recent data suggest that the insulin sensitizer rosiglitazone may be associated with increased risk of cardiovascular disease (CVD) in patients with type 2 diabetes (T2D).

Methods: We evaluated the patterns of rosiglitazone use and its effect on CVD in 1792 patients age 60 ± 8.7 years and with T2D for 11.5 ± 7.5 years enrolled in the Veteran's Affairs Diabetes Trial (VADT). The VADT is assessing the effect of intensive glycemic control on a composite CVD endpoint that includes: myocardial infarction (MI), congestive heart failure (CHF), invasive revascularization, inoperable coronary artery disease (CAD), amputation for ischemia, stroke or cardiovascular death.

Results: The frequency of rosiglitazone use was greater in the intensive group than in the standard group ($p < 0.05$) (table). However, the use in both groups decreased over time according to safety prescription guidelines and as participants required increasing use of other agents to maintain appropriate separation in A1c values (median A1c after 6 months, 6.9% intensive vs. 8.4% standard), with the median insulin dose steadily 20% higher in the intensive arm during the study. After an interim average follow-up of 5.3 years, a total of 966 primary endpoints (in 540 patients) have been confirmed. The effect of dosage and duration of rosiglitazone use on CVD outcomes will be evaluated in the entire cohort with time-dependent covariate survival analysis, with data collected until April 30th, 2008.

Conclusion: These results suggest that in older patients with T2D the use of rosiglitazone may help sustain glycemic control. We will present a full report of the effect of rosiglitazone on CVD outcomes based on the complete data available at the end of the study.

Rosiglitazone use during the first 5 years according to treatment group

Treatment Group	Year 1	Year 2	Year 3	Year 4	Year 5
Standard	77.6% (633/816)	66.8% (510/764)	63.6% (466/733)	57.6% (392/681)	53.8% (220/409)
Intensive	82.5% (661/801)	76.2% (578/759)	73.4% (523/713)	68.2% (451/661)	65.5% (258/394)

Effect of thiazolidinediones on bone metabolism in diabetic patients

B. Carteni, M. D'Adamo, B. Miccheli, V. Guglielmi, G. Donadel, D. Lauro, M. Federici, R. Lauro, P. Sbraccia
Internal Medicine, University of Rome, Italy

Background and aims: Thiazolidinediones (TZDs) have been shown in vitro to have an effect on bone metabolism through the inhibition of osteoblasts differentiation and function. Studies in mice treated with rosiglitazone (ROSI) have confirmed this finding showing decreased bone mass. Furthermore recent studies have documented the effect of 12 weeks of ROSI treatment in post-menopausal women on bone metabolism showing reduced levels of bone formation.

The aim of our study was to assess the association between TZDs treatment and bone metabolism.

Materials and methods: To this end, we studied a group of 20 diabetic subjects treated with TZDs (18 pioglitazone, 2 ROSI; 12M/8F; aged 62.3 ± 1.9) alone or in association with other oral hypoglycaemic agents (OHA) and/or insulin (TZD group), compared to 18, age and sex -matched diabetics treated with other OHA and/or insulin (No-TZD group); both treatments lasted for at least 6 months. The two groups did not differ as regard to metabolic control (HbA1c), disease duration and BMI.

All subjects underwent DEXA scan to evaluate bone mass at the lumbar and femoral site; evaluation of bone metabolism was performed by serum measurement of bone formation markers alkaline phosphatase, total and bone isoforms (ALP, B-ALP), and osteoprotegerin (OPG), and bone resorption marker C-telopeptide of collagen (CTX-I), whereas calcium metabolism was assessed by measurement of serum calcium and phosphate, plasma parathyroid hormone (PTH), 25-OH Vitamin D₃.

Results: Bone mineral density (BMD) at the hip was similar in the two groups, whereas BMD at the lumbar spine was significantly lower in the TZD group vs. No-TZD (Z-score 0.05 ± 0.34 vs. 1.12 ± 0.36 , $p=0.03$), although values were in the normal range for both groups. Serum calcium and phosphate levels, PTH, OPG and 25-OH VitD₃ were not different in the two groups. CTX-I was higher in TZD vs. No-TZD (0.27 ± 0.03 ng/ml vs. 0.17 ± 0.02 ng/ml, $p=0.01$), whereas the difference between serum B-ALP levels in the two groups approached the statistical significance, with the TZD group showing lower levels (21.64 ± 1.6 UI/L vs. 29.39 ± 9.3 UI/L). Moreover, bone metabolism markers levels did not correlate with HbA1c, disease duration, age, and years since menopause (in females).

Conclusion: In summary our data show that TZD treated diabetic subjects have higher levels of bone resorption compared to a control group (No-TZD), and slightly, although not significant, lower levels of bone formation. Our findings appear in agreement with recent in vitro study showing a novel role for PPAR γ in osteoclast differentiation.

Glucokinase activator RO4389620 improves beta cell function and plasma glucose fluxes in patients with type 2 diabetes

R.C. Bonadonna¹, C. Kapitza², T. Heise², A. Avogaro³, M. Boldrin⁴, J. Grimsby⁴, M.E. Mulligan⁴, C. Arbet-Engels⁴, R. Balena⁵

¹Department of Biomedical and Surgical Sciences, University of Verona School of Medicine, Italy, ²Profil Institut für Stoffwechselforschung GmbH, Neuss, Germany, ³Department of Experimental Medicine, University of Padova School of Medicine, Italy, ⁴Hoffmann-La Roche Ltd, Nutley, United States, ⁵Hoffmann-La Roche Ltd, Basel, Switzerland

Background: Glucokinase (GK) plays a key role in glucose (G) regulation.

Aims: We tested the acute G lowering effects of RO4389620, an allosteric GK activator (half-life: ~7.5 hours), developed for type 2 diabetes treatment.

Research Methods: Fifteen patients with diet-treated type 2 diabetes (51 ± 2 years (mean \pm SEM); BMI 29.2 ± 0.9 kg m⁻²) received a single oral dose of placebo (Plc), 25 mg (D25) or 100 mg (D100) RO4389620 120 min before an oral 75 g G load labeled with 1-²H-G, in a randomized, double-blind, 3-period crossover study. 6,6-²H-G was infused to measure endogenous G output (EGO) and G utilization (GU). G fluxes units are presented as $\mu\text{mol min}^{-1} \text{m}^{-2}$ BSA.

Results: Fasting G (see Figure) was lower with RO4389620 (7.5 ± 0.3 vs. 6.7 ± 0.4 vs. 5.4 ± 0.3 mM, Plc vs. D25 vs. D100, respectively; $p < 0.001$) due to a decline in EGO (314 ± 12 , 266 ± 15 , 117 ± 20 ; $p < 0.01$) and a tiny increase in GU (340 ± 13 , 341 ± 11 , 383 ± 16 ; $p < 0.05$). Plasma G levels during the OGTT (see Figure) were lower with both D25 and D100 (mean difference over 5-hours vs Plc, corrected for fasting G: -1.03 ± 0.28 mM and -2.34 ± 0.28 mM/L, respectively; $p < 0.001$), probably due to somewhat higher GU in the early phase of the OGTT (D100 vs. Plc. 0-120 min, 1182 ± 63 vs 1003 ± 65 , $p < 0.03$). Analysis of OGTT plasma G and C-peptide concentration curves by state-of-art mathematical modeling showed that the sensitivity of β -cells to both the rate of increase of G (derivative or dynamic control) (1223 ± 244 vs. 1781 ± 542 vs. 2666 ± 500 pmol m⁻² per mM/min; $p < 0.02$ for D100 vs Plc) and to G concentration (proportional or static control) (191 ± 25 vs 145 ± 18 , 353 ± 44 vs 215 ± 24 , 799 ± 116 vs 462 ± 59 , 1257 ± 197 vs 723 ± 100 pmol min⁻¹ m⁻², D100 vs Plc at G = 5.0, 7.5, 11.7 and 15.0 mM, respectively; $p < 0.01$) was higher with RO4389620.

Conclusion: Single dose administration of GK-activator RO4389620 lowers both fasting and post-challenge G in patients with type 2 diabetes, by improving β -cell function, EGO and GU. GK activation is a promising route to pursue in type 2 diabetes therapy.

Phase I assessments of a novel glucokinase activator RO4389620 in healthy male volunteersS. Zhai¹, M.-E. Mulligan¹, J. Grimsby¹, C. Arbet-Engels¹, M. Boldrin¹, R. Balena², J. Zhi¹¹Roche, Nutley, United States, ²F. Hoffmann-La Roche Ltd, Basel, Switzerland

Background and aims: RO4389620 is a nonessential, mixed-type activator of glucokinase (GK). It binds to an allosteric site on GK, which leads to an increase in the catalytic effectiveness of GK to metabolize glucose, and increases the glucose phosphorylation capacity of pancreatic β -cells and hepatocytes. Thus, RO4389620 is proposed as a novel treatment of type 2 diabetes. The aim of the present phase I studies was to assess the pharmacokinetics (PK) and pharmacodynamics (PD), tolerability, and, safety of single ascending doses (SAD) of RO4389620, as well as the potential food effect (FE) on RO4389620 PK.

Material and methods: SAD was a double-blind, randomized, placebo-controlled study and FE was an open-label, two-way crossover study; both were conducted in healthy male volunteers (HVs). In the SAD study, 24 HVs received a single oral dose of RO4389620 or placebo; the dose escalation was a leap-frog design at doses of 5, 10, and, 25 mg. In the FE study (N = 16), a single dose of 10 mg was administered with and without a high fat, high calorie meal. Blood and urine samples were collected up to 48 hours for PK analysis. PD assessments included 4 h profile of plasma glucose, insulin, C-peptide, and glucagon.

Results: RO4389620 was rapidly absorbed with an elimination half-life of 8 to 10 hours. C_{max} and $AUC_{0-\infty}$ (RO4389620 and its inactive metabolite M4) were proportional to doses. Approximately 13% of the dose was excreted in urine as unchanged drug. Administration of RO4389620 resulted in a dose dependent glucose reduction in 4-h fasting plasma glucose; the nadir in fasting glucose levels decreased with RO4389620 dose, ranging from a median change from baseline of -13% at 5 mg to -22% at 25 mg. No clinically meaningful food-effect on RO4389620 PK was observed from the FE study. RO4389620 was well tolerated up to 25 mg in HVs. The most common adverse event was headache, with no clear dose-related pattern. No clinically significant laboratory, vital sign, or ECG abnormalities were reported.

Conclusion: RO4389620 administered to healthy male subjects as a single oral dose of 5 mg, 10 mg, or 25 mg was well tolerated. Oral administration of RO4389620 consistently showed dose-dependent exposure and significant, dose-dependent reduction of fasting plasma glucose, demonstrating potential utility in the treatment of type 2 diabetes.

Liver selective glucokinase activation a new paradigm for treatment of type 2 diabetesC. Valcarce¹, T. B  dvars  t  r², P. Wahl², M. Larsen², K. Fosgerau², N. Blume², J. Selmer¹, A. Mjall  ¹¹Transtech Pharma, High Point, United States, ²Novo Nordisk, Maal  ev, Denmark

Background and aims: Data from transgenic animals suggest that selective activation of liver glucokinase (GK) will provide a mechanism that ensures reduction of blood glucose without increasing the risk for hypoglycemia.

The aim of the studies presented here was to demonstrate that TTP355, an oral, liver selective GK activator, regulates blood glucose without inducing hypoglycemia in multiple animal models of diabetes and has the potential to be a safe and effective first line therapy for the treatment of diabetes

Materials and methods: The effects of TTP355 on glucose metabolism and insulin secretion was evaluated: *in vitro* (isolated enzyme, hepatocytes and islets), and *in vivo* (normal rats as well as in rodent and non-rodent animal models of type 2 and type 1 diabetes).

Results: TTP355 activates recombinant GK in the presence of 15 mM glucose. TTP355 increases glucose utilization in hepatocytes without affecting the interaction of GK with GKR   or its translocation to the nucleus. TTP355 does not increase insulin secretion by perfused islets or perfused pancreas at concentrations where a significant increase in glucose metabolism is observed in hepatocytes. Administration of TTP355 to normal rats causes a dose-dependent decrease in glucose excursion during OGTT ($p < 0.01$ vs. vehicle) without an increase in insulin secretion. In mildly diabetic Goto Kaki-zaki-rats (GKrats), once daily oral dosing of TTP355, significantly reduces HbA_{1c} after only one week of treatment, ($p < 0.05$), after 5 weeks of treatment,

HbA_{1c} levels were normalized (3.1 ± 0.05), as compared to normal Wistar rats. GKrats have a reduced number of β cells from birth and throughout life. In TTP355 treated GKrats there was an improvement in β cell morphology and an increase of approximately 33% (n.s.) in β cell mass. In diabetic ob/ob mice diurnal glycemia is normalized after three weeks of dosing and HbA_{1c} levels are decreased by -2.63 ± 0.29 , $p < 0.001$. There was a significant progression in the effect of the treatment over time, as measured by the difference in the glucose AUC between the 1st (after 1st dose) and the 2nd (after 18th dose) 24h blood glucose profiles (ΔAUC $p < 0.001$). Chronic treatment with TTP355 does not increase lactate levels in blood, as observed in metformin treated animals. No significant effect on body-weight, food intake, liver or plasma lipids and insulin levels were observed. In Type 1 STZ-minipigs, chronic treatment with TTP355 reduces the exogenous insulin required to maintain glucose control, and reduces the daily glucose excursions in response to meal. The data indicate that TTP355 increases GLP-1 secretion and may preserve residual β cell function in this model. TTP355 prevents the development of ketoacidosis when insulin is withdrawn. No episodes of hypoglycemia were observed when fed or fasted, normal or diabetic, animals were administered high doses of TTP355.

Conclusion: Evidence from studies *in vitro* and *in vivo* shows that liver GK is a suitable pharmaceutical target for the treatment of diabetes, and that the liver selective GK activator TTP355 provides the expected therapeutic effects. Because of TTP355's efficacy is independent of the severity or the etiology of the diabetes in the animal models tested, this therapeutic approach may be suitable for a broad range of diabetic patients, from glucose intolerant to β cell deficient. Preliminary data in man indicate that TTP355 may have the same or better efficacy when administered to humans.

930

Quick release bromocriptine (Cycloset^{  }) improves glycaemic control in patients with diabetes failing metformin/sulfonylurea combination therapyR.E. Scranton¹, W. Farwell^{1,2}, M. Ezrokhi¹, J.M. Gaziano², A.H. Cincotta¹¹Veroscience, Tiverton, United States, ²Harvard Medical School, Boston, United States

Background and aims: Pre-clinical studies of insulin resistance indicate that administration of the dopamine D2 receptor agonist, bromocriptine, pulsed at the time of day of the circadian peak in hypothalamic dopaminergic tone corrects ("resets") aberrant hypothalamic signaling that in turn reduces elevated postprandial glucose, lipid excursions and insulin resistance. Clinical studies of insulin resistance also indicate that timed (morning) administration of Cycloset^{  } (bromocriptine mesylate), improves postprandial glucose and lipid metabolism across the day while the drug is substantially removed from the circulation before lunch time. Post prandial hyperglycemia is improved without increases in insulin levels. However, no studies have investigated the potential of Cycloset to improve glycemic control in subjects with type 2 diabetes (DM) inadequately controlled on the combination of metformin plus sulfonylurea. The aim of this study was to assess the impact, if any, of Cycloset on glycemic control in such subjects.

Materials and methods: The Cycloset Safety Trial was a one year, 2:1 randomized trial of the overall safety of Cycloset versus placebo among 3070 persons with DM. Within the study design, pre-specified six month efficacy analyses were conducted among a sub-group of subjects receiving metformin plus a sulfonylurea and having an HbA_{1c} (A1C) of $\geq 7.5\%$ and $\leq 10\%$ at screening. Study investigators were instructed to alter the dose (or after 3 months in the study - the dose and regimen) of non-study (concomitant) DM therapies if needed to maintain or achieve ideal glycemic control. Two physicians blinded as to treatment group assignment assessed changes in concomitant DM therapies. Changes in DM therapies were classified as unchanged, intensified (increase dose of DM medication or addition of DM medication) or decreased. An ANCOVA model which included study center and baseline A1C in the model was used to assess between group differences in the change from baseline A1C after 24 weeks of treatment. The proportion of subjects reaching an A1C of $\leq 7.0\%$ at Week 24 was compared between the two treatment groups using the Cochran-Mantel-Haenszel test. The intent to treat population (ITT) was comprised of 267 subjects (177 Cycloset; 90 placebo).

Results: The ITT study population had a mean A1C of 8.3, a mean age of 60, was 66% male, and had a mean body index of 32 kg/m². After 24 weeks of treatment, % A1C decreased by 0.67 among Cycloset treated subjects, and remained relatively unchanged ($+ 0.02$) among the placebo subjects resulting in a between-treatment difference from baseline of -0.7 ($P = 0.0002$). More Cycloset versus placebo treated subjects reached a target A1C of ≤ 7.0 (39%

vs. 11%, respectively; $p = 0.0004$). In addition, placebo treated subjects were more likely to intensify concomitant diabetes therapy compared to Cycloset (22% vs. 16%, respectively). Cycloset subjects were also twice as likely to decrease the intensity of concomitant diabetes therapies compared to placebo (6% vs. 3%, respectively).

Conclusion: Cycloset represents an effective and novel treatment approach to the management of type 2 diabetes among subjects failing a standard and widely employed combination therapy of metformin plus sulfonylurea.

Eight week treatment of db/db mice with a small molecule antagonist of the glucagon receptor lowers HbA_{1c} and plasma triglyceride levels without α -cell hyperplasia

S.C. Potter, P.D. van Poelje, J. Gomez-Galeno, M.L. McCaleb, D.L. Linemeyer, M.D. Erion

Metabasis Therapeutics, La Jolla, United States

Objective: Impairment of hepatic glucagon signaling by genetic knockdown of the glucagon receptor has demonstrated marked improvements in glucose homeostasis in murine models of type 2 diabetes; however, significant α -cell hyperplasia has been associated with this genetic manipulation. Compound H (Cmpd H) is a small molecule glucagon receptor antagonist that displaces glucagon with IC₅₀ values of 7 and 35 nM in human and mouse receptor binding assays, respectively, and inhibits the downstream effects of glucagon stimulation on primary human hepatocytes. The aim of this study was to evaluate the effects of 8 weeks of Cmpd H treatment to db/db mice on glycemic control, glucoregulatory hormones, and pancreatic histology.

Methods: Eight-week old db/db mice were pre-screened and divided into matched groups based on blood glucose, glycosylated hemoglobin A_{1c} (HbA_{1c}), plasma triglycerides, body weight and body fat mass (by NMR). Mice were fed Purina 5008 chow (control) or chow supplemented with 0.1% Cmpd H (w/w) ad libitum. The daily Cmpd H dose was ~100 mg/kg. Blood glucose and HbA_{1c} were measured bi-weekly; body weight was monitored routinely throughout. After 8 weeks of drug treatment body composition was measured, mice were anesthetized, and plasma and liver were collected for biochemical analyses. Additionally, pancreata were excised, fixed, and weighed. Three sections of each pancreas were immunostained for glucagon and analyzed by digital microscopy.

Results: Cmpd H treatment for 8 weeks reduced fed blood glucose by 123 mg/dL compared to control animals. HbA_{1c} was significantly lower in the Cmpd H-treated group compared to the control group at all time points measured, with a 1.6% difference after 8 weeks of treatment. Cmpd H treatment was associated with elevated plasma insulin and glucagon compared to control animals. There were no effects of Cmpd H treatment on body weight, fat mass, plasma cholesterol, liver glycogen content, or pancreas weight. Plasma triglycerides were decreased 40%. Pancreatic histology revealed more islets and a larger islet area in Cmpd H-treated mice compared to control mice. Cmpd H treatment resulted in a greater total glucagon staining area; however, when normalized to islet area there was no difference compared to control mice. Furthermore, visual inspection did not reveal a treatment-related effect on α -cell number per islet.

Conclusion: Eight week administration of Cmpd H dosed as a 0.1% food admixture significantly reduced HbA_{1c} and fed blood glucose in db/db mice without effects on weight gain or body fat composition. Moreover, potential β -cell sparing and improvements in plasma triglycerides were observed with Cmpd H treatment. Importantly, these benefits were realized without the α -cell hyperplasia previously associated with genetic manipulations of hepatic glucagon signaling.

A novel low-molecular-weight antagonist of glucose-dependent insulinotropic polypeptide receptor, SKL-14959, prevents obesity and insulin resistance

Y. Tsubamoto, T. Nakamura, H. Kinoshita, H. Tanimoto, H. Noda
Drug Discovery Laboratories, Sanwa Kagaku Kenkyusho Co., Ltd., Mie, Japan

Background and aims: Besides the physiological roles such as potentiation of insulin secretion from pancreatic beta cells and control of blood glucose level, glucose-dependent insulinotropic polypeptide (GIP) promotes fat deposition in adipose tissue leading to pathophysiological conditions of obesity and insulin resistance. These functions of GIP in animals suggest that the antagonism of GIP signaling is efficacious as a treatment of obesity and insulin resistance in human. In fact, GIP receptor deficient mice developed neither obesity nor insulin resistance even when they were fed high fat diet. Furthermore, recent investigations showed that GIP receptor antagonist peptides ameliorated obesity and insulin resistance. To develop a treatment of obesity and insulin resistance with this new mechanism of action, we studied and found a novel low-molecular-weight antagonist for GIP receptor, SKL-14959. In this presentation, we show the efficacy of SKL-14959 in diet-induced obesity and type 2 diabetes models in mice.

Materials and methods: To evaluate the efficacy of SKL-14959 in obesity, male ICR mice received a high fat diet (40% fat) with or without SKL-14959 at 0.14% for 14 weeks. Body weight and food intake were recorded throughout the experiment. At the end of the experiment, the white adipose tissue, liver and skeletal muscles were excised and weighed. Triglyceride contents in the liver and skeletal muscles were then analyzed. Efficacy of SKL-14959 in insulin resistance was evaluated by giving saline or SKL-14959-Na solution subcutaneously to female KKA^y mice at a dose of 10 or 100 mg/kg once a day for 4 weeks. Blood samples were taken from tail vein once a week to measure plasma glucose, insulin and HbA_{1c}. After administration period, insulin sensitivity test was performed and liver was excised to measure triglyceride contents.

Results: In the diet-induced obesity mice, body weight increased with high fat diets and SKL-14959 reduced the gain by 38% ($p < 0.05$) without affecting daily food intake. Amount of white adipose tissue and weight of the liver increased in high fat fed group and SKL-14959 was efficacious in suppressing their increases. Also, SKL-14959 prevented triglyceride accumulation in the liver, soleus muscle and lateral vastus muscle by 45% ($p < 0.05$), 48% and 18%, respectively. In the diabetic mice, SKL-14959 significantly decreased plasma glucose (10 mg/kg: 210±10 mg/dL, 100 mg/kg: 195±7 mg/dL), insulin (10 mg/kg: 31±8 ng/mL, 100 mg/kg: 47±15 ng/mL) and HbA_{1c} (10 mg/kg: 3.7±0.2%, 100 mg/kg: 3.5±0.2%) from the control levels (272±35 mg/dL, 96±28 ng/mL and 4.3±0.4%, respectively). In the insulin tolerance test, the daily dose of SKL-14959 improved insulin sensitivity in the type 2 diabetes model. Amount of accumulated triglyceride in the liver was decreased from the control level (48±6 μ mole/g liver) by SKL-14959 (10mg/kg: 37±5 μ mole/g liver, 100mg/kg: 32±6 μ mole/g liver). In these experiments, data on serum chemistry suggested that SKL-14959 had very little adverse effects.

Conclusion: We have found SKL-14959, a novel low-molecular-weight GIP receptor antagonist, had quite favorable effects of suppressing weight gain without reduction of food intake in diet-induced obesity model as well as amelioration of insulin resistance and glycemic control in type 2 diabetes model. We expect that SKL-14959 could become an effective treatment of obesity and insulin resistance in human.

933

Association of fetuin-A with decreased serum triglyceride after six weeks of extended-release niacin intervention in individuals with metabolic syndromeS.T. Mathews¹, S.V. Kaushik¹, E.P. Plaisance², T. Kim¹, E. Huang¹, A.J. Mahurin³, P.W. Grandjean⁴¹Nutrition and Food Sciences, Auburn University, ²Anatomy, Physiology and Pharmacology, Auburn University, ³Residency program, Baptist Health Family Medicine, Montgomery, ⁴Kinesiology, Exercise Technology Laboratory, Auburn University, United States

Background and aims: Fetuin-A (also known as alpha-2-HS glycoprotein, AHSII) has been increasingly shown to be associated with insulin resistance and metabolic syndrome (MetS) in humans. Further, several single nucleotide polymorphisms in the AHSII gene are associated with adipocyte insulin action and type 2 diabetes. At the molecular level, fetuin-A inhibits insulin receptor tyrosine kinase activity, insulin signaling and insulin action in skeletal muscle, liver, and fat cells. Phosphorylation of fetuin-A has been shown to be critical for its inhibitory activity. Niacin is one of the most effective pharmacological agents for the treatment of dyslipidemia and has been shown to reduce CVD morbidity and mortality presumably by improving blood lipid characteristics. However, recent evidence suggests that other factors may be involved. Our purpose was to determine the effect of niacin administration on serum total- and phosphorylated fetuin-A concentrations in individuals with metabolic syndrome and to correlate these with changes in blood lipids, insulin sensitivity, and vascular inflammation.

Materials and methods: Fifteen sedentary, obese, male participants, who met the NCEP ATP III criteria for metabolic syndrome, were treated with extended-release niacin (Niaspan) for 6 weeks. Serum fetuin-A levels were assayed by a sandwich ELISA method and Ser312-fetuin-A phosphorylation (phosphofetuin-A) status was estimated by Western blot analysis.

Results: Serum phosphofetuin-A concentrations were positively correlated with triglycerides in MetS, while C-reactive protein (CRP) was negatively correlated with fetuin-A in MetS. Serum total fetuin-A and phosphofetuin-A concentrations decreased significantly following niaspan treatment ($p < 0.005$). Changes in fetuin-A concentrations were correlated with changes in triglyceride concentrations after niaspan treatment ($r = 0.58$, $p < 0.05$). We observed that the change in high density lipoprotein cholesterol following Niaspan intervention was negatively correlated with the change in serum fetuin-A and phosphorylated fetuin-A concentrations. Interestingly, serum cortisol levels were significantly elevated following niaspan intervention. The change in cortisol was significantly correlated with the change in serum non-esterified fatty acids (NEFA), suggesting that increased cortisol and NEFA concentrations may contribute to the mild hyperglycemia and insulin resistance observed in niacin-treated individuals.

Conclusion: This is the first report demonstrating that serum total- and phosphofetuin-A levels are amenable to intervention by extended-release niacin treatment and are correlated with changes in serum triglycerides. These findings are consistent with earlier findings that fetuin-A may be involved in lipid metabolism and modulation of inflammatory pathways. The increase in serum cortisol following niacin treatment may also provide further insight into potential mechanisms by which niacin reduces insulin sensitivity.

934

The flavonoid silibinin reverses metabolic alterations in insulin resistance model of high fructose-fed rats by decreasing hepatic gluconeogenesis and glycolysis in perfused liver cellsC. Sánchez¹, D. Dettaille¹, N. Sanz¹, G. Rodríguez-Villanueva¹, F. Gómez-Peralta², J. Recio-Córdova², J. López-Novoa¹, M. El-Mir¹¹Physiology and Pharmacology, ²Endocrinology Unit, University Hospital of Salamanca, Salamanca, Spain

Background and aims: Insulin resistance, hyperinsulinaemia and disturbances in glucose metabolism can be produced in normal rats by feeding a fructose-enriched diet. The flavonoid silibinin (SB), a natural antioxidant, has been recently proposed to be beneficial in type 2 diabetes. Previous “in vitro” studies of our group have shown that SB inhibits hepatic gluconeogenesis (GNG) and glycolysis in perfused rat hepatocytes. The aim of this study was to determine “in vivo” the capacity of silibinin to reverse the alteration of carbohydrate metabolism associated to insulin resistance induced in high fructose-fed rats.

Materials and methods: Male Wistar rats (160–180 g) were divided into two batches. One batch received a standard diet, and the other was fed with a fructose-enriched diet, containing 60% fructose. After 4 weeks of this dietary regimen, each batch of rats was subdivided into two groups. One group received SB (50 mg/kg/day, i.p. injection) for additional two weeks, and the other group received SB vehicle. At the end of the treatment, a sample of blood was taken from each rat for subsequent measurement of glucose, insulin, triglycerides and other plasma parameters. Hepatocytes were isolated from rat livers (all groups) according to the method of Berry and Friend, and they were perfused at 37°C with Krebs-bicarbonate-calcium saturated with O_2/CO_2 and titrated with increasing concentrations of dihydroxyacetone (DHA) as energetic substrate to get seven consecutive steady states. For each steady state, we measured, in cellular perfusate, hepatic glucose production (GNG) and glycolysis (lactate and pyruvate).

Results: Blood glucose, triglycerides and insulin, as expected, were significantly elevated in fructose-treated groups compared with the control. Treatment with SB lowered all these parameters till normal values. On the other hand, in perfused liver cells, fructose-treated rats show alterations of glucose hepatic metabolism typical to insulin resistance state by increasing both gluconeogenesis (J_{Gluco}) and glycolysis as compared to control by 34% and 45%, respectively (DHA 2.4 mM; $p < 0.001$). The most attractive data was that silibinin treatment completely reversed these metabolic alterations in fructose-fed animals by returning GNG (J_{Gluco}) and glycolysis (J_{L+P}) to normal values (DHA 2.4 mM; $p < 0.001$). Concerning the global metabolism of DHA (J_{2G+L+P}), this parameter is activated in fructose-fed rats as compared to control rats (DHA 2.4 mM; $p < 0.001$). SB also completely normalizes this alteration (DHA 2.4 mM; $p < 0.001$). Furthermore, the administration of fructose caused an inhibition of cytosolic NADH/NAD⁺ ratio (estimated by lactate/pyruvate ratio) by 22% compared with control rats (DHA 2.4 mM; $p < 0.001$). Treatment with SB significantly lowered cytosolic NADH/NAD⁺ ratio in all groups of rats (DHA 2.4 mM; $p < 0.01$).

Conclusion: Silibinin “in vivo” reverses metabolic alterations in insulin resistance induced in fructose-fed rat by decreasing hepatic gluconeogenesis and glycolysis. These results strongly suggest that silibinin, beyond its whole antioxidant properties, could be useful as a complementary therapy to decrease hyperglycaemia and hyperinsulinaemia in pre-diabetes and type 2 diabetes.

Use of gene expression signature technology to identify VVP-808, a novel insulin sensitiser with efficacy in vitro and in vivoK.R. Walder¹, J.C. Molero¹, N. Konstantopoulos¹, D. Segal¹, V. Foletta¹, K. Windmill¹, J. Curran², T.D. Dyer², K. Shields³, J. Jowett³, G. Krippner⁴, J. Blangero², G.R. Collier²¹School of Exercise and Nutrition Sciences, Deakin University, Warrnambool, Australia, ²Genetics, Southwest Foundation for Biomedical Research, San Antonio, United States, ³International Diabetes Institute, Caulfield, Australia, ⁴Verva Pharmaceuticals, Geelong, Australia, ⁵ChemGenex Pharmaceuticals, Geelong, Australia

Background and aims: The aims of the current study were to develop a new small molecule library screening strategy based on gene expression signature (GES) technology, and to utilise this screen to identify new insulin sensitising agents.

Materials and methods: Differentiated 3T3-L1 adipocytes were rendered insulin-resistant using TNFα (3 ng/ml for 72h), and insulin sensitivity was restored by adding a cocktail of known antidiabetic agents for the last 24h. Mouse cDNA microarrays were used to establish gene expression profiles for the insulin resistant cells, and the cells with insulin sensitivity restored. Bayesian linear model selection was performed to find the optimal set of 11 genes (the GES) that best defined the difference between the two cell states. Insulin resistant 3T3-L1 cells were then treated with a library of ~1500 compounds, and analysed for similarity of expression of the 11 GES genes. Hit compounds were selected for further testing *in vitro* and *in vivo*.

Results: Using the GES, we identified a family of compounds that dose-dependently improved insulin stimulated glucose transport and incorporation into lipid in 3T3-L1 adipocytes ($p = 9 \times 10^{-7}$). The lead compound, designated VVP808, was further tested in animal models of insulin resistance and diabetes. Treatment of *db/db* mice with VVP808 for 7 days resulted in a dose-dependent reduction in fasting blood glucose concentration (up to 65% reduction at 50 mg/kg/d, Day 0: 24.7 ± 1.8 vs Day 7: 9.5 ± 1.0 mmol/L, $p = 0.00004$). The improvement in glycemia was associated with a 7% reduction in body weight ($p = 0.002$), however a subsequent pair-feeding study showed that the

reduction in blood glucose concentration was independent of body weight loss. Treatment of diet-induced obese (DIO) C57Bl/6 mice with VVP808 for 21 days resulted in a dose-dependent improvement in glucose tolerance and reduction in fasting blood glucose concentration. The area under the blood glucose curve during an ipGTT was reduced by up to 28% ($p=0.037$), while fasting blood glucose was significantly reduced at doses from 20–100 mg/kg/d ($p<0.05$). These effects were accompanied by a dose-dependent decrease in body weight of 5–11% ($p<0.05$).

Conclusion: The GES screening strategy successfully identified a family of compounds with insulin sensitising and antidiabetic effects *in vitro* and *in vivo*. VVP808 is a novel insulin sensitiser that also causes moderate loss of body weight in obese animals, and therefore has excellent potential for development as an antidiabetic agent. A clinical study evaluating the safety and efficacy of VVP808 in type 2 diabetic patients is planned for the second half of this year.

Association of *KCNJ11* and *ABCC8* genetic polymorphisms with response to repaglinide in Chinese diabetic patients

Y. He, R. Zhang, X. Shao, C. Hu, C. Wang, Y. Bao, J. Lu, W. Jia
Endocrinology & Metabolism, Shanghai Jiaotong University affiliated No.6 People Hospital, Shanghai Diabetes Institute, China

Background and aims: Repaglinide stimulates insulin secretion by inhibiting ATP-sensitive potassium (K_{ATP}) channels in pancreatic beta cells. Common variants of two genes encoding K_{ATP} channels (*KCNJ11* E23K, *ABCC8* exon16 -3T/C) have been reported to be associated with type 2 diabetes. To investigate whether there is an association between *KCNJ11* E23K, *ABCC8* exon16 -3T/C polymorphisms and the therapeutic effect of repaglinide in patients with type 2 diabetes.

Materials and methods: A total of 100 Chinese patients with newly diagnosed type 2 diabetes were treated with repaglinide for 24 weeks. Arginine stimulation tests were performed to evaluate beta cell function. Gene variations were detected with polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP). Responders were defined by a >25% decrease in fasting plasma glucose (FPG) or a >20% decrease in hemoglobin A1c (HbA1c) values (or both) after the 24-week repaglinide treatment.

Results: Both baseline Hemoglobin A1c (HbA1c) and the decrease of HbA1c (Δ HbA1c) were significantly higher in patients with K allele of *KCNJ11* E23K variant when compared with E/E homozygotes ($p=0.0103$ and 0.0221 respectively). The decrease in 2h postprandial plasma glucose (2hPG) was significantly greater in E/K heterozygotes than E/E homozygotes ($p=0.0367$). There was a significant difference in the response rate to repaglinide treatment between E allele carriers and K allele carriers (68% versus 79%, $p=0.03$). The changes in fasting insulin (Δ FIN) and homeostasis model assessment of insulin resistance (Δ HOMA-IR) were significantly greater in patients with *ABCC8* exon16-3 C/C, vs. T/C and T/T variant ($p=0.0372$ and 0.0274 respectively).

Conclusion: Our results showed that *KCNJ11* E23K variant was associated with the therapeutic effect of repaglinide. In addition, *ABCC8* exon16 -3T/C variant was related to insulin sensitivity after repaglinide treatment.

Effects of treatment with repaglinide or gliclazide on glucose control and early-phase insulin secretion in patients with newly diagnosed type 2 diabetes

H. Zhang¹, P. Bu¹, M. Lei², Z. Mo³, E. Liao¹

¹Institute of Endocrinology and Metabolism, The Second Xiangya Hospital of Central South University, ²Department of Endocrinology, Xiangya Hospital of Central South University, ³Department of Endocrinology, The Third Xiangya Hospital of Central South University, Chang Sha, China

Background and aims: A loss of early-phase insulin secretion is an early marker of type 2 diabetes (T2D), and the restoration of it can improve insulin sensitivity, β cell function, and lipid metabolism. The aim of this study was to evaluate the effects of treatment with Repaglinide (Rg) or Gliclazide (Gli) on glucose control, insulin secretion, and lipid profile in patients with T2D.

Materials and methods: In the 4-week open-labelled parallel study, 40 patients newly diagnosed with T2D were randomized 1:1 to Rg t.i.d or Gli qd treatment, and 34 patients completed the study. Both drugs were titrated to achieve a fasting blood glucose target of ≤ 7 mmol/L. No lipid regulators were given during the study. A standard mixed meal tolerance test was performed at baseline and end of study. Plasma glucose (PG) and serum insulin concentration were measured at fasting and 5 points after meal (30', 60', 90', 120', and 180'). Total insulin secretion was evaluated by the area under insulin concentration curve (AUC_{ins}). The homeostasis model assessment of insulin resistance (HOMA-IR) was used to estimate insulin sensitivity. β cell function was measured by early-phase insulin secretion index (the ratio of insulin change to glucose change over the first 30' after meal, $\Delta I_{30}/\Delta G_{30}$).

Results: Demographic and baseline characteristics were comparable between the two groups. At week 4, fasting and postprandial PG decreased significantly, and postprandial insulin concentrations increased significantly in

		Rg (n=19)	Gli (n=15)	Between groups P value
AUC _{ins} (mU/l/h)	Baseline	33.27 (8.68, 106.77)	44.91 (9.82, 102.55)	1.000
	Week 4	77.14 (32.59, 185.31) *	79.655 (10.16, 152.77) *	0.656
HOMA-IR	Baseline	0.46 (0, 10.43)	0.51 (0, 8.07)	0.837
	Week 4	2.33 (0, 9.66)	1.29 (0, 8.28)	0.302
$\Delta I_{30}/\Delta G_{30}$	Baseline	2.64 (0.08, 71.06)	3.17 (0.16, 14.38)	0.716
	Week 4	10.88 (2.45, 85.42) *	6.32 (0.87, 19.96) *	0.030 ‡

HOMA-IR = (FPG×FINS)/22.5;

ΔI_{30} = 30-min insulin - fasting insulin; ΔG_{30} = 30-min plasma glucose - fasting plasma glucose.

Values of AUC_{ins}, HOMA-IR, and $\Delta I_{30}/\Delta G_{30}$ are presented as median (min, max); Value of TG and CHOL are presented as Mean (SD).

* vs. baseline, $p < 0.05$.

‡ Comparisons between groups were performed using analysis of variance (ANOVA) followed by post hoc testing with Bonferroni test, $p < 0.05$

both groups (all points, $p < 0.05$). The time to maximum insulin concentration occurred earlier in the Rg group than in the Gli group (90' vs. 120') (Figure). AUC_{ins} increased significantly in both groups ($p < 0.05$), and no difference was found between the two groups. $\Delta I_{30}/\Delta G_{30}$ increased significantly in both groups ($p < 0.05$), especially in the Rg group ($p < 0.05$ vs. Gli). There was no significant difference in HOMA-IR during the study. TG and CHOL decreased significantly in the Rg group ($p < 0.05$), but not in the Gli group (Table).

Conclusion: No significant differences were observed in glucose control and total insulin secretion after treatment between the two groups. However, treatment with Rg was associated with significantly greater improvements in β cell function and lipid metabolism.

Postprandial C-peptide in type 2 diabetes in relation to HbA_{1c} and the use of sulphonylurea

Å. Nybäck-Nakell, P.-E. Lins, U. Adamson, L. Landstedt-Hallin
Department of Clinical Sciences, Karolinska Institutet, Danderyd Hospital, Stockholm, Sweden

Background and aims: Progressive decline in beta cell function is of importance for the deterioration of glycaemic control, over time, in patients with type 2 diabetes treated with oral glucose-lowering drugs (OGLD). Sulphonylurea have been implicated to be involved in this process via exhaustion of beta cell function. The aim of this observational study was to describe changes in glycaemic control and beta cell function, assessed as postprandial C-peptide, in relation to treatment with sulphonylurea over a period of 10 years.

Material and methods: 462 patients with a clinical diagnosis of type 2 diabetes attended a four day diabetes course at Danderyd Hospital in Stockholm 1997-1998. HbA_{1c}, postprandial C-peptide (PP-CPT) and postprandial P-glucose were measured on day 1 (see Table).

After 10 years, 341 patients who were still alive, were invited to a follow-up visit, 171 of them accepted. Median age at follow-up was 68 years (range 40-87), BMI 29.9 kg/m² (20-46) and known duration of diabetes 14 years (8-46).

Results: As expected blood glucose lowering therapies had been modified over time. The use of insulin had increased from 33 to 74% and OGLD + insulin from 18 to 52% while the use of insulin secretagogues remained similar 56 and 48% respectively. Over ten years there was a significant decrease in HbA_{1c} ($p = 0.002$), PP CPT ($p < 0.0001$) and PP CPT/glucose ratio, a measurement correcting for the prevailing glucose level ($p = 0.03$). There was a nega-

tive correlation between HbA_{1c} and PP CPT ($p < 0.0001$, $r = -0.30$) as well as between HbA_{1c} and PP CPT/glucose ratio ($p < 0.0001$, $r = -0.52$).

In a stepwise multiple regression analysis with the long-term change in PP CPT/glucose ratio as the dependent variable, the baseline PP CPT/glucose ratio explained 44% of the change, HbA_{1c} at follow-up explained 14% while the use of a sulphonylurea only explained an additional 2% and BMI and diabetes duration explained 1% each.

Conclusion: We conclude that this observational study, does not support the concept, that sulphonylurea treatment is of major importance for the observed progressive decline in beta cell function.

Table	1997-1998 n=171	2007 n=171
HbA _{1c} (median, range)	7.3 % (4.3-12.3)	6.7 % (4.5-13)

Effects of a one-year treatment with metformin on metabolic and cardiovascular risk factors in non-diabetic upper-body obese subjects with mild glucose anomalies: the BIGPRO1 trial

A. Fontbonne¹, I. Diouf², M. Baccara-Dinet^{3,4}, E. Eschwege², M.-A. Charles²
¹UR 024, IRD, Montpellier, ²U780, INSERM, Villejuif, ³Endocrinology, Lapeyronie Hospital, Montpellier, ⁴Merck Santé, Lyon, France

Background and aims: Metformin has recently been considered as a possible pharmacologic complement to lifestyle measures for type 2 diabetes prevention in high-risk ("pre-diabetic") subjects. As few trials of metformin have been conducted in non-diabetic subjects, little is known about its effects on metabolic and cardiovascular risk factors in this population. The aim of the present analysis was to study these effects, using the data of the BIGPRO1 trial, which was conducted in the early 1990s in non-diabetic upper-body obese subjects.

Material and methods: The BIGPRO1 trial was a multicenter randomized double-blind controlled clinical trial, metformin 850 mg bid vs placebo tablets for one year, conducted in 324 (164 metformin, 160 placebo) non-diabetic subjects aged 35-60 (men), 40-65 (women), without cardiovascular diseases, with a high waist-to-hip ratio (≥ 0.95 , men; ≥ 0.80 , women), and no contraindications to metformin. This analysis was performed on two subsets of subjects who could qualify as "pre-diabetic": subset A, subjects with impaired glucose tolerance or impaired fasting glucose according to current WHO definition (49 metformin, 52 placebo); subset B, subjects fulfilling the inclusion criteria of the Diabetes Prevention Program (28 metformin, 23 placebo). In each subset, we compared the change between 1 year and baseline for variables of interest, between the metformin (M) and the placebo (P) groups.

Results: At baseline, there was a significant difference in age between the two treatment groups in both subsets (subset A, 53 ± 6 (mean \pm SD) [M] vs 49 ± 7 yr [P], $p < 0.01$; subset B, 53 ± 6 [M] vs. 48 ± 7 yr [P], $p < 0.01$), and a trend towards a difference in sex ratio (subset A, 25% men [M] vs 42% [P], $p < 0.06$; subset B, 29% [M] vs 48% [P], $p < 0.15$), hence subsequent comparisons were adjusted for age and sex. In subset A, 1-yr changes were significantly different for systolic blood pressure (SBP: -13 ± 18 [M] vs -2 ± 14 mmHg [P], $p < 0.01$), fasting blood glucose (FBG: -0.35 ± 1.34 [M] vs 0.65 ± 2.05 mmol/L [P], $p < 0.04$), and total cholesterol (TC: -0.15 ± 0.89 [M] vs 0.36 ± 0.77 (mmol/L) [P], $p < 0.03$). Similar results were observed in subset B (SBP: -16 ± 16 [M] vs 3 ± 12 mmHg [P], $p < 0.01$; FBG: -0.75 ± 1.58 [M] vs 1.74 ± 3.02 (mmol/L) [P], $p < 0.02$; TC: -0.13 ± 0.73 [M] vs 0.44 ± 0.74 (mmol/L) [P], $p < 0.05$), with the addition of a significant difference in 1-yr change for diastolic blood pressure (DBP: -10 ± 15 [M] vs 2 ± 10 mmHg [P], $p < 0.02$). There was no significant difference in 1-yr change for weight, waist-to-hip ratio, 2h post-load blood glucose, fasting and 2h post-load insulin, and triglyceride, between the two treatment groups.

Conclusion: Compared to placebo, metformin significantly reduced blood pressure, fasting blood glucose and total cholesterol in “pre-diabetic” upper-body obese subjects, with no significant effect on weight or plasma insulin. This brings support to some current recommendations to use metformin as a complement to lifestyle measures in subjects at high risk to develop diabetes or cardiovascular disease.

Long-term treatment with metformin in type 2 diabetes treated with insulin is associated with vitamin B12 deficiency, but not with increasing homocysteine levels: a randomised, controlled trial

A. Kooy¹, J. de Jager¹, P. Leher², D. Bets³, J. van der Kolk¹, C.D.A. Stehouwer⁴

¹Bethesda Diabetes Research Center, Hoogeveen, Netherlands, ²Department of Statistics, FUCAM - Louvain Academy, Louvain, Belgium, ³E. Merck Nederland BV, Amsterdam, Netherlands, ⁴Internal Medicine, University Hospital Maastricht, Netherlands

Background and aims: Metformin is a key treatment option in type 2 diabetes. However, metformin may decrease vitamin B12 levels and increase levels of homocysteine, a cardiovascular risk factor. We investigated whether long term treatment with metformin during 52 months affects serum concentrations of homocysteine, folate and vitamin B12 in subjects with type 2 diabetes treated with insulin.

Materials and methods: In this placebo-controlled, randomised trial, 745 patients with type 2 diabetes, treated with insulin and not known with a contraindication for the use of metformin, were approached; 390 gave informed consent and entered the study. 277 subjects (= 72%) completed the trial. At the final visit, laboratory samples were available for 257 patients (127 M, 130 P).

Results: During placebo treatment, vitamin B12 increased by 0.2 pmol/l [0% (-3 to +4)], folate increased by 1.01 nmol/l [+8% (+4 to +12)], and homocysteine increased by 1.60 μ mol/l [+20% (95% CI: +16 to +25)]. During metformin treatment, vitamin B12 decreased by 89.8 pmol/l [-19% (-22 to -15)], folate increased by 0.21 nmol/l [+3% (-1 to +6)], and homocysteine increased by 3.26 μ mol/l [+26% (+21 to +31)]. Compared with placebo, metformin treatment was associated with decreases in vitamin B12 of -19% [(-24% to -14%); $p < 0.001$] and folate of -5% [(-10 to -0.4); $p = 0.033$], and an increase in homocysteine of +5% [(-1 to +11); $p = 0.091$]. The effects of metformin on vitamin B12, folate, and homocysteine were not affected after adjustment for age, previous metformin treatment, duration of diabetes, gender, insulin dose, and smoking habits. At baseline, 3 patients (2.2%) in the metformin group and 4 patients (1.6%) in the placebo group had vitamin B12 values below the value of 150 pmol/l. At the end of the study period 16 patients (8.3%) in the metformin group and 3 patients (1.6%) in the placebo group had vitamin B12 values below the value of 150 pmol/l [$p = 0.003$]. The hazard ratio for developing vitamin B12 deficiency during metformin therapy was 5.5 [(1.6 to 19.1); $p = 0.01$]. We used General Mixed Model with Generalised Estimation Equations (GEE) to explore the effects of metformin on vitamin B12, folate, and homocysteine and to investigate whether metformin-associated changes in homocysteine, if any, could be explained by changes in folate and (or) vitamin B12, and, if so, whether the changes were independent of age, gender, duration of diabetes, smoking, body mass index, insulin dose, serum creatinine, HDL cholesterol, or glycated haemoglobin. The goodness of fit between alternative models was compared using the maximum likelihood technique. P-values < 0.05 were considered statistically significant.

Conclusion: In patients with type 2 diabetes, 52 months of treatment with metformin reduces levels of folate and vitamin B12, without a significant increase in homocysteine. The increased risk of developing a significant vitamin B12 deficiency (vitamin B12 < 150 pmol/l) in metformin therapy may support the strategy to determine vitamin B12 levels at the start and after 4 months of treatment.

Metformin lowers plasma asymmetric dimethylarginine (ADMA) levels of subjects with type 2 diabetes independent of glycaemic control

J.G. Boyle, I.P. Salt, G.C. Jones, M. Small, J.M.C. Connell, N. Sattar, S.J. Cleland;

University of Glasgow, Division of Cardiovascular & Medical Sciences, Glasgow, United Kingdom

Background and aims: Circulating levels of the endogenous competitive inhibitor of NO synthase, asymmetric dimethylarginine (ADMA) are elevated in patients with diabetes, and in several prospective studies, have been noted to predict higher risk of cardiovascular events. Metformin is widely used in the treatment of type 2 diabetes, in part because it lowers MI risk, but its precise mode of action remains uncertain. Metformin's vascular protection in UKPDS was apparently independent of glucose lowering actions. We studied the effect of Metformin and Glucophage on plasma ADMA and glycaemic control in subjects with type 2 diabetes.

Materials and methods: We randomised twenty men with type 2 diabetes aged between 50-70 years to Metformin (500 milligrams three times daily) and Glucophage (80 milligrams twice daily) in randomised, double-blinded, glycaemia controlled, cross-over design over 10 weeks in each arm. There was a six week run in and washout period. At the end of each ten week phase of therapy blood sampling was performed. Plasma ADMA was measured by high performance liquid chromatography.

Results: The mean age 56.5 years and BMI was 31 kg/m². BMI was not different after each period of therapy ($p = 0.80$) but mean HbA1c was lower post glucophage versus post metformin [7.8% versus 8.3%, $p < 0.001$]. However, ADMA was significantly lower following metformin therapy [0.48 mmol/l versus 0.50 mmol/l, $p = 0.019$].

Conclusion: To our knowledge our results provide the first evidence that metformin lowers ADMA in subjects with type 2 diabetes independent of its effects on glycaemia. The results therefore significantly extend prior supportive evidence of ADMA lowering from uncontrolled study of metformin in women with PCOS. We propose that beneficial effects of Metformin in subjects with type 2 diabetes are in part mediated by lowering ADMA levels in plasma.

Metformin action is mediated through reactive nitrogen species in primary mouse hepatocytes

Y. Fujita¹, M. Hosokawa¹, S. Fujimoto¹, A. Abudukadier¹, H. Fujiwara¹,

E. Mukai¹, M. Sasaki¹, E. Ogawa¹, Y. Seino^{1,2}, N. Inagaki¹

¹Department of Diabetes and Clinical Nutrition, Kyoto University,

²Department of Diabetes, Kansai Denryoku Hospital, Osaka, Japan

Background and aims: Metformin is one of the most commonly used antidiabetic drugs for type 2 diabetes. The effect of metformin is known to be mediated by activation of AMP-activated protein kinase (AMPK), but the mechanism remains controversial. Recent studies suggest that metformin activates AMPK via peroxynitrite, a reactive nitrogen species (RNS) in bovine aortic endothelial cells (BAECs). The aim of this study is to elucidate the relationship between metformin and RNS in primary mouse hepatocytes. Since metformin is known as a mild mitochondrial complex 1 inhibitor, we compared its action with rotenone, a typical mitochondrial complex 1 inhibitor, to investigate the mechanism of action.

Materials and methods: Hepatocytes were isolated from male 8-week-old C57/BL6J mice by collagenase digestion. Primary hepatocytes were maintained in DMEM with 10% fetal bovine serum. Protein expressions of AMPK α and phospho-AMPK α were analyzed by Western blot. For gluconeogenesis measurements, hepatocytes were isolated after overnight fast and incubated for 120 minutes in glucose-free DMEM with 1 mM pyruvate. Glucose pro-

duction was determined by glucose oxidase method. Immunohistochemical staining of anti-nitro tyrosine was performed for intracellular peroxynitrite detection. NO production was determined by Griese method. ATP, ADP and AMP content was assessed by luminometric method. In addition, we used endothelial nitric oxide synthase (eNOS) knockout mice to confirm the requirement for intracellular NO production in metformin action.

Results: Both 120-minute exposure of 2 mM metformin and 100 nM rotenone increased phosphorylation of AMPK α in mouse hepatocytes. Direct exposure of peroxynitrite increased phosphorylation of AMPK α . Both metformin and rotenone significantly decreased gluconeogenesis (metformin, 363 ± 22 ; rotenone, 174 ± 33 ; control, 422 ± 19 nmol/mg protein; $P < 0.05$ control vs. metformin and rotenone). On the other hand, metformin increased anti-nitro tyrosine staining but rotenone did not. Metformin increased NO production by 27% while rotenone dramatically reduced it to 47%, compared to control. Rotenone significantly increased the AMP/ATP ratio ($P < 0.05$ control vs. rotenone) but metformin did not. Exposure of metformin to hepatocytes of eNOS knockout mice did not phosphorylate AMPK α or suppress gluconeogenesis. Moreover, exposure of rotenone in eNOS knockout mice increased phosphorylation of AMPK α and suppressed gluconeogenesis similarly to that in C57/BL6J mice (metformin, 455 ± 61 ; rotenone, 205 ± 19 ; control, 480 ± 57 nmol/mg protein; $P < 0.05$ control vs. rotenone, not significant control vs. metformin).

Conclusion: Activation of AMPK by metformin is RNS-dependent in primary mouse hepatocytes. Differently from the action of rotenone, metformin action is AMP-independent, suggesting that metformin does not affect mitochondrial metabolism. Loss of NO synthesis in eNOS knockout mice attenuates the inhibitory effect of metformin on gluconeogenesis, indicating that intra-hepatocellular eNOS is required for the pharmacological effect of metformin in liver.

Metformin combined with exogenous glucagon-like peptide-1 gives added benefit by improving acute glycaemic control in type 2 diabetic subjects

J. Cuthbertson¹, S. Patterson², F.P.M. O'Harte², P.M. Bell¹

¹Endocrinology and Diabetes Research Centre, Royal Group of Hospitals, Belfast, ²School of Biomedical Sciences, University of Ulster, Coleraine, United Kingdom

Background and aims: Glucagon-like peptide-1 (GLP-1) and glucose-dependent insulinotropic polypeptide (GIP) constitute the incretin hormones that form a major element of the enteroinsular axis which promotes postprandial insulin secretion. The therapeutic potential of these hormones in diabetes is limited by their rapid inactivation by the enzyme dipeptidylpeptidase-IV (DPP-IV). Metformin has been reported to act as an inhibitor of DPP-IV. We investigated the acute effects of metformin and GLP-1 alone or in combination on plasma DPP-IV activity and active GLP-1 concentrations in type 2 diabetes.

Materials and methods: Ten subjects with type 2 diabetes (9 M/1 F), age 69.0 ± 2.7 years (mean \pm SEM), body mass index 29.6 ± 1.7 kg/m², HbA_{1c} $7.0 \pm 0.1\%$ received one of three combinations after an overnight fast in a randomised crossover design; metformin 1 g orally plus subcutaneous injection (sc) saline (Met), GLP-1 (1.5 nmol/kg body weight sc) plus placebo tablet (GLP) or metformin 1 g plus GLP-1 (Met+GLP-1). At 15 min glucose was raised to 15 mmol l⁻¹ by rapid intravenous infusion and responses assessed over the next 3 hours. This stimulus does not activate the enteroinsular axis and secretion of endogenous GLP-1, enabling the effect of exogenously administered GLP-1 to be examined in isolation. The DPP-IV assay is a fluorimetric method to measure free AMC (7-amino-4-methyl-coumarin) liberated from the DPP-IV substrate, Gly-Pro-4-AMC. Mean sample fluorescence values obtained were converted to DPP-IV activity, equivalent to AMC concentration, from the standard curve. GLP-1(7-36)amide was measured by a GLP-1 (active) enzyme-linked immunoassay kit. The assay is based on the use of a monoclonal antibody that binds specifically to the N-terminal region of active GLP-1 molecule.

Results: Mean area under curve (AUC)_{0-180 min} plasma glucose responses were lowest following Met+GLP (1629 ± 90) (mean \pm SEM, student t-test, ANOVA) compared to GLP (1885 ± 86 , $p < 0.002$) and Met (2045 ± 115 , $p < 0.001$) mmol/l/min respectively. At 60 min mean glucose levels were also lowest following Met+GLP (8.8 ± 0.7 compared to GLP (10.9 ± 0.5 , $p < 0.0001$) and Met (12.4 ± 0.7 , $p < 0.0001$) mmol/l respectively. Mean AUC serum insulin responses were similar following either Met+GLP (5426 ± 498) or GLP (5655 ± 854) treatment but both were higher than Met (3521 ± 410 , $p < 0.0001$ and $p < 0.04$) mU/

l/min respectively. Mean AUC for plasma DPP-IV activity was lower following Met+GLP (1505 ± 2 , $p < 0.001$) or Met (1508 ± 2 , $p < 0.002$) compared to GLP (1587 ± 3) μ mol/ml/min respectively. Mean AUC measures for plasma active GLP-1 concentrations were higher following Met+GLP ($820 \times 10^4 \pm 51 \times 10^4$) compared to GLP ($484 \times 10^4 \pm 31 \times 10^4$ $p < 0.000$) and Met ($419 \times 10^4 \pm 34 \times 10^4$, $p < 0.001$) pmol/l/min respectively.

Conclusion: In patients with type 2 diabetes metformin inhibits DPP-IV activity and thus increases active GLP-1 concentrations. Metformin given in combination with GLP-1(sc) significantly lowers plasma glucose concentrations in type 2 diabetic subjects. Metformin may have additional beneficial effects in combination therapy with incretin hormones over and above its traditional insulin sensitising role.

Transient neonatal diabetes with UPD6 mutation; one of the many faces of monogenic diabetes in the young

T. Dugal, A. Gossage

Diabetes and Endocrinology, East Surrey Hospital, Redhill, United Kingdom

Background and aims: 1–2% patients with diabetes have monogenic diabetes. It is important to make an early diagnosis as this can have a dramatic impact on the management and quality of life of the patient as well as having implications for the family. Transient neonatal diabetes (TNDM) is a rare but distinct form of monogenic diabetes (incidence 1:400,000). Neonates classically present in the first week of life with growth retardation and diabetes. Although remission occurs usually after three months, there is a tendency to develop diabetes later in life needing treatment.

Case: A female baby at 41 weeks gestation was delivered normally. She appeared small for dates and weighed only 2.25 kgs. She went home on the 14th day of life weighing 2.4 kgs and was fed on Cow&Gate, taking fairly large quantities of 200cc/kg/day. She was admitted at age 15 days, passing a lot of urine and few loose stools. She weighed only 1.8 kgs, after losing 25% of her body weight in 2 days. She was dehydrated with a blood glucose of 88 mmol/L. There was no acidosis and no ketones. Family history was unremarkable. With rehydration her biochemistry returned to normal with 48 hrs without insulin. She recovered well with good weight gain. However was readmitted after one year with gastroenteritis, blood sugar was 2mmol/L and OGTT was normal. Aged three, she represented with polydipsia. OGTT was impaired. She was managed on diet only till she was 28 years old and from then has maintained good blood sugar control on rather small doses of Mixtard 10U/5U. She was found to have uniparental disomy of chromosome 6 (UPD6). She subsequently gave birth to a male child who was genetically tested and not found to have the anomalies associated with TNDM, i.e. UPD6, 6q24methylation or 6q24 duplication.

Conclusion: TNDM is a rare disorder and can be associated with syndromes, several with mental retardation. Evidence suggests it is the result of overexpression of an imprinted and paternally expressed gene in the 6q24 region.

Two imprinted genes (*ZAC* & *HYAMI*) have been identified. Three genetic mechanisms have been shown to result in TNDM, paternal unipaternal isodisomy of chromosome 6, paternally inherited duplication of 6q24 and a methylation defect.

It is different from permanent neonatal diabetes (PNDM) which is usually a disorder of ATP channels and their inability to close, hence requiring life long sulphonyurea therapy. This is mediated through mutations in *KCNJ11* gene encoding Kir6.2 subunit of the ATPase sensitive potassium channel.

Early recognition and appropriate treatment for all forms of neonatal diabetes is essential, for this awareness of the condition is needed.

Factors associated with obesity in new onset insulin treated diabetes in childhood

M. Cedillo¹, A.K. Adeniji², I.M. Libman¹, V.C. Arena², D.J. Becker¹

¹Pediatric Endocrinology, Children's Hospital of Pittsburgh, ²Biostatistics, University of Pittsburgh, United States

Background and aims: From the 1980s to 2000s, there has been a continual increase in body mass index (BMI) at onset in children diagnosed with insulin requiring diabetes. We investigated associations of demographic, metabolic and genetic factors with BMI at onset and after 3 months with the hypothesis that low risk HLA and higher C-peptide at onset predict higher BMI.

Materials and methods: All children age <19 years, diagnosed with insulin-requiring diabetes from January 1st, 2004 to December 31st, 2006 at Children's Hospital of Pittsburgh were recruited and 321 consented. All received a minimum of 3 insulin injections per day and dietary education from a nutritionist at onset. Clinical and research data were obtained from hospital and research medical records. Blood samples were drawn at diagnosis and 3 months including C-peptide levels, HbA1c, islet cell antibodies and HLA typing. Results are presented for Caucasians (n=276) and African Americans (n=19) who have BMI measures both at baseline and 3-months. Predictors of BMI at baseline, 3 months and change from baseline to 3 months were examined using multiple linear regression analyses.

Results: BMI percentile (mean \pm standard deviation, median and interquartile range) increased significantly from onset 52.2 ± 34.2 , 53.07, [18.7–86.9]

Table 1 Characteristics of Diabetes presenting in the first 6 months of life

Gene	PNDM/ Clinical syndrome	TNDM/ Inheritance	Number of cases described % in Consanguineous or isolated populations	Median birth weight (SDS)	Age of diagnosis in weeks. Median (range)	Pancreatic appearance	Other features
ZAC/HYAMI imprinting defect on 6q24	TNDM		=150 rare	2,100g (-2.94)	0.5 (0 - 4)	Normal	Macroglossia (23%)

GCK (glucokinase) recessive	PNDM		6 85%	1720 -2.75		Normal	Parents have fasting hyperglycaemia as heterozygotes
IPF1 recessive	PNDM		2 50%	2140 -2.97		Absent	Parents may have early-onset diabetes as heterozygotes
HNF-1 β dominant (60%) spontaneous	TNDM		2 Rare	1900 -3.21		Atrophy	Renal developmental disorders
PTF1A recessive	PNDM		3 100%	1390 -3.8		Atrophy	Severe neurological dysfunction and cerebellar hypoplasia

Distribution of subjects within BMI percentile by age group

Time	BMI %ile	Age at Diagnosis				Total % (n=295)
		0 to <5 (n=44)	5 to <10 (n=111)	10 to <15 (n=116)	15 to <19 (n=24)	
Baseline	< 25	41%(18)	34%(38)	24%(28)	16%(4)	30% (88)
	≥ 85	14%(6)	23%(26)	32%(37)	25%(6)	25%(75)
3 months	< 25	9%(4)	1.8%(2)	5.2%(6)	0%(0)	4%(12)
	≥ 85	36%(16)	46%(51)	38%(44)	37%(9)	41%(120)

to three months (73.5 ± 23.1 , 79.4 , [58.7–93.1]) ($p < 0.0001$; paired t-test). This change was similar between Caucasians (20.4 ± 23.8) and African Americans (21.7 ± 32.6). BMI percentile (%ile) at diagnosis was significantly associated with the independent factors of African American race, higher baseline C-peptide and older age. BMI %ile at 3 months was independently associated with African American, higher baseline C-peptide, higher baseline HbA1c and male gender. Greater change in BMI %ile from onset to 3 months was significantly associated with lower baseline c-peptide, higher baseline HbA1c, male gender and younger age at onset. There was no association between BMI and number of islet cell antibodies or HLA haplotype (only 10 had low risk haplotypes). Table 1 shows the prevalence of BMI < 25th %ile and ≥ 85th %ile at baseline and 3 months.

Conclusion: Consistent with our previous experience, higher BMI percentile at onset was associated with being African American, older age, and higher C-peptide. Those with the most severe insulin deficiency (lower C-peptide and higher HbA1c) had a greater rise in BMI, likely representing catch up to prior levels so that after 3 months 43% of children age 0–9 years and 38% children 10–18 years had a BMI ≥ 85th percentile, with males being the most obese. As predicted, those with the highest C-peptide were at greatest risk, but there was no support for an HLA relationship.

946**Increase in obesity after diagnosis of insulin-requiring diabetes in children: cause for concern**

I.M. Libman¹, C. Baldwin¹, S. Brooke², P. Balfour³, D. Becker¹

¹Pediatric Endocrinology and Diabetes, Children's Hospital of Pittsburgh,

²School of Medicine, Drexel University, Philadelphia, ³Internal Medicine, University of Virginia Medical Center, Charlottesville, United States

Background and aims: Our group has shown a continual increase in obesity prevalence in pediatric cohorts at onset of insulin requiring diabetes over the last decades. Also, our adolescents, after a mean diabetes duration of 5 years, consume fewer carbohydrate calories but more fat, exceeding the recommended intake. We hypothesize that the prevalence of obesity increases after diagnosis, in spite of dietary recommendations and education.

Materials and methods: All children age <19 years, diagnosed with insulin-requiring diabetes from 1/1/1995 to 31/12/2002 at Children's Hospital of Pittsburgh, with residence in Allegheny County, Pennsylvania, were identified. Data were obtained from retrospective review of records at diagnosis and 4 clinic visits (2–3, 6, 12 and 36 months). Obesity was defined as a body

mass index (BMI) ≥ 85th %ile for age and sex. All were started on a minimum of 3 insulin injections per day and received dietary education from a nutritionist at onset.

Results: Complete data were available for 270 of 351 children (77%).

Prevalence of obesity by visit and by BMI percentile group at onset

In group I, BMI %ile (median and [interquartile range]) was 5.7 [1.2–15.3] while at 2–3 months this increased to 53.3 [36.6–68.2] ($p = 0.0005$; paired t-test). A second significant increase was seen between 12 and 36 months (58.0 [35.2–74.9] vs 68.8 [46.6–81.5] ($p = 0.0005$)). In group II and III significant changes were seen between onset and 2–3 months (Group II: 33.5 [28.4–39.4] vs 68.9 [57.5–82.9] and group III: 66.6 [57.1–75.4] vs 85.2 [75.2–91.3] ($p = 0.0005$)).

Conclusion: 1) 17% were obese at onset. After 3 years ~ 1 in 3 children age 0–9 years and 1 in 2 children 10–18 years had a BMI ≥ 85th %ile 2) prevalence of obesity in those with BMI < 85th %ile at onset increased with time, while in those initially obese, it decreased minimally 3) non-obese children had a remarkable increase in BMI percentile during the first 2 to 3 months after diagnosis. The initial months after diagnosis are critical in preventing excessive weight gain. Despite education to provide recommended dietary allowances for age, these are exceeded or these recommendations are currently excessive. Recommendations to calorie restrict, if obese at onset, at best prevents further excessive weight gain. The relevance of this problem beyond our population and the implications long term should be explored.

Disposition modeling of blood glucose control in children: novel insights from a longitudinal studyA.N. Jeffery¹, B.S. Metcalf¹, J. Hosking¹, L.D. Voss¹, M.J. Murphy², T.J. Wilkin¹¹Department of Endocrinology and Metabolism, Peninsula College of Medicine and Dentistry, Plymouth, ²Department of Biochemical Medicine, Ninewells Hospital, Dundee, United Kingdom

Background and aims: The hyperbolic relationship between insulin sensitivity (%S) and insulin secretion (%B) defines the behaviour of the glucose-insulin feed-back loop, and underpins the HOMA model. Disposition modeling - plotting the shifting relationship between %S and %B over time - offers new insights into the dynamic behaviour of the loop as it seeks constantly to optimize control of glucose while environmental pressures change.

Methods: Disposition is the point on a disposition curve defined by concurrent values of %B and %S. Disposition index (DI) is the product of %B and %S which, being constant for a hyperbola, defines the disposition curve. DI determines blood glucose (inversely). We monitored 218 healthy children (126 boys) from the EarlyBird cohort annually from age 5 to 10y, measuring changes in BMI SDS, fasting glucose, HOMA-%S, HOMA-%B, disposition and DI. The relationship between %B and %S was plotted year-by-year for the cohort as a whole, and for tertiles BMI SDS at 5y to examine the impact of BMI on disposition.

Results: Glucose rose (4.3–4.8mmol/l, $p<0.001$) throughout the 5y period, consistent with the fall in DI (186.3–115.6, $p<0.001$) and a progressive weakening of loop control. BMI (SDS) did not change significantly from 5–7y (+0.02SD, $p=0.4$) but rose substantially from 7–10y (+0.17SD, $p<0.001$). The disposition map for the cohort as a whole (see figure) shows that, from 5–7y, the fall in DI was attributable to loss of %B, with some compensatory increase in %S. From 7y, however, %S ceased to rise further, the trajectory reversed, and the continuing fall in DI became attributable to falling %S (rising insulin resistance) with a compensatory rise in %B but a higher glucose level. When analyzed by BMI tertile, %B was higher and %S lower in the heaviest compared with the lightest children at each age ($p<0.01$ at 5y, 7y, 8y, 9y, 10y; $p=0.14$, 0.15 at 6y). Furthermore, the switch in trajectory occurred earlier (6–7y), and at lower sensitivity (221%), in the heaviest compared with the lightest children (7–8y, 331%).

Conclusion: The switch in disposition is a novel observation, demonstrating how the loop reverts to beta cell reserve once insulin sensitivity nears its limit. The inflexion may be a crucial prelude to beta cell insufficiency, and BMI appears to be a key determinant of the stage at which it occurs. Disposition mapping may help us better understand the changes that lead to childhood diabetes.

Three kind of mealtime insulin administration and metabolic control in diabetic children on insulin pumps

E. Pankowska, A. Szypowska, M. Lipka, M. Szpotańska, M. Blazik, L. Groele, D. Golicka

Pediatric Diabetology and Birth Defects, Medical University, Warsaw, Poland

Background: Insulin pump is an advanced technology which offers a new option of bolus used for delivering meal time insulin. There are a possibilities to administrate normal bolus (N), dual-wave (D-W) and square-wave (S-W) in which insulin is delivered in prolonged time.

Aims: of the study was to assess whether using of D-W boluses has an impact on metabolic control (HbA1c) and to estimate the compliance of pediatric patients in implementing this system in real-life.

Materials and methods: Cross-sectional study included 499 patients -pump records from outpatient clinic. We analyzed the number of D-W/S-W boluses per two weeks, insulin requirement(U/kg/d) from records of downloaded insulin pumps, HbA1c and patients' weight measured at visit. Patients were educated to calculate a dose of meal-time insulin using a carbohydrate unit (CU) and fat-protein unit (FP). One CU unit was defined as 10 grams of carbohydrate and one FP as a 100 calories from fat and/or protein products. The same insulin-ratios (IR) was for CU and FPU which was implemented for calculation insulin's amount for N boluses and S-W boluses, where dose for N bolus=IR x number of CU; S-W= IR x number of FPU.

Results: Averagely D-W/S-W bolus were used 16.6 SD 0.77/14 days (0–95) in group aged 10.6 SD4.1 years (1.1–18.8) with HbA1c 7.42 SD 1.47% (4.4–13.5) and insulin requirement 0.79 SD 0.22 U/kg/d (0.11–1.94). 18.8% of patients did not programmed D-W/S-W boluses during a two weeks and had a higher HbA1c (7.82 SD1.69% vs 7.32 SD1.4%, $p=0.0052$). 47 % of patients used at least one 1 D-W/S-W boluses per day. The significantly lowest HbA1c was found in group programmed from 1 to 2 D-W/S-W bolus/day ($p=0.0001$) compared with group less than 1 D-W/S-W bolus /day and more than 2 S-W/S-W bolus/day. For patients with HbA1c <7.5% statistically relevant was higher number of D-W/S-W boluses 19.55 (95%CI:17.44–1.65 vs 12.42 (95% CI:10.22–14.6), but there was no correlation between number of boluses and HbA1c in patients in remission phase ($<0.5\text{U/kg/d}$) ($r=0.012$, $p=0.9$).

Conclusion: The patients using at least one D-W/S-W bolus per day get a recommended level of HbA1c. The pediatric diabetes patients on CSII are able to use D-W/S-W boluses in daily practices.

The optimal type of bolus following a pizza meal in children and adolescents with type 1 diabetesA.E. Scaramuzza¹, D. Iafusco², E. Giani¹, D. Spiri¹, A. De Palma¹, A. Bosetti¹, L. Santoro¹, C. Mameli¹, A. Gazzarri¹, M. Macedoni¹, S. Riboni¹, G.V. Zuccotti¹¹Paediatrics, University of Milano, ²Paediatrics, Second University of Naples, Italy, ³Nutrition and Dietetics, University of Milano, Italy

Background and aims: We attempted to identify an optimal insulin pump meal bolus by comparing postprandial blood sugar levels following 6 methods of insulin pump meal bolusing for a consistent pizza meal.

Materials and methods: We evaluated 26 children and adolescents, aged 4–22 yrs (mean 14.81 ± 4.28 yrs) with type 1 diabetes mellitus (T1DM) from 1 to 19 yrs (8.23 ± 4.41 yrs), BMI 22.16 ± 4.28 kg/m², in therapy with subcutaneous insulin infusion (insulin requirement 0.84 ± 0.32 U/kg/day). Each patient participated in a study to compare postprandial glucose values following 6 meal bolus regimens for a consistent pizza meal. Each patient utilized the following aspart regimens on three consecutive days, and glucose values were recorded with SMBG: a) 6-h dual-wave bolus (30% of insulin given immediately and 30% given over a 6-h period) given 15 min prior a pizza “margherita” meal; b) 6-h dual-wave bolus (30% of insulin given immediately and 30% given over a 6-h period) given just before a pizza “margherita” meal; c) a single-wave bolus (100% of insulin given immediately) given 15 min before a pizza “margherita” meal; d) a single-wave bolus (100% of insulin given immediately) given just before a pizza “margherita” meal; e) 6-h dual-wave bolus (30% of insulin given immediately and 30% given over a 6-h period) given 15 min prior a pizza with vegetables meal; and f) a single-wave bolus (100% of insulin given immediately) given 15 min before a pizza with vegetables meal. Total CHO was kept constant for each meal; insulin dose was calculated according to

Glycaemic values following various types of bolus in children with T1DM

Type of bolus	T0	T30	T60	T90	T120	T180	T240	T300	T360

Efficacy and safety of insulin glulisine versus insulin lispro as part of a basal-bolus insulin regimen in children and adolescents with type 1 diabetes mellitus

A. Philotheou¹, S. Arslanian², L. Blatnick³, V. Peterkova⁴, E. Souhami⁵, T. Danne⁶

¹UCT Diabetes Clinical Trials Unit, New Groote Schuur Hospital, Cape Town, South Africa, ²Div. Pediatric Endocrinology, Metabolism and Diabetes Mellitus, Children's Hospital of Pittsburgh, University of Pittsburgh School of Medicine, United States, ³Buda Children's Hospital, Budapest, Hungary, ⁴Endocrinological Scientific Centre, Russian Academy of Science, Moscow, Russian Federation, ⁵sanofi-aventis, Antony, France, ⁶Children's Hospital auf der Bult, Hannover, Germany

Background and aims: The aim of the study was to assess efficacy and safety of insulin glulisine (glulisine) versus insulin lispro (lispro) in children and ad-

olescents with type 1 diabetes mellitus (T1DM) treated with insulin glargine (glargine) once daily or NPH twice daily as basal insulin.

Materials and methods: A 26-week, multicentre, open, randomised, parallel-group, non-inferiority trial conducted in 572 patients with T1DM aged 4-17 years and HbA_{1c} 6-11%, treated with glargine once daily (evening) or NPH twice daily as basal insulin. Patients received glulisine (n=277) or lispro (n=295) 0-15 min pre-meal.

Results: At baseline, patients (glulisine versus lispro; mean±standard deviation) were: age 12.5±3.1 versus 12.6±2.9 years, body mass index 20.8±3.4 versus 20.5±3.3 kg/m², HbA_{1c} 8.2±1.1 versus 8.2±1.0% (33% were at ADA age-specific HbA_{1c} targets) and T1DM duration 5.3±3.6 versus 5.2±3.2 years. Treatment at randomisation (baseline): NPH 30.3 versus 27.1%, glargine 69.7 versus 72.9%. 58.0% (glulisine) and 60.5% (lispro) of patients had 3-4 bolus insulin injections, remaining stable throughout. Glulisine versus lispro baseline to endpoint HbA_{1c} adjusted mean changes were similar (glulisine-lispro: -0.06, 95% CI: [-0.24, 0.12], pre-specified non-inferiority margin=0.4%). Overall, for all age groups together, significantly more (p=0.0386) patients achieved ADA age-specific HbA_{1c} targets at endpoint with glulisine (38.4%) versus lispro (32.0%). This difference was most pronounced in 13-17-year olds, with 31.1 versus 21.1% of glulisine versus lispro patients achieving ADA age-specific HbA_{1c} target <7.5% at endpoint (p=0.0251). From Month 4 to endpoint, symptomatic hypoglycaemia rates were similar (see table). Data for 3-point self-monitored blood glucose profiles are also shown in the table.

Conclusion: In conclusion, glulisine was as effective and safe as lispro in children and adolescents with T1DM. Compared with lispro, glulisine allowed higher numbers of patients to reach ADA age-specific HbA_{1c} targets, particularly amongst adolescents aged 13-17 years.

Glargine treatment can ameliorate clinical features in children and adolescents with cystic fibrosis and early glucose derangementsA. Franzese¹, I. De Simone¹, E. Mozzillo¹, G. Valerio², V. Raia¹, R. Spadaro¹, R. Nugnes¹¹Paediatrics, University Federico II, ²School of Movement Sciences, Parthenope University, Naples, Italy

Background and aims: A strict association of diabetes and increased morbidity and mortality in cystic fibrosis (CF) patients has been previously described. Since 1998, Moran et al suggested that pre-diabetic status may have adverse effects on nutrition and lung function in CF patients. Successively several studies confirmed a decline in nutritional and pulmonary status 2 to 4 years before the diagnosis of CF-Diabetes. Conversely insulin treatment can ameliorate clinical findings of the CF-diabetic patients. To evaluate the effect of glargine on Body Mass Index z-score (BMI z-score), lung function, as forced expiratory volume in the first second (FEV1%), number of acute pulmonary infections and Hemoglobin Glycosylated A1c (HbA1c) in (CF) patients with early pre-diabetic glucose derangements.

Materials and methods: 17 CF patients 10–20 years of age and 5 patients ≤ 10 years with glucose abnormalities in Oral Glucose Tolerance Test (OGTT: glucose peak > 11.1 mmol/L and/or T120 glucose value > 7.7) and/or in Continuous Glucose Monitoring System (CGMS: recorded data > 7.7 mmol/L at every time) were enrolled in a preliminary open trial with glargine. BMI z-score, FEV1%, number of acute lung infections and HbA1c in the first year of treatment were recorded.

Results: The results of the patients who completed 12 months of treatment are reported. BMI z-score and HbA1c did not significantly change in the whole group, while a significant improvement in BMI z-score was found in patients with a baseline BMI-z score < -1 (p=0.017). On the contrary a 8.8 % increase in FEV₁ (p=0.01) and 42 % decrease in the number of lung infections (p=0.003) was found in the whole group.

Conclusion: One year treatment with Glargine improved the course of lung disease in CF young patients with early glucose derangements.

Glucose RapidSpray™ for a new management of hypoglycaemia in children up to 5 years of age with type 1 diabetesE. Pronina¹, H. Petraikina¹, M. Antsiferov¹, O. Duchareva¹, C. Guglielmi², M. Khazrai², P. Pozzilli²¹Endocrinology, Morozovskaya Children City Clinical Hospital of Moscow, Russian Federation, ²Endocrinology and Diabetes, Università Campus Bio-Medico, Roma, Italy

Background and aims: Hypoglycaemia continues to be a complex condition to tackle especially in children up to 5 years of age because of difficulties in administering the correct dose of glucose as well as child compliance. Moreover a very rapid absorption of glucose is needed in these kids which may be not easy to achieve due to the inability of the child to swallow under particular circumstances such as severe hypoglycaemia. Finally, the small body weight of children requires only small amount of glucose to reverse hypoglycaemia. This may help to avoid hyperglycaemic rebound which is due to the counter regulatory hormone response as well as the usually high amount of glucose that the parents administer to their children. The aim of this study was to evaluate the effect of administering small amounts of glucose through the Glucose RapidSpray™ (GRS) during first signs of hypoglycaemia in children affected by type 1 diabetes (T1D) to improve the metabolic control as measured by HbA1c over a period of 6 months follow up. This device consists of a 19 ml bottle containing 10 g glucose solution with the addition of artificial flavours and excipient to facilitate buccal absorption delivering by spray puffing glucose in quantities as small as 0.5 grams.

Materials and methods: We designed an open randomized trial in 27 children up to 5 years of age affected by T1D. Patients were randomly allocated into two groups: group A) GRS (10 to 20 puffs of GRS, 0.5 g to 1 g glucose) depending on hypoglycaemic symptoms; group B) traditional treatment of hypoglycaemia episodes (sugar, fruit juice, candies, etc). The following parameters were evaluated at entry into the trial, at 3 months follow-up and at the end of the study (6 months): HbA1c, number and characteristics of hypoglycaemic episodes, compliance to treatment and quality of life of patients and their parents.

Results: HbA1c at entry into the trial was 9.4% ± 1.2 in group A and 9.1% ± 0.6 in group B (p NS). After 3 months both groups showed a significant

improvement in HbA1c but not different between groups (group A: 8.7% ± 1, group B: 8.6% ± 0.7 p NS) which further improved at 6 months (group A: 8.4% ± 0.9, group B: 8.4% ± 0.6). There was a statistically significant difference in the improvement of the HbA1c in the GRS treated group vs. control group over the period of observation (0.98% vs. 0.60% difference, respectively, p<0.02, paired T test). Patients in group A showed a tendency for less mild and/or severe hypoglycaemic episodes during the day compared to group B in the course of the 6 months observational period (2.5±0.8 vs. 3.1±0.9, p=0.09). Regarding compliance patients appeared to be keen to be sprayed in the mouth, appreciating the strawberry or orange taste of the GRS. Parents found easy the use of this device and felt more comfortable in managing hypoglycaemic episodes in their children. No adverse effects were observed with GRS treatment.

Conclusion: Hypoglycaemia remains a major hazard in toddlers and children with T1D. A more acceptable and practical tool to control and manage hypoglycaemia is required. The availability of GRS, in view of the small amount of glucose it delivers and the fine tuning allowed in glucose administration, represents an ideal tool in very young patients which can also improve the overall metabolic control.

Insulin resistance, hepatic glucose metabolism and mitochondrial function in offspring rats exposed to malnutrition during fetal and early life

J. Choi, M. Kang, S. Hong, J. Song

Division of Metabolic Disease, Center of Biomedical Science, National Institutes of Health, Seoul, Republic of Korea

Background and aims: Malnutrition, either a protein depletion or high fat intake, during prenatal and postnatal periods may predispose to chronic diseases including obesity and diabetes in later life. We investigated how the maternal and postnatal diets containing different level of dietary protein and fat affected the growth, insulin resistance, hepatic glucose metabolism and mitochondrial function in the adult offspring.

Materials and methods: Dams were fed one of the four diets during gestation and lactation: a low fat and low protein diet (5% fat, 8% protein, LF-LP), a low fat and normal protein (5% fat, 20% protein, LF-NP); a high fat and low protein (23% fat, 8% protein, HF-LP); a high fat and normal protein (23% fat, 20% protein, HF-NP). Eight offspring per dam were allocated. After weaning, offspring were fed on the same diet as dam's diet by age 12 weeks. In dams and offspring, food intake, body weight, organ growth, glucose tolerance test, the plasma glucose, insulin and lipids levels were observed with the measurement of hepatic lipids and glycogen content, glucose metabolizing enzyme activities and mitochondrial functions.

Results: Maternal diet modification affected offspring growth with no change in litter size. Offspring with LP diets showed lower body weight and organ weights such as liver, kidney and fat tissue with the smaller protein intakes by their dams and the smaller intakes of protein and energy by offspring themselves. At age 12 weeks, HF-NP offspring showed the worst glucose tolerance than the others. The levels of plasma insulin were significantly higher in the NP groups than LP groups. With low insulin in LP groups, glucose level was not increased in LF-LP but high in HF-LP. In the HF groups, the levels of hepatic total lipid and triglyceride were higher in HF-NP group, whereas no difference could be observed in LF groups. With no significant difference in glucose 6-phosphatase activity could be observed among groups, hepatic glycogen content was highest in HF-LP and glucokinase activity was significantly higher in LF-NP and HF-LP. High fat diet decreased hepatic mitochondrial succinate dehydrogenase and cytochrome C oxidase activity. Low fat and adequate protein intake secured the proper activity of cytochrome C oxidase activity since we observed the highest activity in LF-NP group.

Conclusion: Postnatal growth, insulin sensitivity and glucose and energy metabolism varied depending on the diets throughout prenatal and postnatal growth periods. With normal dietary protein level, a high fat diet exacerbated insulin resistance through increasing plasma insulin, fat deposit and decreasing energy metabolism. In contrast, a high fat and low protein diet reduced partly adverse effects on insulin resistance through enhancing hepatic glucose metabolism in the present study.

The metabolic syndrome of ω 3-deficient rats

W.J. Malaisse¹, Y. Zhang¹, N. Bulur¹, E. Hupkens¹, L. Portois², M. Hacquebard², K. Louchami¹, Y.A. Carpentier², A. Sener¹

¹Laboratory of Experimental Hormonology, ²Laboratory of Experimental Surgery, Université Libre de Bruxelles, Belgium

Background and aims: Extensive investigations conducted in 2nd-generation rats depleted in long-chain polyunsaturated ω 3 fatty acids (ω 3D rats) have documented that they represent a novel animal model for the metabolic syndrome. They indeed display visceral obesity, liver steatosis, insulin resistance, hypertension and consequent cardiac hypertrophy. The major aim of the present study was to find out whether a comparable situation may be found in rats deprived of dietary ω 3 for only three months, i.e. under condition more likely to simulate the insufficient intake of ω 3, as presently often prevailing in Western populations.

Materials and methods: Two groups of 6-week old female rats each were given free access for 3 months to either a control or ω 3-depleted diet.

Results: Although the liver protein content was identical in control and ω 3D rats, its triglyceride content was increased ($p < 0.05$) in ω 3D rats (6.42 ± 0.50

vs 4.16 ± 0.25 μ mol/g wet wt). This coincided, in liver phospholipids, with a lower total fatty acid content, the absence of detectable amounts of C18:3 ω 3, C20:5 ω 3 and C22:5 ω 3, a 4-times lower content of C22:6 ω 3, a much higher content of C20:4 ω 6 and C22:4 ω 6, and an apparent increase in the activity of Δ 6-desaturase (C18:3 ω 6/C18:2 ω 6 ratio), Δ 5-desaturase (C20:4 ω 6/C20:3 ω 6 ratio) and elongase (C20:2 ω 6/C18:2 ω 6 and C22:4 ω 6/C20:4 ω 6). The weight percentages of C16:0, C18:0 and C24:0 were also significantly increased in the liver phospholipids of ω 3D rats, with increased C16:1 ω 7/C16:0 ratio. Inversely, despite a higher weight percentage of C18:1 ω 9 in the liver phospholipids of ω 3D rats, that of further precursors of nervonic acid (C20:1 ω 9 and C22:1 ω 9) only represented in the ω 3D rats $53.4 \pm 15.6\%$ ($p < 0.06$) of the mean corresponding value recorded in control animals. An increase in the absolute or relative to body wt values for parametrical adipose tissue mass was initiated after 3 months of ω 3 deprivation, but only became statistically significant in the ω 3D rats a few months later. Last, the ω 3D rats, displayed significantly increased plasma glucose concentration (16.1 ± 0.7 vs 13.4 ± 0.7 mmol/l) and insulin resistance index (1.73 ± 0.17 vs 1.18 ± 0.12).

Conclusion: A dietary deficiency of ω 3 in otherwise normal rats is sufficient to cause within 3 months insulin resistance, liver steatosis, and typical changes in the fatty acid pattern of hepatic phospholipids, with emphasis on the depletion in ω 3 fatty acids, excess of C20:4 ω 6 and C22:4 ω 6 and apparently increased activity of Δ 5-, Δ 6- and Δ 9-desaturases. In conclusion, therefore, in the search of an animal model for the metabolic syndrome provoked by a dietary deficiency in ω 3, the present study not only validates the prior use of 2nd-generation ω 3D rats, but also introduces a much more simple and realistic approach for the same purpose.

955

Effects of the dietary omega-3 polyunsaturated fatty acids in the treatment of cardiomyopathy in type 2 diabetes mellitus patients

A.A. Serhiyenko, V.A. Serhiyenko, A.M. Urbanovich

Endocrinology, National, Lviv, Ukraine

Background and aims: The present study has examined the effect of simvastatin (SIM), ω -3 polyunsaturated fatty acids (ω -3 PUFA) and their combinations on heart rate variability (HRV), QTc interval parameters; dynamics of biochemical parameters in type 2 diabetic patients with diabetic cardiomyopathy (DCMP).

Materials and methods: 86 patients with type 2 DM and DCMP (51.2 ± 4.3 years), BMI 26.3 ± 2.79 kg/m², DM duration 7.6 ± 2.4 years were observed. The following short-term HRV measures were assessed by a computer assisted technique: coefficient of variation (CV), root mean square successive difference (RMSSD), spectral power in the low- (LF) and high-frequency (HF) bands. We investigated levels of total cholesterol (TC), low (LDL-C), high density lipoprotein-cholesterol (HDL-C), triglycerides (TG) concentrations, superoxide dismutase (SOD), glutathione peroxidase (GPO). Patients were allocated to three groups. Patients of group A (n=25) received SIM 20 mg tid; B (n=37) - capsules of fish oil [(1,0 g eicosapentaenoic (EPA), 1,0 g docosahexaenoic (DHA)] acid and 0,1% α -tocopherol acetate tid; C (n=24) - SIM 10 mg tid plus capsules of fish oil. All patients were on the same diet. Research joined patients with the diagnosed lipid abnormalities (NCEP ATP III). The duration of the study was 3 months. Statistics: ANOVA.

Results: Lipid disorders [high level of total TC, LDL-C, TG (7.3 ± 10.1 ; 4.5 ± 0.3 ; 2.87 ± 0.2 mmol/l, $p < 0.05$) and decrease level of HDL-C] in the patients with DCMP is accompanied by a decrease of RMSSD, QTc interval parameters, SOD, GPO activities in the RBC's. It has been discovered that the monotherapy by SIM is accompanied by negative dynamics of activity of enzymes of a liver that proved by of ultrasonic scanning. After 3 months of treatment there was a more significant decrease in LDL-C, TC, TG concentration, positively influenced HRV, QTc interval parameters, some indexes of the oxidative stress were observed in the 3-rd group (table). In particular, the increasing of RMSSD parameters (4.72 ± 0.53 ms was watched before the treatment; 6.81 ± 0.63 ms-after treatment, Fisher's t-criterion=59.56, $p < 0.001$), LF, HF (859.7 ± 12.6 ms² and 1134.6 ± 17.4 ms², $p < 0.001$), CV (8.7 ± 0.3 % and 6.2 ± 0.2 %, $p < 0.001$). The authentic decreasing of QTc interval parameters (0.57 ± 0.069 and 0.52 ± 0.057 , $p < 0.05$), the increasing activity of SOD, GPO (10.94 ± 0.22 ; 321.7 ± 19.2 mcmol GSH/min 1 g Hb, $p < 0.001$) were observed in the 3-rd group (table).

Treatment difference are presented with 95% CI. * $p < 0.01$; ** $p < 0.001$

Conclusion: Usage of SIM and ω -3-PUFA are accompanied by decreasing of clinical developments of DCMP, significantly improvement of the lipid profile, RMSSD, QTc interval parameters, some indexes of the oxidative stress. The combined purpose SIM and ω -3 PUFA allows to lower a dose SIM, that

allows to recommend their combination in the treatment of lipid disorders in patients with DCMF.

Mean % change from baseline at 3 months	SIM (n=25)	ω -3 PUFA (n=37)	SIM / ω -3 PUFA (n=24)

Relationship of carbohydrate intake to the increase in fasting glucose levels with increasing age

A. Dzien¹, C. Dzien-Bischinger¹, M. Lechleitner², E. Theurl³, H. Winner³

¹Internal Medicine, Medical Center Henschelhof, Innsbruck, ²Internal Medicine, Hospital Hochzirl, Innsbruck, ³Economics and Statistics, University of Innsbruck, Innsbruck, Austria

Background and aims: Aging is associated with an increase in insulin resistance and an increased risk for type 2 diabetes. Various life-style recommendations, including dietary advice, are associated with a reduction in the diabetes risk. We were interested in the age-associated changes in reported food intake and the relationship with fasting glucose values.

Methods: 1 492 non-diabetic patients (977 women, 515 men) attended our outdoor center for diagnostic and therapeutic procedures. Beside clinical and laboratory controls, all patients were asked to report about their food intake using a standardized questionnaire. Data are presented as mean±SD. Two-sample comparisons of normally distributed variables were analysed by the Student's *t*-test. The Wilcoxon-Mann-Whitney test was used for variables that did not have a normal distribution, and the Pearson correlation coefficient to evaluate the relationship between variables.

Results: Fasting glucose levels increased continuously with increasing age from 87.5±12.0 mg/dL in the age group up to 30 years to 101.8±16.2 mg/dL at an age of 90 years (Table 1), while the reported daily calory intake decreased from 2173 in the youngest to 1783 in the oldest subgroup. The carbohydrate consumption decreased from 197 g to 164 g, the fat intake decreases, and the intake of dietary fibres remained stable (Table 1). The consumption of white bread products increased with increasing age. No significant differences could be observed between men and women. The carbohydrate intake revealed a strong relationship with fasting glucose levels ($R=0.874$ in the age group up to 30 years and $R=0.733$ in the oldest group up to 90 years.)

Conclusion: In our evaluation the intake of white bread products paralleled an increased in fasting glucose levels with advancing age. Dietary recommendation should thus focus on an intake of complex carbohydrates especially in the elderly.

Table 1

Age group (years)	n	Fasting glucose (mg/dL)	Total calories	Protein intake (g)	Fat intake (g)	Fibre intake (g)	Carbohydrate intake (g)	White bread portions (intake/month)
>30	344	87.5±12.0	2173	93	83	22.6	197.7	15
30-50	551	93.0±10.8	2095	89	78	21.9	184.1	19
50-70	435	100.9±13.0	1942	80	66	21.3	164.9	24
70-90	162	101.8±16.2	1783	74	59	21.9	163.9	25

Viscosity of fiber preloads affects food intake in adolescents

A. Jenkins¹, V. Vuksan², S. Panahi², P. Breitman², E. Jovanovski²

¹Nutritional Sciences and Clinical Nutrition and Risk Factor Modification Centre, ²Department of Nutritional Sciences, Faculty of Medicine, University of Toronto, Canada

Background and aims: The prevalence of obesity is increasing most rapidly in adolescents and the inability to control food intake is one of the most challenging factors contributing to increases in body weight. Viscous dietary fiber that develops viscosity in the gastrointestinal tract is capable of addressing various aspects of food intake control, thus representing a promising treatment modality.

Our objective was to assess subsequent food intake and appetite in relation to the level of viscosity following three liquid preloads each containing 5gr of either a high (viscous polysaccharide blend; VPB), medium (glucomannan; GLM), or low (cellulose; CE) viscosity dietary fiber.

Materials and methods: In this acute, double-blind, randomized, controlled and crossover trial, 31 healthy weight adolescents (25:females; 6:males; age:16.1±0.6 years; BMI:22.2±3.7kg/m²) consumed one of the three preloads in random order 90 min prior to an *ad libitum* pizza meal. Preloads were identical in taste, appearance, nutrient content and quantity of fiber, but different in their viscosities (10, 410 and 700 poise for CE, GLM, and VPB, respectively). Pizza intake (primary outcome), appetite ratings, 24-hour food intake after the pizza meal from the 24-hour diaries, and physical comfort (secondary outcomes) were assessed.

Results: Pizza intake was significantly lower ($p<0.05$) after consumption of the high viscosity VPB (278±111g) compared to the medium viscosity GLM (313±123g) and low viscosity CE (316±138g) preloads, without difference between GLM and CE. Appetite scores, physical symptoms and 24-hour intake did not differ among treatment groups.

Conclusion: A highly viscous fiber preload leads to reduced subsequent food intake in healthy-weight adolescents and may represent a part of weight management strategy for adolescent population.

Differential effect of weight-loss diet strategies on spouses and effect of spouse support on the participant; The Dietary Intervention Randomized Clinical Trial (DIRECT)-Spouse Study

R. Golan¹, D. Schwarzfuchs², R. Zuk-Ramot², O. Tangi¹, I. Shai¹

¹Epidemiology, Ben Gurion University of the Negev, Beer Sheva,

²Epidemiology, Nuclear Research Center Negev, Dimona, Israel

Background and aims: The effect of diet strategy on spouses may be a key factor for long-term success of the participants' weight loss. We examined to what extent, attendance to a 2-years weight loss intervention study in one of 3 diet strategies affects weight, and nutritional patterns of the participant's spouse. We further evaluated the effect of spouse support on the participant.

Materials and methods: Moderately obese participants with or without type 2 diabetes of the Dietary Intervention Randomized Controlled Trial (DIRECT) were randomly assigned to one of the three following 2-year intervention arms: low-fat, Mediterranean, and low-carbohydrate diets. Our study included 6 months of meetings with 74 spouses of the DIRECT participants and an additional 18 months of follow up among a sub-group of 59 spouses of this group.

Results: The spouses were all women, age 50.7 years, Mean BMI 26.66kg/m²±4.72. After 6 months, spouses of the DIRECT participants who followed the low-carb diet lost 4.62kg±6.56, $P=0.025$, spouses of DIRECT participants who followed the Mediterranean diet lost 2.30kg±2.39, $P=0.023$, spouses of DIRECT participants who followed the low-fat diet lost 1.48kg±2.72, $P=0.035$, as compared to baseline (Figure 1). The weight change correlation between DIRECT-participants and their spouses were significant in the low-carb diet ($r=0.32$, $p=0.005$). In overall, 74 DIRECT participants, whose spouses took part in group support meetings, lost significantly more weight (-5.15kg±5.04) than 248 DIRECT participants whose spouses did not participate in group meetings (-3.54kg±5.12) within 2 years ($P=0.02$). Spouses demonstrated changes in their nutritional patterns, with a decrease in the consumption of the following food groups; Saturated fat and Trans fat, meat and poultry, Bread and pastry, Grains, pasta and potato, Fruit, Sweets and Sweetened beverages. Spouses increased their intake of Fish and Vegetables.

The changes fitted the principals of the three diet strategies the DIRECT participants were assigned to.

Conclusion: The low- carb diet may be considered as the strategy with the most successful halo-effect on the spouse in terms of weight loss and household dietary patterns. In each out of the three diet strategies, focusing on both man and wife as a 'unit' for designing weight loss, could provide a cost-effective approach to public health.

Figure 1. Changes in weight of 74 spouses after 6 months (maximal weight-loss phase) of the DIRECT, across the randomized assigned dietary arm groups of the DIRECT-Participants; an indirect effect

PS 087 Insulin therapy: acronym studies

959

The DURABLE trial 24-week results: safety and efficacy of insulin lispro mix 25 vs. insulin glargine added to oral antihyperglycaemic agents (OHAs) in patients with type 2 diabetes (T2D)

B.H.R. Wolffenbuttel¹, J. Buse², W.H. Herman³, H. Jiang⁴, J. Fahrback⁴, M. Palaia⁵, S. Martin⁴

¹Endocrinology & Metabolism, University Medical Center, Groningen, Netherlands, ²Medicine and Clinical Epidemiology, University of North Carolina, Chapel Hill, United States, ³Internal Medicine and Epidemiology, University of Michigan, Ann Arbor, United States, ⁴Eli Lilly, Indianapolis, United States

Background and aims: In a clinical setting, when OHAs fail to achieve glycaemic control in patients (pts) with T2D, adding insulin is an appropriate next step. The DURABLE trial (assessing DURability of Basal vs Lispro Mix 25 [LM25] insulin Efficacy) compares ability of 2 common starter insulin regimens to achieve glycaemic control during a 24-wk initiation phase and then maintain control during a subsequent 2-yr maintenance phase. We report results of the 24-wk initiation phase.

Materials and methods: A total of 2091 pts with T2D (63% Caucasian, 6.3% African descent, 12.1% Hispanic, 15.4% Asian, and 3.3% other race/ethnicities), aged 30–80 yrs, HbA1c >7.0% on at least 2 OHAs (minimum dose: 1500 mg/day metformin, 1/2 maximum dose sulfonylurea, and/or either 30 mg/day pioglitazone or 4 mg/day rosiglitazone) were randomized to either LM25 (25% lispro, 75% insulin lispro protamine suspension) bid or glargine (GL) qd added to pre-study OHAs. Insulin was titrated with dosing algorithms to achieve HbA1c ≤6.5%: fasting plasma glucose (FPG) and pre-evening meal target <6.1 mmol/l for LM25, FPG target ≤5.5 mmol/l for GL.

Results: Baseline characteristics were similar between groups (mean): age 57 yrs, T2D duration 9.5 yrs, BMI 32 kg/m², and HbA1c (LM25 9.1%, GL 9.0%, p=0.414). At 24-wk endpoint, LM25 use resulted in lower HbA1c (mean ± SD) than GL (7.2 ± 1.1 vs 7.3 ± 1.1%, p=0.005), greater HbA1c reduction from baseline (1.8 ± 1.3 vs 1.7 ± 1.3%, p=0.005), and a significantly higher % of pts reaching HbA1c target of <7.0% (47.5 vs 40.3%, p<0.001). FPG was lower with GL (6.8 ± 1.9 vs 7.4 ± 1.9 mmol/l, p<0.001). With LM25, 2-hr postprandial glucose values were lower after morning and evening meals (9.3 ± 2.8 vs 9.5 ± 2.7 mmol/l, p=0.016 and 9.1 ± 2.6 vs 9.8 ± 2.7 mmol/l, p<0.001, respectively) but not significantly different between groups after midday meal. Midday premeal glucose was lower for pts on LM25 (7.2 ± 2.4 vs 7.6 ± 2.4 mmol/l, p<0.001), while evening premeal glucose was not significantly different. LM25 was associated with a higher endpoint insulin dose (0.47 ± 0.23 vs 0.40 ± 0.23 U/kg/day, p<0.001) and more weight gain (3.6 ± 4.0 vs 2.5 ± 4.0 kg, p<0.0001). At 24 wks, pts on LM25 experienced higher rates of hypoglycaemia: symptoms or self monitored plasma glucose ≤3.9 mmol/l, (mean 28.0 ± 41.6 vs 23.1 ± 40.7 episodes/pt/yr, p=0.007; median 8.7 vs 7.0), but lower rates of nocturnal hypoglycaemia (mean 8.9 ± 19.3 vs 11.4 ± 25.3 episodes/pt/yr, p=0.009; median 0 vs 0). Rates of severe hypoglycaemia were low and similar between the two groups (LM25: 0.10 ± 1.6 vs GL: 0.03 ± 0.3 episodes/pt/yr; p=0.167).

Conclusion: In a large multi-national T2D population, both LM25 and GL added to 2 or 3 OHAs demonstrated significant HbA1c reduction. Compared to GL, LM25 resulted in lower endpoint HbA1c and a higher % of pts reaching HbA1c target of <7.0%, but with slightly more weight gain and higher rates of hypoglycaemia. Nocturnal hypoglycaemia rates were lower with LM25. Durability of regimens (length of time glycaemic control is maintained) will be evaluated in the following 2-yr maintenance phase.

Real-world analysis of percent of patients with type 2 diabetes achieving glycaemic goal with insulin glargine

D. Misurski¹, B. Schroeder², R. Wade³, R. Quimbo³, L. Nielsen², R. Fabunmi², M. Wintle²

¹Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, ²Amylin Pharmaceuticals, Inc., San Diego, ³Consulting and Strategies, HealthCore, Inc., Wilmington, United States

Background and aims: The primary aim of type 2 diabetes (T2D) therapy is helping patients achieve glycaemic goals (HbA_{1c} <7%) as recommended

by the ADA. In the recent randomised controlled trials 4-T and INITIATE, patients treated with basal insulin alone achieved goal 28% and 40% of the time, respectively, despite progressive insulin titration. In this retrospective cohort study using a large, US commercial health plan claims database, we describe the clinical effectiveness of newly prescribed basal insulin glargine (IG) in insulin-naïve patients.

Materials and methods: A total of 13,154 insulin-naïve (not prescribed insulin in previous 6mo) patients were identified with a new prescription claim for IG between Jan 1, 2004 and June 30, 2006, ≥ 6 mo of pre-index eligibility (first claim=index date), ≥ 12 mo of post-index eligibility, and ≥ 18 y old.

Results: From this cohort, 7730 (59%) patients had no other insulin claims other than IG in the entire post-index period. All patients with baseline (100d pre-index) and post-index (60–365d) HbA_{1c} data available and baseline HbA_{1c} $\geq 7.0\%$ were analysed ($n=313$; mean baseline HbA_{1c} [±SD]= $9.8\pm 2.1\%$). Mean (±SD) age was 52 ± 8 y (41% female; 3% ≥ 65 y). In this cohort of patients who did not add any additional insulin ($n=313$), 27% achieved HbA_{1c} $<7\%$ in the post-index period [mean [min, max] time index to post-index HbA_{1c}=238d [63,365]]. Mean (±SD) post-index HbA_{1c} was $8.2\pm 1.9\%$.

Conclusion: In this real-world analysis of patients initiated on IG, the percentage of patients achieving HbA_{1c} $<7.0\%$ and mean post-index HbA_{1c} indicate that most patients do not achieve recommended glycaemic targets—results that mirror controlled clinical studies. In addition, more than half of patients initiating IG did not supplement with additional insulin therapy over the course of the first year of therapy, despite not reaching glycaemic goals. Because the contribution of postprandial glucose to HbA_{1c} increases as HbA_{1c} approaches goal, agents targeting fasting glucose alone, like IG, may be insufficient in helping patients with T2D achieve glycaemic goals.

961

Characteristics of patients needing basal insulin to be given twice-daily or a second insulin formulation during the first year of the 4-T Trial

J.C. Levy¹, A.J. Farmer², K.I. Thorne³, S.K. Paul³, J.L. Darbyshire³, M.J. Davies⁴, R.R. Holman³

¹Oxford Centre for Diabetes, Endocrinology and Metabolism, Churchill Hospital, Oxford, ²Department of Primary Health Care, Oxford University, ³Diabetes Trials Unit, Oxford University, ⁴Department of Cardiovascular Sciences, University of Leicester, Leicester, United Kingdom

Background and aims: 4-T (Treating to Target in Type 2 diabetes) is a three arm parallel group, open-label randomised trial comparing biphasic, prandial and basal analogue insulin regimens when added to the treatment of patients with type 2 diabetes who had sub-optimal glycaemic control on maximally tolerated doses of metformin and sulfonylureas. We have carried out an exploratory analysis to identify potential differences in the characteristics of trial patients failing to achieve or maintain glycaemic control within pre-specified safety limits over one year on a single insulin formulation.

Materials and methods: Fifty-eight UK and Irish centres randomised 708 patients to twice-daily biphasic insulin ($n=235$, NovoMix 30), thrice-daily prandial insulin ($n=239$, NovoRapid), or once-daily basal insulin ($n=234$, Levemir). Insulin doses were titrated using a predefined algorithm based on self-monitored capillary glucose measurements to achieve fasting and pre-meal targets of 4.0–5.5mmol/l. We compared the characteristics of patients requiring basal insulin twice-daily because of protocol-defined evening hyperglycaemia, with those achieving acceptable values on once-daily basal insulin. We also compared baseline characteristics of patients with HbA_{1c} $>10\%$ from 24 weeks (or $>8\%$ on two subsequent occasions) up to one year who required a second insulin preparation per protocol, with those achieving lower values on a single insulin preparation.

Results: Of patients allocated to basal insulin, 79 (34%) required it twice-daily. Compared with those requiring basal insulin once-daily, they were older (mean (±SD) 65.0 ± 9.2 vs. 60.4 ± 10.0 years, $p=0.002$), lighter (80.7 ± 15.7 vs. 87.5 ± 16.5 kg, $p=0.006$) and had lower triglycerides (median (IQR) 1.2 (1.0–1.7) vs. 1.6 (1.2–2.2), $p=0.002$). Overall, 73 (10.3%) patients required a second insulin preparation (biphasic insulin 21 (8.9%), prandial insulin 10 (4.2%) basal insulin 42 (17.9%)). Compared with those remaining on a single insulin preparation, they had higher mean HbA_{1c} (9.0 ± 0.7 vs. $8.5\pm 0.8\%$, $p<0.0001$), BMI (31.2 ± 4.5 vs. 29.7 ± 4.6 kg/m², $p=0.0089$) and higher median triglycerides (1.9 (1.4–2.6) vs. 1.5 (1.1–2.1), $p=0.0012$).

Conclusion: Patients who required Levemir insulin to be given twice a day were older, lighter and had lower triglycerides. In contrast, those who required two insulin preparations within the first year were more hyperglycaemic, heavier and had higher triglycerides. These differing characteristics may

help guide therapy choices when adding insulin to metformin and sulfonylurea therapy in patients with sub-optimal glycaemic control.

Clinical and lifestyle characteristics in newly diagnosed type 2 diabetes: baseline data from the DESMOND randomised controlled trial

H.M. Dallosso¹, M.E. Carey¹, M.J. Davies², S. Heller³, K. Khunti⁴, C. Skinner⁵

¹Diabetes Research, University Hospitals Leicester, United Kingdom, ²Cardiovascular Sciences, University Leicester, United Kingdom, ³Academic Unit Diabetes, Endocrinology and Metabolism, University Sheffield, United Kingdom, ⁴Health Sciences, University Leicester, United Kingdom, ⁵Psychology, University Wollongong, Australia

Background and aims: Biomedical and psychosocial data on people newly diagnosed with type 2 diabetes (T2DM) are lacking. The aim of the study is to describe baseline characteristics of patients entering the randomised controlled trial of the DESMOND structured group education programme, in order to provide an up-to-date profile of newly diagnosed type 2 diabetes and identify areas of priority that need including in treatment and group education programmes.

Methods: Practices from 13 sites in the UK referred people newly diagnosed with T2DM between 2004 and 2005. Eligibility criteria were age >18 years, referral within 4 weeks of diagnosis and ability to participate in group education programme. Clinical data were collected at diagnosis by the practice and patients completed a questionnaire which included questions on lifestyle, diabetes related illness beliefs, and depression.

Results: 1109 patients were referred and 824 entered the study (74%). Mean (SD) age was 59.5 (12.1) years, 54.7% were male and 96.6% were Caucasian. Mean (SD) HbA_{1c} was 8.08 (2.11) % and did not differ by sex. HbA_{1c} was $>6.5\%$ in 72.3%. Mean (SD) total cholesterol was 5.35 (1.31) mmol/l and significantly higher in men ($p<0.001$). Total cholesterol was >5 mmol/l in 53.9%. Mean (SD) blood pressure values were 140.6 (17.6) and 81.8 (10.5) mmHg with 45% $>140/90$ mmHg. Mean (SD) BMI was 32.36 (6.25) and was significantly higher in women ($p<0.001$). 69% women and 54% men were obese (BMI >30). There was a low level of physical activity (16% reporting vigorous activity ≥ 3 times a week and 29.5% reporting moderate activity ≥ 5 times a week). 27.8% reported smoking in previous week. Median (IQR) 10 year risk estimate of coronary heart disease or stroke (UKPDS Risk Engine) was 17.7% (11.6% to 29.1%). Risks were higher in men ($p<0.001$) and increased with age ($p<0.001$). Scores for depressive symptoms were higher ($p=.01$) in women than men, with 16.1% women and 8.2% men reporting symptoms indicative of depression. These values reflect general population levels in the UK. Data on illness beliefs provided measures of whether patients understood their diabetes, perceptions of its duration, ability to affect its course, its impact and seriousness. For example 40.1% agreed “symptoms of their diabetes are puzzling” and 7.1% agreed “life will be shorter because I have diabetes”.

Conclusion: The high referral (equivalent to 0.96 per 1000 patient years) and consent rates and wide eligibility criteria mean the data provide an up-to-date and representative picture of the newly diagnosed. HbA_{1c} was lower than earlier studies on the newly diagnosed which may be the result of earlier diagnosis and more pro-active case finding. Mean BMI was higher than earlier studies and is indicative of the growing prevalence of obesity. Cardiovascular risk factors such as obesity, total cholesterol and physical activity are important lifestyle factors that need to be included in education programmes. Patients’ misconceptions about their diabetes need addressing in education programmes in the newly diagnosed.

may all contribute to a diminished awareness of hypoglycaemia, and so insulin regimens must be adapted to account for these issues. Clinical trials have shown insulin detemir to incur a lower risk of hypoglycaemia compared with NPH at equivalent levels of glycaemic control; this property might be particularly advantageous in elderly patients. PREDICTIVE™ is an open-label, cross-nation observational study designed to assess the safety and efficacy of insulin detemir (IDet) in everyday clinical practice, including in vulnerable patient groups.

Materials and methods: Older patients (>65 years) from countries participating in PREDICTIVE™ were enrolled into the study for at least 12 weeks (11 countries), at least 26 weeks (6 countries) or for at least 52 weeks (France only) and were treated with IDet at their physician's discretion. Data were obtained for efficacy and safety endpoints and stratified by diabetes type 1 (T1DM, n=864) or type 2 (T2DM, n=4950). The primary endpoint was the incidence of serious adverse drug reactions.

Results: A total of 588 patients with T1DM were recruited to the 12-week cohort (37% male, mean age 71.0 years, mean duration of diabetes 25.2 years; mean weight 73.9 kg) and 4102 patients with T2DM (42% male, mean age 72.0 years, mean duration of diabetes 13.4 years; mean weight 83.5 kg). In the 26-week cohort, n=216 for patients with T1DM (41% male, mean age 71.3 years, mean duration of diabetes 25.2 years; mean weight 74.5 kg) and n=570 for patients with T2DM (46% male, mean age 71.9 years, mean duration of diabetes 14.2 years; mean weight 83.0 kg). Finally, the French (52-week) cohort comprised 60 patients with T1DM (50% male, mean age 72.3 years, mean duration of diabetes 21.9 years; mean weight 68.6 kg) and 278 patients with T2DM (47% male, mean age 73.0 years, mean duration of diabetes; 17.7 years mean weight 78.2 kg). The Table shows safety and efficacy data for all three cohorts. Serious adverse drug reactions were infrequent, with incidence under 1% in the 12-week and 26-week cohorts, and less than 5% in the 52-week cohort. Treatment with IDet reduced the frequency of total, major and nocturnal hypoglycaemia without compromising glycaemic control, which improved in all groups (p<0.05). IDet use incurred little or no weight gain, and patients in the 12-week and 26-week cohorts lost a modest amount of weight (p<0.05).

Conclusions: IDet can be initiated in elderly patients, and represents a good choice of basal insulin, as it incurs a low risk of serious adverse drug reactions and a low risk of hypoglycaemia, while facilitating good glycaemic control.

Comparison of in-patient insulin regimens: DEtemir plus Aspart vs. NPH plus regular in medical patients with type 2 diabetes (DEAN Trial)
G. Umpierrez¹, T. Hor², D. Smiley¹, A. Temponi¹, D. Umpierrez¹, M. Ceron¹, C. Muñoz², C.A. Newton¹, D. Baldwin²

¹Division of Endocrinology, Metabolism and Lipids, Emory University School of Medicine, Atlanta, GA, United States, ²Section of Endocrinology, Rush University Medical Center, Chicago, United States

Background and aims: The association of inpatient hyperglycaemia and poor clinical outcome is well established. Few studies, however, have focused on the optimal management of hyperglycaemia in non-intensive care unit patients with type 2 diabetes mellitus (T2DM). We conducted a prospective, multi-centre, randomised trial to compare the efficacy and safety of a 'basal-bolus' regimen (insulin detemir/insulin aspart) vs. a standard split-mixed (NPH/regular insulin) regimen in patients with T2DM.

Materials and methods: A total of 130 non-surgical patients (M60/F70; age: 58 ± 10 yrs (± SEM), BMI: 33 ± 10 kg/m²) admitted to general medicine services with a blood glucose (BG) between 7.7–22.2 mmol/L (mean admission BG: 13.2 ± 4 mmol/L, HbA_{1c}: 8.3 ± 2%), and a history of T2DM >3 months were randomised to receive insulin detemir/insulin aspart (n = 67) or NPH/regular insulin (n = 63). Half the detemir total daily dose (TDD) was given once-daily and for aspart, 17% of TDD was given with each meal. NPH and regular insulin were given 3/5 of TDD before breakfast and 2/5 of TDD before dinner. The starting TDD was 0.4 U/kg for BG between 7.7–11.1 mmol/L or 0.5 U/kg for BG between 11.2–22.2 mmol/L. Doses were adjusted daily, based on pre-meal and bedtime BGs. There were no differences in the pre-treatment BG, mean daily BG, or pre-meal BG levels between groups.

Results: The mean daily BG level after the first day of detemir/aspart vs. NPH/regular insulin was 8.8 ± 4 mmol/L and 8.6 ± 4 mmol/L, respectively, p=NS. The BG target <7.7 mmol/L before meals was achieved in 45% in the detemir/aspart group (breakfast 58%) and in 48% of the NPH/regular group (breakfast 57%), p=NS. Insulin dose in the detemir/aspart group (detemir: 30 ± 29 U/d, aspart: 27 ± 20 U/d) was not significantly different than that used in the NPH/regular insulin group (NPH: 27 ± 20 U/d, regular: 18 ± 14 U/d). Of the 1090 BG readings in the detemir/aspart group, 19 readings (18 patients) were <3.3 mmol/L (1.7%) and 2 readings were <2.2 mmol/L (0.2%). Of the 1038 BG readings in the NPH/regular insulin group, 13 readings (12 patients) were <3.3 mmol/L (1.3%) and 2 were <2.2 mmol/L (0.2%), p=NS. None of the episodes of hypoglycaemia were associated with adverse outcomes. There were no differences in length of hospital stay or mortality between groups.

Conclusion: A basal/bolus insulin regimen with detemir once-daily and aspart before meals results in equivalent glycaemic control with minimal hypoglycaemia when compared with a split-mixed insulin regimen of NPH and regular twice-daily in hospitalised patients with T2DM.

Reducing fasting blood glucose variability is associated with a lower incidence of nocturnal hypoglycaemic events after starting insulin detemir: 3 month PREDICTIVE™ data from 11 European countries

L. Niskanen¹, A. Virkamäki², J.B. Hansen³, T. Saukkonen⁴

¹Department of Medicine, Kuopio University Hospital, Finland, ²Mehiläinen Diabetes Clinic, Mehiläinen Oy, Helsinki, Finland, ³Novo Nordisk A/S, Bagsvaerd, Denmark, ⁴Novo Nordisk Farma, Espoo, Finland

Background and aims: It has been suggested that plasma glucose variability (FGV) is an independent risk factor for diabetes complications, and a marker of instability of diabetes. Its relation to the occurrence of hypoglycaemic episodes is, however, poorly studied.

Materials and methods: PREDICTIVE™ is a global prospective multinational observational study of the empirical use of the basal analogue insulin detemir (IDet). This analysis includes pooled 3-month European follow-up data from patients with type 1 (DM1) or type 2 diabetes (DM2) who had any other long-acting basal insulin (NPH insulin, insulin glargine) as part of pre-study therapy and who switched to IDet.

Results: At baseline, the percentage of patients reporting at least one nocturnal hypoglycaemic episode (NOCT) during the preceding 4 weeks was 36.0% (2186 of 6135) for DM1 patients (DM1 NOCT+) and 13.4% (832 of 6289) for DM2 patients (DM2 NOCT+). DM1 NOCT+ patients were on av-

erage older (43.6 ± 15.9 vs. 41.3 ± 16.6 yrs, $p < 0.001$), had a longer duration of diabetes (18.7 ± 12.6 vs. 16.3 ± 12.3 yrs, $p < 0.001$), lower HbA_{1c} (8.0 ± 1.4 vs. $8.2 \pm 1.6\%$, $p < 0.001$) and fasting plasma glucose (FPG; 9.1 ± 3.0 vs. 9.5 ± 3.0 mmol/L; $p < 0.001$) compared with DM1 patients without nocturnal hypoglycaemia (DM1 NOCT-). However, FGV assessed by the coefficient of variance of FPG was higher in DM1 NOCT+ than in DM1 NOCT- (33.8% vs. 26.6%, $p < 0.001$). DM2 patients with nocturnal hypoglycaemia (DM2 NOCT+) were of similar age, but had a longer duration of diabetes (13.7 ± 8.3 vs. 12.6 ± 7.6 yrs, $p < 0.001$), lower body weight (85.4 ± 17.3 vs. 91.0 ± 18.7 kg, $p < 0.001$), HbA_{1c} (7.9 ± 1.5 vs. $8.2 \pm 1.5\%$, $p < 0.001$) and FPG (9.0 ± 2.5 vs. 9.8 ± 2.6 mmol/L, $p < 0.001$), yet FGV was higher (21.8 vs. 14.7%, $p < 0.001$) than in DM2 patients without nocturnal hypoglycaemia (DM2 NOCT-). After 3 months' treatment of IDet, HbA_{1c} improved ($-0.4 \pm 1.1\%$ in DM1, $p < 0.001$; $-0.5 \pm 1.1\%$, $p < 0.001$ in DM2), but the percentage of subjects with NOCT decreased (from 36.0 to 13.5% in DM1, $p < 0.001$, and from 13.4 to 2.8% in DM2, $p < 0.001$). FGV was reduced also (29.5 to 24.5% in DM1, $p < 0.001$, 15.7 to 12.9% in DM2, $p < 0.01$). The change in FGV correlated with reduced number of NOCTs in both DM1 ($r = 0.116$, $p < 0.001$) and DM2 ($r = 0.145$, $p < 0.001$; both adjusted for the change in HbA_{1c}). At 3 months, the risk of NOCT increased with increasing FGV. Those with nocturnal hypoglycaemic events had a significantly higher FGV compared with those without (32.8 vs. 23.0% in DM1, $p < 0.001$, and 20.7 vs. 12.7% in DM2, $p < 0.001$).

Conclusion: Lowering FGV is associated with a lower incidence of nocturnal hypoglycaemia in both type 1 and type 2 diabetes after treatment with insulin detemir for 3 months, and this relationship is independent of the changes in metabolic control. Therefore, FGV can serve as a useful marker of nocturnal hypoglycaemia in a clinical setting. Reduced FGV may contribute to the simultaneous improvement of metabolic control and reduction of nocturnal hypoglycaemia frequency with insulin detemir therapy.

A comparison of approaches to treatment intensification in patients with type 2 diabetes: insights from the PREDICTIVE™ Study

A. Dornhorst¹, S. Sreenan², M. Pinget³, S. Gonbert⁴

¹Department of Metabolic Medicine, Imperial College, London, United Kingdom, ²Department of Endocrinology, Connolly Hospital, Dublin, Ireland, ³Service de Médecine E, Hôpital Civil, Strasbourg, France, ⁴Novo Nordisk Pharmaceutique SAS, Paris, France

Background and aims: Patients with type 2 diabetes who experience poor glycaemic control using an oral antidiabetic drug (OAD) combined with basal insulin (basal + oral therapy - BOT) require intensification of their treatment. Some physicians seek to achieve this by increasing basal insulin dose frequency, but, if prandial glucose levels are not addressed, this strategy may have limited effectiveness. The PREDICTIVE™ study is a prospective, multinational observational study of the use of insulin detemir (IDet) in a variety of treatment regimens. This analysis uses pooled 12-week data from PREDICTIVE™ to compare outcomes following different approaches to insulin intensification.

Materials and methods: Data were analysed from 685 participants with T2DM who had been in PREDICTIVE™ for approximately 12 weeks. Patients on a BOT regimen at baseline were switched to once-daily (OD) IDet as the basal insulin. Of these, 456 patients (group 1) received OD IDet + OADs (50% male, mean age 60.9 years; mean weight 86.9 kg; mean duration of diabetes 10.3 years), and 166 had their treatment intensified at their physician's discretion: 40 patients (Group 2) received BD IDet + OADs (38% male, mean age 62.0 years; mean weight 89.4 kg; mean duration of diabetes 11.9 years) and 126 patients (Group 3) received the addition of a bolus insulin to OD IDet (45% male, mean age 61.5 years; mean weight 91.3 kg; mean duration of diabetes 9.4 years).

Results: Switching to IDet incurred significant advantages in glycaemic control (HbA_{1c} , fasting blood glucose [FBG], FBG variability) in groups 1 and 3, but significant benefits were not seen for patients switched to a BD + OAD regimen (table). Risk of hypoglycaemia was reduced in all three groups, significantly so in groups 1 and 2, with little or no weight gain for all three groups. Serious adverse drug reactions, the primary endpoint for the PREDICTIVE™ study, were not observed for any patient (excluding major hypoglycaemia). Increase in basal insulin dose was greater in the BD group.

Conclusion: These data suggest that patients on a BOT regimen can benefit from a switch of their basal insulin to IDet. However, the data also suggest that if intensification of the regimen is required, then switching from an OD

to a BD basal insulin regimen will provide few benefits, despite an increase in the basal insulin dose. In contrast, the addition of prandial insulin to OD IDet can significantly improve HbA_{1c} , FBG and FBG variability without increasing hypoglycaemia or body weight.

Improved glycaemic control in subjects with type 1 diabetes using Accu-Check[®] Advisor Insulin Guidance Software

S. Garg, C. Beatson, T. Bookout, K. McFann, S. Ellis
Barbara Davis Center, University of Colorado Health Sciences Center,
Aurora, United States

Background and aims: Management of type 1 diabetes could be significantly improved with the availability of computerized insulin algorithms for home use.

Materials and methods: This was a one year open label randomized control trial involving 123 adult subjects with type 1 diabetes (A1c's 7.5–11%) assigned to either the Insulin Guidance Software (Advisor) for personal data assistant (experimental group) or the control group.

Results: The primary end point was an improvement in A1c at 6 and 12 months by $\geq 0.4\%$. Baseline demographics were similar in the two groups. Baseline mean A1c was 8.54 ± 0.11 in the control group and 8.42 ± 0.11 ($p=.4265$) in the experimental group. The mean A1c was significantly lower from 3 to 12 months in the experimental group ($p<0.02$). A1c reduction of $\geq 0.6\%$ was maintained at 12 months in the experimental group. Also, a significantly higher number of subjects achieved A1c $<7.5\%$ in the experimental group from 3–9 months. Within target range (WTR) glycemia (70–150mg/dL) increased in the PDA group from 3 to 9 months without change in insulin dose or body weight. Above target range (ATR) glycemia was improved in the PDA group throughout the study as did the number of tests/subject/day. Nocturnal hypoglycemia was not different between groups, however, the PDA group did have more severe hypoglycemic events.

Conclusion: This is the first report that shows improved glycemic control can be maintained over 12 months in patients with type 1 diabetes by using Advisor software with no change in insulin dose or weight.

Pharmacodynamics and pharmacokinetics of long-acting insulin analogues detemir and glargine after 7 days of use and after its first administration in subjects with type 1 diabetes

G. Bock, A. Wutte, G. Köhler, S. Korsatko, B. Semlitsch, T.R. Pieber
Internal Medicine, Medical University Graz, Austria

Background and aims: To get further insight into the pharmacodynamic and pharmacokinetic properties of long-acting insulin analogues this study has been designed to compare the duration of action between the insulin analogues Detemir (Det) and Glargine (Glar) after a single dose (SD) and the steady state (SS) effect after 7 once daily injections in patients with Type 1 diabetes.

Materials and methods: 36 subjects (37 ± 10 years, BMI 24.7 ± 2.6 kg/m², HbA1c 7.6 ± 0.8 , mean \pm SD) were randomised to receive either long acting insulin analogue Det or Glar and underwent 30 hours euglycemic clamp procedures twice, on one occasion after s.c. injection of the first dose of 0.4 U/kg Det or Glar and on the second occasion after multiple dosing of 0.4 U/kg Det or Glar in double-blind fashion.

Results: The primary endpoint "duration of action", defined as period from insulin injection to end of insulin action (plasma glucose > 8.3 mmol/l without glucose infusion) was 23.3 hours (10.5–29.0) for insulin Det and 27.1 hours (4.0–30.0) for insulin Glar after multiple dosing. 66% of the subject with insulin Det had more than 24 hours of insulin action, whereas 89% in the glargine group had a longer duration than 24 hours. The duration of action after single dose administration was shorter for insulin Glar (19.8 hours; 0.0–30.0) than insulin Det (25.9 hours; 15.0–30.0). After single dose administration of insulin Glar 1/3 of subjects did not have an onset of action (defined as 50% reduction of the regular i.v. insulin from clamp onset to maintain euglycemia) within 10 hours after insulin injection. A larger variability in duration of action for insulin Glar was observed during both clamps in comparison to insulin Det.

Conclusion: The results of this study indicate that both basal insulin analogues have duration of action approximating 24 hours, and hence both are suitable for once daily dosing in patients with type 1 diabetes. In steady state insulin Glar demonstrates a longer duration, whereas the lower variability of insulin detemir would be expected to be beneficial for patients with insulin therapy due to less day-to-day fluctuations in blood glucose lowering effect.

	Detemir	Glargine
	N mean(SD) range	N mean(SD) range
Duration of action SD (h)	18 25.9 (4.6) 15.0–30.0	18 19.8(14.4) 0.0–30.0
Duration of action SS (h)	18 23.3 (4.9) 10.5–29.0	18 27.1 (7.7) 4.0–30.0

Insulin detemir provides sustained glycaemic control over a 4-year period in type 1 diabetic subjects

B. Norberg, J. Jendle

Endocrine and Diabetes Center, University of Orebro, Karlstad, Sweden

Background and aims: The advantages of basal insulin analogs for the treatment of diabetes are being questioned. The present analysis sought to determine whether in a clinical setting a sustained improvement of diabetes control could be achieved when switching patients with type 1 diabetes on a basal-bolus treatment regimen from NPH insulin or insulin glargine to basal insulin treatment with insulin detemir and continuing on the short acting insulin.

Materials and methods: Subject with type 1 diabetes ($n=102$) inadequately controlled by a basal-bolus regimen with short acting insulin analogs (insulin aspart or lispro) in combination with a basal insulin where treated with insulin detemir in combination with the previous short acting insulin treatment. Insulin detemir was given sc OD or BID. 58 males and 44 females were included and followed during up to 48 months, 11 drop-outs (change therapy; 4 CSII, 2 glargine, 5 lost follow-up). Baseline data; 44 \pm 7 years (body weight of 77 ± 15 kg with a BMI 25.3 ± 3.9 kg/m²). The diabetes duration was 20 ± 8 years.

Results: Baseline HbA1c was reduced from $7.9 \pm 1.6\%$ to $7.3 \pm 1.2\%$, $p<0.001$. The total daily insulin dose was increased from 51.8 ± 18.4 U/d to 55.1 ± 19.8 U/d, $p=0.019$. The basal insulin dose was not significantly changed from baseline 27.7 ± 11.8 U/d to 29.1 ± 11.9 U/d, $p=0.179$. The average bolus dose was increased from 23.9 ± 9.8 to 26.0 ± 9.8 U/d, $p=0.028$. Neither weight gain, nor any significant change in BMI was observed during the study period. No serious hypoglycaemic episodes were registered.

Conclusion: Our study suggests a beneficial effect on the glycaemic control without any weight gain up to 4 year treatment when changing type 1 diabetics inadequately controlled on basal-bolus treatment to insulin detemir in combination with previous short acting insulin analog.

970

Deleterious outcomes on abrupt transition from insulin glargine to detemir in type 1 DMU.M. Kabadi^{1,2}¹Endocrinology, VAMC, Des Moines, ²Internal Medicine, University of Iowa college of Medicine, Iowa City, United States

Background: Iowa Care (Iowa Medicaid), USA switched insulin glargine to detemir in subjects with Diabetes Mellitus (DM) without the knowledge or approval of healthcare providers beginning 8/2006.

Objective: To examine the impact of this transition on various parameters of diabetes management in type 1 DM.

Study Design

A retrospective review of the records of subjects with type 1 DM was conducted until 8/2007 in whom the transition had occurred. Only those subjects completing at least 6 months of therapy with insulin detemir are included in this report. Twenty four subjects with type 1 DM, duration 19 ± 3 years with age 36 ± 4 years who were switched from GI to DI (Group 1) fulfilled 6 months' duration of therapy with DI. Glycemic control (HbA_{1c}), body weight (BW), daily insulin dose (Units), total (T) as well as glargine (GI) or detemir (DI) and rapid acting insulin, Aspart (AI) as well as Hypoglycemic events during the last 4 weeks of the period, pre switch and again at the end of 6 months post switch were assessed. Records of 21 subjects matched for age (39 ± 5 years) and continuing GI for 6 months (Group 2) during the same period were examined for comparison.

Methods: Initially, subjects were switched from GI to DI in the same daily dose in AM. The daily doses of DI and AI in Group 1 were adjusted by telephone at weekly intervals based on self blood glucose monitoring until stabilization was achieved. They were also followed in the outpatient clinic at intervals of 3 months similar to subjects continuing GI.

Results: All subjects in Group 1 were changed to DI twice a day because of significant rise in hypoglycemia when the whole daily dose was used once a day. Glycemic control remained stable on continuing GI once daily; HbA_{1c} 7.6 ± 0.3 to 7.8 ± 0.3%, while it worsened on switching to DI being injected twice a day; HbA_{1c}, 7.9 ± 0.6 to 8.8 ± 0.8 despite a higher daily dose; DI, 46 ± 9 units Vs Pre Switch GI, 36 ± 8 units and Group 2 GI, 35 ± 6 units; and greater total insulin dose; 80 ± 12 units Vs 68 ± 10 Pre Switch and Group 2 GI, 62 ± 10 units [P < 0.05 for all comparisons]. Body weights and hypoglycemic events were not significantly different Pre and Post switch [p > 0.05 for all groups].

Conclusion: Therefore, insulin glargine and detemir appear to be far from being bioequivalent. Moreover, switching to detemir insulin from glargine insulin is likely to result in lapse of glycemic control causing decreased quality of life as well as higher costs and undue hardship to both patients and providers because of the resulting higher daily insulin dose as well as an increased number of injections, and need for frequent recurrent evaluations during the initial period of switch.

971

Once-daily dosing of insulin detemir is associated with lower risk of hypoglycaemia at similar levels of HbA_{1c} compared to once-daily NPH insulin in subjects with type 1 diabetes mellitusJ.E. Shaw¹, J. Larsen², C.B. Pedersen², S. Tang-Fui³¹Department of Medicine, International Diabetes Institute, Melbourne, Australia, ²Novo Nordisk, Bagsvaerd, Denmark, ³Endocrinology, Diabetes & Specialist Centre, Melbourne, Australia

Background and aims: This is an explorative analysis comparing the efficacy and safety of once daily dosing with insulin detemir (IDet) and NPH insulin (NPH), in combination with mealtime insulin aspart (IASp). The analysis is based on a 24-month, multi-national, open-label, parallel-group trial in subjects with type 1 diabetes mellitus (T1DM) using a treat-to-target concept.

Materials and methods: IDet or NPH was administered in the evening and titrated to a pre-breakfast plasma glucose (PG) target ≤ 6 mmol/L (108 mg/dL). If the pre-breakfast target was obtained, but the pre-dinner PG remained > 6 mmol/L a second dose could be added in the morning. A total of 497 subjects were randomised 2:1 to IDet (n=331) or NPH (n=166). Of these, 133 (40.2%) subjects on IDet and 77 (46.4%) on NPH, remained on a once-daily basal insulin regimen throughout the trial and the results reported here are based on this subset of subjects.

Results: The baseline characteristics of subjects remaining on a basal once daily regimen were generally comparable between IDet and NPH (men: 61%, mean age: 33 years, duration of diabetes: 12 years, body mass index (BMI):

24.8 kg/m², HbA_{1c}: 8.0%), although weight, BMI and diabetes' duration were slightly higher in the NPH arm. After 24 months, HbA_{1c} was comparable between treatments (IDet: 7.25%; NPH: 7.36%, difference [IDet-NPH]: -0.11% points, [95% CI: -0.43; 0.20]) with reductions of 0.73% and 0.62% points, respectively. The risk of major hypoglycaemia (requiring assistance) was 82% lower with IDet than with NPH, while the risk of all nocturnal episodes as well as minor nocturnal episodes (PG < 3.1 mmol/L) was 53% lower with IDet (all: p < 0.005). The average number of all hypoglycaemic episodes per subject per year was 13.4 with IDet and 22.5 with NPH. A similar proportion (45%) of subjects in both groups achieved an HbA_{1c} ≤ 7%, but 38.2% of all patients using once-daily IDet reached this level of control in the absence of confirmed hypoglycaemia during the last month of treatment compared to 21.6% using NPH (p=0.018). At 24 months, self-measured 9-point PG profiles were generally lower with IDet from bedtime to lunch next day, but higher between lunch and bedtime compared to NPH. The median daily dose of IDet and NPH was 30 and 28 units, respectively, with a median daily dose of IASp of 36 units in both groups. Fasting PG tended to be lower with IDet than with NPH (7.80 vs. 8.86 mmol/L; NS), resembling that observed with IDet relative to NPH in the analysis of the full intention-to-treat population of 495 subjects.

Conclusion: This study showed that once-daily administration of IDet can provide relatively good glycaemic control and a significantly lower risk of hypoglycaemia in a large proportion of T1DM subjects as compared to once-daily dosing with NPH.

Early insulin treatment in latent autoimmune diabetes in adults (LADA) did not improve residual beta cell function or metabolic controlM. Thunander^{1,2}, H. Thorgeirsson², C. Törn³, C. Petersson⁴, M. Landin-Olsson²¹Endocrinology and Diabetes, Vaxjo Central Hospital, Vaxjo,²Endocrinology and Diabetes, Lund University Hospital, Lund, ³Clinical Sciences, Diabetes Laboratory, Lund University, ⁴Primary Care, and R&D-center, Kronoberg, Vaxjo, Sweden

Background and aims: Most adults with autoimmune diabetes not insulin-requiring at onset become so within 3-5 yrs. Latent autoimmune diabetes in adults (LADA) has been identified suitable for evaluating new therapies in autoimmune diabetes. We investigated the effect of early insulin treatment on residual beta-cell function, and metabolic control, during the first three years, compared to a group treated with diet only or oral hypoglycaemic agents (OHA).

Methods: During three yrs 38 of newly diagnosed patients in our regions, not insulin-requiring at diagnosis and positive for at least one of ICA or GAD-ab, (92% were positive for both) were included. Mean age was 53.0 (±16) (range 19-80) yrs, M/F ratio 19/17. No strict randomization was possible since many patients refused insulin treatment before it was clinically necessary. 20 patients started early insulin therapy, the remaining 18 served as controls, treated with diet only or OHA, and received insulin subsequently when/if necessary. Residual beta cell capacity was evaluated with glucagon-stimulated C-peptide at baseline, and after 12, 24 and 36 months. Metabolic control was assessed by HbA_{1c}.

Results: At baseline age was 49 vs 58 yrs, p < 0.04, mean glucagon-stimulated C-peptide 1.2 vs 1.7 nmol/l (ns) and mean HbA_{1c} was 6.5(±1.5) vs 5.9 (±1.2)% (ns) in the early insulin treated compared to the controls. During follow-up mean C-peptide was 0.75(±0.51), 0.67(±0.61), 0.61(±0.59) among insulin treated and 2.04(±1.05), 1.46± (0.71), 1.40 (±0.93) among controls. The annual absolute -0.29(±0.37), -0.51(±0.33), -0.64(±0.44) vs 0.47(±1.20), -0.17(±0.63), -0.17(±0.92) and the relative 0.39(±0.29), 0.45(±0.38), 0.39(±0.29) vs 0.88(±0.49), 0.95(±0.34), 0.88(±0.49) decline in C-peptide were not significantly different between the groups. In the control group insulin treatment was initiated due to clinical need in 7/18 (39%) patients during the 3 years. By logistic regression the only factor determining a residual C-peptide level > 0.5 nmol/l after 3 years was initial level of C-peptide, but not age, HbA_{1c} or early insulin treatment.

Conclusion: In this study when comparing both the absolute and the relative decline of C-peptide early insulin treatment did not result in superior preservation of beta cell function or better metabolic control. The study does, however, suffer from incomplete randomization leading to differences in baseline C-peptide levels.

PS 089 Insulin therapy: body weight and cardiovascular disease

973

Body weight change associated with insulin therapy in type 2 diabetes patients - a five-year observational study

L. Czupryniak, M. Nieznaj, M. Saryusz-Wolska, M. Pawlowski, J. Loba
Diabetology and Metabolic Diseases Dept, Medical University of Lodz,
Poland

Background and aims: In type 2 diabetes patients body weight increase is a major unwanted effect of insulin treatment (IT), and many physicians are reluctant to initiate insulin therapy in poorly controlled but obese patients. Physicians' or patients' insulin therapy-associated fear of weight gain may cause a significant delay in IT introduction, even if it might be an only effective method of improving blood glucose control. We conducted a five-year observational study aiming at assessing longitudinal body weight change and its determinants after IT initiation in type 2 diabetes patients.

Materials and methods: The study group comprised 269 type 2 diabetes patients at IT initiation, with HbA1c >8.0% despite maximum oral treatment (155 women, 114 men, mean [±SD] age 60.3±11.6 years, mean diabetes duration 4.9±3.2 years); they were followed up for five years, with yearly assessments. Upon the results at one year of IT the study subjects were subdivided according to their body weight change: patients with body weight increase after 1 year of IT were included into Weight Gain (WG) group, and those in whom body weight decreased within this period - into Weight Reduction (WR) group.

Results: After 1 year of IT weight gain was noted in 177 (66%) subjects (WG group), while in 92 (34%) patients body weight decreased (WR group). There was no difference in age at diabetes diagnosis, time to IT initiation or HbA1c after 5-year follow-up between the groups, however at baseline WG subjects were significantly less obese than WR ones: mean body weight in WG Group was 79.0±13.4 kg (BMI 29.5±6.4 kg/m²), and after 1, 2, and 5 years of IT it increased to 83.3±13.4 kg (31.2±6.7 kg/m²), 85.0±13.7 kg (31.8±7.3 kg/m²), and 86.1±14.1 kg (33.0±10.0 kg/m²), respectively; in WR Group baseline body weight was 82.9±15.7 kg (30.4±5.3 kg/m²) (p<0.05 vs WG Group), and after 1, 2, and 5 years of IT it was 80.7±15.8 kg (29.6±5.2 kg/m²), 81.6±15.2 kg (29.9±5.0 kg/m²), and 83.1±13.4 kg (30.8±5.1 kg/m²) (p<0.05 vs WG group), respectively. Absolute body weight change since the baseline at 1, 2, and 5 years of IT in WG was 4.4±3.2, 5.8±4.7, 5.8±7.4 kg, and in WR -2.2±3.2 kg, -2.1±4.8, and 0.03±7.2 kg (all p<0.01 between the groups), respectively. The patients who gained over 10 kg after 1 year of IT were significantly less overweight at baseline (75.3±13.9 vs 80.6±14.3 kg; BMI 28.1±4.9 vs 29.9±6.1 kg/m²; respectively, p<0.05), younger at diabetes diagnosis (50.8±13.9 vs 55.6±11.5 years, p<0.05), and their time to IT was longer (5.9±6.9 vs 4.9±5.0 years, p<0.05) than those who gained less than 10 kg. Weight gain after 1 year of IT showed significant negative correlation with the baseline body weight (r= -0.16; p<0.01). Gender, concomitant antidiabetic oral therapy or the number of insulin injections per day were not related to the body weight change.

Conclusion: Insulin therapy initiation in type 2 diabetes is not associated with weight gain in all the subjects; one out of three patients actually loses weight within the first year of insulin treatment. The risk of weight gain is greater in younger, less overweight subjects than in older obese patients, who may actually experience weight loss following IT initiation. It might be also suggested that those patients in whom IT was delayed are at particularly high risk of weight gain. Overall, obesity, older age or the fact of a patient's having been recently diagnosed with diabetes should not preclude physicians from prescribing insulin for the treatment of type 2 diabetes.

974

Cardiovascular risk profile deteriorates in patients with type 2 diabetes with pronounced weight gain on long-term insulin therapy

H.J. Jansen, C.J. Tack, M. van der Graaf, G.M. Vervoort
General Internal Medicine, Radboud University Nijmegen Medical Centre,
Netherlands

Background and aims: Insulin therapy is frequently needed to achieve adequate glycaemic control in type 2 diabetes mellitus (T2DM), but often at the expense of weight gain.

The aim of the study was to compare two pre-defined subgroups (weight gainers and non-gainers). We hypothesized that gainers would have developed more trunk fat, and that a large weight gain would have resulted in an increased cardiovascular risk profile. To determine the underlying cause of excessive weight gain, we assessed physical activity and caloric intake.

Patients and methods: We studied 20 patients with T2DM who had been started on insulin therapy between 2001-2006. Two subgroups were defined: weight gainers (≥1 kg per 2 months within the first 18 months, and a weight gain of >10% after total follow-up; n=10) and non-gainers (maximal weight gain ≤2 kg within the first 18 months, and thereafter stable body weight). Body mass index (BMI) was measured. DEXA was performed to assess trunk fat and percentage body fat. Magnetic resonance spectroscopy (MRS) was performed to determine liver fat content. Table 1 shows laboratory measurements. Energy expenditure (EE) was measured by wearing a Sensewear® Body Monitoring System for five consecutive days. Standardised questionnaire survey for assessing patients dietary habits were taken for three consecutive days.

Results: After a mean of 4 years of insulin therapy, mean body weight increased from 79.1 ± 14.6 kg to 92.7 ± 13.5(SD) with a BMI of 33.0 kg/m² and from 88.0 ± 15.2 to 86.0 ± 14.0 kg with a BMI 28.5 kg/m² for gainers (0.8 U/kg insulin) and non-gainers (0.7 U/kg insulin), respectively. Blood pressure was similar between the two groups. Table 1 shows the laboratory results between gainers and non-gainers. Asterix denotes a significant difference. MRS: Percentage of liver fat content between the two groups 9.68 ± 0.43 % vs. 9.80 ± 0.98 % (P=NS). DEXA: The percentage of total body fat was significantly higher in the gainers than in non-gainers (35.9 ± 9.0 versus 27.0 ± 8.5 %, P=0.04). Trunk fat mass was 18.2 ± 5.9 kg compared to 13.5 ± 4.8 kg in non-gainers (P=NS). Gainers had a significantly lower EE than non-gainers (9911 ± 3625 vs. 13184 ± 3016 kcal, P=0.046). The total number of steps taken by gainers was 27321 ± 18634 versus 29103 ± 16552 by non-gainers (P=NS). Gainers appeared to have higher caloric intake than non-gainers (1878 ± 397 vs. 1706 ± 424 kcal, P=NS).

Conclusion: The increase in body weight after start of insulin treatment in patients with type 2 diabetes shows large inter-individual variation despite a similar drop in HbA1c, and a similar insulin need. Pronounced weight gain was associated with a differentiated change in metabolic and cardiovascular parameters. The increase in body weight in gainers seems mainly explained by lower physical activity levels. It may be important to assess lifestyle characteristics before onset of insulin treatment in order to predict and potentially intervene those at risk for extensive body weight increase.

Laboratory results gainers vs. non-gainers

decrease mean HbA1c(%)	10.1 to 7.13	9.2 to 7.59
fasting insulin (pmol/l)	22.9 ± 10.6	32.2 ± 19.7
C-peptide (pmol/l)	0.59 ± 0.28	0.67 ± 0.30
Total cholesterol (mmol/l)*	4.9 ± 0.9	3.8 ± 0.6
LDL-cholesterol (mmol/l)*	3.0 ± 0.9	2.0 ± 0.5

Insulin detemir reduces gain in body weight and fat mass in ZDF rats when compared with both NPH and insulin glargine

C. Fledelius, J. Damgaard, A. Vinterby, U. Ribøl, J.S. Petersen, J. Sturis
Insulin Pharmacology, Novo Nordisk, Malov, Denmark

Background and aims: Studies have shown that even a modest body weight (BW) reduction can improve the cardiovascular risk profile in T2D patients. BW gain is a well-known consequence of insulin therapy in T1D and T2D patients. Compared with conventional basal insulin therapy, insulin detemir has been consistently shown to result in attenuated BW gain in both T1D and T2D patients at similar degrees of glycemic control. Furthermore, the benefit of detemir on BW has been shown to increase with increasing BMI. At present, it is not known how this difference in BW is associated with changes in fat mass. Therefore, in this study we compared the effects of detemir on glycemic control, BW and fat mass in the ZDF rat model of T2D with two other basal insulins, NPH and insulin glargine.

Materials and methods: Diabetic ZDF rats received vehicle, NPH, detemir, or glargine subcutaneously twice daily for four weeks. Pilot studies were performed that identified doses of the three insulins that were equivalent on glucose lowering profiles and that documented duration of action compatible with twice daily dosing in these animals. BW, fat mass, and glycemic control were determined at baseline and at the end of study. HbA1c was used as an index of glycemic control. Fat mass was estimated using quantitative magnetic resonance.

Results: HbA1c, BW, and fat mass did not differ significantly between groups at baseline, HbA1c averaging $7.4 \pm 0.3\%$ (mean \pm SD). Compared with vehicle, NPH, detemir, and glargine treatment all resulted in decreased HbA1c and increased BW and fat mass. Four-week reductions in HbA1c did not differ significantly between groups (NPH: $1.6 \pm 0.4\%$; detemir: $1.7 \pm 0.4\%$; glargine: $1.7 \pm 0.4\%$, NS ANOVA). Increases in BW (NPH: 138 ± 16 g; detemir: 125 ± 12 g; glargine: 138 ± 16 g, $p < 0.05$ ANOVA) and fat mass (NPH: 97 ± 10 g; detemir: 88 ± 6 g, glargine: 95 ± 7 g, $p < 0.01$ ANOVA) were both significantly smaller with detemir compared to NPH and glargine, whereas no significant differences were observed between NPH and glargine.

Conclusion: In conclusion, four weeks treatment with detemir resulted in significantly less increased BW and fat mass in comparison to NPH and glargine in the ZDF rat model of T2D, at equivalent levels of glycemic control. The results indicate that the attenuated weight gain observed with detemir in this model can largely be attributed to a reduced increase in adiposity.

976

Insulin-naïve patients with type 2 diabetes and higher BMI experience weight loss when initiated onto insulin detemir: 12-week, 26-week and 52-week follow-up data from PREDICTIVE™

H. Hanaire¹, S. Sreenan², A. Dornhorst³, S. Gonbert⁴, J.B. Hansen⁵

¹Service Diabetologie, Hopital Rangueil, Toulouse, France, ²Department of Endocrinology, Connolly Hospital, Dublin, Ireland, ³Department of Metabolic Medicine, Imperial College, London, United Kingdom, ⁴Novo Nordisk Pharmaceutique SAS, Paris, France, ⁵Novo Nordisk A/S, Bagsvaerd, Denmark

Background and aims: Weight gain is a well-recognised barrier to insulin initiation and compliance, and it can undermine patient quality of life. Evidence from clinical trials has consistently shown less weight gain for patients taking insulin detemir compared with NPH and insulin glargine. The multinational observational study, PREDICTIVE™, provides the opportunity to determine this trend in clinical practice. The aim of this subset analysis was to determine whether a weight sparing effect correlates with BMI in insulin-naïve patients with type 2 diabetes initiated onto insulin detemir and treated for over 12, 26 or 52 weeks.

Materials and methods: This analysis concerned insulin-naïve patients with type 2 diabetes recruited into the PREDICTIVE™ study, and initiated onto insulin detemir with OADs. Data were stratified by patients' baseline BMI. Weight change (kg) and BMI (kg/m^2) were monitored at baseline and endpoint.

Results: A total of 1964 patients (47% male; mean age 60.5 years; mean duration of diabetes 8 years; mean weight 84.3 kg, and BMI $29.8 \text{ kg}/\text{m}^2$) from 11 countries were treated for 12 weeks. 277 patients (53% male; 60.2 years; mean duration of diabetes 9.1 years; mean weight 88.2 kg, and BMI $31.1 \text{ kg}/\text{m}^2$) from 6 countries were treated for 26 weeks, and 159 French patients (56% male; mean age 61.7 years; mean duration of diabetes 13.1 years; mean weight 82.1 kg, and BMI $29.2 \text{ kg}/\text{m}^2$) were treated for 52 weeks. Patients treated for 12 weeks lost weight when initiated onto insulin detemir ~ 0.6 kg of weight ($\text{SD} = 3.4$ kg, $p < 0.0001$), those treated for 26 weeks tended to lose a small (non-significant) amount of weight ~ 0.4 kg ($\text{SD} = 4.2$ kg, $p = 0.20$) and patients in the French cohort treated for 52 weeks had minimal (non-significant) weight gain ~ 0.1 kg ($\text{SD} = 5.8$ kg, $p = 0.85$).

Weight change data for each of the three treatment periods were then stratified by BMI, and reanalysed (table). The pattern of weight change was different in subjects with normal BMI and those who were overweight or obese; on average, patients in the highest BMI categories ($\geq 30 \text{ kg}/\text{m}^2$) lost weight when initiated onto insulin detemir.

Conclusion: Data from the PREDICTIVE™ study show a modest but statistically significant mean weight loss for insulin-naïve patients initiated onto and treated with insulin detemir for 12 weeks. Subsets with longer treatment periods (26 weeks, 52 weeks) experienced no significant weight changes. Across groups, insulin detemir's weight sparing benefit was more noticeable in patients with high BMI ($> 30 \text{ kg}/\text{m}^2$) who tended to lose weight

977

A specific patient population achieves glycaemic control with prandial premixed (lispro/ILPS) insulin therapy with lower insulin dose and less weight gain than basal bolus therapy

S. Martin, J. Scism-Bacon, H. Jiang

Eli Lilly and Company, Indianapolis, United States

Background and aims: After failure of oral antihyperglycemic agents (OHAs) + basal insulin to control hyperglycemia in T2D patients (pts), advancement of insulin therapy is required. In this post-hoc analysis of data from T2D pts previously treated with glargine + OHAs, we attempted to identify pts for whom prandial premixed therapy (PPT) would provide comparable safety and efficacy to basal bolus therapy (BBT) for insulin therapy advancement.

Materials and methods: The original study was a 24-wk, multicenter, randomized, parallel, open-label study evaluating the effectiveness of PPT [lispro mix 50; 50% insulin lispro, 50% insulin lispro protamine suspension (ILPS)] tid with meals or BBT [glargine at bedtime + mealtime lispro] in 374 T2D pts inadequately controlled ($7.5\% \leq \text{HbA1c} \leq 12\%$) on basal insulin glargine plus OHAs. In the current analysis, efficacy and safety were assessed in subgroup populations defined by incremental 0.5% ranges of baseline HbA1c from 7.5–12% inclusive.

Results: We report data for one subset of pts from the original study ($n = 269$) with baseline HbA1c ($7.5\% \leq \text{HbA1c} \leq 9.5\%$). In this group, baseline values for age, BMI, percentage male, and HbA1c were similar between BBT and PPT regimens. At study end, HbA1c, fasting plasma glucose (FPG), and post-prandial glucose (PPG) were reduced significantly ($P < 0.0001$) from baseline for both insulin regimens with no significant treatment difference (Table). Weight gain and TDI dose were significantly lower with PPT than BBT. There was no significant difference between therapies in the number of serious adverse events (BBT 8; PPT 5, $P = 0.573$) or number of pts reporting severe hypoglycemia (BBT 4; PPT 5, $P = 0.744$). Due to the small number of pts ($n \sim 40$ in each treatment arm), no conclusions could be drawn for the subset of pts with baseline HbA1c $> 9.5\%$.

Conclusion: In T2D pts with HbA1c values of 7.5% to 9.5%, PPT (3 daily injections) resulted in similar glycemic improvement as BBT (4 daily injections), but with less weight gain and less total daily insulin dose. Thus, PPT offers a suitable alternative to BBT for pts with $7.5\% \leq \text{HbA1c} \leq 9.5\%$ who prefer 3 daily injections to 4 daily injections.

	BBT (n=138)	PPT (n=131)	P-value between therapies

biphasic insulin aspart 30/70 (BIAsp 30) in the treatment of type 2 diabetes. Here we present a subgroup analysis of the safety and effectiveness of BIAsp 30 in previously insulin-naïve patients.

Materials and methods: By 22 February 2008, 30,171 insulin-naïve patients had been recruited from Canada (n=216), China (n=18,800), India (n=5,391), Japan (n=1816), Poland (n=3,901), and Russia (n=47); all had reported data at final visit and are included in this analysis. Of these, 25.6% (n=7717) had received no therapy prior to enrolment; 24.8% (n=7470) received one oral antidiabetic drug (OAD); 36.9% (n=11,139) two OADs, and 12.4% (n=3727) had received more than two OADs. Sulphonylureas were the most commonly taken OAD (70.9% of patients), followed by biguanides (69.1%) and alpha-glucosidase inhibitors (19.8%).

Results: The mean (SD) age of the insulin-naïve cohort was 55.0 years (12.3); diabetes duration 5.9 years (5.5); BMI 25.6 (4.3) kg/m²; weight 70.5 (13.8) kg and 60.0% were male. At final visit, glycaemic control improved significantly from baseline in the total insulin-naïve cohort and in all four subgroups (Table). Overall, HbA_{1c} decreased by 2.4% from 9.4% to 6.9%, corresponding to 58.7% of patients reaching target HbA_{1c} <7.0%. The greatest improvement was seen in patients who previously received 'no therapy' (-3.2% HbA_{1c}). Not surprisingly, this subgroup had the shortest duration of diabetes and the highest baseline HbA_{1c} (Table). Increasing numbers of OADs were associated with longer duration of diabetes and smaller reductions in HbA_{1c}. Fasting plasma glucose was significantly reduced from baseline in all subgroups, as was postprandial plasma glucose after all three meals (p<0.001 for all subgroups); the greatest reductions occurred after breakfast. There was no significant change in weight across subgroups. Major hypoglycaemia was reduced from baseline in all subgroups, while minor hypoglycaemia generally increased from baseline. At the end of the study, only 0.1% of insulin-naïve patients reported any major hypoglycaemia and 9.6% reported any minor hypoglycaemia. The overall mean BIAsp 30 dose at baseline was 0.4 U/kg, which increased by 0.1 U/kg over the 26-week study.

Conclusion: Starting insulin therapy with BIAsp 30 significantly improved glycaemic control, regardless of whether patients had previously received no

therapy or one or more OADs. Fewer OADs and shorter diabetes duration were associated with greater improvements in glycaemic control. BIAsp 30 also reduced major hypoglycaemia without significant weight change. BIAsp 30 is an effective first insulin treatment, even when used before any OAD therapy.

979

Initial dose of insulin glargine in type 2 diabetes based on BMI is safe

D.R. Franco^{1,2}, J. Baptista¹, F.R.M. Abreu¹, R.B. Baptista¹, M.R.C. Alves³, F.G. Eliaschewitz^{1,4}

¹Clinical Research, CPCLIN, São Paulo, ²Endocrinology, Intermédica Saúde,

³Fac. Public Health, Un. São Paulo, ⁴Internal Medicine, H. Heliópolis, São Paulo, Brazil

Background and aims: Basal Glargine insulin (GI) therapy is an efficient approach to treat type 2 diabetic patients that fail to achieve glycemic control on oral drugs (OAD). Several algorithms have been developed and validated, most of them starting with a 10 UI dose at bedtime for all patients. However, with this approach the titrating period can be quite long, affecting adherence to treatment. The aim of this study was to verify the safety, measured by frequency of hypoglycemic events (glycemia < 56 mg %), of two algorithms (AG) that calculate the initial insulin dose according to BMI, in comparison with further two algorithms that use the standard 10 UI as the initial dose.

Materials and methods: We conducted a single-center study with 125 type 2 diabetic patients screened for treatment failure with one or two OADs, naïve for insulin therapy, with an HbA_{1c} between 7% and 12%. 92 patients were randomized and received at least one dose of insulin (ITT population). A screening period of two weeks was followed by 12 weeks treatment with 10 visits plus a 4-week follow-up. 26 patients were randomized to LAMET AG with an initial insulin dose of 10 UI and a 2/2 UI titration two times/week until the FPG reached the target of 100 mg%; 23 patients were grouped to DeGold AG with an initial dose varying from 0.2UI to 0.35 UI/Kg according to BMI

Table. Changes from baseline in glycaemic measurements for insulin-naïve patients and the four constitutive subgroups

Measurement, mean (SD)		Pre-study therapy				
		Insulin-naïve cohort (n=30,171)#	No therapy (n=7717)	1 OAD (n=7470)	2 OADs (n=11,139)	>2 OADs (n=3727)

and with the same titration as above; 21 patients were grouped to FTT AG also with 10 UI as the initial dose and titration varying from 2 to 8 UI according to the FPG, and 22 patients were randomized to FAST AG with the initial dose varying according to BMI and the titration schedule varying according to FPG. Patients in the 4 groups were comparable in age, gender, weight, diabetes duration and previous medication. Comparisons used ANOVA/Kruskal-Wallis or Mann-Whitney tests. Other end points were time to target, variation in HbA_{1c}, weight, FPG and insulin doses from basal to the end of the study.

Results: There were no significant differences in FPG variation, HbA_{1c}, time to target, proportion of patients reaching HbA_{1c} <7% and between 7.1–7.5%, and hypoglycemic events (<55 mg %) between the 4 groups, as shown in Table 1. Each group was also compared to the standard risk LAMET AG, again without evidencing statistical difference. DeGold (0.17±0.38) was comparable to LAMET (0.42±0.7) and was much lower than FTT (1.5±3.3) and FAST (1.23±2.21), though not reaching statistical significance. However, when LAMET and DeGold were jointly compared with the 2 fast titration groups (FTT and FAST), the increase in hypoglycemic events became evident ($p<0.039$).

Conclusion: Starting IG titration with an initial dose based on BMI is safe. We show that the hypoglycemic risk is greater with increasing titration rhythm rather than when a higher initial insulin dose is employed.

Incidence rates of heart failure, stroke and acute myocardial infarction in type 2 diabetics patients using insulin glargine and other insulin

J. Juhaeri¹, S. Gao¹, M.-P. Dain²

¹Epidemiology Unit, Global Pharmacovigilance and Epidemiology, sanofi-aventis, Bridgewater, United States, ²Global Diabetes Franchise, sanofi-aventis, Bridgewater, United States

Background and aims: Although the efficacy of insulin glargine in improving blood glucose profile is well known, its impact on cardiovascular diseases (CVD) risks remains unclear. The aim of this study were to examine and compare incidence rates of heart failure, stroke and acute myocardial infarction (AMI) in Type 2 diabetic patients using insulin glargine and other types of insulin.

Materials and methods: Using a retrospective cohort design, data from PharMetrics database in the US were used to examine risk of CVD across different types of insulin, insulin glargine and other long or intermediate acting

insulins. Insulin was ascertained using the National Drug Code directory. International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9CM) codes were used to identify CVD events, including heart failure (ICD-9CM code of 428), stroke (ICD-9CM codes of 430–438), and AMI (ICD-9CM code of 410). Only new CVD events were analyzed and patients with previous history of CVD were excluded. We used Poisson regression to examine the associations between insulin treatment and CVD. Age, gender, history of hypertension, history of dyslipidemia, days of supply and duration of diabetes were the covariates adjusted in the multivariate analyses.

Results: The insulin glargine only group had larger proportions of patients aged 40–60 years, men and a history of hypertension or dyslipidemia, longer days of supply, and a longer duration of diabetes than other long/intermediate acting insulins group. The incidence rates of heart failure, stroke and AMI in the insulin glargine only group were 304.8 (95% CI: [275.0, 334.6]), 158.5 (95% CI: [137.0, 180.0]) and 93.3 (95% CI: [76.8, 109.8]) cases per 10,000 person-years, respectively. After adjustment for the covariates, the incidence rates of CVD events in the insulin glargine only group were comparable to those in other long/intermediate acting insulins group (reference), except for AMI, which tended to be lower in the insulin glargine group than in other long/intermediate acting insulins group. The corresponding incidence rate ratios (RR) were 1.0 (95% CI: [0.9, 1.2]) for heart failure, 1.0 (95% CI: [0.8, 1.3]) for stroke, and 0.8 (95% CI: [0.62, 0.95]) for AMI, respectively.

Conclusion: Incidence rates of CVD events in the insulin glargine and in other long/intermediate acting insulins groups were comparable, except for AMI where the risk tended to be lower in the insulin glargine group. Insulin glargine use alone, or in combination with other insulins might be associated with a lower risk of CVD events, although the possible underlying mechanisms are unclear.

Glycaemic control and cardiovascular risk in insulin-treated patients with type 2 diabetes in Germany and the UK

S. Gough¹, K.B. Frandsen², A.D. Toff²

¹Institute of Biomedical Research, University of Birmingham, United Kingdom, ²Novo Nordisk, Bagsvaerd, Denmark

Background and aims: One of the major aims of insulin initiation in type 2 diabetes is to improve glycaemia in patients not controlled by lifestyle and oral therapy and reduce an increased risk of future diabetes-related complications. Monitoring of the response to insulinisation in such patients may suggest strategies for improving the attainment of target levels in clinical practice. This analysis determined 'real-life' HbA_{1c} values and other cardiovascular risk factors in patients in Germany and the UK in insulin-treated patients with type 2 diabetes.

Materials and methods: We analysed data from IMS - one of the biggest databases collating population-based data directly from computerised patient records in practices in the EU. Patients with type 2 diabetes, with a first insulin prescription between 1 August 2002 and 31 July 2006, and a recorded HbA_{1c} value at least 6 months after the initial dose, were included. For this analysis, patients' last recorded HbA_{1c} value was used. Results were analysed separately for patients receiving insulin only or insulin + oral antidiabetic drugs (OADs).

Results: Data were obtained for 6625 patients treated by specialists (n=1108) or primary care practitioners (PCPs) (n=5517) in Germany, and 2118 patients treated by PCPs in the UK (table). Results are reported for insulin/insulin + OADs. Mean HbA_{1c} values were 7.5/7.7% in Germany and 8.2/8.2% in the UK. Percentage of patients with HbA_{1c} >7.0% was 63/69 in Germany and 77/82 in

	Germany		UK	
	Insulin n=3702	Insulin + OADs n=2923	Insulin n=845	Insulin + OADs n=1273
Mean age (years ± SD)	69.3 ± 11.7	67.3 ± 10.9	64.3 ± 13.9	63.2 ± 12.0
Mean weight (kg ± SD)	85.9 ± 19.3	90.1 ± 20.2	85.8 ± 20.9	92.6 ± 19.8
Mean HbA _{1c} (% ± SD)	7.5 ± 1.3	7.7 ± 1.3	8.2 ± 1.7	8.2 ± 1.5
Mean duration of insulin therapy (years ± SD)	2.3 ± 1.1	2.2 ± 1.1	2.1 ± 1.0	2.0 ± 1.0
Mean duration of diabetes (years ± SD)	4.0 ± 3.2	4.8 ± 3.4	10.0 ± 9.0	10.5 ± 7.7
Mean BP (mmHg)	141/80	145/81	135/75	136/75

Lipid-lowering drugs (% patients)	32.3	39.6	63.4	72.4

Characteristics of patients who initiated insulin between August 2002 and July 2006

the UK. For $HbA_{1c} > 10.0\%$, percentages were 6/6 in Germany and 13/13 in the UK. Mean duration of insulin therapy was just over 2 years in all groups, but patients in the UK had had diabetes for longer (10.0/10.5 years vs. 4.0/4.8 years in Germany). In both countries, most patients were receiving anti-hypertensive drugs, but mean systolic blood pressure was higher than the 130 mmHg target recommended for people with diabetes. A sizeable proportion of patients (greater in the UK) were on lipid-lowering medication. Results did not differ markedly for patients treated by specialists or PCPs in Germany.

Conclusion: In patients who had been on insulin for around 2 years, approximately two-thirds in Germany and four-fifths in the UK did not meet the HbA_{1c} target of 7%. Thus, despite widespread awareness of HbA_{1c} targets, better control is still needed. Insulin therapy was initiated earlier in the disease in Germany, and mean HbA_{1c} levels were lower, compared with the UK. Initiating patients on insulin sooner is one possible strategy for reducing the risk of longer-term diabetes-related complications.

Effects of insulin treatment on myocardial function, perfusion and glucose metabolism in patients with primary left ventricular dysfunction and type 2 diabetes: a pilot study

S. Masi¹, P. Iozzo¹, C. Simi¹, F. Frassi¹, M. Emdin¹, P. Pisani¹, S. Pardini¹, C. Porciello¹, A. Giorgetti¹, D. Petroni¹, D. Giannessi¹, P. Di Cecco¹, P.A. Salvadori¹, D. Neglia¹, E. Ferrannini^{1,2}

¹Institute of Clinical Physiology, CNR National Research Council, Pisa,

²Department of Internal Medicine, University of Pisa School of Medicine, Italy

Background and aims: Chronic hyperglycaemia is a major risk factor in heart disease. The role of insulin in cardiac protection is controversial, as acute insulin stimulation increases myocardial perfusion and glucose disposal, but chronic insulin exposure is implicated in the development of sympathetic activation, arrhythmogenic risk, dyslipidaemia, insulin resistance and atherosclerosis. Direct effects of prolonged insulin treatment on myocardial metabolism and perfusion, especially in relation to changes in glucose control, are not known. We investigated myocardial and metabolic outcomes of insulin glargine (GLAR) treatment in a human model of non-ischaemic left ventricular dysfunction (LVD) and Type 2 diabetes (T2DM).

Materials and methods: The study included 9 patients (age range 55–72 years, BMI 27.7 ± 2.9 kg/m², HbA_{1c} $6.2 \pm 0.8\%$), undergoing a 1-month run-in or wash-out period, as appropriate, followed by 6 months of GLAR treatment. After run-in and at the end of the treatment period, insulin-mediated myocardial perfusion (MBF) and glucose uptake (MGU) were evaluated by ¹³N-ammonia or ¹⁸F-fluoro-deoxy-glucose and positron emission tomography, during euglycaemic hyperinsulinaemia ($1 \text{ mU} \cdot \text{min}^{-1} \cdot \text{kg}^{-1}$). On a different day, MBF was measured at rest and during pharmacologic stress with adenosine. Coronary flow reserve (CFR) was computed as the ratio of stress to rest MBF. Left ventricular (LV) ejection fraction (EF) and end-diastolic diameter (EDD) were determined by 2D-echocardiography. Safety measurements included the lipid profile, circulating noradrenaline levels, inflammatory markers, liver enzymes and serum creatinine.

Results: Fasting plasma glucose (PG) levels were reduced within 15 days (from 6.9 ± 1.5 to 5.9 ± 1.1 mmol/L, $p < 0.01$), and maintained throughout the study. Fasting insulin levels were almost doubled during the treatment period, but whole-body insulin-mediated glucose disposal was preserved (19.4 ± 7.2 vs $17.1 \pm 8.2 \text{ } \mu\text{mol} \cdot \text{min}^{-1} \cdot \text{kg}^{-1}$, $p = \text{ns}$); other cardiac risk factors (lipid profile, neuroendocrine activation, C-reactive protein, blood pressure, heart rate) were not affected, and body weight was stable. No change in liver or kidney function was noted. Baseline MGU and CFR were $0.39 \pm 0.28 \text{ } \mu\text{mol} \cdot \text{min}^{-1} \cdot \text{g}^{-1}$ and 1.82 ± 0.49 and did not change after treatment ($0.31 \pm 0.16 \text{ } \mu\text{mol} \cdot \text{min}^{-1} \cdot \text{g}^{-1}$ and 1.68 ± 0.48 , respectively, $p = \text{ns}$ vs baseline). At entrance, LVD was characterized by EF and EDD of $42 \pm 11\%$ and $66 \pm 8 \text{ mm}$, respectively. The improvement in glucose control with insulin treatment was a significant predictor of positive changes in stress-MBF ($r = 0.86$, $p = 0.007$), CFR ($r = 0.75$, $p = 0.032$) and MGU ($r = 0.74$, $p = 0.022$). Patients with a lower EDD at entrance were the best responders in terms of CRF ($r = 0.67$, $p = 0.071$) and insulin-mediated MBF ($r = 0.70$, $p = 0.053$).

Conclusion: We found that treatment with GLAR improves glucose control without affecting metabolic and cardiac risk factors or LV function in these patients with non-ischaemic LVD and T2DM. Changes in PG levels induced by GLAR appeared to predict a beneficial response in myocardial perfusion and metabolism. These results will need to be confirmed in a study with a larger number of patients.

PS 090 Insulin pumps

983

One year continuous use of real time glucose monitoring combined with insulin pump, as a mean to normalise glucose variability and HbA_{1c} in IDDM

C.S. Zoupas¹, O. Kepartzoglou¹, N. Kefaloyannis², I. Taraoune¹, F. Giannakopoulos¹, M. Sfakianaki², P. Garoutsou¹, H. Vasilopoulos³, E. Kyrilaki², A. Pappas²

¹Diabetes Center, Hygeia General Hospital, Athens, ²Diabetes Center, Venizelio-Panania General Hospital, Heraklion, Crete, ³Diabetes Center, Evaggelismos General Hospital, Athens, Greece

Background and aims: The usefulness of long term impact of continuous use of Paradigm REAL- Time System (PRT, Medtronic Minimed) on glycemic control is not yet known. PRT is an Insulin Infusion Pump combined with a Continuous Glucose Monitoring System (CGMS). The aim of this study was to evaluate the effect of the system on glycemic control, glucose fluctuations and insulin requirements for a long period of time.

Materials and methods: A total of 15 patients, mean age 34.0 ± 20.3 years and diabetes duration 16.7 ± 9.1 years ($X \pm SD$), wore the Sensor-Augmented Pump system continuously for 12 months. For educational purposes all subjects were on real time CGM for the 1st month without the Pump function (remained on MDI). The Pump therapy was added in a second stage. HbA_{1c} , average daily and monthly glucose, hypo/hyperglycemic excursions and total daily dose (TDD) were evaluated at baseline, 4 and 6 and 12 months respectively.

Results: $HbA_{1c}(\%)$ decreased from 8.31 ± 1.49 at baseline, to 7.09 ± 0.67 after 4, 7.15 ± 0.73 after 6 months and 6.87 ± 0.69 ($X \pm SD$) after 12 months, ($p = 0.009$). Glycemic control improved from the beginning and the average Daily and Monthly Glucose Values did not significantly differ after 1, 4, 6 and 12 months (Table 1). The average Area Under the Curve (AUC) above $180 \text{ mg/dl} \cdot 24\text{h}$ was $13.78 \pm 6.77 \text{ mg/dl} \cdot 24\text{h}$ after the 1st month use of real time CGM without Pump. Tend to be reduced after the introduction of Pump and remained lower, 10.76 ± 4.79 , 10.75 ± 4.79 and $9.83 \pm 3.15 \text{ mg/dl} \cdot 24\text{h}$ at 4, 6 and 12 months respectively. Average monthly AUC below 70 mg/dl remained constant throughout the study period (Table 1), and severe hypoglycemia occurred only once! No significant weight gain were noticed. There was a statistically significant decrease of Total Daily Insulin Dose from 54.1 ± 16.1 to 43.1 ± 19.0 , 40.4 ± 17.3 and 39.8 ± 16.8 units ($X \pm SD$) at 4, 6 and 12 months. In addition the Total Daily Bolus Insulin Dose decreased gradually despite the increased number of boluses given by the patients in order to avoid extreme high glucose excursions. (Table1).

Conclusion: Our results indicate that one year continuous use of PRT provide a useful tool to normalize glycemic control in IDDM. It decreases HbA_{1c} and AUC of high glucose excursions. Patients were driven by the system to the intensification of insulin therapy with more efficient use of bolus. As the time pass the patient learns to react correctly to the predictive alarms of high and low excursions and remains motivated to achieve his targets for a long period of time.

MONTHS	BASELINE	1	p	4	6	12	p

The natural history of residual beta cell function in patients with type 1 diabetes under continuous subcutaneous insulin infusion therapy

S. Cernea¹, C. Moretti², C. Tubili³, C. Suraci⁴, D. Pitocco⁵, I. Barchetta⁶, S. Manfrini¹, N. Napoli¹, R. Buzzetti², P. Pozzilli¹

¹Endocrinology and Diabetes, University Campus Bio-Medico,

²Endocrinology and Diabetes, University, ³Endocrinology, San Camillo-Forlanini Hospital, ⁴Endocrinology, San Perti Hospital, ⁵Endocrinology, Catholic University, ⁶Clinical and Experimental Hepatology, University "Sapienza", Roma, Italy

Background and aims: Evidence exists that preservation of even some β cell function improves the metabolic control and impacts on long-term disease outcomes. Few data exist regarding the relationship between continuous subcutaneous insulin infusion (CSII) therapy with residual β cell function. Small studies have suggested that implementation of intensive insulin therapy by CSII at diagnosis is effective in protecting β cell function even 2 years after diagnosis. The aim of this study was to investigate the residual β cell function as measured by C peptide levels in patients with type 1 diabetes (T1D) receiving CSII across different ages, duration of disease and of CSII therapy.

Materials and methods: This was a cross-sectional study in which patients with T1D on CSII were recruited by participating centers of the IMDIAB group. Clinical features and parameters of metabolic control were obtained. Patients had the basal C peptide levels measured and we calculated the "stimulated" C peptide values by using an empirical formula based on an extrapolation of stimulated C peptide values from the DCCT trial. We have used the cutoff level of 0.2 nM as the clinically relevant "stimulated" C peptide value. According to the time of CSII initiation, patients were divided in 4 groups: A) <1 year; B) 2-5 years; C) 6-15 years; and D) 16-40 years after diagnosis. C peptide values were compared between groups by means of ANCOVA and t tests and statistical significance assumed at $p < 0.05$.

Results: The study included 42 patients with T1D on CSII with a mean age of 37.5 ± 11.3 years and a mean duration of diabetes (DD) of 16.1 ± 11.5 years. Group A (n=5) had a mean DD of 4.4 ± 3.1 years, started pump therapy at 0.8 ± 0.4 years after diagnosis and has been on CSII for 3.4 ± 3.1 years. The HbA1c level was 7.1 ± 0.8 %, BMI: 23.3 ± 2.2 kg/m² and the insulin dosage: 0.47 ± 0.02 IU/kg/day. In this group the basal C peptide level was 0.17 ± 0.2 nM and calculated C peptide was 0.49 ± 0.5 nM, more than twice above the clinical relevant threshold. Group B (n=10) had a mean DD of 5.9 ± 2.3 years, but started CSII at 3.5 ± 1 years after disease onset and had been on a pump for 2.4 ± 2 years. The metabolic control (HbA1c: 7.4 ± 1.5 %) and insulin requirement: (0.52 ± 0.1 IU/kg/day) were similar to group A, $p = \text{NS}$. The C peptide values were much lower than in group A (basal: 0.04 ± 0.04 nM; calculated: 0.11 ± 0.1 nM) ($p < 0.05$), already half of the significant threshold. As expected, the C peptide levels in group C (n=14) with mean time of CSII initiation of 10.5 ± 3.2 years was also low (basal: 0.05 ± 0.07 nM; calculated: 0.14 ± 0.2 nM) and even lower in group D (n=13) (time of CSII initiation 25.1 ± 6.6 years) (basal: 0.02 ± 0.01 nM; calculated: 0.07 ± 0.05 nM).

Conclusion: Data from our study suggest that even as far as 4 years after diagnosis there is still some residual β cell function, as evaluated by C peptide measurement in patients with T1D. The severe decrease in C peptide levels seen with delayed CSII startup suggests that early initiation of pump therapy is critical in preservation of residual β cell function.

985

The hourly basal insulin dose of Japanese type 1 diabetic patients is flatter than that of European patients

M. Hirose, T. Kawamura, T. Hashimoto, T. Higashide, K. Kimura, H. Inada, S. Niihira, S. Aono, T. Yamano
Pediatrics, Osaka City University Graduate School of Medicine, Osaka, Japan

Background and aims: About CSII treatment of type 1 diabetes patients, some European studies have showed that the percentage of basal dose made up over the half of total daily insulin dose (TDD), and hourly basal dose was the highest in the dawn period (1.2-1.5 times from average basal insulin dose). In our experience of CSII in Japanese Type 1 diabetes patients, the basal insulin infusion rates were lower than that reported in these European studies. In the present study, we analyzed the hourly basal insulin dose of Japanese type 1 diabetes patients on CSII.

Materials and methods: Subjects are 51 (male : female = 12 : 39) type 1 diabetic patients with CSII treatment of Minimed 508. The average age is 14.4 ± 7.1 (from 1 to 33 years old). And their average BMI is 20.9 ± 3.7 , and their average HbA1c is 7.8 ± 1.4 %.

The dose of bolus insulin was adjusted by carbohydrate counting. The hourly basal insulin dose was adjusted according to the stability of blood glucose level without meal and correction insulin, such as 30 rule.

We downloaded their all insulin infusion history for 4 weeks by Medtronic Com Station.

We have analyzed the various parameters which might affect on the basal insulin rate such as, age, puberty, sex, metabolic and metabolic control.

Results: TDD was 41.6 ± 19.6 U / day, and the basal insulin dose in TDD was 40.9 ± 11.9 %. The average hourly basal insulin dose of all patients was $0.63 \sim 0.76$ U/h and almost constant all through the day, so called the flat pattern . In one third of the subjects have the two wave pattern of hourly basal doses which were high at early morning and early evening. However, the highest hourly basal dose was less than 1.1 times of the average dose. In the poor diabetic control group (HbA1c > 7.5%), the percentage of basal insulin dose in TDD was significantly higher than that of good controlled group (HbA1c < 7.5) (44.9 % vs. 37.3 %). Adversely TDD in this group was lower than that of good control group (0.87 vs. 0.92 U/kg/day). Furthermore in the poor control group, the hourly basal insulin dose was the highest in daytime. We speculated that they have increased daytime basal insulin dose because of the shortage of their bolus insulin dose. Neither sex nor puberty nor age was related to the patterns of hourly basal rate in this study.

Conclusion: From all data downloaded by CSII, the basal insulin dose and the changes of the hourly basal insulin dose of Japanese type 1 diabetes patient are less than that of European patients. Japanese patients may have little effect of insulin in dawn phenomenon. And we have speculated these results may be caused by Japanese dietary habit such as high-carbohydrate diet.

Drop out from continuous subcutaneous insulin infusion: an Italian survey

F. Lombardo¹, D. Iafusco², R. Bonfanti³, P. Buono⁴, V. Cherubini⁵, G. D'Annunzio⁶, P. Frongia⁷, D. Lo Presti⁸, F. Prisco⁹, I. Rabbone¹⁰, G. Salzano¹¹, R. Schiaffini¹², A. Scaramuzza¹³, S. Toni¹⁴, S. Tumini¹⁵

¹Department of Pediatrics, University of Messina, ²Ped., 2nd Univ.Naples, ³Ped., HSR, Milan, ⁴Ped., Federico II, Naples, ⁵Ped, Univ., Ancona, ⁶Ped., Univ, Genoa, ⁷Ped., G.Brotzu H., Cagliari, ⁸Ped, Univ, Catania, ⁹Ped, 2nd Univ. Naples, ¹⁰Ped, OIRM, Turin, ¹¹Ped, Univ, Messina, ¹²Ped, OPBG, Rome, ¹³Ped, L. Sacco H., Milan, ¹⁴Ped, Meyer H., Florence, ¹⁵Ped, Univ, Chieti, Italy

Background and aims: The continuous subcutaneous insulin infusion (CSII) is an efficacious option to the multiple daily injections (MDI) in the treatment of children and adolescents with type 1 diabetes mellitus (T1DM). Unfortunately, this is an expensive therapy and the identification of the most appropriate sub-population suitable for CSII treatment is crucial in order to avoid drop-out. For this reason, recently, a detailed guideline on CSII has been published by the Italian Society for Pediatric Endocrinology and Diabetology (ISPED) (*Acta Bio Medica* 2008). For the last three years we have been involved in a collaborative study aiming to characterize the reasons for the drop-out. Our results showed that the main reason was not only the patient's

selection but also a time-based failure: in fact, the drop-out rate is higher in the first 6-months of CSII therapy (*J Ped* 2007).

Materials and methods: This is the first national study on behalf of the Italian Study Group on Diabetes of ISPED. We collected data from 22 Italian Pediatric Diabetes Centres during a 2-month period from January to February 2008. The overall study population consisted in 9314 children and adolescents with T1DM. We are analyzing all the data in order to calculate the prevalence of patients which chose to drop-out, the main reasons and the timing of drop-out, the metabolic control obtained during the CSII therapy.

Results: This abstract presents only preliminary results of the collaborative study. We can assure that results will be completed at the time of the EASD Congress. Among the overall the study population with T1DM, 1165 children and adolescents are on CSII, representing a rate of 12.5%. 83 patients (42 M, 41 F) dropped-out (7.1%) after 20.8 ± 17.2 months treatment period. The main reasons of the drop-out were psychological issues and poor compliance. The rate of major adverse events, such as DKA or severe hypoglycaemic events, during the CSII treatment, does not statistically differ from the one reported in the MDI period treatment. No other adverse effects were reported during CSII therapy. The rate of drop out was respectively 16 patients (19.2%), in the first 6 months, 16 patients (19.2%), between 6 and 12 months, 23 patients (27.2%) between 12 and 24 months, 12 patients (14%) between 24 and 36 months and 16 patients (19.2%) > 36 months.

Conclusion: Our study represents, to our knowledge, the first national report on CSII-drop out rate. CSII is an useful tool, it is reasonable to use it when there are appropriate indications, especially in the pediatric age. The national data are in disagree with the results of a previous study performed in two pediatric diabetes centres of Southern Italy in which we found that the drop out rate was higher in the first six months of CSII therapy. In fact, on the basis of our national preliminary data, in Italy CSII drop-out incidence is likely to be homogeneously distributed over time.

Cross-sectional study: continuous subcutaneous insulin infusion or multiple daily injections for functional insulin treatment in type 1 diabetes?

J. Pumprla, K. Howorka, M. Puck, I. Mihaljevic, N. Howorka, E. Perneczky, M. Gabriel

Centre of Biomedical Engineering & Physics, Res Group Functional Rehabilitation, Vienna, Austria

Background and aims: Continuous subcutaneous insulin infusion (CSII) in type 1 diabetes results usually in moderate improvement of glycaemic control and diabetes-related quality of life. Such improvement is dependent on diabetes education provided and inversely related to the initial glycaemic control on pre-pump treatment. Our aim was to investigate motifs and characteristics of FIT- (functional insulin treatment) educated patients with type 1 diabetes who later on have chosen CSII vs. those who have chosen multiple daily injections, MDI. Furthermore, we evaluated the impact of such freely chosen treatment strategy (CSII or MDI) on parameters of metabolic control, quality of life and treatment satisfaction.

Materials and methods: Cross-sectional study comparing the outcomes in FIT-educated patients with CSII and in MDI controls using functional insulin treatment with injections. Additionally, the impact of CSII and MDI on metabolic control was assessed in a longitudinal retrospective pilot investigation. Structured outpatient FIT UPDATE module (educational week-end specifically developed for FIT patients) including detailed information on insulin pumps and pens was used for the invitation to participate in the study. Eventually, 25 type 1 patients with CSII, and 112 with MDI (6.3 ± 1.4 daily injections, insulin analogs in 93%) comparable in diabetes (20 yrs) and FIT (11 yrs) duration, and associated diseases were included in the study, and 4 invited patients (2 with CSII and 2 with MDI) rejected such voluntary participation.

Results: Differences have been found for reported number of daily blood glucose self-measurements (CSII: 5.6 ± 0.9 vs MDI: 5.1 ± 0.8 , $p=0.01$), perceived dietary flexibility ($p=0.03$), DTSQ for FIT subscore for basal insulin satisfaction (13 ± 3 vs 12 ± 4 , $p=0.02$) but not for HbA1c (7.1 ± 0.9 vs $7.3 \pm 1.0\%$, $p=0.4$), neither for frequency of daily dosage adjustment ($p=0.3$), treatment satisfaction total score (Bradley s et al. DTSQ extended for FIT: 90 ± 20 vs 86 ± 20 , $p=0.4$) and its subscores (DTSQ classic total score, $p=0.7$, subscores predictability $p=0.8$, hypoglycaemia proneness $p=0.5$, correctional insulin $p=0.3$, prandial insulin $p=0.5$) nor for diabetes-specific quality of life (Bradley

s ADDQoL), and subscores (all $p>0.3$: for working life, family life, friendship, sex, physical appearance, things to do, holidays and travel, self-confidence, society reaction, future, finances and dependence), with tendency towards significance for subscore in motivation showing higher motivation in pump patients ($p=0.07$).

Conclusion: Functional insulin use with in average more than 6 daily injections results in FIT-educated patients in similar outcomes independently of the mode of insulin delivery. Pump treatment is associated with slightly more "motivation" for treatment.

988

The access to insulin pump therapy in type 1 children and adolescents has largely increased in France since 2001

N. Tubiana-Rufi¹, V. Sulmont², V. Lassmann-Vague³, B. Guerci⁴, H. Hanaire⁵, H. Leblanc⁶, E. Leutenegger⁷, M. Mihaileanu⁸

²Endocrinology and Pediatrics Department, American Memorial Hospital,

Reims, ³Marseille, ⁴Diabetology and Endocrinology Department, Jeanne

d'Arc Hospital, Nancy, ⁵Diabetology, metabolic diseases and nutrition

department, Rangueil Hospital, Toulouse, ⁶Diabetology and Endocrinology

Department, Saint-Louis Hospital, Paris, ⁷ABR Pharma, Paris, France,

⁸Medical department, VitalAire, Paris, France

Background and aims: Insulin pump therapy in paediatric patients with type 1 diabetes (T1D) has been developing in many countries in the last few years. The present study aims at updating assessment of the use of pump therapy in T1D children and teenagers aged <18 in France, in comparison with a previous survey performed in 2001 (one year after the treatment started to be reimbursed by the French health service).

Materials and methods: A national survey was performed in France in 2007. A questionnaire on insulin pump prescription in T1D children and teenagers was sent to all French paediatric centres and 113 adult diabetes centres.

Results: 60 paediatric centres (89%) and 28 adult diabetes centres (25%) answered the survey. The answering paediatric centres are localized in all the French regions and follow up 8,477 T1D children and adolescents (Med: 85 patients/centre. Min: 15. Max: 650). Only 4 centres do not use insulin pump, meaning that 93% of the answering paediatric centres use this therapy. The number of young patients treated with pump is 1,304, representing 15.4% of the total T1D patients ($18 \pm 14\%$ per centre on average). The insulin pump treatment was initiated during the preceding year in 491 young patients (38% of patients treated with pump). Among the 28 adult diabetes centres answering the study, 22 effectively manage young diabetes patients. They follow up 596 T1D children and teenagers (Med: 23 patients/centre. Min: 1. Max: 60). 157 of these patients are treated with insulin pump (26.3% of the total young patients managed) ($32 \pm 22\%$ per centre). Compared to the results of the 2001 study in paediatric centres, these data indicate that the number of young T1D patients treated by insulin pump has increased almost 10 times within 6 years: in 2001, 13 paediatric centres were following only 140 children and adolescents treated by an insulin pump, versus 56 centres and 1,304 young patients under pump therapy in 2007.

Conclusion: This study, conducted in a large sample of French T1D children and adolescents, representing 60 to 75% of the total national estimated population, emphasizes the large increase within the last 6 years of the use of pumps in paediatric centres in all French regions. At the moment, 16% of a total of 9073 T1D paediatric patients benefit from this therapy (89% in paediatric centres). The medical training programs, the implementation of pumps reimbursement and appropriate medical care organisation, have enabled to improve the access to insulin pump treatment for paediatric patients in France. The study is actually on going through an observational program, in order to evaluate more precisely the indications and the modalities of paediatric insulin pump management in France.

989

Insulin requirement in children under 6-year-old treated with insulin pump from the onset of type 1 diabetes mellitus: a 5-year follow-up

L. Groele, A. Szybowska, M. Lipka, M. Błazik, D. Golicka, E. Pańkowska
Department of Diabetology, Neonatology and Birth Defects, Medical University of Warsaw, Poland

Background and aims: Continuous increase of type 1 diabetes (T1DM) incidence among young children is a challenge to establish an effective and safe

method of insulin delivery. The aim is to assessment of insulin requirement of total daily dose (TDD) and basal insulin regarding to metabolic control in young children treated with insulin pump from the onset of T1DM

Materials and methods: 58 children (31 girls) under 6-year-old (mean age 3.3 ± 1.5 years) were analyzed for 175 patient-years of follow-up. Data was collected every six month: HbA_{1c}, SDS BMI, diabetic ketoacidosis (DKA) and severe hypoglycaemia (SH), TDD and basal insulin were downloaded from pump memory.

Results: HbA_{1c} decreased from 9.6% at recognition to 6.7% at 3rd month ($p < 0.0001$). During 5-year follow-up metabolic control was sustained (HbA_{1c}: 6.8 vs 6.7 vs 6.9 vs 7.0 vs 7.1 vs 7.3 vs 7.1 vs 6.9 vs 7.2%) $p = 0.002$. TDD increased from 0.4 U/kg/d to 0.7 U/kg/d $p < 0.0001$. The insulin daily dose increased from 0.5 U/kg/d in the 6th months to 0.6 U/kg/d in the 12th months and than was sustained 0.7 U/kg/d $p < 0.0001$. The basal insulin raised from 10% to 25% of TDD $p < 0.0001$, SDS BMI ranged from 0.0 to 0.4 $p = 0.48$. There was one episode of DKA and one of SH. 66% children walked to kindergarden and 70% mothers work professionally

Conclusion: The insulin requirement has been increased throughout the first year after T1DM recognition, than has been kept at 0.7 U/kg/d with basal insulin below 30% TDD. Initiating insulin pump therapy at onset of T1DM in young children provides sustained metabolic control, with minimal risk of SH and DKA and without increase of body mass

990

Achievement of good glycaemic control with increased C-peptide secretion in poorly controlled type 2 diabetic patients via long-term continuous subcutaneous insulin infusion

S.B. Choi¹, J.H. Lee², J.H. Lee², J.H. Park², Y.I. Jo¹, Y.H. Noh²

¹Internal Medicine, ²Biochemistry, Konkuk University, Seoul, Republic of Korea

Background and aims: Continuous subcutaneous insulin infusion (CSII) therapy is increasingly considered a promising therapeutic strategy in both T1DM and T2DM, however, little is known about the long-term beneficial effects of CSII in T2DM in terms of glycaemic control and possibility of the prevention and/or delay of the development of diabetic complications. To see whether hyperglycaemia is optimally controlled via CSII in patients with T2DM who had failed with OHA and/or insulin injection and the achievement of good glycaemic control is accompanied with improvement of other abnormal conditions, we compared HbA_{1c} levels and laboratory findings including lipid profile and serum C-peptide [before (AC) and 2 hours after meal (PP2)] levels before and up to 24 months after CSII therapy.

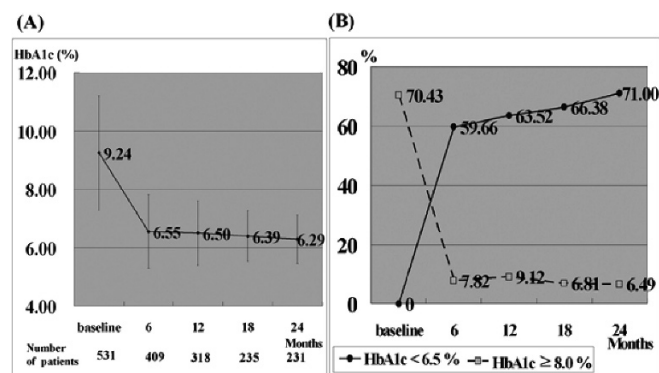

Materials and methods: Among T2DM patients treated with CSII at the Diabetes Center of Konkuk University Hospital from 2005 to 2007 we selected 531 patients (male 53%, HbA_{1c} 9.24 ± 1.96 %, Table 1) with poorly controlled but without severe nephropathy at baseline (HbA_{1c} ≥ 7.0 % and serum creatinine ≤ 1.5 mg/dl). We analyzed HbA_{1c} and the other laboratory data examined at 6 month to 1 year interval rate.

Results: CSII therapy nearly normalized HbA_{1c} level by 6.55 ± 1.26 % (29 % reduction compared to baseline level, $p < 0.001$, Fig. 1A) at 6 month with gradual improvement over 24 months. The proportion of patients achieving HbA_{1c} target < 6.5 % greatly increased (0% at baseline vs 71% at 24 month, Fig. 1B). AC and PP2 C-peptide levels increased by 20% (at 12 month) and 27.6% (at 18 month), respectively ($p < 0.001$, for both) and were continuously improved. Patients with proteinuria decreased from 30% (at baseline) to 16% (at 24 month), however, creatinine clearance levels calculated by Cockcroft-Gault equation remained unchanged. Diastolic but not systolic blood pressure level decreased throughout all the period (78.6 ± 11.6 at baseline vs 70.5 ± 9.8 mmHg at 24 month, $p < 0.001$), although the mean BMI increased by 7.7 ± 1.0 % compared to baseline level ($p < 0.001$). HDL, LDL, and TG levels increased 12, 19, and 7 %, respectively ($p < 0.001$, for all), but the increased mean LDL and TG levels at 24 month were within normal range.

Conclusion: CSII achieved optimal glycaemic control and improved C-peptide secretion, proteinuria, and diastolic BP, suggesting resolution of glucotoxicity via CSII may be plausible even in T2DM patients with secondary failure.

Table 1. Clinical characteristics of the subjects at baseline

* $p < 0.05$ vs Male	All subjects	Male	Female

Insulin glulisine improves glycaemic control in type 2 diabetic patients not optimally controlled with oral antidiabetic drugs: results of a randomised controlled study

J.-T. Woo¹, S.-W. Kim², S.-H. Baik³, K.-H. Yoon⁴, R. Kawamori⁵, Y. Iwamoto⁶, T. Kadowaki⁷, M. Iwasaki⁸

¹Department of Endocrinology and Metabolism, Kyung Hee University Medical Center, Seoul, Republic of Korea, ²Department of Internal Medicine, Sungkyunkwan University School of Medicine, Kangbuk Samsung Hospital, Seoul, Republic of Korea, ³Department of Internal Medicine, Korea University Guro Hospital, Seoul, Republic of Korea, ⁴Department of Endocrinology and Metabolism, Kangnam Saint Mary's Hospital, Seoul, Republic of Korea, ⁵Department of Medicine, Metabolism and Endocrinology, School of Medicine, Juntendo University, Tokyo, Japan, ⁶Diabetes Center, Tokyo Women's Medical University, Japan, ⁷Department of Metabolic Diseases, Graduate School of Medicine, The University of Tokyo, Japan, ⁸Department of Computer and Information Science, Seikei University, Tokyo, Japan

Background and aims: The rapid-acting, insulin glulisine (GLU) with or without oral antidiabetic drugs (OAD) was compared with OAD therapy for efficacy and safety in Japanese and Korean type 2 diabetic (T2DM) patients inadequately controlled with OAD (sulfonylurea (SU) or SU + biguanide). Three treatment groups were assessed in this study: 3 daily injections of GLU in combination with OAD (GLU+OAD), GLU-only or OAD-only and the primary objective was the HbA_{1c} change from baseline to endpoint. Secondary objectives were plasma glucose parameters and safety.

Materials and methods: In an open, randomized, parallel group, comparative, 16-week, controlled trial, 393 patients were randomized and 387 patients (Japan: 198; Korea: 189) were treated with GLU+OAD (N = 130), GLU-only (N = 127) or OAD-only (N = 130). T2DM patients diagnosed for at least 1 year, BMI <30 kg/m², HbA_{1c} ≥ 8.0% to ≤11.0%, treated with a stable regimen

of SU or SU + biguanide were eligible. GLU was titrated to achieve a 2-hour postprandial blood glucose value of 128 to 172 mg/dL using plasma-referenced blood glucose meter. In both GLU+OAD and OAD-only groups, prior OAD therapy was continued on a stable dose.

Results: Baseline HbA_{1c} values were similar among treatment groups. Both GLU groups had larger reductions in adjusted mean HbA_{1c} than the OAD group: (GLU+OAD -2.07%, GLU-only -1.25%, OAD-only -0.61%). Superiority of GLU+OAD and GLU-only to OAD-only was shown by a difference in adjusted mean HbA_{1c} change of -1.46% (*P*<0.0001) and -0.64% (*P*<0.0001), respectively (Table 1). Both GLU groups had better 2-hour postprandial plasma glucose control than the OAD-only group. Mean daily GLU doses increased from baseline to endpoint: (GLU+OAD 13.3 to 22.5 U, GLU-only 14.2 to 38.0 U). The rate of all symptomatic hypoglycemia per patient year in the entire treatment phase was 11.9 in GLU+OAD, 8.8 in GLU-only and 1.7 in OAD-only. There was only 1 event of severe hypoglycemia (GLU+OAD). Efficacy and safety was similar in Japanese and Korean subpopulations.

Conclusion: This study demonstrated that both GLU+OAD and GLU-only are well tolerated and effective in T2DM patients not optimally controlled with OAD therapy.

Results are given for all randomized and treated patients; 4 patients (insulin glargine, 3; LM, 1) were randomized, but not treated. Results are mean ± standard deviation; HbA_{1c} = haemoglobin A_{1c}; FPG = fasting plasma glucose; LM = lifestyle management; n/a = not applicable

Background and aims: To determine whether earlier administration of insulin glargine versus intensified lifestyle management (LM) improves glycaemic control in Type 2 diabetes (T2DM) patients with haemoglobin A_{1c} (HbA_{1c}) 7–8% treated with oral agents.

Materials and methods: TULIP (Testing the Usefulness of insulin gLargine [glargine] when Initiated Promptly in T2DM) was a 9-month, 12-visit, open-label, multinational, multicentre, randomized study to evaluate starting glargine or intensifying LM in T2DM patients aged 40–75 years, body mass index (BMI) 24–35 kg/m² and HbA_{1c} 7–8%, treated with maximum doses of metformin and sulphonylurea for ≥2 years. Glargine was injected once daily (evening) and titrated to capillary fasting blood glucose (FBG) 70–100 mg/dL. In the LM arm, dietary and physical activity counseling recommended stable weight for people with BMI <27 kg/m² or weight loss of 3 kg for patients with BMI ≥27 kg/m². Daily calorie distribution could be maintained or reduced in patients whose BMI was <27 kg/m² and reduced by one-third for patients whose BMI was ≥27 kg/m². Patients were recommended a diet composed of 50–55% carbohydrates, 30–35% lipids and 10–15% protein. Patients were recommended to undertake 2 hours of brisk walking or equivalent per week (in segments of 20 minutes) in addition to their daily activity. A total of 215 patients were randomized to glargine (n=106) or LM (n=109). The primary objective was to determine the percentage of patients achieving HbA_{1c} <7% at endpoint. Secondary endpoints included changes in HbA_{1c} and fasting plasma glucose (FPG), and hypoglycaemia incidence.

Results: 211 (52.6% male) patients were randomized and treated; mean (± standard deviation) age 60.7±7.9 years, weight 84.5±13.1 kg, BMI 29.9±3.5 kg/m² and HbA_{1c} 7.6±0.4%. More patients reached HbA_{1c} <7% (66 vs 38%; p<0.0001) or <6.5% (34 vs 11%; p=0.0001) with glargine versus LM. In contrast to the glargine-treated group, the LM-treated group showed a decrease in weight (+0.9±2.9 vs -2.5±3.2 kg; p<0.0001) as well as the expected lower hypoglycaemia. Results for hypoglycaemia, HbA_{1c}, FPG and weight are shown in the table.

Conclusion: In T2DM patients with HbA_{1c} 7–8%, adding glargine to existing oral therapy resulted in greater improvements in glycaemic control versus intensified LM. Nevertheless, lifestyle management should be maintained by all patients with diabetes, including those using insulin.

Daily blood glucose profiles in subjects with type 2 diabetes in a randomised, crossover, double-blind comparison of insulin detemir and insulin glargine

A. King

Diabetes Department, Diabetes Care Center, Salinas, United States

Background and aims: Basal insulin analogues such as insulin detemir and insulin glargine are indicated for once-daily use as monotherapy or in combination with other antihyperglycaemic treatments in patients with type 2 diabetes (T2D). Both insulin detemir and insulin glargine have similar durations of action, as indicated by isoglycaemic clamp studies. The aim of this

study was to compare 24-hr glycaemic control with insulin detemir vs. insulin glargine using a continuous glucose monitoring system (CGMS).

Materials and methods: T2D patients using basal but not bolus insulin (N=35) were randomised to receive a single daily injection of insulin detemir or insulin glargine at 8 PM for 1 week and switched to the other insulin the next week. Insulin was titrated to achieve blood glucose (BG) measurements <120 mg/dL (<6.7mmol/L) but without >5% of readings <70 mg/dL (<3.9mmol/L) during the basal period (12 PM to 6 AM). From 6 PM until breakfast the following morning, no food was to be eaten, in order to obtain accurate basal BG readings. During both weeks, subjects wore a CGMS (Medtronic CGMS System Gold) until basal BG targets were achieved. CGMS readings for the last 24-hr period were recorded and mean values were compared between treatments using a single-tail, paired t-test.

Results: All subjects achieved basal BG targets in a mean of 3.65 days. Mean BG values during the basal period and the entire 24-hr period were not significantly different between insulin detemir and insulin glargine, except at 2 AM (p<0.05) (Figure).

Conclusion: There was no clinically significant difference between insulin detemir and insulin glargine in glycaemic control during the basal period or throughout the day and we can conclude that once-daily dosing of insulin detemir and insulin glargine provides comparable glycaemic efficacy over a 24-hour period in subjects with T2D.

Daily blood glucose measured by CGMS (mean ± SE):
insulin glargine vs. insulin detemir

Patient characteristics as predictors of treatment efficacy: premix analogue versus basal insulin in type 2 diabetes

V. Fonseca¹, J. Davidson², P. Home³, W. Duckworth⁴, J. Snyder⁵, C. Koenen⁶, A.D. Toft⁶, A. Barnett⁷

¹Tulane University Medical Center, Tulane University Health Sciences Center, New Orleans, United States, ²UT Southwestern Medical School & Medical City Dallas Endocrine & Diabetes Assoc of Texas, Dallas, United States, ³School of Medical Sciences, University of Newcastle Upon Tyne, United Kingdom, ⁴Diabetes Research, Veterans Affairs Medical Center, Phoenix, United States, ⁵Endocrinology, Southwest Medical Associates, Las Vegas, United States, ⁶Novo Nordisk A/S, Bagsvaerd, Denmark, ⁷Diabetes and Obesity Group, University of Birmingham, United Kingdom

Background and aims: Insulin therapy for people with type 2 diabetes is often started with a basal insulin analogue or premix insulin analogue. This pooled analysis aimed to determine if baseline factors can predict improved glycaemic control with these regimens.

Materials and methods: Published studies performed by Novo Nordisk (as individual data were needed) were identified which met criteria of: treat-to-target design, insulin-naïve, type 2 diabetes, treated with biphasic insulin aspart 30 (BIAsp 30) once/twice-daily plus oral agents (OAs) or basal insulin analogue (insulin glargine or insulin detemir) plus OAs. Patient data were pooled and age, diabetes duration, gender, BMI, HbA_{1c}, fasting plasma glucose (FPG), mean postprandial plasma glucose (PPG) and bedtime plasma glucose (PG) at baseline were investigated for prediction of improved HbA_{1c}, FPG or PPG with the two insulin types. Statistical analyses employed a linear mixed model with insulin type, OAs, time, and time² as fixed effects, and patient and trial as random effects.

Results: Six trials met the criteria: n=288 for BIAsp 30, n=1101 for basal analogue. Baseline age and bedtime PG were inter-related predictors of HbA_{1c}: at higher age or higher PG, BIAsp 30 was more beneficial, and at lower age and PG, basal insulin was better (Figure). Thus, at bedtime PG of 9.9 mmol/L, BIAsp 30 was better for those over 35 years old, whereas at 45 years, basal insulin was better if PG was below 7.2 mmol/L. Basal analogue had more effect than BIAsp 30 on FPG. For the two pairs of co-variables baseline HbA_{1c} and FPG, and baseline FPG and post-breakfast PG, it was not possible to define regions within which one insulin was predicted to give a greater improvement in HbA_{1c} than the other. Mean PPG was similar between regimens for younger people, but for older people BIAsp 30 was better. Minor hypoglycaemia was reported by 56% of BIAsp 30-treated people and 45% of basal analogue-treated people.

Conclusion: The data suggest that people with low bedtime PG starting insulin therapy early should start with basal analogue, but older people and those with higher bedtime PG should start with BIAsp 30 to achieve greater HbA_{1c} reductions.

Figure. treatment difference in predicted HbA_{1c} (%) (BIAsp 30 - basal) according to age and bedtime plasma glucose

Thrice-daily BIAsp 70 more closely mimics physiological insulin secretion compared with twice-daily BIAsp 30

M. Kikuchi¹, S. Irie², T. Eto², A. Yamada², K. Matsuguma², T. Sasaki³, Y. Katayama³, K. Tsukuda¹

¹The Institute for Adult Diseases, Asahi Life Foundation, Marunouchi Hospital, Tokyo, ²Clinical Pharmacology Department, Kyushu Clinical Pharmacology Research Clinic, Fukuoka, ³Novo Nordisk Pharma Ltd, Tokyo, Japan

Background and aims: Biphasic insulin aspart (BIAsp) is a premixed insulin analogue, containing soluble, rapid-acting insulin (IAsp) and intermediate-acting protamine-bound IAsp. We compared the insulin profiles of BIAsp 70 three-times-daily (TID) and BIAsp 30 twice-daily (BID) (containing 70 and 30% of the rapid-acting fraction, respectively) in Japanese type 2 diabetes patients with the insulin profile of healthy subjects. The aim of this study was to investigate how closely physiological insulin profiles are reproduced.

Materials and methods: This study was a two-site, randomised, open-label, treat-to-target, parallel group comparison. At the first site, type 2 diabetes patients were randomised into two treatment groups, BIAsp 70 TID (n=20) and BIAsp 30 BID (n=20) and at the second site, untreated healthy subjects (n=20) were also included as a comparator (control group). Patient inclusion criteria included type 2 diabetes with current insulin treatment ≥ 12 weeks, aged 20–69 years, HbA_{1c} <9.0%, BMI 18.5–25.0 kg/m², and total daily insulin dose 0.2–1.0 U/kg body weight. Healthy subjects were defined as individuals with normal glucose tolerance (OGTT). Pharmacokinetic measurements (24 h) were performed at both sites. Serum insulin concentrations (24 h) were obtained with 3 standard meals. This included endogenous and exogenous insulin after 4 weeks of treatment in subjects with type 2 diabetes.

Results: Total serum insulin concentrations rapidly increased after BIAsp 70 administration at breakfast, lunch, and dinner until C_{max} was reached with a median t_{max} of 1 h. Significant differences in plasma insulin concentrations were noted between BIAsp 70 TID and BIAsp 30 BID after lunch when BIAsp 30 was not administered and during the early phase after injections at breakfast and dinner. The 24 h plasma insulin profile of the BIAsp 70 TID group was more similar to physiological insulin secretion in healthy subjects compared with the BIAsp 30 BID group. This was reflected in smaller differences in the insulin profile curve areas between the BIAsp 70 TID group and healthy subjects compared with the BIAsp 30 BID group (p<0.0001). The frequency of adverse events was similar between the BIAsp 70 and BIAsp 30 groups. All reported events were judged as unlikely to be related to the trial product.

Conclusion: BIAsp 70 TID provides a pharmacokinetic profile which more closely mimics physiological insulin secretion compared with BIAsp 30 BID. This can be attributed to the increased insulin concentration during the early phase after injection, reflecting the increased rapid-acting fraction. BIAsp 70 TID offers a useful treatment option in Japanese type 2 diabetes patients. With a range of premix ratios, individual treatment regimens may be tailored to achieve improved glycaemic control, while maintaining a limited number of daily injections.

A thrice-daily regimen of BIAsp 70 improves glycaemic control without increasing the risk of hypoglycaemia in Japanese patients with type 2 diabetes: a comparison of thrice-daily BIAsp 70 and twice-daily BIAsp 30

T. Kadowaki¹, M. Kanai², Y. Katayama², K. Kaku³

¹Department of Diabetes and Metabolic Diseases, The University of Tokyo, ²Novo Nordisk Pharma Ltd, Tokyo, Japan, ³Diabetes and Endocrine Division, Kawasaki Medical School, Okayama, Japan

Background and aims: Biphasic insulin aspart (BIAsp) is a premixed insulin analogue containing soluble, rapid-acting insulin aspart (IAsp) and intermediate-acting protamine bound IAsp. In this study, we compared the efficacy and safety of two different BIAsp formulations: BIAsp 30 and BIAsp 70, (containing 30% and 70% rapid-acting insulin, respectively), in a 28-week, two-arm, open-label, treat-to-target clinical trial. Titration was based on a pre-determined algorithm.

Materials and methods: Type 2 diabetes patients (n=296) treated with intermediate-acting insulin, long-acting insulin, or premixed human insulin (once- or twice-daily regimen for at least 24 weeks) were randomised 1:1 to treatment with BIAsp 30 twice daily (BID) or BIAsp 70 three-times-daily

(TID). Insulin was injected immediately before meals. After 16 weeks of treatment, subjects in the TID regimen with a fasting plasma glucose (FPG) >130 mg/dL (>7.2 mmol/L) could be switched to BIAsp 30 at the pre-dinner dosing to complete the remaining 12 weeks of the study, resulting in 67% of the subjects being switched. The primary endpoint was HbA_{1c} after 16 weeks of treatment. The secondary efficacy endpoints included HbA_{1c} after 28 weeks of treatment and parameters derived from the 7-point plasma glucose (PG) profile after 16 weeks of treatment. The study was designed to test non-inferiority of the BIAsp 70 TID regimen compared with the BIAsp 30 BID regimen. If non-inferiority was shown, statistical superiority was evaluated.

Results: After 16 weeks of treatment, the HbA_{1c} of subjects on the BIAsp 70 TID regimen was significantly lower than with BIAsp 30 BID (7.22 vs. 7.57, $p<0.0001$). The HbA_{1c} of BIAsp 70 TID was shown superior to BIAsp 30 BID by -0.35% (95% CI [-0.51; -0.19], $p<0.0001$). Similarly, after 28 weeks of treatment, the HbA_{1c} of BIAsp 70 TID (including switching to BIAsp 30 at dinner) was shown to be superior to BIAsp 30 BID by -0.30% (95% CI [-0.47; -0.14], $p=0.0004$). The mean PG of the BIAsp 70 TID regimen, derived from the 7-point PG profile, was significantly lower than BIAsp 30 BID by -8.2 mg/dL (-0.46 mmol/L) (95% CI [-16.1; -0.4], $p=0.0402$). The postprandial increment of BIAsp 70 TID was lower by -34.4 mg/dL (-1.91 mmol/L) (95% CI [-45.1; -23.7], $p<0.0001$). The insulin dose increased more with BIAsp 70 TID compared with BIAsp 30 BID. The incidence of adverse events was similar in the two treatment groups. Despite a lower HbA_{1c}, the frequency of hypoglycaemic events was not increased in the BIAsp 70 TID regimen compared with BIAsp 30 BID (18.84 and 21.29 episodes/patient-year respectively, relative risk 0.88, $p=0.4077$).

Conclusion: The glycaemic control of BIAsp 70 TID was demonstrated to be superior to BIAsp 30 BID, without increasing the risk of hypoglycaemia.

Effect of switching from insulin lispro mix 50 to lispro mix 25 at the evening meal during prandial premixed (Lispro/ILPS) therapy (PPT) in type 2 diabetes (T2D) patients

H. Jiang¹, Z. Milicevic², J. Scism-Bacon¹, S. Martin¹

¹Eli Lilly and Company, Indianapolis, United States, ²Eli Lilly and Company, Vienna, Austria

Background and aims: This post-hoc analysis investigated the efficacy and safety of switching from lispro mix 50 (LM50) (50% lispro, 50% insulin lispro protamine suspension [ILPS]) to lispro mix 25 (LM25) (25% lispro, 75% ILPS) at the evening meal during PPT (LM50 tid with meals). The analysis was based on two 24-wk randomized, multicenter, parallel, open-label studies in T2D patients (pts) treated with 0-2 daily insulin injections (1 study) or glargine (1 study) and randomized to PPT tid vs once-daily glargine (+ metformin) or glargine + mealtime lispro (+ oral antihyperglycemic agents). Investigators could substitute LM25 for LM50 at the evening meal at any time during the studies to help achieve fasting plasma glucose (FPG) target of 6.1 mmol/L.

Materials and methods: A total of 138/314 pts (44%) in the PPT arms were switched to LM25 at the evening meal. Analysis of continuous variables was based on ANCOVA, and percentages of pts reaching HbA_{1c} target was based on logistic regression models, with baseline HbA_{1c}, age, BMI and duration of T2D as covariates.

Results: Baseline HbA_{1c} and postprandial glucose (PPG) were higher in pts switched to LM25 at the evening meal than those not switched (Table). Other characteristics were similar. After 24 weeks, improved glycemic control was shown in both groups with significant reductions from baseline in HbA_{1c}, FPG and PPG ($P<0.0001$). There was no significant difference between groups in endpoint total daily insulin dose, however pts switched to LM25 had a higher evening mealtime insulin dose than those not switched (Table). The switched group was associated with greater reduction in HbA_{1c} and higher proportion of pts achieving HbA_{1c} target <7.0%, but with greater risk of hypoglycemia. Four pts in the switched group and 5 in the non-switched group reported severe hypoglycemia.

Conclusion: PPT tid resulted in improved glycemic control for T2D pts who were insulin-naïve or previously treated with insulin, with a large proportion achieving HbA_{1c} target <7.0%. Patients not reaching FPG goals on LM50 tid who were switched to LM25 at the evening meal demonstrated better glycemic control, use of larger evening meal insulin dose, and greater risk of hypoglycemia.

Outcomes of initiating different insulin regimens in patients with type 2 diabetes at the Steno Diabetes Center 2004-2006

E. Eldrup¹, A.D. Toft²

¹Steno Diabetes Center, Gentofte, Denmark, ²Novo Nordisk, Bagsvaerd, Denmark

Background and aims: For patients initiating insulin therapy at the Steno Diabetes Center (SDC) from 2004-2006, standard procedure was starting a regimen of bedtime basal NPH insulin (basal-only therapy, BOT) in addition to oral antidiabetic drugs. Some patients were initiated with premixed insulin (biphasic insulin aspart 30/70 or biphasic human insulin 30/70). We retrospectively analysed insulin regimen and HbA_{1c} measurements over 12 months after insulin initiation.

Materials and methods: During 2004-2006, a total of 621 people in the SDC Type 2 Diabetes Clinic initiated insulin treatment (approximately 50% of the 450 patients referred to the clinic annually). The majority initiated insulin as out-patients (77%, n=479). After initiating insulin therapy with BOT or premix, some patients transferred to the alternative treatment (and in rare cases, transferred back again). Medical records at the SDC were used to assess insulin regimens used and HbA_{1c} values after 4, 8 and 12 months' treatment.

Results: The mean (SD) age of all 621 patients included was 59.4 (13.2) years; duration of diabetes 8.7 (6.4) years; weight 89.1 (21.0) kg and 58% were male. Baseline HbA_{1c} was 9.0 (1.9)% and complications were common: retinopathy 28% of patients, neuropathy 32% and microalbuminuria 35%. The only difference at baseline between patients initiated with premix or BOT was BMI: 29.5 (6.5) and 30.8 (6.2) kg/m², respectively ($p<0.05$). Of the 192 patients initiated with premix, 61 (32%) were in-patients and 131 (68%) out-patients. Of the 429 patients initiated with BOT, 81 (19%, $p<0.001$ vs. premix) were in-patients and 348 (81%) out-patients. The proportion of patients that stayed on their initial therapy was higher for premix (90% and 92% of those initiated as in-patients and out-patients, respectively) than for BOT (60% and 66% of those initiated as in-patients and out-patients, respectively; both $p<0.05$ vs. BOT). For patients who switched from BOT to premix, mean (SD) HbA_{1c} at the time of switching was 8.9 (1.6)%. In 557 patients followed for more than 3 months, the final mean HbA_{1c} was 7.7 (1.4)% (n=345) if premix was their final insulin regimen, compared with 7.6 (1.3)% (n=212) if BOT was their final regimen ($p>0.05$). The proportion of patients reaching HbA_{1c} <7.0% while attending the Type 2 Clinic was 35 vs. 29% for premix and BOT, respectively ($p>0.05$). For patients initiated with premix or BOT, HbA_{1c} of out-patients was lower than that of in-patients at baseline and at 12 months (i.e. all pa-

Table. HbA_{1c} values during 12 months for people with type 2 diabetes who initiated insulin treatment with premix or BOT as in- or out-patients during 2004–2006. Patient data only included until a switch away from original treatment.

tients who *finished* on each regimen) (Table). A small amount of weight gain was seen in patients finishing on premix or NPH-based BOT after 12 months: 3.0 (4.8) kg vs. 3.2 (6.3) kg.

Conclusion: If patients with type 2 diabetes initiate insulin with premixed insulin, approximately 30% more patients will stay on this regimen than if a BOT regimen is initiated, and equally good metabolic control may be obtained within 12 months.

insulin therapy can be made large multi-centre trials are needed with a long follow-up and relevant outcome measures.

Insulin therapy in type 2 diabetes; what is the evidence?

M.J.P. Van Avendonk, K.J. Gorter, M. Van den Donk, G.E.H. Rutten
Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Netherlands

Background and aims: There is no consensus about the insulin regimen to be chosen, in case maximal tolerated dosages of oral blood glucose lowering agents (OHA) are not sufficient to achieve good glycaemic control in type 2 diabetes. Our aim was to systematically review the recent literature regarding insulin therapy (human and analogue), in order to provide the best clinical evidence for prescribing insulin in type 2 diabetes patients.

Materials and methods: A MEDLINE search was performed to identify randomised controlled trials (RCT) published in English between January 1, 2000 and April 1, 2007, involving insulin use in adults with type 2 diabetes mellitus.

Results: The search resulted in 943 hits, 93 RCTs were selected by title. Eventually 67 trials met the inclusion criteria. The studies were very diverse and of different quality. They comprised all possible insulin regimes. We distinguished the following comparisons: 1) combination of insulin therapy with OHA versus insulin monotherapy, 2) long-acting insulin versus another long-acting insulin, 3) premix insulin versus OHA, other premixes or long-acting insulin, 4) preprandial or basal-bolus therapy versus other basal-bolus therapies. Three trials could not be assigned to one of these comparisons. Continuing metformin and/or sulfonylurea after start of therapy with basal long-acting insulin results in better glycaemic control with less insulin requirements, less weight gain and less hypoglycaemic events compared to insulin monotherapy. Long-acting insulin analogues in combination with OHA are associated with similar glycaemic control but fewer hypoglycaemic episodes compared to NPH. Most of the trials demonstrated better glycaemic control with premix insulin therapy than with a long-acting insulin once daily, but premix insulin causes more hypoglycaemic episodes. Analogue premix provides similar improvements in HbA_{1c}%, but lower postprandial glucose levels compared to human premix, without increase in hypoglycaemic events or weight gain. Drawing conclusions from the limited number of studies concerning basal-bolus regimen is not possible, mainly because of its diversity.

Conclusion: A once daily basal insulin regimen added to OHA is an ideal starting point for insulin therapy in type 2 diabetes. All next steps, from one to two or even more injections per day should be taken very carefully and in thorough deliberation with the patient, who has to comply with such a regimen for many years. The clinician should keep in mind that a positive balance between benefits and adverse events is not obvious at all. Insulin analogues may have some small advantages compared to conventional human insulins. However, long-term effects of treatment with these analogues have not been investigated until now. Before any final judgement about relevant effects of

Cost advantages and improved patient treatment satisfaction with insulin glargine in type 2 diabetes patients. The long-acting insulin glargine vs. NPH insulin cost evaluation study in Germany (LIVE-DE)
T. Scholten¹, T. Kohlmann², J. Moock², R. Holle³, W. Landgraf⁴, O. Pirk⁵, H. Hauner⁶

¹Allgemeines Krankenhaus Hagen, University Witten/Herdecke, ²Institute of Community Medicine, University of Greifswald, ³Institute of Health Economics & Health Care Management, Helmholtz Center Munich, ⁴Sanofi-Aventis, Berlin, ⁵IMS Health HEOR, Nürnberg, ⁶Center for Nutrition Medicine, TU Munich, Munich, Germany

Background and aims: Rational decisions for reimbursement of innovative drugs cannot be derived appropriately from randomized clinical trials alone but also require real-life data to demonstrate overall effectiveness and benefits of a drug. Since such data from countries with different healthcare systems cannot be easily transferred to German conditions, real-life data from Germany were collected.

Materials and methods: LIVE-DE was a non-interventional, cross-sectional, retrospective study performed between February and May 2007 in 199 randomly selected centers of primary care physicians in Germany. The study enrolled 1602 consecutive type 2 diabetes (T2D) patients with statutory health insurance status who were eligible for documentation when either treated with insulin glargine (GLA) or NPH insulin based regimens for at least 6 months prior of documentation. Primary objective was to assess total direct diabetes treatment costs (DTC) derived from antidiabetic medications (insulins, OADs), blood glucose self-monitoring (test strips, lancets), hypoglycemic treatment (glucagon use) and needles for a 6 months period under real-life conditions. Secondary objectives included patient reported outcomes (PROs) using established (DTSQs, SF-12, PAID) and a newly developed questionnaire (Insulin Treatment Experience Questionnaire, ITEQ).

Results: Mean total DTC were 658 ± 258 € and 685 ± 242 € per patient during 6 months in GLA and NPH patients, respectively (mean difference -27 €, $p = 0.001$, Wilcoxon Test). Despite higher drug costs for GLA relevant savings were observed in consumption of short-acting insulins (-62 €), test strips (-52 €) and needles (-6 €). GLA patients had also on average fewer basal insulin injections per day (1.09 vs 1.47) and required less blood glucose self-measurements. Glucagon use for treatment of severe hypoglycemic events was only documented for NPH (4 patients). SF-12 and ITEQ results showed that GLA patients reported significantly better physical well-being and higher satisfaction with insulin treatment. In addition, DTSQs scores indicated slightly better treatment satisfaction in GLA vs NPH insulin users. General need of care, number of referrals, hospital admissions, glycemic control and demographics were similar in both groups, but NPH was mainly used in a basal-bolus (79%) whereas GLA was frequently prescribed in a basal/OAD (BOT) regimen (43%). After statistical adjustment of these factors, total DTC per patient during 6 months in GLA users were slightly increased compared to NPH (adjusted mean +73 €, $p < 0.001$, ANCOVA) but improved patient satisfaction with GLA remained significant.

Conclusion: Under real-life conditions total DTC are similar in GLA and NPH T2D patients while patient treatment satisfaction is higher with GLA. LIVE-DE provides new evidence to the German healthcare system demonstrating that treatment preferences and reimbursement decisions should adopt a comprehensive perspective including all relevant cost categories and PROs.

1001

2-year glycaemic control after initiation of insulin glargine or NPH insulin in type 2 diabetes

J.L. Leahy¹, M.-P. Dain², G.G. Rhoads³, L. Kennedy⁴

¹Endocrinology, Diabetes and Metabolism, University of Vermont College of Medicine, Burlington, United States, ²sanofi-aventis, Paris, France, ³School of Public Health, University of Medicine and Dentistry of New Jersey, Piscataway, United States, ⁴Shands Hospital, University of Florida, Gainesville, United States

Background and aims: To compare 2-year glycemic control, hypoglycemia rates, and health care costs associated with insulin glargine versus NPH insulin in patients with T2DM in a real world setting.

Materials and methods: Retrospective observational analysis from a large US managed care database of patients diagnosed with T2DM between 2001 and 2005. Patients who had failed treatment with oral antidiabetic drugs (OADs) initiated glargine ($n=2,105$) or NPH ($n=734$) in addition to OADs, with continuous plan enrollment for >18 months (6 months before and at least 12 months after insulin initiation), and with available A1C values from a central laboratory were evaluated. The analysis controlled for baseline demographics, A1C, comorbidities, health care utilization, pharmacy copayment, and follow-up antidiabetic medications. Costs were evaluated using actual paid claims by health insurance, adjusting for inflation to the most current year value.

Results: Patients at baseline had the same mean age of 54 years, and no difference in medical insurance claims for hypoglycemia (3.2% vs. 4.3% in glargine vs NPH initiators, respectively). There were differences between glargine and NPH groups at baseline between sex (44% vs. 52% female), baseline A1C (9.3% vs. 8.9%), access to endocrinologist (36% vs 46%), average number of OADs (2.3 vs. 2.0), Charlson comorbidity score for overall comorbidities (0.64 vs 0.82), and 6-month total healthcare costs (\$8,797 vs \$12,924). Differences in baseline characteristics were controlled for in the analyses. Adjusted 1-year mean A1C was 8.05 vs 8.51% ($\delta=-0.45$, $p=0.0036$) and 2-year mean A1C was 8.03 vs 8.37% ($\delta=-0.33$, $p=0.0099$) for glargine and NPH, respectively. In the last quarter of the 2-year follow-up period, 16.6% in the NPH group filled a prescription for insulin glargine, whereas 2.7% in the glargine group filled a prescription for NPH insulin. Adjusted rate of patients per quarter in the first year with medical claims for hypoglycemia was 1.7 vs. 2.9% ($\delta=-1.2$ %, $p=0.0559$) and 2-year quarterly rate was 1.55 vs. 2.51% ($\delta=-0.96$ %, $p=0.0139$). Adjusted 1-year total healthcare costs were \$16,184 vs. \$21,104 (quarterly $\delta=-\$1,034$, $p=0.0372$) and 2-year costs was \$30,032 vs. \$42,208 (quarterly $\delta=-\$1,522$, $p=0.0029$) (Table).

Conclusion: This analysis from real-world clinical practice indicates that initiation of insulin glargine, relative to NPH, was associated with sustained improvements in glycemic control with lower rate of medically claimed hypoglycemia and lower total healthcare expenditures in patients with T2DM.

Adjusted Total Health Care Costs in Patients Initiating Therapy With Insulin Glargine vs NPH Insulin

Health Care Costs	Insulin Glargine (n=2105)	NPH Insulin (n=734)	Quarterly Difference	P Value
1-year	\$16,184	\$21,104	\$1034	0.0372
2-year	\$30,032	\$42,208	\$1522	0.0029

A cost-effectiveness analysis of continuous subcutaneous insulin injection vs. multiple daily injections in type 1 diabetes patients: an Italian perspective

P. Lynch¹, S. Giardina², A. Nicolucci³, P. Ponzi², M. Orsini Federici², M.E. Minshall⁴

¹Health Economics, Medtronic Diabetes, Northridge, United States, ²Medtronic Italia SPA, Sesto San Giovanni, Italy, ³Department of Clinical Pharmacology and Epidemiology, Consorzio Mario Negri Sud, S. Maria Imbaro, Italy, ⁴Health Economics and Outcomes Research, IMS Health, Noblesville, United States

Background and aims: The objective of this study was to project long term costs and outcomes for continuous subcutaneous insulin infusion (CSII) compared with multiple daily injections (MDI) of insulin in adult type 1 diabetes mellitus (T1DM) patients in Italy from the National Health Service (NHS) perspective.

Materials and methods: The CORE Diabetes Model (CDM) was used to determine the incremental cost-effectiveness ratio (ICER) of CSII compared with MDI among adult patients with T1DM in Italy. The primary input variable was change in HbA_{1c} and was assumed to be a 1.2% improvement for CSII as compared to MDI in a cohort of Italian T1DM patients with an average HbA_{1c} baseline value of 8.95%. Based on existing evidence, it was also assumed that CSII patients had 50% less hypoglycemic events compared with MDI patients. A series of Markov constructs simulated the progression of diabetes-related complications. The average annual cost for CSII and MDI were €5,699.20 and €2,734.71, respectively. The cost of pump, procedures, complications, and optimal drug therapy were derived from Italian-specific

sources and other published data. A 60-year time horizon and a discount rate of 3.0% *per annum* on costs and clinical outcomes were used.

Results: Treatment with CSII was associated with improvements in life expectancy of 0.893 years vs. MDI and quality adjusted life expectancy (QALE) of 0.974 years vs. MDI with corresponding ICERs of €36,803 per life-year and €33,751 per quality-adjusted life year (QALY) gained for CSII compared with MDI. Improved glycemic control from CSII treatment led to a lower incidence of diabetes complications. The cumulative incidence of proliferative diabetic retinopathy (PDR) was reduced by 27% (relative risk [RR] = 0.728) with a number needed to treat (NNT) of 11 patients to avoid one case of PDR. The cumulative incidence of end-stage renal disease (ESRD) was reduced by 18% (RR=0.816) with a NNT of 22 patients to avoid one case of ESRD. Finally, findings for cardiovascular complications showed that the cumulative incidence of peripheral vascular disease (PVD) was reduced by 14% (RR=0.856); with a NNT of 46 patients to avoid one case of PVD.

Conclusion: Setting the willingness to pay at €40,000/QALY (based on a £30,000 NICE threshold), the analysis demonstrated that CSII is a cost-effective treatment option when compared to MDI for adult patients with T1DM in Italy.

1003

Glycaemic control and costs with insulin glargine plus glulisine versus premix - a randomized, prospective, observational study

F. Lee¹, Q. Zhang², J. Mersey¹, L. Bromberger¹, M. Bhushan³, R. Bhushan³, P. Levin¹

¹Diabetes, Model Clinical Research, Baltimore, ²sanofi-aventis, United States, Bridgewater, ³Diabetes, Metabolic Center Of Louisiana Research Foundation, Baton Rouge, United States

Background and aims: Despite extensive use of basal-bolus and premixed analog insulin therapy, real-world comparative effectiveness of the regimens has not been determined.

Materials and methods: Patients with T2DM at 2 US endocrinology practice centers were randomized to GLAR/GLU (n=106) or analog premix (n=91). Subsequent to randomization, patients continued treatment following center's usual practice with no additional therapeutic protocols. Data collected at 0, 3, 6 and 9 months included A1C, hypoglycemia, insulin dose, concomitant medications, and therapy change. Medication costs were estimated using published average wholesale price.

Results: Treatment groups were comparable at baseline with mean age 56 years, 46% male, 59% Caucasian, and 38% African-American, duration of diabetes 13 years, A1C 9.25%, and BMI 35.8kg/m². During 4 months before randomization, 88% used insulin with mean daily dose of 71IU, about 70% of patients used oral hypoglycemic agent(s) and 29% had chart records for hypoglycemia. Mean follow-up time was 183 days. 1 patient (1%) randomized to GLAR/GLU switched to premix therapy relative to 9 (10%) randomized to premix switched to GLAR/GLU. In ITT analysis, adjusted mean follow-up A1C was 6.98% in GLAR/GLU vs. 7.57% in premix (δ =−0.59%, p =0.009) and A1C reduction was 2.27% (95% CI: 1.63–2.91) vs. 1.68% (1.20–2.16). Mean number of concomitant oral anti-diabetic agents were 0.94 vs. 1.22 (δ =−0.28, p =0.041). Mean daily insulin dose was 74IU vs. 85IU (δ =−11, p =0.267). Hypoglycemia was recorded in charts for 36% vs. 43% (δ =−7%, p =0.374) patients in GLAR/GLU vs. premix. Daily costs for all anti-diabetic medications were \$10.82 for GLAR/GLU vs. \$12.06 in premix (δ =−\$1.24, p =0.209). For each additional 1% A1C reduction during the follow-up period (178 days), GLAR/GLU saved \$225.54 compared to diabetes treatment cost for premix (\$1933.20 vs. \$2158.74)

Conclusion: Glargine plus glulisine, compared to analog premix, produces improved glycemic control with no increased medication costs.

1004

The relative cost effectiveness of insulin glargine versus detemir insulin using UK real life data in patients with type 2 diabetes mellitus

A.P. Tetlow, P. McEwan, J. Gordon

CRC, Cardiff Research Consortium, United Kingdom

Aims: The purpose of this study was to evaluate the cost effectiveness of insulin glargine compared with insulin detemir in Type 2 diabetes mellitus (T2DM) patients newly initiating insulin treatment using observational data collected from general practices throughout the UK.

Methods: Data used for this study was the THIN (The Health Improvement Network) database, a UK primary care database including 2,335,667 active patients recorded over 15 years from 211 practices. Subjects were identified with T2DM, no prior insulin history, who had received at least 12 months of oral therapy, 35 years of age and older, with a baseline HbA_{1c} >=6.5% and initiated on either glargine (n=2197) or detemir (n=357). Effectiveness, measured by changes in HbA_{1c} over a 12 month period following initiation, was standardised to adjust for differences in insulin units per kg prescribed. Data analysis was undertaken using a hierarchical linear mixed-effects model with dose-adjusted change in HbA_{1c} as the dependent variable adjusting for baseline HbA_{1c}, hypoglycaemia, number of oral antidiabetic drug (OAD) prescriptions, insulin type, mean increase in HbA_{1c} in the year prior to insulinisation, prior co-morbidities, concurrent bolus usage and disease duration as fixed-effect covariates with general practice modelled as a grouping variable. A published discrete event simulation model based on the UKPDS 68 study was used to model macrovascular and microvascular complications over a 40 year time horizon. Direct costs and quality of life (EQ5D) were taken from published sources and the HODaR database respectively. Costs and benefits were discounted annually at 3.5%.

Results: Overall baseline demographic and risk factor profiles were similar in the glargine and detemir groups. Mean age was 61 years versus 59 years; proportion male was 45% versus 47%; mean weight was 85.8kg versus 85.5kg; duration 6.2 years versus 5.7 years and baseline HbA_{1c} 9.66% versus 9.53% in the glargine and detemir cohorts respectively. Compared with detemir, glargine patients showed a superior reduction in HbA_{1c} by 0.29% (p =0.021) over the 12 months following insulinisation. Over the 12 month period mean insulin units per kg per day were 0.53 for glargine and 0.56 for detemir. Insulin costs were the same per unit of effectiveness for glargine and detemir. Mean OAD prescriptions over the 12 months post insulinisation were identical for both insulin preparations. Incorporating this into a simulated cohort of 10,000 patients followed over a 40 year time horizon translated into 139 fewer cardiovascular events. For glargine and detemir discounted cost per patients was £6,536 and £6,556 respectively; quality adjusted life years (QALYs) were 7.71 and 7.64 for glargine and detemir respectively. This resulted in a dominant (more effective and cost saving) discounted incremental cost effectiveness ratio.

Conclusion: This study sought to characterise the real life observational profile of glargine and detemir usage in insulin naïve T2DM patients and to assess the relative cost-utility of the decision to either initiate patients on glargine or detemir. In this context, and after adjusting for available confounding variables, glargine was more effective with marginal cost savings.

Comparative analysis of treatment outcomes of patients on insulin detemir and insulin glargine

B. Alemanyeh¹, B. Borah², H. Henk², M. Aagren³, F. Forma¹

¹Novo Nordisk Inc., Princeton, United States, ²i3 innovus, Eden Prairie, United States, ³Novo Nordisk Inc., Virum, Denmark

Background and aims: The primary aim when prescribing insulin is to effectively lower blood glucose level, HbA_{1c}. The objective of reducing HbA_{1c} is limited by the threshold for acceptable hypoglycaemic event rates, and this tolerability level and the dose applied to achieve glycaemic control are key determinants of the costs related the medical treatment. Thus these parameters are important in decision of therapy. This study was undertaken to assess differences in glycaemic control, overall and diabetes-related costs of type 2 diabetes patients treated with basal analog insulins (i.e. insulin detemir, IDet, and insulin glargine, IGLar) using retrospective data of patients enrolled in a large US health plan with medical and pharmacy benefits.

Methods: Patients were identified if their first prescription claim (index) for IDet or IGLar occurred between 05/01/2006 and 12/31/2006. Eligible patients were required to be age 18 or above, have 6 months of continuous enrollment of the health plan pre- and post-index date, no evidence of any insulin use during pre-index and an HbA_{1c} reading during both the pre- and post-index period. Patients were excluded from the analysis if they were treated with other insulins than basal analog insulin. Thus, only insulin naïve patients starting on IDet or IGLar (\pm oral antidiabetics) are included. Primary outcomes include daily average consumption (DACon) of IDet or IGLar, change in HbA_{1c}, and overall and diabetes-related costs. Differences in outcomes between IDet and IGLar users were adjusted for baseline characteristics through generalized linear modeling (GLM). Propensity score matching was used to reduce selection bias between the two groups.

Results: There were 48 basal IDet patients and 258 IGlur patients in the study. There was no significant difference in adjusted DACON or HbA_{1c}, between IDet and IGlur cohorts. However, adjusted diabetes-related costs and total medical costs for IDet cohort were lower than the IGlur cohort (\$2,262 vs. \$3,409; $p<0.03$) and (\$707 vs. \$1,510, $p<0.03$) respectively. Adjusted overall medical costs were not statistically different, but the trend also suggested lower costs for the IDet cohort (\$2,319 vs. \$3,704; $p=0.07$). No differences in overall or diabetes-related pharmacy costs were observed.

Conclusion: No significant difference in DACON or HbA_{1c} measures and no significant difference in adjusted pharmacy cost between insulin detemir and insulin glargine users were observed during the study period. However, insulin detemir patients experienced a significantly lower diabetes-related and overall adjusted medical cost during the follow up period.

Post-intervention adjusted treatment outcomes between insulin detemir and Insulin glargine

Outcomes	insulin detemir (N=48)	insulin glargine (N=258)	P-Value
Average Daily Consumption (DACON)	29.31	29.59	0.937
HbA _{1c} Level	8.24	7.92	0.152
Follow-up total cost	\$ 6,014	\$ 7,023	0.268
Follow-up medical cost	\$ 2,319	\$ 3,704	0.071
Follow-up pharmaceutical cost	\$ 3,074	\$ 2,899	0.452
Follow-up diabetes-related total cost	\$ 2,262	\$ 3,409	0.033
Follow-up diabetes-related medical cost	\$707	\$ 1,510	0.026

Open label study to assess the safety, pharmacokinetics (PK) and pharmacodynamics (PD) of five oral insulin formulations in healthy subjects

M. Kidron^{1,2}, I. Raz¹, M. Wolfensberger³, K. Kessler³, H. Shwob³, C. Schrufer³

¹Diabetes Unit, Hadassah Hebrew University Hospital, Jerusalem, Israel,

²Clinical Research, Oramed Pharmaceuticals, Jerusalem, Israel, ³R&D, Swiss Caps AG, Kirchberg, Switzerland

Background and aims: To evaluate the difference of activity as well as safety, pharmacokinetics and pharmacodynamics of five oral insulin formulations

Materials and methods: Eight subjects completed the study which consisted of 5 visits. During each of the visits, the subjects were given a different formulation of the oral insulin capsule. All of the formulations contained 8mg of insulin. Subjects received the drug in the morning after an overnight fast. The treatments were separated by a 72 to 96 hour washout period. Individual blood samples (29 totals) for PK/PD analysis were collected up to 5 hours post-dose. Glucose, insulin and c-peptide levels were measured.

Results: Administration of an oral form of insulin in the fasted state demonstrated a significant decrease in c-peptide levels in all formulations (16%-92%) as well as reduction in blood glucose (7%-32%). All of the formulations were well tolerated by the volunteers, and no serious adverse events have been reported.

Conclusion: The results of this study gave a positive indication for the final formulation of oral insulin. This study showed that there was a biological active absorption of oral insulin in healthy volunteers. Phase IIa study, has commenced in order to assess the clinical potential of the oral insulin formulation, in type 2 diabetic volunteers

Pramlintide or mealtime insulin added to basal insulin treatment in patients with type 2 diabetes

M. Riddle¹, R. Pencek², S. Charenkavanich², K. Lutz², L. Porter², K. Wilhelm²

¹Internal Medicine, Oregon Science & Health University, Portland, ²Amylin Pharmaceuticals, Inc., San Diego, United States

Background and aims: Intensification of basal insulin therapy with mealtime insulin can improve glycaemic control in patients with type 2 diabetes, but is often accompanied by an increased risk of hypoglycaemia and weight gain. The addition of pramlintide (PRAM) to basal insulin has also been demonstrated to improve glycaemic control and has been associated with reduced body weight and no increase in the risk of hypoglycaemia. This randomised, open-label, 24-week, multicenter study compared the efficacy and safety of the addition of mealtime PRAM or rapid-acting insulin (RAI) to basal insulin in patients with type 2 diabetes (N=112; age 54±11 y, duration of diabetes 9±6 y, HbA_{1c} 8.3%±0.8%, FPG 8.9±2.5 mmol/L, BMI 36±6 kg/m²; mean±SD).

Materials and methods: Patients were either insulin-naïve (52% PRAM, 57% RAI) or on insulin therapy for <6 months and taking <50 U/day (20±10 U/day PRAM, 24±12 U/day RAI); prior OADs were continued. Basal insulin (glargine or detemir) dosage was titrated from Day 1 seeking an FPG ≥3.9 to <5.5 mmol/L in both treatment groups. PRAM treatment (fixed dose; 120 µg), which alone does not cause hypoglycaemia, was started at Day 1, whereas RAI treatment (titrated to effect) was started at Week 4 to allow initial basal insulin dose titration without added risk of mealtime insulin-induced hypoglycaemia.

Results: PRAM and RAI resulted in similar and significant mean (±SE) HbA_{1c} reductions (-0.9±0.2% vs. -1.1±0.2%) and similar FPG (6.7±0.4 mmol/L vs. 6.8±0.3 mmol/L) at Week 24. The percent patients achieving an HbA_{1c} of ≤7% or ≤6.5% with PRAM was 45% and 29%, respectively, compared to 55% and 32% with RAI. Basal insulin doses at Week 24 were 52±4 U (PRAM) and 57±4 U (RAI). RAI dose was titrated to 37±3 U by Week 24, resulting in a total daily insulin dose of 94±7 U. Weight gain was associated with RAI treatment (+4.2±0.6 kg), but not with PRAM treatment (-0.3±0.7 kg; $p<0.0001$ vs. RAI). Incidence of hypoglycaemia was lower with PRAM compared to RAI (55% vs. 82%); no severe hypoglycaemic events were reported. PRAM was associated with a higher incidence of nausea (21% vs. 0%; primarily mild in

intensity). More patients treated with PRAM vs. RAI (30% vs. 11%; $p < 0.05$) achieved the primary composite endpoint of $HbA_{1c} \leq 7\%$ with no increase in body weight and no severe hypoglycaemia.

Conclusion: A fixed dose of pramlintide resulted in similar improvements in glycaemic control to titrated rapid-acting insulin when added to basal insulin therapy, and compared to mealtime insulin, a lower risk of hypoglycaemia and no weight gain.

Continuous subcutaneous pramlintide infusion (CSPI) therapy in patients with poorly controlled type 1 diabetes: data from a Pilot Study

D.M. Huffman, G.W. McLean

Diabetes, University Diabetes & Endocrine Consultants, Chattanooga, United States

Background and aims: Pramlintide acetate, an amylin analog approved for premeal injection in patients with type 1 diabetes mellitus (T1DM), reduces postprandial blood glucose excursions, A1C and body weight. Since amylin is normally co-secreted from beta cells in a basal-bolus manner, we investigated the efficacy and safety of continuous subcutaneous (SC) pramlintide infusion (CSPI) in patients with T1DM.

Materials and methods: A 16-wk, open-label, single-arm pilot study enrolled patients ($n=11$, mean \pm SD; age 39.0 ± 4.0 y, A1C $8.20 \pm 0.60\%$, wt 92.3 ± 18.4 kg, BMI 29.7 ± 5.1 kg/m²) with long-term T1DM (20.7 ± 1.3 y) and inadequate blood glucose (BG) control despite long-term insulin pump therapy (duration of pump therapy 9.5 ± 6.0 y, total daily insulin dose 74.1 ± 41.9 U, total basal 26.6 ± 10.3 U; total bolus 47.5 ± 31.9 U). Subjects initiated pramlintide using a separate continuous SC infusion (Animas® 2020 insulin pump) at a basal rate of $9 \mu\text{g/hr}$ (1.5 U/hr). After 3 days of basal pramlintide therapy, premeal boluses were initiated at $15 \mu\text{g}$ (2.5 U) and titrated in $15 \mu\text{g}$ increments to $60 \mu\text{g}$ (10 U) per meal. Basal insulin doses were reduced 10% upon initiation of basal CSPI; insulin boluses were reduced ~10% upon beginning bolus pramlintide therapy. Basal and bolus insulin doses were adjusted weekly to safely improve glycemic control. A meal tolerance test (MTT) was performed at baseline and after 16 wks of pramlintide therapy. Three days of continuous glucose monitoring (CGM), were performed at baseline and following 4 and 16 wks of pramlintide therapy.

Results: After 16 wks pramlintide therapy, mean \pm SD) A1C decreased to $7.85 \pm 0.74\%$ (0.35%). Mean fasting glucose fell from 198.2 ± 66.9 to 135.8 ± 63.9 mg/dl by wk 16. Mean daily glucose measured by CGM decreased from 155.8 ± 34.6 mg/dl pre-CSPI to 139.8 ± 19.7 at wk 16 of CSPI. Glucose variability measured by MAGE from CGMS data decreased from 95.7 ± 26.7 mg/dl to 82.7 ± 23.0 by week 16. Weight declined to 91.8 ± 20.1 kg (-0.5 kg) and waist circumference decreased from 99.9 ± 13.4 cm to 93.8 ± 14.6 cm by wk 16. Mean BMI was 29.5 ± 5.6 kg/m² at wk 16. After 16 wks of CSPI, mean insulin:CHO ratio was 20% lower than baseline, basal insulin doses remained unchanged (27.7 ± 11.7 U) and total daily insulin dose decreased 20% to 60.2 ± 28.4 U. Triglycerides fell from 172 ± 154 mg/dl to 92 ± 54 mg/dl; total cholesterol decreased from 198.9 ± 28.5 to 155.82 ± 36.0 mg/dl; and LDL-C decreased from 113.0 ± 35.5 to 91.3 ± 30.1 mg/dl at wk 16. MTT after 16 wks of CSPI demonstrated reduced and delayed postprandial glucose excursions and delayed triglyceride excursions. All subjects experienced mild postprandial hypoglycemia during the study period, but no severe hypoglycemia was reported. Three of eleven subjects experienced mild nausea upon beginning basal CSPI, but all subjects successfully titrated bolus doses to $60 \mu\text{g}$ within three wks.

Conclusion: In this pilot study in subjects with T1DM treated with insulin pumps, CSPI was well tolerated, improved A1C and postprandial glucose excursions, and produced favorable changes in body weight and lipids. Subjects reported improved well-being during CSPI and a majority wished to continue CSPI after study end. Further investigation of CSPI will be needed to fully assess the advantages, optimal dosages and long-term efficacy of this therapy. Supported by: Amylin Pharmaceuticals Inc.

Pharmacokinetics, pharmacodynamics, safety and tolerability of pramlintide in adolescent subjects with type 1 diabetes

G. Lorenzi¹, P. Chase², B. Zhang¹, R. Pencsek¹, K. Lutz¹

¹Amylin Pharmaceuticals, Inc., San Diego, ²Pediatrics, University of Colorado Health Science Center, Denver, CO, United States

Background and aims: Pramlintide improves glycaemic control in adult subjects with diabetes by reducing postprandial glucagon secretion, slowing gastric emptying, and reducing food intake. Pramlintide has not previously been investigated in adolescent subjects. The present randomised, single-blind, dose-rising, placebo-controlled, crossover study evaluated the pharmacokinetics, pharmacodynamics, safety and tolerability of pramlintide in adolescent subjects (12–17 y) with type 1 diabetes.

Materials and methods: Subjects (9F:3M; 15 y; HbA_{1c} 8.4%, BMI 25 kg/m^2) were randomised to 1 of 3 treatment sequences of study medication ($15 \mu\text{g}$ pramlintide, $30 \mu\text{g}$ pramlintide, or placebo), which was administered as a single SC dose at each of 3 study-site visits just before a standardised breakfast. Insulin lispro (50% of usual mealtime dose) was injected separately. Acetaminophen (1000 mg) was administered orally after the first bite of the meal to measure gastric emptying rates.

Results: In 9 evaluable subjects, plasma pramlintide concentrations increased dose-proportionately, mean C_{max} was reached ~15 min (median T_{max}) after administration, and concentrations then declined in parallel. Incremental plasma glucagon AUC_{0-3h} and glucose AUC_{0-3h} were reduced with pramlintide vs. placebo. Acetaminophen C_{max} was decreased with pramlintide vs. placebo, and pramlintide delayed the median T_{max} by ~2.5–3.8-fold.

Conclusion: Pramlintide was well tolerated, and there were no treatment-related adverse events in this study.

Pharmacokinetic and Pharmacodynamic Results

	Placebo	Pramlintide 15 μg	Pramlintide 30 μg
Plasma Pramlintide			
$AUC_{0-\infty}$ ($\text{pg} \cdot \text{hr/mL}$)		98 ± 31	251 ± 151
C_{max} (pg/mL)		100 ± 28	218 ± 70
Median T_{max} (min)		17	15
Plasma Glucagon Incremental	34.5 ± 27.9	3.7 ± 19.8	5.1 ± 21.1
AUC_{0-3h} ($\text{ng} \cdot \text{hr/L}$) (95% CI difference)		(-44.7, -8.1)	(-60.4, -21.9)
Plasma Glucose Incremental	12 ± 9	7 ± 7	7 ± 6
AUC_{0-3h} ($\text{mmol} \cdot \text{hr/L}$) (95% CI difference)		(-13 \pm 2)	(-12 \pm 4)
Plasma Acetaminophen			
AUC_{0-3h} ($\mu\text{mol} \cdot \text{hr/L}$)	326.3 ± 78.6	338.0 ± 75.0	316.5 ± 67.8
C_{max} ($\mu\text{mol/L}$) (95% GCIR)	85.2 ± 23.8	77.3 ± 29.5 (4.2 \pm 7.3)	62.8 ± 13.4 (3.7 \pm 6.6)
Median T_{max} (min)	47	120	180

All data are mean \pm SD unless otherwise indicated; the 95% confidence interval (CI) difference for pramlintide vs. placebo is indicated for the plasma glucagon and glucose parameters; the geometric 95% confidence interval ratio (GCIR) for pramlintide vs. placebo is indicated for the acetaminophen parameter; each subject received one dose of study medication per visit (Visits 2, 3, 4); the time interval between Visits 2 and 4 was ≤ 5 weeks; the time interval between Visits 2, 3, and 4 did not need to be evenly spaced; for any visits that occurred on consecutive days, the time interval between the two doses of study medication was >24 hours.

Pramlintide reduced postprandial glucagon and glucose excursions and slowed gastric emptying in adolescent subjects with type 1 diabetes, similar to what has been observed in adults. These effects were observed in the absence of treatment-related adverse events. Long-term studies evaluating the efficacy and safety of pramlintide in adolescents are warranted.

1010

Pramlintide, as an adjunct to premixed insulin, reduced HbA_{1c} and body weight in patients with type 2 diabetes

T. Darsow, G. Lorenzi, B. Zhang, H. Maier, K. Wilhelm
Amylin Pharmaceuticals, Inc., San Diego, United States

Background and aims: Pramlintide, as an adjunct to mealtime insulin, reduces HbA_{1c}, glucose fluctuations and body weight in patients with type 2 and type 1 diabetes. A significant percentage of patients with diabetes choose a premixed insulin formulation over basal + bolus insulin therapy as a means of simplifying their treatment regimen.

Materials and methods: The present post-hoc analysis of an open-label study examined the effects of pramlintide over 26 weeks in a subset of patients with type 2 diabetes using premixed insulin (70/30 or 75/25) (N=28, age 56±9 y, DM duration 13±5 y, HbA_{1c} 8.1±1.2%, postprandial glucose [PPG] concentration 11.6±3.4 mmol/L, BMI 39±6 kg/m², weight 112±23 kg, daily insulin dose 88±47 units; mean±SD). Outcome measures included changes from baseline in HbA_{1c}, PPG concentrations, body weight, daily insulin doses, and safety.

Results: After 26 weeks of pramlintide therapy (120 µg administered subcutaneously either two or three times daily with major meals), a mean (±SE) change in HbA_{1c} of -0.66±0.14% (95% CI: -0.97, -0.36) was observed. Mean (±SE) PPG concentrations were reduced from baseline by 1.2±0.8 mmol/L despite significant reductions in mean (±SE) daily insulin doses (-9.1±3.9% [95% CI: -17.1, -1.2]). Pramlintide treatment also resulted in a significant and progressive reduction from baseline in mean (±SE) body weight (-4.1±0.8 kg [95% CI: -5.7, -2.4]) at Week 26. Pramlintide was generally well tolerated. Nausea (29%) and hypoglycaemia (11%) were mostly mild-to-moderate in intensity. No events of severe hypoglycaemia occurred.

Conclusion: In summary, pramlintide treatment resulted in significant reductions from baseline in HbA_{1c}, daily insulin doses, and body weight in patients using premixed insulin. These results suggest that patients with type 2 diabetes who are not achieving optimal glycaemic control with premixed insulin may experience glycaemic improvements and weight loss with adjunctive pramlintide therapy.

1011

Pramlintide improved glycaemic control and reduced weight in patients with type 2 diabetes treating to target with basal insulin

K. Wilhelm¹, M. Riddle², B. Zhang¹, H. Maier¹, O. Kolterman¹

¹Amylin Pharmaceuticals, Inc., San Diego, ²Internal Medicine, Oregon Science & Health University, Portland, United States

Background and aims: As HbA_{1c} approaches 7%, the relative contribution of fasting plasma glucose (FPG) to elevated glycaemia (HbA_{1c}) decreases and the contribution of postprandial glucose (PPG) increases. While basal insulin can effectively control FPG, pramlintide, an analog of the β-cell hormone amylin, reduces PPG.

Materials and methods: To explore the effect of pramlintide on glycaemia in patients achieving a FPG target, a post hoc analysis of a 16-week, double-blind, placebo-controlled, randomised study was performed in a subset of patients achieving a FPG <6 mmol/L at Week 16 with insulin glargine titration (target FPG 4–6 mmol/L) and pramlintide (120 µg) or placebo with major meals.

Results: Patient (pramlintide, n=28; placebo, n=33) characteristics were well balanced between groups (age 56±8 y, DM duration 11±6 y, BMI 35±5 kg/m²; mean±SD).

In the subgroup of patients achieving a FPG <6 mmol/L at Week 16, FPG reductions were achieved with moderate increases in daily insulin doses in both groups. Pramlintide reduced PPG increments compared to placebo. Pramlintide reduced HbA_{1c} to a greater extent than placebo and to a greater extent than what was observed in the population as a whole. More patients in this subgroup achieved an HbA_{1c} ≤7.0% with pramlintide vs. placebo (43% vs. 27%). As was observed in the total population, improvements in glycaemia were accompanied by progressive weight loss with pramlintide and weight gain with placebo. Pramlintide was generally well tolerated. The most frequent adverse events were mild to moderate hypoglycaemia (pramlintide 57%; placebo 55%) and nausea (pramlintide 39%; placebo 18%). No severe hypoglycaemia occurred.

Conclusion: In patients attaining target FPG concentrations with basal insulin titration, pramlintide led to additional improvements in postprandial glucose increments and HbA_{1c} compared with titration of basal insulin alone.

These effects were achieved with weight loss and without an increased risk of hypoglycaemia.

Inhaled insulin: safe and efficacious administration with a commercially available dry powder inhaler

L. Heinemann¹, A. Brugger², C. Cook², U. Eckers¹, A. Hutchcraft²,

L. Nosek¹, K. Rave¹, J. Troeger², P. Valaitis², T. Heise¹

¹Management, Profil Inst. für Stoffwechselforschung, Düsseldorf, Germany,

²Research, Baxter Healthcare Corporation, Round Lake, United States

Background and aims: Inhaled insulin is usually delivered with specifically developed inhalers, which are often large and not easy to handle. In this study we investigated the PK, PD and safety of recombinant human insulin inhalation power (RHIIP) manufactured using PROMAXX technology, which allows formation of uniform protein microspheres.

Methods: RHIIP was administered with a small commercially available dry powder inhaler (DPI). Thirty healthy male subjects (30±1.1 years (mean±SEM), BMI 24.2±0.3 kg/m²) in a randomized crossover study received 10 IU human regular insulin sc (sc RHI) and 6.5 mg of RHIIP (187 IU) delivered via the CyclohalerTM under euglycemic glucose clamp conditions. Subjects were trained to inhale RHIIP with an inhalation flow rate of 90±30 L/min prior to dosing.

Results: Inhalation of RHIIP was well tolerated with no episode of cough or shortness of breath. RHIIP showed a faster onset of action than sc RHI (time to reach 10% of total area under the glucose infusion rates (GIR) curves 73±2 vs 95±3 min; GIR-tmax 173±13 vs 218±9 min, p<0.0001) (s. Figure). Duration of action (371±11 vs 366±7 min) and total metabolic effect (GIR-AUC0-10h 2734±274 vs 2482±155 mg/kg) were comparable. PK results were in accordance with these PD findings: RHIIP was absorbed faster (time to reach 10% of total area under the insulin curves 44±3 vs 66±3 min, p<0.0001), and maximum insulin levels were reached earlier (86±10 vs 141±12 min, p=0.002). Relative BA of RHIIP was 12±2%; relative BP was 6±1%.

Conclusion: In this study, PROMAXX technology allowed for safe and efficacious administration of human insulin powder to the deep lung with an off-the-shelf DPI designed for upper airway drug delivery. RHIIP showed a fast onset of action and BA comparable to that reported for other inhaled insulin formulations using specifically designed devices. Thus, RHIIP seems to have the potential to achieve even higher BA through further improvements in the insulin delivery technique.

Technosphere insulin: defining the mechanism of action

R. Angelo, K. Rousseau, M. Grant, A. Leone-Bay, P. Richardson
MannKind Corporation, Paramus, United States

Background and aims: Technosphere Insulin is a novel dry powder formulation of insulin adsorbed to Technosphere microparticles for pulmonary delivery. Technosphere Insulin delivers insulin to the blood stream with a pharmacokinetic profile (time to maximum concentration, approximately 13–15 minutes) that closely mimics early endogenous insulin release. Technosphere Insulin is composed of insulin and fumaryl diketopiperazine (FDKP), a proprietary excipient. To characterize the role of FDKP in insulin absorption, Calu-3 cells (bronchial cells) were exposed to either Technosphere Insulin solutions or a panel of known penetration enhancers.

Materials and methods: Monolayers of Calu-3 cells were treated for up to 2 hours with Technosphere Insulin, capric acid, deoxycholate, and various surfactants. Exposure to capric acid, deoxycholate, and the surfactants disrupted the actin cytoskeleton of the cells and increased the permeability of Lucifer yellow, an accepted paracellular transport marker.

Results: Technosphere Insulin had no detectable impact on either the actin cytoskeleton or Lucifer yellow permeability. Additionally, Technosphere Insulin did not reduce monolayer integrity (measured by transepithelial electrical resistance) or promote cytotoxicity (lactate dehydrogenase assay). Incubation of both Calu-3 and A549 alveolar cells with fluorescently labeled insulin in the presence of FDKP revealed no visible intracellular insulin accumulation. In contrast, treatment with penetration enhancers capric acid (17 mM) or digitonin caused significant accumulation of the fluorescently labeled drug. These experiments demonstrate that Technosphere Insulin does not compromise either tight junctions or the plasma membrane. Finally, cellular permeability of insulin and solutions of insulin formulated as Technosphere Insulin were comparable in Calu-3 monolayers, indicating that FDKP does not facilitate insulin absorption.

Conclusion: Together, these data suggest that FDKP is not a penetration enhancer and does not promote insulin absorption. Rather, it comprises particles that efficiently deliver insulin to the deep lung, where it is absorbed by natural processes.

1014

Technosphere insulin pharmacokinetics unchanged in subjects who smoke

R. Baughman¹, J. Cassidy¹, B. Levy², M. Hompesch³, M. Diaz¹, A. Boss¹, P. Richardson¹

¹MannKind Corporation, Paramus, ²Johnson & Johnson Pharmaceutical Services, LLC, Raritan, ³Profil Institute for Clinical Research, Inc., Chula Vista, United States

Background and aims: Smoking has been found to alter insulin absorption with some inhaled insulin formulations, increasing both maximum and overall insulin exposure 2- to 3-fold. This phase I, open-label, single-dose, euglycemic clamp study compared the pharmacokinetics and tolerability of Technosphere Insulin Inhalation Powder in subjects with type 2 diabetes who smoke (n=12) to subjects with type 2 diabetes who do not smoke (non-smoking >2 years; negative urine cotinine, n=12).

Materials and methods: Subjects (age range: 41–63 years) who met inclusion criteria, including extensive pulmonary function testing, were administered

30 U Technosphere Insulin on a single occasion while fasting, 4 to 6 hours after starting intravenous insulin infusion during a clamp procedure. Serial blood samples were drawn for insulin and C-peptide assay.

Results: Insulin concentrations following Technosphere Insulin dosing were adjusted to account for infused insulin and basal endogenous insulin. Confirmation of steady endogenous insulin was inferred from the absence of a measured change in the plasma C-peptide concentration after dosing. All values presented were determined from the baseline-adjusted concentrations. The mean maximum insulin concentration for smokers ($C_{\max, \text{smokers}}$) was 22 $\mu\text{U/mL}$ and the mean $C_{\max, \text{non-smokers}}$ was 24 $\mu\text{U/mL}$, $p=0.905$ (see Figure). The median time of maximum insulin concentration ($T_{\max, \text{smokers}}$) was 20 minutes and median $T_{\max, \text{non-smokers}}$ was 12 minutes, $p=0.010$. The mean baseline adjusted AUC_{0-480} was 2100 $\mu\text{U/mL} \cdot \text{min}$ for smokers and 1700 $\mu\text{U/mL} \cdot \text{min}$ for non-smokers, $p=0.479$. Dosing was well tolerated with 1 adverse event in the smoker group and 4 adverse events in 2 subjects in the non-smoker group, with no hypoglycemia or respiratory (other than cough) adverse events observed. No adverse event was attributed to the study drug.

Conclusion: The rapid absorption of insulin following Technosphere Insulin dosing does not appear to be significantly altered in this smoking population. This differs from what has been reported with other inhaled insulins.

Note: One subject in the non-smoker group was not included in the mean data (non-responsive).

1015

Pharmacokinetic and pharmacodynamic properties of a dry powder inhaled insulin administered via a novel dual-piezo inhalation device compared to sc administered regular human insulin

M. Hompesch¹, A. Kollmeier¹, D. Becker², D. Byron², E. Peers^{3,4}, E. Reynolds², A. Scrimgeour³, N. Whitfield³, L. Heinemann⁵

¹Profil Institute for Clinical Research, Inc., Chula Vista, CA, United States, ²MicroDose Technologies, Inc., Monmouth Junction, United States, ³Vectura Group Plc, Ruddington, United Kingdom, ⁴Sanofi-aventis operations, subsequently sanofi-aventis, Paris, France, ⁵Profil Institut fuer Stoffwechselforschung GmbH, Neuss, Germany

Background and aims: Primary objective of this study was to evaluate the pharmacokinetic (PK) and pharmacodynamic (PD) properties of a newly developed dry powder inhaled insulin (INH) formulation delivered by a novel electronic inhaler capable of delivering 2 discrete blister doses simultaneously.

Materials and methods: In this randomized, four way crossover study, euglycemic automated glucose-clamps (target blood glucose 90 mg/dl) were completed in 14 out of 16 enrolled healthy volunteers (age 30.4±7.4 years (mean±SD); BMI 24.4±2.1 kg/m²). Each volunteer received three different doses of INH on three different study days (see Table 1) and 10 IU Humulin R[®] (RHI) by SC injection into the abdomen on a fourth day.

Results: PD parameters as shown in the table below reveal a more rapid onset of action with INH; Maximal metabolic effect (GIR_{\max}) and $\text{AUC}_{\text{GIR } 0-480}$ were lower with the 1.5 mg INH doses in comparison to the 3 mg INH dose and the 10 IU SC RHI dose respectively. The metabolic effects of 3 mg INH were equivalent to those of the 10 IU SC. Overall relative biopotency was 11–17% for the INH doses. PK data reflect the PD results. No clinically relevant adverse events were observed.

Mean (SD); *pair wise t-test, **Wilcoxon Signed Rank test: p values referring to 3 mg INH and 10 IU SC

Conclusion: Inhalation of this INH formulation by a novel inhalation device was well tolerated and shows a bioavailability and biopotency that is better

Table 1

Rimonabant reduces intra-abdominal and liver fat, and improves glycaemic control: the ADAGIO-LIPIDS substudy in patients with type 2 diabetes

J.-P. Despres¹, R. Ross², G. Boka³, N. Alm  ras¹, I. Lemieux¹

¹Quebec Heart Institute, Laval Hospital Research Center, Quebec, Canada, ²Department of Medicine, Queens University, Kingston, Canada, ³Department of Research and Development, sanofi-aventis, Antony, France

Background and aims: In overweight/obese patients with type 2 diabetes (T2DM) either na  ve to antidiabetic therapy or on monotherapy with metformin or sulphonylurea or treated with insulin, rimonabant, the first selective cannabinoid receptor type-1 (CB₁) antagonist, improves glycaemic control and associated cardiometabolic risk factors.

In the ADAGIO-Lipids study, the beneficial effect of rimonabant on a comprehensive set of cardiometabolic risk variables was demonstrated in 803 abdominally obese (AO) patients with atherogenic dyslipidaemia (high triglycerides [TG] and/or low high-density lipoprotein cholesterol [HDL-C]). Furthermore, a computed tomographic (CT) imaging substudy showed a reduction in both intra-abdominal and liver fat with rimonabant treatment. Among the study patients, 17% had T2DM.

Materials and methods: We report the analyses from the ADAGIO-Lipids study conducted in a subsample of patients with T2DM, randomised to placebo (n=66) or rimonabant 20 mg/day (n=71) plus hypocaloric diet (600 kcal/day deficit) and treated for 1 year, with a 2-month safety follow-up. HDL-C and TG were co-primary endpoints. Intra-abdominal (visceral) fat and liver fat were measured in a total of 36 patients.

Results: At baseline the mean (SD) HbA1c was 7.0 (1.1)% and 7.1 (1.5)%, and the mean fasting plasma glucose (FPG) was 8.0 (2.2) mmol/L and 7.9 (2.8) mmol/L, in the placebo and rimonabant groups, respectively. Significantly greater changes from baseline were observed with rimonabant 20 mg vs placebo for HbA1c, FPG (p<0.0001), HDL-C and TG levels (p<0.0001), intra-abdominal and liver fat, body weight and waist circumference (p<0.0001, p=0.0008, respectively) (Table). Gastrointestinal, nervous system, psychiatric and general adverse events were more common with rimonabant 20 mg.

Conclusion: In T2DM patients with AO and atherogenic dyslipidaemia, rimonabant 20 mg significantly improved glycaemic control and cardiometabolic profile while significantly reducing the intra-abdominal and liver fat.

Changes (mean [SD]) from baseline in efficacy variables

Miscoded blood glucose meters: is this a problem in diabetes management?

S. Ozcan¹, S. Celik², G. Bayrak³, A. Yuncu⁴, B. Bektas⁵, N. Yildirim⁶, G. Cosansu¹, N. Olgun⁷, A. Kahraman⁸

¹Florence Nightingale School of Nursing, Istanbul University, ²Istanbul Medical Faculty Hospital, ³Medical Faculty Hospital, Ondokuz Mayıs University, Samsun, ⁴Medical Faculty Hospital, Akdeniz University, Antalya, ⁵Medical Faculty Hospital, Dokuz Eylul University, Izmir, ⁶Diabetes Outpatient Clinic, Dr Sami Ulus Children Hospital, Ankara, ⁷School of Nursing, Marmara University, Istanbul, ⁸Cerrahpasa Medical Faculty Hospital, Istanbul University, Turkey

Background and aims: This study aimed to evaluate the frequency of mis-coding behaviour for blood glucose meters and the factors that are related to miscoding.

Materials and methods: Instrument: A questionnaire that prepared by researchers filled by checking and comparing the codes of patients' glucometers and strips. Patients: 454 patients were involved in the study from 4 centers.

Including criteria: Patients with Type 1, Type 2 who applied to diabetes unit for regular visit; who didn't have acute problems; who accepted to be involved in research study; and who brought their glucometers and strips. Procedure: The study was carried out between July-September 2007. A questionnaire was filled by interviewing with patient and checking his glucometer and strips' codes. If patient didn't have his glucometer and strips he invited again by giving an appointment.

Ethical issues: Legal permissions from each hospitals and informed consent from patients were taken.

Results: Mean of diagnosis' duration in the subjects was 10.48±7.27 yrs. Mean age of them was 53.03±15.13 yrs. 50,2% of patients were female. 18% of the subjects were found miscoding their blood glucose meters in the study. Low literacy groups, patients who are in low economical status, patients with Type 2 diabetes and older patients had more coding errors in their glucometers. Patients who did not take "general diabetes education" and "education about coding of meters" had more coding errors (p<0.001). Patients who had miscoded meters had significantly high levels of fasting and postprandial blood glucose and HbA1c.

Conclusion: Frequency of use miscoded meter was high in the study (18%). According to the study results, use miscoded meters could effect negatively the blood glucose control. While patient education could help reduce the miscoding error, it is advisable that manually coded meters should be checked by HCPs regularly.

Maintenance of glycaemic control in type 2 diabetic patients during the Ramadan fast, with evening administration of once daily sulphonylurea

A.H. Zargar¹, M. Siraj², A. Jawa³, M. Hasan⁴, H. Mahtab⁵

¹Department of Endocrinology, Sher-i-Kashmir Institute of Medical Sciences, Srinagar, India, ²Medicine, OHRC, Hyderabad, India, ³Medicine, KEMC, Lahore, Pakistan, ⁴Endocrinology, Mayo Hosp., Lahore, Pakistan, ⁵Advisor, NHCN, Dhaka, Bangladesh

Background and aims: During Ramadan, adult Muslims are required to abstain from food, water, & beverages from sunrise to sunset for 1 month. Most patients break their fast with a meal after sunset, followed by dinner about 3 hours later & a breakfast like meal just before dawn the next day. The diurnal variation in plasma glucose is altered during Ramadan & the postprandial surges in plasma glucose are shifted between 8 pm to 6 am. In type 2 diabetic patients it is difficult to maintain glycemic control with multiple dose

sulphonylureas because of the need to administer them during the non-fast overnight span of 10–16 hours. However, sulphonylureas with a sustained 24-hour duration of action, administered in the evening with the first meal after the days' fast could, in theory, maintain glycemic control during Ramadan. The objective of this study was to assess whether type 2 diabetic patients under glycemic control with a once daily sulphonylurea taken at breakfast, were able to maintain the same degree of control by switching the timing of its administration to the evening during Ramadan & reverting to the morning dose thereafter.

Materials and methods: In an open label prospective study, type 2 diabetic patients from Bangladesh, Pakistan, & India, under glycemic control with gliclazide switched to its evening administration at the same dose during Ramadan, & reverted to the morning schedule thereafter. The primary outcome was the difference in fasting plasma glucose before & after Ramadan.

Results: In 136 patients, mean (95% CI) FPG decreased by 1.1 mg/dl (0 to 3.4, $P=0.3$) with evening medication by the end of 25 days fasting, & increased by 3.1 mg/dl (1.1 to 6.3, $P=0.01$) after reverting to morning medication 20 days later. There were 5 (3.5%) hypoglycemic episodes before, 3 (2.2%) during, & 2 (1.5%) after Ramadan. Mean HbA1c decreased by 0.8 % (0.7 to 1.0, $P=0.00$), mean lipid ratio improved by 0.6 (0.3 to 0.9, $P=0.00$), while mean body weight increased by 0.4 Kg (0.2 to 0.6, $P=0.00$) between pre & post Ramadan.

Conclusion: Against the background of misuse of hypoglycemic agents, alterations in diet & risk of hypoglycemia, type 2 diabetic patients under glycemic control with a long acting sulphonylurea can maintain the same degree of control by switching to an evening administration of the same dose during Ramadan & reverting to a morning schedule thereafter. The frequency of hypoglycemia is low & weight gain minimal.

1019

Unmet treatment needs among patients with type 2 diabetes uncontrolled on basal-only insulin therapy: implications of adding bolus insulin therapy

E. Durden¹, E. Sarpong², G. Lenhart¹

¹Medstat, Thomson, Boston, ²Eli Lilly and Company, Indianapolis, United States

Background and aims: Patients with type 2 diabetes mellitus (T2DM) tend to have difficulty achieving glycemic control. An abundance of research findings suggest that failure to achieve optimal glycemic control among T2DM patients has implications for diabetes related complications, health care re-

Table 1 Response of type 2 diabetic patients undertaking the Ramadan fast to monotherapy with long acting sulphonylurea

Other values are numbers of patients with percentages of the group in parenthesis.

source utilization and costs. However, little is known about the characteristics of patients who remain uncontrolled on current basal monotherapy and the extent to which the addition of bolus therapy affects glycemic and economic burden. The objectives of this study are to evaluate the characteristics of T2DM patients and to quantify the impact of adding bolus therapy to previous basal-only insulin regimens on complications, resource utilization and costs.

Materials and methods: US health claims and clinical laboratory data from 2003–2005 were used to identify and stratify patients for analysis. The patient cohort was limited to T2DM patients receiving a basal-only insulin regimen at baseline with at least one HbA_{1c} value in the database and six months continuous eligibility pre-post index HbA_{1c}. Data on HbA_{1c}, complications, demographic characteristics and resource utilization of all patients were analyzed using descriptive statistics. Negative Binomial (NBR) and Multinomial Logit (MNL) models were estimated to evaluate the association between insulin therapy and complications, resource utilization and costs.

Results: Of 1,607 patients on basal monotherapy at baseline (mean age 53 years; female 63%, glargine monotherapy 32%), 8% added bolus insulin therapy during the follow-up period. Approximately 73% of the study cohort had HbA_{1c} values greater than 7%; a greater proportion of patients initiating bolus therapy had HbA_{1c} values >9% at baseline (45% vs 35%; $p<.05$). Those initiating bolus therapy were younger ($p<.05$), had more comorbidities (Charlson Comorbidity Index), and a higher proportion had diabetes-related complications relative to those who did not initiate bolus therapy. Our NBR estimates indicates that patients who initiated bolus insulin therapy had significantly greater number of inpatient admissions and higher total costs during the follow-up period than patients who did not initiate bolus therapy. Interestingly, our MNL regression revealed no significant differences in follow-up HbA_{1c} between the two groups.

Conclusion: In our study, healthcare resource utilization among patients with T2DM who initiated bolus therapy was significantly higher as compared to patients who did not initiate bolus therapy during the follow-up period. A considerable proportion of T2DM patients who initiated bolus therapy show signs of complications in the pre-period, suggesting the urgency of therapy intensification. Ostensibly, the results are somewhat surprising. However, the results suggest what may be occurring in the “real world”; that is patients who add bolus therapy may have already been in poorer health due to already developed diabetes-related complications. Thus, not only should we expect these patients to incur more utilization and costs in the short term, but further postponement of therapy intensification may compromise the achievement of any meaningful reductions in patients’ glycemic and economic burdens. Additional research that captures a longer follow-up period of observation is needed to assess concretely the potential beneficial impact of adding bolus therapy to basal monotherapy.

Influencing factors of metabolic control level in patients with diabetes mellitus type 2

J. Reviriego, J. Diago, P. Polavieja, F. Chacon
Lilly Spain, Alcobendas, Spain

Background and aims: To assess the association of several factors with metabolic control (MC) in non-insulin treated type 2 diabetes mellitus (DM2) patients in standard clinical practice in Spain. To estimate mean HbA_{1c} at the point when additional Oral Glucose Lowering Drugs (OGLD) are added to treatment.

Materials and methods: A retrospective, observational, naturalistic and multicentre study, that reviews clinical records of a 2-year period previous to the inclusion of patients. A total of 216 physicians participated (endocrinologists, internal medicine specialists and general practitioners). A logistic regression model was carried out using poor MC as response variable, and doctor’s specialty, sociodemographic data and clinical variables as covariables. MC was defined according to IDF and ADA (American Diabetes Association) criteria (good metabolic control = HbA_{1c}≤6.5; HbA_{1c}<7%, respectively).

Results: Clinical records from 2,266 patients were reviewed, 47.2% female. Mean age (SD) was 64.4 (11.1) years. Median time (IQR) of diagnosis was 5.9 (2.9–10.1) years. According to IDF and ADA criteria, 41.8% and 59.9% of patients had good MC, respectively. Table 1 shows the variables influencing MC and their impact after applying a logistic regression model.

Odds Ratio Estimates

IDF Criteria

Effect	Point Estimate	95% Wald Confidence Limits
No studies against Illiteracy	0.5	0.2 1.5
Primary studies against Illiteracy	0.4	0.2 1.2
Secondary studies against Illiteracy	0.3	0.1 0.9
University degree against Illiteracy	0.3	0.1 0.8
Other non-university studies against Illiteracy	0.5	0.0 9.8
Self-monitoring of blood glucose (number)	1.4	1.1 1.9
Number of OGLD	1.7	1.4 2.0
Accomplishment of the following indicator: “Begin oral glucose-lowering drugs when lifestyle interventions alone are unable to maintain blood glucose at target levels”	1.5	1.1 1.9

Odds Ratio Estimates

ADA Criteria

Effect	Point Estimate	95% Wald Confidence Limits
Number of HbA _{1c} values in the last two years	0.9	0.8 0.9
Number of OGLD	1.9	1.6 2.2

Age, gender, time since diagnosis, presence of CVRF, or cholesterol values did not show any influence on MC. The first OGLD was administered with a HbA_{1c} mean value (SD) of 7.8(1.4)% for all patients. The second and third OGLD were added when HbA_{1c} mean value (SD) was 8.0(1.3)% and 8.1(1.1)%, respectively. Endocrinologists prescribed the first OGLD with a HbA_{1c} mean value (SD) of 8.0(1.5)%, whereas internal medicine specialists and GPs began OGLD treatment with a HbA_{1c} mean value (SD) of 7.8(1.4)% and 7.5(1.3), respectively. The same trend was observed for the second OGLD (8.1[1.2]% for endocrinologists; 7.9[1.3]% for internists and 7.8[1.3]% for GPs), and for the third (8.3[1.1]%, 8.0[1.0]% and 7.7[1.1]%, respectively).

Conclusion: Regarding IDF criteria, educational level is the only sociodemographic variable influencing DM2 MC, suggesting that there is a need to promote DM2 educational programs and improve follow-ups in low-educated patients. Nevertheless, blood glucose self-monitoring, OGLD treatment, and the number of OGLD and HbA_{1c} controls in the last 2 years, appear to be associated with DM2 MC. However, these measures might be directly related to the treatment of those patients with worse disease evolution. According to the evolution of DM2 in non-insulin treated patients, every new OGLD is added when MC worsens. Endocrinologists prescribe OGLD with worse HbA_{1c} levels than internists or GPs, probably because they care for patients in worse clinical status who are referred from other physicians.

Glycated albumin more accurately reflects glycaemic control than HbA_{1c} in diabetic subjects on peritoneal and hemodialysis

B.I. Freedman¹, R.N. Shenoy¹, J.A. Planer¹, A.J. Bleyer¹, C.Y. Cardona¹, T.P. Peacock¹, L. Andries¹, J.R. Byers¹, K.D. Clay¹, G.B. Russell², Z.K. Shihabi³

¹Internal Medicine/Nephrology, ²Biostatistical Sciences, ³Pathology, Wake Forest University School of Medicine, Winston-Salem, United States

Hemoglobin (Hb) A_{1c} less accurately reflects glycemic control in diabetic hemodialysis (HD) patients, relative to the glycated albumin (GA) assay. The accuracy of the HbA_{1c} in diabetic patients on peritoneal dialysis (PD) is unknown. We measured a simultaneous HbA_{1c} and GA in an expanded diabetic cohort of 472 cases with end-stage renal disease (ESRD; 55 on PD and 417 on HD) and in 49 non-nephropathy controls. Analyses were performed to determine factors associated with HbA_{1c} and GA.

In the 417 HD cases, 55 PD cases, and 49 non-nephropathy controls, respectively, mean [SD] of 3 monthly serum glucose concentrations during the preceding 90 days were 169.6 mg/dl [62], 168.6 mg/dl [66], and 146.1 mg/dl [66] (overall $p=0.11$); with a corresponding HbA_{1c} of 6.78% [1.6], 6.87% [1.4], and 7.30% [0.4] (overall $p=0.08$). In HD cases, PD cases, and non-nephropathy controls, respectively, the mean % GA using the bromocresol green serum albumin assay was 18.8% [7.3], 16.0% [4.9], and 15.3 [5.5]; and mean % GA computed using bromocresol purple serum albumin assay was 21.1% [8.2], 19.0 % [5.7], and 16.4 % [5.7] ($p=0.02$ for comparison of PD vs non-neph-

ropathy controls; $p=0.0001$ for HD vs non-nephropathy controls). The mean ($GA \div HbA_{1c}$) ratio in diabetic ESRD cases on HD (3.12 [0.84]) and PD (2.77 [0.53]) were both significantly higher compared to non-nephropathy controls (2.21 [0.49]; $p=0.0001$ for PD and HD cases vs controls), implying a difference in the relationship between GA vs serum glucose and HbA_{1c} vs serum glucose in dialysis patients. A best-fit linear model was then created with HbA_{1c} or GA as the outcome variable, and glucose concentration, race, dialysis modality, and serum albumin concentration as independent variables. After adjustment for serum glucose concentration, dialysis modality had significant effects in the model for HbA_{1c} , demonstrating that dialysis status affects the relationship between HbA_{1c} and serum glucose concentration. However, dialysis modality was not significant in a similar model with GA as the outcome variable. Among patients on PD, the GA assay was not significantly impacted by serum albumin concentration. In diabetic hemodialysis and peritoneal dialysis patients, the relationship between HbA_{1c} and GA differs significantly from that in subjects without nephropathy. Relative to the GA assay, HbA_{1c} underestimates glycemic control and is impacted by ESRD in patients on peritoneal dialysis and hemodialysis. The GA assay is not significantly impacted by either peritoneal or hemodialysis, allowing for more accurate determination of recent glycemic control among diabetic ESRD patients.

Measurement of serum fructosamine concentration is a low-cost, easy-specimen handling, and precise method to monitor glucose fluctuations in type 1 diabetes mellitus

M. Guevara-Aguirre¹, E. Vidgen², J. Guevara-Aguirre¹, J. Saavedra¹, A.L. Rosenbloom³, G. Bernstein⁴

¹IEMMYR, Institute of Endocrinology, Quito, Ecuador, ²University of Toronto, Canada, ³University of Florida, Gainesville, United States, ⁴Generex Biotechnology Corp., Toronto, Canada

Background and aims: Precise laboratory measurements are needed for proper monitoring of metabolic control of type 1 diabetes mellitus (T1DM) and determination of glycated hemoglobin concentrations (HbA_{1c}) is considered the gold standard for monitoring; however, whole-blood specimen handling has inherent logistic difficulties in places such as developing countries with poor transportation and communication systems; moreover, obvious economic restraints coexist. It has been recently shown that glycated albumin is better related to fasting plasma glucose than is HbA_{1c} (Clin Biochem 40: 1398-05, 2007); moreover, it is well known that fructosamine (Fruc) represents an accurate measure of glycated albumin. Measurement of Fruc has advantages over that of HbA_{1c} in regard to specimen processing and handling; precision, reproducibility and cost of the test.

Materials and methods: 26 adult T1DM participated in a 3-phase, 2-cohort 585-day study. First Phase, was a 144-day stabilization period at which all subjects received basal twice daily (BID) subcutaneous (s.c.) isophane insulin (NPH) + meal time (Thrice daily -TID-) s.c. regular insulin. It was followed by 99-day Phase 2, a first comparison phase where the 26 T1DM were allocated to two cohorts of 13 subjects each. Control subjects received BID s.c. NPH + TID s.c. regular insulin whereas Treated subjects received Basal twice daily sc-isophane insulin (NPH) + TID Meal time Oral insulin (Generex Oral-lyn™). When this period ended, Phase 3 was initiated and the two treatment cohorts were maintained for a 372-day second comparison; however, Control subjects were switched to a schedule of Basal Once a Day s.c. glargine insulin-analogue and pre-meal TID s.c. lispro insulin analogue whereas Treated subjects continued receiving basal BID s.c. NPH and + TID meal time Generex Oral-lyn™. During all phases, glucose readings were self-obtained by research subjects (pre-breakfast, pre-lunch and pre-dinner) (Mean-G), and downloaded every two weeks using an Accu-Check Software. Both analytes, Fruc and HbA_{1c} were determined every 2 weeks. Self-measured glucose levels (Gluc) were measured before each major meal and meter readings were downloaded using an Accu-Check software. Study data for control and treated cohorts during the entire period were combined aiming to determine the relationship among these 3 variables.

Results: The 3-way Pearson product-moment correlation showed strong linear association between all three sets of measurements (Gluc- HbA_{1c} $r=0.43$ $p<.0001$ // Gluc-Fruc $r=0.45$ $p<.0001$ // HbA_{1c} -Gluc $r=0.43$ $p<.0001$ // HbA_{1c} -Fruc $r=0.76$ $p<.0001$ // Fruc-Gluc $r=0.45$ $p<.0001$ // Fruc- HbA_{1c} $r=0.76$ $p<.0001$). As it can be appreciated, both analytes, HbA_{1c} and Fruc provide adequate assessment of glucose fluctuations and glycemic control when compared to daily glucose determinations during the 585-day period.

Conclusion: We conclude that Fruc is a valid alternative to HbA_{1c} because its measurement is easier, less costly, precise, and adequately reflects glucose fluctuations in T1DM. These characteristics make it suitable especially in places where specimen handling, transportation and test costs are relevant.

A study on the use of syringe, pen needle, lancet for self monitoring of blood glucose

E. Jung¹, M. Hong², J. Yoo³

¹Nursing division, Severance Hospital, ²Nursing division, Seoul Paik Hospital, ³Nursing division, Seoul Boramae Hospital, Seoul, Republic of Korea

Background and aims: Active self-care behaviors such as that injected insulin and SMBG is required to reach the treatment target for diabetes. Insulin therapy is a medical necessity for all types of diabetes patients who cannot reach their glycemic goals without insulin therapy. Also SMBG is helpful in pattern recognition for the patient to note; concurrent doses of medicines for diabetes, meal plan and exercise. It is strongly emphasized in diabetes education that syringe, pen needle and lancet must be disposed after single use; however, many diabetic patients do not follow the principle. The reuse of syringe, pen needle used for insulin injection may make the tip of the syringe or pen needle break in the skin since it has become weaker and also cause pain, bleeding, or bruise. In addition, it would increase risk for infection and makes it difficult to perform the right dose administration of insulin. The purposes of this study are to research the status of the reuse of syringe and pen needle for insulin injection and lancet for SMBG and patients' perception of reuse. And we aim to find out actual reasons for reuse and factors that lead to reuse.

Materials and methods: The study subjects were 1,053 persons who are treated with injected insulin in general hospitals in the Republic of Korea. Systematic questionnaires were used, and one-to-one interviews were performed from January 22, 2007 to February 12, 2007. The research results were processed for statistics by using SPSS.

Results: 1. Type 1 diabetic patients accounted for 11.0%, and type 2 diabetic patients accounted for 81.0%. The average prevalence period of the subjects was 13.2 years, and the average injected insulin period was 5.7 years. 2. The re-users accounted for 34.0% and used them 4.4 times on average. 3. As for reasons why syringe or pen needle were used again, the answer 'I thought that there were nothing wrong with using syringe or pen needle several times' accounted for 69.0%. The second most answer was 'For the reduction of cost'. 4. 94.0% of the subjects had been educated on how to inject insulin. 88% out of them answered that they had been educated on using insulin needle. 5. As for the subjects' perception for the side effects of reuse of syringe or pen needle, the answers were as follows: 'Reuse may increase pain' (48.0%), 'A needle may be broken in the skin' (39.0%). In general, the perception for the side effects of reuse was perceived negatively below 50%. 6. 89% of the subjects had performed SMBG. 7. The re-users of lancet for SMBG accounted for 67.0%. The reasons were as follows: 'I thought that there were no side effects' 'I had used them several times by habit'

Conclusion: The results of this research turned out that diabetic patients tended to use syringe, pen needle, or lancet again due to lack in the awareness of hazards from reuse even if they had been educated on how to inject insulin, SMBG, and to use needles. Thus, diabetes educators need to include the side effects of reuse in their teaching by providing concrete cases or proofs and educate diabetic patients repeatedly. Also, they should consciously make effort to eradicate reuse-induced harm by providing efficient education based on the age, educational background, and income level of the patients. In addition the application of insurance should encompass consumables for diabetic management such as insulin syringes, pen needles, and lancets to reduce a financial burden of diabetic patients before long.

PS 095 Cognitive and psychological aspects

1024

The structure of cognitive impairment in type 2 diabetes

I. Semenova¹, L. Chugunova¹, M. Shestakova¹, A. Vorontsov²,

V. Vladimirova², A. Ilin³, P. Kamchatnov⁴, A. Chugunov⁴

¹Nephrology, National Research Center for Endocrinology, ²Radiology, National Research Center for Endocrinology, ³Biochemistry, National Research Center for Endocrinology, ⁴Neurology, Russian State Medical University, Moscow, Russian Federation

Background and aims: Diabetes mellitus is associated with cognitive deficit right up to dementia. Taking into account all possible factors the modest and mild cognitive impairment (MCI) are debated as early presentation of cerebrovascular disease in diabetic patients, but MCI is more severe impairment which often precedes dementia. The aim of the present study was to estimate frequency of early cognitive impairment and their metabolic, vascular and cerebral MRI scan (T1, T2 weighted) characteristics in middle-aged patients with type 2 diabetes.

Materials and methods: Our study included 126 (42 men and 84 women) patients 50–75 years old with type 2 diabetes and 20 (3 men and 17 women) control subjects without diabetes and hypertension. Glycated hemoglobin (HbA1c), body mass index (BMI), systolic (SBP) and diastolic blood pressure, biochemistry assay, MAU, haemostatic factors, cerebral MRI scan, neuropsychological tests: Frontal Assessment Battery (FAB), Mini Mental State Examination (MMSE), Global Deterioration Scale (GDS), Clock Drawing test (CDT) were measured.

Results: Mean age of patients was 60.5 ± 7.5 years. Mean duration of diabetes was 8.03 ± 6.23 years. Median HbA1c was 7.8% [7.1; 8.7]. Mild cognitive impairment was detected in 64 cases (52.8%) by MMSE tests and 29 patients (23.9%) had modest cognitive impairment (MMSE 28–30 scores, GDS = 2). Only 23.3% patients didn't have cognitive impairment. Patient with MCI had significant more duration of diabetes ($p < 0.043$), hypertension ($p < 0.003$) and mean level of triglyceride ($p < 0.015$) comparing with patient with modest cognitive impairment. MCI patients had MRI leukoencephalopathy and silent lacunar stroke significantly more frequent than other patients and control subjects ($p < 0.001$). MAU exhibited a significant negative correlation with MMSE ($r = -0.264$, $p < 0.003$), FAB ($r = -0.216$, $p < 0.015$) and CDT ($r = -0.269$, $p < 0.002$). Association between HbA1c and neuropsychological tests scores was not estimated.

Conclusion: High frequency of mild cognitive impairment in type 2 diabetes is strongly associated with vascular MRI abnormalities, cerebrovascular risk factors and with MAU level as marker of endothelial dysfunction.

A systematic review and meta-analysis of the prevalence of eating disorders in patients with type 2 diabetes mellitus

Y.S. Cheah¹, D. Hopkins², J. Treasure³, K. Ismail³

¹Department of Endocrinology & Diabetes, The Lewisham Hospital NHS Trust, London, ²Department of Diabetic Medicine, King's College Hospital, London, ³Academic Department of Psychological Medicine, Institute of Psychiatry, King's College London, United Kingdom

Background and aims: Unlike type 1 diabetes mellitus, the relationship between type 2 diabetes mellitus and eating disorders is less well defined. To examine this further we performed a systematic literature review and meta-analysis of the pooled prevalence of all Eating Disorders (ED), comprising of anorexia nervosa (AN), bulimia nervosa (BN), binge eating disorder (BED) and other eating disorders not otherwise specified (EDNOS, excluding BED) in adults with type 2 diabetes mellitus.

Materials and methods: The Meta-analysis of Observational Studies in Epidemiology (MOOSE) guidelines were used on reporting observational data.

Inclusion Criteria

1. Cross-sectional, cohort studies
2. Adults aged > 18 years with type 2 diabetes mellitus
3. Documented prevalence of ED (AN, BN, BED, EDNOS) meeting the Diagnostic and Statistical Manual of Mental Disorders (DSM) III-Revised or IV, or the International Classification of Disease 10 (ICD-10) criteria.

Search Strategy

Searches of relevant electronic libraries for all studies on ED and type 2 diabetes mellitus to September 2007 were undertaken. The Cochrane Depression, Anxiety and Neurosis Group search strategy for Eating Disorders, and the Cochrane Metabolic and Endocrine Disorder Group search strategy for type 2 diabetes mellitus were used. Hand searches of the last 4 years' proceedings from the American Diabetes Association and Diabetes UK conferences were also undertaken. Full manuscripts of abstracts meeting the inclusion criteria were obtained. Experts in the fields of diabetes and ED identified from the literature were directly contacted to identify unpublished data.

Data Analysis

The prevalence of ED and its subtypes from each study meeting the inclusion criteria were extracted. A meta-analysis of the pooled data using a random effects model was performed.

Results: The search strategy identified 1873 abstracts. Thirteen abstracts fulfilled the inclusion criteria. Two studies were excluded: one for not specifying the type of diabetes mellitus and one for not specifying the diagnostic criteria for ED. The results of 3 articles reporting separate data from a single study were amalgamated. Therefore 9 studies with a total of 2291 patients were included for the meta-analysis, of which only 2 were case-controlled studies.

There were no cases of AN. The weighted pooled prevalence of BN was 0.7% (95% confidence interval 0.3–1.9%), BED 6.5% (3.5–11.7%), EDNOS 5.9% (3–11.2%) with all ED 13.2% (7.1–23%).

Conclusion: As there were only 2 case-controlled studies, a meta-analysis to compare ED in diabetic with non-diabetic adults was not possible. A recent population-based study of 9282 adults found a lifetime prevalence of AN, BN and BED to be 0.6%, 1.0% and 2.8% respectively. Although not a direct comparison, our review suggests that ED are more prevalent in the diabetic population, BED being the most prevalent subtype.

The small number of studies in this field have suggested that ED develop before the diagnosis of type 2 diabetes mellitus. Further research is required to establish the possible role ED may have in the pathogenesis and natural history of type 2 diabetes mellitus, obesity, and the metabolic syndrome, and the impact of ED on glycaemic control and diabetes complications.

Initial experience with Dose Adjustment for Normal Eating (DAFNE) training in routine clinical practice in Ireland: biomedical and psychosocial outcomes at 12 months

L. Daly¹, D. O'Shea², D. Smith³, C.H. Courtney⁴, S.F. Dinneen¹

¹Diabetes Day Centre, Galway University Hospital, ²Diabetes Day Centre, St. Vincent's University Hospital, Dublin, ³Diabetes Day Centre, Beaumont Hospital, Dublin, ⁴Diabetes Day Centre, Royal Victoria Hospital, Belfast, Ireland

Background and aims: Dose Adjustment for Normal Eating (DAFNE) is a 5-day training course in flexible, intensive insulin therapy for patients with Type 1 diabetes. In the UK DAFNE has been shown to improve glycaemic control without increasing severe hypoglycaemia, while significantly reducing the negative impact of diabetes on quality of life. The aim of this study was to investigate the effect of DAFNE training on glycaemic control, hypoglycaemia and psychosocial outcomes in Irish DAFNE Centres.

Material and methods: Twenty-two DAFNE courses were delivered in 5 centres in Ireland between March 2004 and November 2006. Clinical outcomes measured at baseline and 12 months post-training included HbA1c, weight and rates of severe hypoglycaemia. The burden of living with diabetes was assessed using the PAID (Problem Areas in Diabetes) and HADS (Hospital Anxiety and Depression Scale) questionnaires. EQ5D was used to assess health status.

Results: Complete data at baseline and 12 months were available for 70 patients (48.6% male). The range of HbA1c among participants at baseline varied from 6.0 to 14.2 percent. For the whole cohort, HbA1c levels (mean ± SD) after 1 year showed minimal change from baseline (8.41 ± 1.41% vs. 8.32 ± 1.30%, $p = 0.446$). Weight reduced from 77.5 ± 14.5 kg at baseline to 76.8 ± 15.8 kg at 12 months ($p = 0.31$). Rates of severe hypoglycaemia were low at baseline and were not significantly different at 12 months. Mean PAID scores decreased from 22.45 ± 17.88 to 14.05 ± 13.79, $p = 0.001$. Mean HADS scores decreased from 4.10 ± 3.33 to 3.34 ± 2.77 (anxiety), $p = 0.047$ and from 3.76 ± 2.77 to 3.14 ± 2.96 (depression), $p = 0.097$. Perceived health status as determined by the visual analogue scale of EQ5D increased from 79.73 ± 12.99 to 80.76 ± 12.70, $p = 0.534$. For the sub-group of patients with baseline HbA1c > 8.4% the level of HbA1c improved at 1 year post DAFNE (mean 9.47 ± 1.19% vs 8.98 ± 1.33%; $p = 0.009$). For this sub-

group there was no significant increase in severe hypoglycaemia and no significant change in weight at 12 months. For the cohort with baseline HbA1c $\leq 8.4\%$ the level of HbA1c increased at 12 months (mean $7.46 \pm 0.75\%$ to $7.72 \pm 0.93\%$; $p = 0.081$). Concurrently there was no significant change in frequency of severe hypoglycaemia and weight decreased from mean $76.86 \pm 13.64\text{kg}$ to $75.36 \pm 13.25\text{kg}$ ($p = 0.003$).

Conclusion: These results demonstrate that DAFNE training in a routine clinical setting in Ireland is associated with significant improvement in measures of psychological distress and diabetes-related anxiety. The lack of a significant improvement in HbA1c at 12 months may have resulted from the very wide range of HbA1c among participants at baseline. This reflects the policy of the participating centres to offer DAFNE training to all patients with Type 1 diabetes. Further work is required to identify sub-groups of patients who derive maximum benefit from DAFNE training and to maintain these benefits for longer. These issues are currently being explored in the Irish DAFNE study.

High prevalence of alexithymia in type 1 diabetic patients

L. Chatzi¹, E. Solidaki¹, I. Christou², E. Kyraki², M. Sfakianaki², P. Bitsios³, M. Kogevinas^{1,4}, N. Kefalogiannis², A. Pappas²

¹Department of Social Medicine, Faculty of Medicine, University of Crete, Heraklion, Greece, ²Diabetic Clinic, Venizelio Hospital, Heraklion, Greece,

³Department of Psychiatry, Faculty of Medicine, University of Crete, Heraklion, Greece, ⁴Centre for Research in Environmental Epidemiology, (CREAL), Institut Municipal d'Investigació Mèdica, Barcelona, Spain

Background and aims: Type 1 diabetes (T1D) has long been identified as a disease with increased comorbidity in mental health disorders such as anxiety and depression. Alexithymia is a psychological construct characterised by inability to express emotions verbally, poor imagination and operational

thinking, leading to failure in psychological self-regulation. The aim of this case-control study was to measure the prevalence of alexithymia and low mood in T1D outpatients who did not meet the criteria for major depression, and to compare it with that of non-diabetic controls.

Materials and methods: The study population included 96 T1D outpatients followed in the Diabetic Clinic of Venizelio General Hospital in Heraklion, Greece and 105 age- and sex-matched healthy controls. Subjects diagnosed for clinical depression were excluded from the study. Alexithymia and low mood were assessed in both groups with the 20-item Toronto Alexithymia Scale, (TAS-20) and the 21-item Beck Depression Inventory (BDI-21) respectively. Multivariate regression models were used to evaluate the association of alexithymia and low mood with the presence of diabetes, diabetes control (HbA1c, number of mild or severe hypoglycemia in the last year), parameters of treatment intensification (number of glucose measurements/week, number of insulin injections/day), and diabetic complications (retinopathy, coronary heart disease, nephropathy).

Results: The prevalence of alexithymia was 20% in T1D patients and 7% in the controls (OR, 4.1; 95%CI, 1.6–10.6). The presence of low mood did not differ significantly between the two groups. Alexithymia was inversely associated with the number of glucose measurements per week ($\beta_c -0.16$, $p=0.074$) and the number of insulin injections per day ($\beta_c -2.06$, $p=0.051$). There were no associations between alexithymia and HbA1c, or somatic complications.

Conclusion: We found high prevalence of alexithymia but not low mood in diabetic patients who did not meet the criteria for major depression compared to healthy controls. While alexithymia may be an adaptive response to protect diabetic patients from developing depression, it may interfere with patients' ability to self-care and comply with treatment. Therefore, special attention should be paid in the medical care of diabetic patients with alexithymic characteristics.

Table: Differences between the intervention and control group at baseline, after 6 and 12 months.

	Baseline	6 months	12 months	Δ 0–6 months	P value (95% CI)	Δ 6–12 months	P value (95% CI)	Δ 0–12 months	P value (95% CI)

A cognitive behavioural treatment improves lifestyle in patients with type 2 diabetes when added to managed care: a randomised controlled trial

L.M.C. Welschen, P.C. van Oppen, P.J. Kostense, J.M. Dekker, G. Nijpels
EMGO Institute, VU University Medical Center, Amsterdam, Netherlands

Background and aims: It has been shown that behavioural interventions lower risk factors of developing complications in patients with diabetes. However, study designs are often lacking a theoretical background and consequently it is difficult to identify successful factors in interventions. We have developed a theory-based cognitive behavioural intervention, which was added to an existing managed care system. Problem Solving Treatment (PST), a practical skill building treatment with goal setting as the main element, was used to guide the intervention. We hypothesised that PST might increase patient's attitude, social influences and self-efficacy, the determinants of behaviour in our theoretical framework, the ASE-model. The increase in the determinants might change patient's intention to change behaviour, resulting in improvement of clinical characteristics and a reduction in the risk of developing coronary heart disease (CHD). The aim of this study was to investigate the effect of adding a cognitive behavioural intervention to managed care on CHD risk.

Materials and methods: For this randomised controlled trial, patients were recruited from general practices (n=14) who are participating in a Diabetes Management System. The intervention group (n=76) received the cognitive behavioural intervention in addition to managed care. The control group (n=78) received managed care only. The primary outcome measure was the risk of developing CHD, calculated with the UKPDS risk engine at baseline and after 12 months. Other outcome measures were clinical characteristics, lifestyle (physical activity, dietary behaviour, and smoking status), determinants of behaviour change (attitude, social influences and self-efficacy, based on the ASE-model), quality of life and depression. These outcome measures were all measured at baseline, after 6 and 12 months. Differences between the two groups after 6 and 12 months were analysed by two-way analysis of variance.

Results: The intervention reduced CHD risk but not significant (see Table). The amount of heavy physical activity at 6 months increased significantly in the intervention group compared with the control group but this effect disappeared after 12 months. More patients in the intervention group quit smoking, although not statistically significant. Quality of life and level of depression improved as well. No effects were found on clinical characteristics, dietary behaviour and determinants of behavioural change.

Conclusion: Adding a cognitive behavioural intervention to managed care improved physical activity at the short term and seems to have beneficial effects on cardiovascular risk profile. It remains a challenge to find behavioural interventions that have effects on the long term and on clinical outcome measures.

1029

Bariatric surgery for patients with type 2 diabetes and morbid obesity: improving psychological status?

S. Jackson¹, M. Morris¹, K.T. Lilley¹, A.B. Johnson²

¹Psychology, University of the West of England, ²Diabetes & Endocrinology, Southmead Hospital, Bristol, United Kingdom

Background and aims: Surgical treatment is increasingly recognised as the most effective means of achieving weight loss and potentially normalising glucose tolerance in morbidly obese patients with type 2 diabetes (T2DM). The psychological status of individuals presenting for such treatment is unclear. This study was undertaken to compare the psychological status of morbidly obese individuals with and without (T2DM) pre and six months post bariatric surgery.

Materials and methods: Two groups of participants were recruited: a pre-operative group (T1: n=41, 27 with T2DM, 14 without; age range: 25-58; mean BMI 51.8 kg/m² ± sd=8.31; mean HbA1c 9.15 ± 1.98) and post-operative group (T2: n=11, 9 with T2DM, 2 without; age range: 35-48; mean BMI 42.18 kg/m² ± sd=8.36; mean HbA1c 8.28 ± 1.36). Participants completed psychological scales measuring anxiety and depression (HADS); quality of life (WHOQoL-Bref); and social anxiety (DAS-24). All were considered suitable for surgery after comprehensive assessment. Participants completed psychological scales which measured anxiety and depression (HADS); quality of life (WHOQoL-Bref); and social anxiety (DAS-24).

Results: A comparison of study measures mean scores with clinically relevant normative populations revealed that the T1 group had significantly increased levels of social anxiety (65.0±14.8; norm =29.54±12.39), general

anxiety (9.76±4.42; norm =6.14±3.76) and depression (9.22±4.01; norm =3.68±3.07). For the T2 group (n=11), levels of social anxiety (56.18±18.7) were also significantly raised when compared to normative data. Levels of general anxiety were slightly raised (6.45±3.75), while levels of depression were still significantly raised (5.36±3.80). Non-parametric statistical testing revealed that BMI was significantly lower in the T2 group (p<.002), as were levels of anxiety and depression (p<.05), while ratings of quality of life were significantly higher (p<.05). Where participants in groups T1 and T2 could be matched an average percentage drop of 23.7% was found for HbA1c levels suggesting a clinically useful reduction.

Conclusion: These data suggest that morbid obesity significantly raises levels of social anxiety, general anxiety and depression and that bariatric surgery improves both physiological and psychological status to a certain extent.

1030

The evaluation of the anxiety level and the cognitive functioning of the children and adolescents with type 1 diabetes in dependence on insulin therapy method

A. Grabowska, M. Urban, B. Florys, B. Glowinska-Olszewska
2nd Pediatric Clinic, Medical University, Białystok, Poland

Background and aims: The aim of this study was the evaluation of emotional and cognitive functioning of the children and adolescents with type 1 diabetes in relation to insulin therapy method.

Materials and methods: 110 patients in the age range of 7.2 to 19.1 years suffering from type 1 diabetes since 6.17 years took part in the study. They were divided into two groups in dependence on insulin therapy: intensive vs personal insulin pump. The evaluation of anxiety level was performed on the base of the psychological methods: State-Trait Anxiety Inventory (STAI) and State-Trait Anxiety Inventory for Children (STAIC). The evaluation of cognitive functioning was measured with Wechsler Intelligence Scale for Children-Revised (WISC-R) and Wechsler Adult Intelligence Scale-Revised -Polish versions (WAIS-R(PL)).

Results: We have found higher anxiety level as trait than state in diabetic patients (p<0.00). We have observed higher level of anxiety in the group using the insulin pump than in the group on intensive method (not statistical significance). Patients with personal insulin pump gained higher scores in the subtest: Information (p<0.04), Similarities (p<0.00), Arithmetic (p<0.01), Vocabulary (p<0.01), Comprehension (p<0.02), Picture Completion (p<0.01), Picture Arrangement (p<0.02). In this group we also observed higher level of the Intelligence (Verbal, p<0.00; Nonverbal, p<0.03; General, p<0.00).

Conclusion: Higher level of anxiety as trait than as state occurs in all diabetic patients. 2. Higher level of anxiety was observed in group using insulin pump than in group on intensive insulin therapy. 3. The group treated with personal insulin pump had higher scores in all cognitive tests.

1031

Cognitive function in 6 to 12 year old offspring of women with type 1 diabetes

R.C. Temple¹, M. Hardiman², M. Martinez², M. Pellegrini²

¹Elsie Bertram Diabetes Centre, Norfolk and Norwich University Hospital NHS Trust, Norwich, ²Learning Difficulty Service, Attleborough Day Services, Attleborough, United Kingdom

Background and aims: Recent studies of offspring of women with diabetes have suggested they perform less well academically at school and that impairment of cognitive function may be related to maternal glycaemic control during pregnancy. The aim of our study was to make detailed assessments of cognitive function in 6-12 year old offspring of women with type 1 diabetes and to assess whether there was any relationship between cognitive function and characteristics of the pregnancy.

Materials and methods: Women with type 1 diabetes, who had received care throughout their pregnancy at our hospital and had children aged between 6 and 12 years, were invited to participate in the study. Assessment of the cognitive function of offspring was tested using the WISC -IV test (Wechsler Intelligence Scale for Children). Infant birthweight ratio was calculated by dividing infant birthweight by 50th centile weight matched for gestation and sex.

Results: We present the results in 40 offspring. Mean maternal duration of diabetes was 15.1 (8.4) years and mean gestation at booking for antenatal care was 7.1 (2.8) weeks. HbA1c at booking, 12 weeks, 24 weeks and 34 weeks respectively were 6.7 (1.0)%, 6.0 (0.8)%, 5.6 (0.7)% and 5.7 (0.8)%. Mean ges-

tation at delivery was 37.2 weeks. We found no difference in overall Full Scale IQ compared to UK normative data or in letter-number sequencing, a test of working memory. However, the digit span, a further test of working memory, was poorer than other parts of the WISC-IV test and significantly lower compared to UK normative data. Digit span in offspring in the study was 8.37 (2.23) compared to UK normative of 10.05 (3.2), $p < 0.01$. We found no correlation between measurement of digit span or HbA1c at any stage during pregnancy ($r = -0.225$ to 0.002), gestational age at delivery ($r = -0.178$) or infant birthweight ratio ($r = -0.176$). We divided offspring into 2 groups according to digit span test result. Comparing offspring with a digit span ≥ 9 ($n=20$) with offspring with a digit span < 9 ($n=20$), we found no significant difference in duration of diabetes (16.0 (7.8) vs 14.2 (9.1) years, gestation at booking (7.7 (3.7) vs 6.5 (1.3) weeks, gestation at delivery (37.2 (0.9) vs 37.2 (1.1) weeks or infant birthweight ratio (1.2 (0.1) vs 1.2 (0.2)). There was also no significant difference in HbA1c at booking (6.4(0.8) vs 7.0(1.1)%, at 12 weeks (6.0 (0.7) vs 6.0 (0.9)%, at 24 weeks (5.6 (0.7) vs 5.6 (0.6)% and 34 weeks (5.6 (0.8) vs 5.8 (0.7)% between groups. There was no difference in incidence of maternal severe hypoglycaemic episodes between groups. Comparing infants born before or after 37 weeks gestation, digit span was non-significantly lower (7.9 (1.8) vs 8.0 (2.4)).

Conclusion: These results, in 6–12 year old offspring of women with type 1 diabetes, suggest there is impairment of working memory but no overall impairment of cognitive function. We were unable to identify specific risk factors. These results suggest poor working memory may be a factor in the previously documented lower academic achievement in children of women with diabetes.

1032

Nurse-led multidisciplinary management improves metabolic control, self-care practices and psychological well-being of type 2 diabetic patients

X.H. Wu, L.Y. Chen, Y. Cai, X.P. Wang, C.P. Yuan, J.Y. Gu, C. Liu
Department of Endocrinology, First Affiliated Hospital of Nanjing Medical University, China

Background and aims: Group-based structured education program and nurse-care system have recently been shown to improve the glycemic control and quality of care in diabetic patients in western countries. In china, along with the huge growing numbers of diabetic patients and limited diabetologists in clinic care, it is urgent to develop an effective and feasible disease management strategy based on the routine clinic practice. In the present study, we aimed to verify the effect of the nurse-led multidisciplinary management on metabolic control, self-care practices and psychological well-being of type 2 diabetic patients.

Materials and methods: Totally, 180 type 2 diabetic patients with more than one year duration and HbA1c higher than 6.5% were enrolled and divided randomly into intensive management group ($n=90$) and usual care group ($n=90$). The two groups were comparable regarding age, education level, waist circumference (WC), HbA1c, systolic blood pressure (SBP), diastolic blood pressure (DBP), body mass index (BMI), total cholesterol (TC), triglyceride (TG), high density lipoprotein cholesterol (HDL-C), chronic complications and psychological well-being score. The intensive management group (IMG) was under the instruction of a nurse-led multidisciplinary team including diabetes nurses, diabetologists, dieticians, and rehabilitation physicians. The participants were referred to a 14-week, 28-hour diabetes education program. Subsequent follow-up visits were arranged by the nurses quarterly and IMG offered the individual medication adjustments, meal planning, and exercise reinforcement. In contrast, patients in the usual care group (UCG) continued to follow habitual consultations in the diabetes clinic and received medication and general education. One year later, outcome of metabolic control, self-care practices and psychological well-being of the patients in both groups were evaluated.

Results: After one year intervention, the level of HbA1c, DBP and WC decreased significantly in IMG ($P < 0.05$), whereas UCG did not show any significant pre- and post-intervention change. The decline of DBP, HbA1c and TC were (3.57 ± 1.8) mmHg, (0.79 ± 0.3)% and (0.22 ± 0.2) mmol/L, respectively, in IMG, which were significantly higher than that in UCG. The rate of HbA1c below 6.5% reached 30.8% one year later in IMG, which was significantly higher than 7.1% in UCG ($P < 0.05$). However, there was no significant difference in the change of target-reaching rate of BMI, lipids profile and BP between the two groups. Concerning the self-care practice, the proportion of regular diet, exercise and self glucose monitoring (more than 5 times/month) were

markedly increased in IMG whereas only the proportion of regular exercise significantly increased in UCG ($P < 0.05$). The improvement of psychological well-being in IMG were significantly higher than that in UCG ($P < 0.01$).

Conclusion: The nurse-led multidisciplinary management could significantly improve the blood glucose control, self-care practices and psychological well-being of type 2 diabetic patients. It could be served as an effective and feasible disease management strategy in China.

1033

Patient satisfaction among patients with glucose intolerance attending comprehensive cardiac rehabilitation - does cardiac follow-up treatment with an integrated diabetes care make a difference? Results from a randomized clinical trial

N.K. Nissen¹, A.B. Soja², A.-D. Zwisler², S. Rasmussen¹, T.M. Melchior³, E. Hommel⁴, J. Fischer Hansen⁵

¹Department of Epidemiology, National Institute of Public Health, Copenhagen, ²Department of Cardiology, Rigshospitalet, Copenhagen, ³Department of Cardiology, Roskilde County Hospital, ⁴Steno Diabetes Center, Gentofte, ⁵Department of Cardiology, Bispebjerg University Hospital, Copenhagen, Denmark

Background and aims: Patient satisfaction with comprehensive cardiac rehabilitation (CR) is important in a user-oriented as well as an outcome-oriented perspective. Patients with glucose intolerance (GI) eligible for CR have to cope with both the cardiovascular disease and GI, and this might be the reason for increased level of depression and lack of adherence to treatment among these patients. Therefore treatment should consider these patients' situation and their special needs. We aimed to investigate the patients' satisfaction with CR with integrated diabetes care compared to usual care (UC) in a randomised clinical trial (DANSUK) using standardised methods.

Materials and methods: The DANSUK study was conducted as a sub study during the last year of a centrally randomised clinical trial of the value of a CR clinic. Of 201 patients eligible for CR, 104 were diagnosed with GI having either type 2 diabetes ($N=68$) or impaired glucose tolerance ($N=36$). The metabolic status was based on fasting plasma glucose values and an oral glucose tolerance test. Patients were randomized after being discharged from a cardiac care unit to CR ($N=51$) and usual care ($N=53$). Mean age was 64 years; 34 % were women; 7 % had congestive heart failure, 67 % had ischemic heart disease, and 26 % had high risk for ischemic heart disease. Patients randomized to CR received 6–12 weeks of an individually tailored, multidisciplinary programme with an integrated diabetes module and clinical control after 3, 6 and 12 months. Patient satisfaction was measured as a secondary outcome after 12 month using a standardised interview-questionnaire with closed answers to questions covering overall satisfaction and level of information. A total of 95 patients (91 %) answered the questionnaire about satisfaction.

Results: Among cardiac patients with GI receiving CR, 92% reported a high level of overall satisfaction with follow up treatment compared with 30% among patients receiving usual care ($p < 0.00001$). The CR group reported a higher level of satisfaction according to information about their disease (CR: 94 %, UC: 42 %; $p < 0.0001$), information on diagnose and treatment (CR: 91 %, UC: 47 %; $p < 0.00001$), self-management of life-style changes (CR: 84 %, UC: 43 %; $p = 0.01$), and self-management of medicine (CR: 36 %, UC: 17 %; $p < 0.05$). Subgroup analysis showed no differences in degree of satisfaction according to gender, age or ethnic group.

Conclusion: We found that CR with an integrated diabetes module significantly improves overall satisfaction with follow-up treatment together with level of information and self-management among glucose intolerant patients receiving CR compared with patients receiving usual care. The results should be interpreted with caution due to the non-blinded design.

³Diabetology, Catholic University, ⁴Pediatrics, Bambino Gesù Children's

Hospital, ⁵Diabetology, San Camillo Hospital, ⁶Endocrinology and

Diabetology, San Giovanni's Hospital, Roma, Italy

Background and aims: Poor metabolic control is associated with the development of complications in patients with type 1 diabetes (DM1) and amongst factors contributing to it, sedentary life and lack of physical exercise play a major role. In the present study we investigated the influence of different leisure time behaviors (TV viewing, playing computer games and doing some form of sport) on blood glucose control in a group of young DM1 patients.

Materials and methods: We evaluated, by direct interviews, 86 consecutive subjects (44 males), median age: 18.8 years, range: 6 - 32, 49 subjects younger than 18 years. Median disease duration was 15.3 years (range: 1 - 25), mean HbA1C: $8.1\% \pm 1.4$, mean insulin requirements: 0.74 ± 0.27 U/kg/day. Mean daily hours of watching TV were 2.02 ± 0.89 hours/day; 3 patients (3.5%) watched TV < 1 h/day, 48 patients watched TV 1-2 h/day (56%), 23 subjects (26.6%) watched TV 2-3 h/day, and 12 subjects (13.9%) spent more than 3 h/day watching TV.

Results: Daily hours of watching TV were significantly and positively related to DM1 duration ($p = 0.0005$) and not significantly different in patients younger or older than 18 years (younger: 2.1 ± 1.0 , older: 1.93 ± 0.7 - $p = 0.38$). Mean time spent playing sports was 2.57 ± 2.24 hours/week (range: 0 - 8); it was not significantly different in patients younger or older than 18 years (younger: 2.76 ± 2.1 , older: 2.33 ± 2.2 - $p = 0.36$) and 25 subjects (29%) were completely sedentary. Mean time spent using a personal computer, excluding studying or working by the computer was significantly higher in patients > 18 years (younger: 1.37 ± 1.27 , older: 2.49 ± 1.97 - $p = 0.003$) and not correlated with DM1 duration ($p = 0.34$). HbA1C%, daily insulin requirements and BMI were not related to the number of hours of TV watching ($p = 0.38$ - 0.21 - 0.20 respectively), nor to the number of daily hours spent using the computer ($p = 0.06$ - 0.8 - 0.79 respectively). Conversely, the time spent doing some form of sport (hours/week) was significantly and negatively related to HbA1C levels ($p = 0.02$). Patients who practiced more physical exercise tended to have lower daily insulin requirements and lower BMI, but the association did not reach statistical significance ($p = 0.27$ and $p = 0.22$ respectively).

Conclusion: Previous studies described a direct and significant correlation between excessive TV viewing and elevated HbA1C levels. We do not confirm these findings. On the contrary, physical activity remains one of the most significant determinant of blood glucose control in DM1 patients, and surprisingly increasing duration of the disease is associated with more TV watching (but not computer use), suggesting that DM1 induces a passive lifestyle behavior.

1035

The PREPARE (Prediabetes Risk Education and Physical Activity Recommendation and Encouragement) study: results at 3 months

T. Yates¹, K. Khunti², F. Bull¹, T. Gorely¹, D. Talbot³, M. Davies⁴

¹School of Sport and Exercise Sciences, Loughborough University, ²Health

Sciences, University of Leicester, ³Corporate Research, Unilever, Bedford,

⁴Cardiovascular Sciences, University of Leicester, United Kingdom

Background and aims: The PREPARE study is a randomized controlled trial designed to test the efficacy of a theory-driven, group-based, structured educational programme at increasing physical activity and improving glucose tolerance in individuals with impaired glucose tolerance (IGT); we also investigate whether the efficacy of the educational programme is enhanced by the inclusion of a pedometer and personalized steps/day goals. Three-month follow-up data is reported here.

Materials and methods: Overweight or obese individuals with IGT were recruited. At baseline and follow-up each participant was given an oral glucose tolerance test: outcomes included fasting and 2-hour glucose, fasting insu-

lin, lipid profile and markers of chronic low-grade inflammation. Standard anthropometric measurements were also taken and participants were asked to wear a sealed piezoelectric pedometer for seven consecutive days and to complete a questionnaire measuring their perceptions of IGT. Participants were randomized to receive either usual care, structured education (E group) or structured education which incorporated pedometer use (EP group). The study was powered to detect a 1 mmol/l difference in 2-hour glucose at one year. Differences in change from baseline in the intervention groups compared to the control group were analysed using ANOVA modeling; Dunnett's adjustment for multiple comparisons was applied.

Results: 101 (male $n=64$; female $n=37$) participants were recruited; 30% were from a south Asian ethnic background. Three-month follow-up data was available for 93 (92%) of participants. In the EP group at three months there was: an increase in ambulatory activity of 2611 ± 2846 steps per day ($p < 0.01$ vs. control); a decrease in 2-hour and fasting glucose of -1.4 ± 1.9 mmol/l ($p < 0.01$ vs. control) and -0.2 ± 0.5 mmol/l ($p = 0.04$ vs. control) respectively; and a decrease in tumor necrosis factor- α of -0.1 ± 0.3 pg/ml ($p = 0.04$ vs. control). There was no significant change in any of these variables in the E group compared to the control group. There was no significant change in either intervention group compared to the control group in fasting insulin, interleukin-6, C-reactive protein, blood lipid profile or waist circumference. Compared to baseline, both intervention groups reported a significant ($p < 0.05$) increase in perceived knowledge of prediabetes, although there was no significant difference compared to the control group. Change in ambulatory activity was correlated with change in perceived knowledge of prediabetes ($p = 0.28$, $p = 0.01$).

Conclusion: This study suggests that structured education that enables participants to set realistic, personalized steps per day goals is effective at increasing ambulatory activity, improving glucose tolerance and reducing levels of inflammatory adipokines in individuals with IGT. A decrease in 2-hour glucose of this magnitude has been associated with around a 60% reduction in the relative risk of developing type 2 diabetes. This study also suggests that targeting illness perceptions may be important when promoting health behaviour change in those with IGT.

1036

Long term effects of empowerment-based patient education on weight loss, diet and physical activity in patients with type 2 diabetes

L. Dencker¹, H. Meden¹, S. Molsted¹, J. Tribler¹, O. Snorgaard²

¹Diabetes School, Nordsjællands Hospital, Hillerød, Denmark, ²Department of Endocrinology, Hvidovre Hospital, Denmark

Background and aims: Diet and physical activity (PA) are cornerstones in the treatment of type 2 diabetes (T2D). Patient education programmes are widely used to improve diet and level of PA. The aim of this study was to investigate the effect of an empowerment-based patient education programme on body weight, diet and PA in T2D patients.

Materials and methods: 702 T2D patients consecutively referred from general practice were included. 53 % were women, age was 61 ± 10 (mean \pm SD) years, duration of diabetes was 4.7 ± 4.8 years, and BMI was 31.3 ± 6.0 kg/m². The intervention consisted of 3 periods of education during 12 months: Four days at baseline, 2 days after 3 months, and one day after 12 months. The education was based on the empowerment philosophy and was delivered by a physician, a nurse, a dietician, and a physiotherapist in groups of 10-12 patients. We aimed to improve the patients' self management capacity by identifying rather than solving problems, increasing knowledge and skills, and urging them to set up own goals. The education further included practical skills in preparing healthy food and a programme for PA.

Food intake and PA were assessed with The Danish Health and Morbidity Survey 2000 Questionnaire, which includes a seven-day record. Data for body weight and waist circumference were provided by the general practitioners.

Results: At baseline, the Danish recommendations on diet were followed by 24 % of the subjects according to the reported intake of fruit and cooked or raw vegetables (≥ 600 gram per day), by 41 % according to fish intake (eating fish several times per week), by 15 % according to both fruit/vegetables and fish intake, and by 88 % according to physical activity (30 minutes of moderate PA per day). 71 % reported maintaining a healthy diet in order to stay healthy. Of those however, only 19 % met the recommendations for fruit/vegetables and fish. The patients' goals were loss of weight (61 %), increased PA (57 %) and a more healthy diet (41 %).

During the intervention, the body weight of women decreased from 85.8 ± 18.2 to 83.2 ± 17.3 kg at 3 months ($p < 0.001$) and to 81.8 ± 17.0 kg at 12 months ($p < 0.001$). The body weight of men decreased from 96.7 ± 18.8 to 93.6 ± 17.6 kg at

3 months ($p<0.001$) and to 93.2 ± 17.4 kg at 12 months ($p=0.028$). Waist circumference decreased in women from 103.4 ± 13.9 to 99.5 ± 13.3 cm ($p=0.003$) after 12 months and was unchanged in men. Compared to baseline, 9 % increased intake of cooked vegetables ($p=0.024$), 12 % increased intake of raw vegetables ($p=0.005$), and 22 % increased intake of fish ($p<0.001$). No changes were reported in the intake of fruit. The level of PA was increased in 9 % ($p=0.001$). The weight reduction was positively associated with the change of intake of fruit ($p=0.011$) and PA ($p<0.001$), and negatively associated with the change of intake of fish ($p=0.050$).

Conclusion: An empowerment- and group-based patient education programme had long term (12 months) effects on weight loss, diet, and level of physical activity.

1037

The role of combined physical therapy interventions and exercise on different aspects of health related patients with type 2 diabetes

I. Mokhtari¹, K. Ezzaty², N. Karimi², M. Kamali fard³, K. Esmailzade⁴, M. Ojaghi⁵

¹PM&R Department, Diabetic Foot and Rehabilitation Clinic, Special Medical Center, ²Physiotherapy Department, University of Social Welfare & Rehabilitation, ³Occupational Medicine, Health and Labour Research Center, ⁴PM&R Department, University of Social Welfare & Rehabilitation, ⁵Diabetic Foot and Rehabilitation Clinic, Special Medical Center, Tehran, Islamic Republic of Iran

Background and aims: The purpose of this Randomized Controlled Trial (RCT) study was to investigate the impact of a 4 month physical therapy interventions and exercise on different aspects of health related quality of life including physical and social functioning, bodily pain, general health, vitality, social functioning, role limitation- emotional, and total scores using SF-36 scale in subjects with type 2 diabetes.

Materials and methods: All subjects met the American Diabetes Association diagnostic criteria for type 2 diabetes. Among 142 patients with type 2 diabetes, 95 subjects have the inclusion criteria for this study. They were randomized to control group ($n=48$, age= $53\pm 2/2$ mass= $73\pm 3/1$) and physical therapy interventions group ($n=47$, age= $52\pm 1/7$; mass= $73\pm 4/2$). All patients in the latter group were given a training session and received 30 minute pain modalities (IF, IR and kneading massage) for lower extremity. Then stretching, strength and endurance exercises were trained to them during 3- 4 sessions. The patients did the supervised exercises 3 times per week during 4 month. The control group did not receive any treatment. All subjects were given an SF-36 scale to fulfill pretest and posttest.

Results: There were no significant differences in the main parameters of health related quality of life among groups at the baseline. At the end of the rehabilitation program, In a between group comparison, the results of independent sample t-test analysis showed significant changes in physical functioning, general health, physical component summary and total scores of SF-36 scale ($P<0.001$). But social functioning, role limitation- emotional, mental component summary scores were not significance ($P>0.05$). Also, there were no significant changes in the control group.

Conclusion: Regular supervised integrated exercise and physical therapy is a safe and effective intervention in diabetic patients, which significantly improves health related quality of life especially physical components in patients with type 2 diabetes, which may favorably influence their long-term prognosis.

A randomized controlled trial of nordic walking versus exercise on prescription to improve glycaemic control in type 2 diabetes

B. Gram¹, C. Christiansen², J. Gram²

¹Institute of Sports Science and Clinical Biomechanics, University of Southern Denmark, Odense, ²Dept. of Endocrinology, Ribe County Hospital, Esbjerg, Denmark

Background and aims: The effectiveness of physical exercise in the treatment of type 2 diabetes has long been recognized. It is, however, unknown whether one specific type of training is more suitable than others with respect to the physical/metabolic effects as well as the ability to induce good compliance and change in physical life style.

Our aim was to evaluate the effect of two different physical exercise programs lasting 4 months aiming at introducing long term life style changes in physical activity with a follow-up period of 8 months in patients with type 2 diabetes.

Materials and methods: A randomized, controlled study. 68 patients with type 2 diabetes (37 males, 31 females; mean age 60.7 ± 1.2) were allocated in three groups: 1. Nordic Walking (NW) ($n=22$), 2. Exercise (Exercise on Prescription) (Ex) ($n=24$) and 3. Control group (C) ($n=22$).

During the first 2 months, the participants in the two intervention groups trained 2 times weekly and the next 2 months once a week. Each supervised training session lasted 45 min and the participants were instructed to exercise corresponding to moderate intensity. The controls received no supervised training but, at the inclusion they were advised to be physical active. All participants were tested at 0, 4, and 12 months (biochemistry, anthropometry, DEXA, indirect VO_2 max test, SF36). The primary effect parameter was glucose metabolism evaluated by glycated hemoglobin (HbA_{1c}). The sample size calculation was based on a minimal relevant difference in HbA_{1c} of 0.8% point.

Results: The overall attendance rates were $63\pm 7\%$ in NW and $64\pm 7\%$ in Ex. HbA_{1c} did not change significantly in the intervention groups compared to Control (Δ NW: -0.4% (-0.9 - 0.1) (95% CI) and Δ Ex: -0.2% (-0.6 - 0.2) after 4 months and Δ NW: 0.0% (-0.6 - 0.5) and Δ Ex: 0.3% (-0.3 - 0.9) after 12 months. Neither did Total HDL-cholesterol and triglyceride levels. Fat mass significantly decreased in the NW-group after 4 months (-1.0 kg (-1.7 - 0.1)) and after 12 months both in NW (-1.8 kg (-3.2 - -0.4)) and in Ex (-1.5 kg (-2.9 - -0.05)). No significant changes in blood pressure, VO_2 max, and in quality of life measured by SF36

Conclusion: Four months' physical exercise programs with low to moderate intensity of Nordic Walking or Exercise per prescription did not significantly improve HbA_{1c} in patients with type 2 diabetes neither at end of programs nor at follow-up. Besides loss of fat mass in both intervention groups at 12 months there were no parameters indicating a significant change in physical lifestyle at follow-up.

¹Health Economics, CEMKA-EVAL, Bourg-la-Reine, ²Epidemiology, CEMKA-EVAL, Bourg-la-Reine, ³Diabetology, Hôpital Pitié-Salpêtrière, Paris, ⁴General Practice, Faculté de médecine, Créteil, ⁵Medical Department, GlaxoSmithKline, Marly-le-Roi, ⁶Diabetology, Hôpital Hotel-Dieu, Nantes, ⁷Unité 780, INSERM, Villejuif, ⁸Chronic Diseases, INVS, Saint-Maurice, ⁹Diabetology, Hôpital Jeanne d'Arc, Dommartin les Toul, ¹⁰Diabetology, Hôpital Michallon, Grenoble, ¹¹Health Economics, GlaxoSmithKline, Marly-le-Roi, ¹²Diabetology, ANCRE, Villeneuve Saint-Georges, France.

Background and aims: Recent years have seen a number of healthcare initiatives and developments aimed at improving the quality of diabetes care. The objective of this study was to assess care provision for diabetes in standard care in France and its evolution in the recent years.

Materials and methods: The ECODIA2 study was a descriptive cross-sectional epidemiological study of patients with type 2 diabetes in France performed in 2005. Data were collected using questionnaires completed by a representative sample of physicians treating diabetes. Data were compared with those from the 1999 ECODIA study which used a similar methodology.

Results: Questionnaires were available for 4 071 patients with type 2 diabetes. Compared to the first 1999 ECODIA study, little change was observed for age (mean age: 65 years), gender (ratio: 5 men to 4 women), time since diagnosis (mean: 8.3 years) or the prevalence of risk factors (80.4% were overweight, 10.4% were smokers and 87.3% had hypertension) for the diabetic patients in 2005 in France. In contrast, only 19.2% of patients presented an HbA1c level > 8%, which represents a marked improvement compared to 31.4% in 1999 ($p < 0.001$). Between 1999 and 2005, the proportion of patients treated by diet and exercise alone decreased from 9.5% to 2.7%, the proportion treated with oral antidiabetic drugs who received biguanides increased from 30.8% to 46.6% and the proportion treated with insulin rose from 5.6% to 14.1%. Nonetheless, the improvement on glycaemic control has not yet been translated into a reduction in the incidence of micro- or macro-vascular diabetes-related complications.

Conclusion: These results reveal a promising evolution in the quality and effectiveness of diabetes care in France over the last six years. Similar improvements in care have been observed in other countries. The results obtained reinforce the need to pursue and expand public health policies aimed at implementing best practice recommendations into standard care. It is also important to monitor regularly the impact of these policies in everyday clinical practice.

Gender differences in the prevalence of undiagnosed type 2 diabetes and associated cardiovascular risk factors according to the education level among the employed residents of Chelyabinsk

I.A. Vaychulis¹, I.I. Shaposhnik¹, T.N. Vaychulis²

¹Internal Medicine Department, Chelyabinsk State Medical Academy,

²Endocrinology Department, Chelyabinsk Municipal Hospital No 1, Chelyabinsk, Russian Federation

Background and aims: The association between type 2 diabetes (DM2) and socioeconomic factors differs across various populations. The aim of this study was to estimate the prevalence of unknown DM2 and cardiovascular (CV) risk factors among working residents of Chelyabinsk (Russian Federation) according to the education level and gender to define target social groups for DM2 screening and prevention.

Materials and methods: Chelyabinsk is a big industrial city with the population aged 40 y and older of 493963 (197533 m / 296430 w). We examined a total of 4238 (1661 m / 2577 w) randomly selected workers of 15 enterprises and institutions, located in all 7 administrative districts of the city, aged 40-70 y (mean±SD 52.0±6.8 y). After exclusion of the employees with known DM fasting capillary glucose (FCG) was analyzed with glucometer Accu-Chek Active (Roche Diagnostics) and in people with FCG 5.6-6.0 mmol/l standard OGTT was performed. Weight, height, waist circumference (WC), systolic (SBP) and diastolic blood pressure (DBP) were measured and body mass index (BMI) was calculated. General linear univariate model with age adjustment was used to compare sex-specific prevalence rates of unknown DM2 (WHO criteria, 1999), total obesity (BMI≥30 kg/m²), abdominal obesity (WC>88 cm in w, WC>102 cm in m) and arterial hypertension AH (SBP≥140 and/or DBP≥90 mm Hg and/or medication use) in high vs secondary/professional education groups. Multinomial logistic regression analysis controlling for age, obesity, AH and family history of DM2 was used to estimate the association between undiagnosed DM 2 and level of education.

Results: Age-adjusted prevalence of unknown DM 2 and CV risk factors in men did not significantly differ across the education groups ($p>0.05$, table). In multinomial logistic regression analysis having undiagnosed DM2 was not significantly associated with lower education level neither in men [OR 1.35; 95%CI 0.86-2.12], nor in women [1.39; 0.89-2.17]. However, among women, unknown DM2, AH, total and abdominal obesity were consistently more prevalent in the employees with lower education (table). Age-adjusted prevalence of undiagnosed DM2 was higher in men ($7.4\pm0.6\%$) than in women ($5.7\pm0.8\%$, $p=0.029$), but this difference turned out to be non-significant when compared men to women with lower education ($7.4\pm0.6\%$ vs $6.4\pm1.0\%$, respectively, $p>0.05$).

Conclusion: Education level was not independently related to undiagnosed DM2, but women with lower education have demonstrated significantly higher prevalence of CV risk factors and unknown DM2. Level of education should be considered when selecting first-line target groups for DM2 screening and prevention among the employed women 40 y and older.

Age-adjusted prevalence of unknown DM 2 and CV risk factors by educational level.

Gender	Men		Women	
Education level	Secondary / professional	High education	Secondary / professional	High education
Education level	1133	492	1776	743
Unknown DM2	7.9 ± 1.4	6.2 ± 1.2	6.4 ± 1.0	$3.8 \pm 0.8^*$
Total obesity	21.0 ± 2.2	19.7 ± 1.8	41.5 ± 2.1	$29.4 \pm 1.8^{**}$
Abdominal obesity	18.9 ± 2.1	18.3 ± 1.7	45.4 ± 2.1	$32.0 \pm 1.8^{**}$
Arterial hypertension	59.9 ± 2.6	55.1 ± 2.2	52.3 ± 2.2	$43.2 \pm 1.8^{**}$

Patients opinion on the barriers to diabetes control in areas of conflicts: the Iraqi example

A.A. Mansour

Medicine, Basrah College of Medicine, Basrah, Iraq

Background: The health system in Iraq has undergone progressive decline since the embargo that followed the second gulf war in 1991. The aim of this study is to see barriers to glycemic control from the patient perspective, in a diabetic clinic in the south of Iraq.

Methods: A cross sectional study from the diabetes out-patient clinic in Al-Faiha general hospital in Basrah, South Iraq for the period from January to December 2007. The study includes diabetics whether type 1 or 2 if they have at least one year of follow up in the same clinic. Those with HbA1C $\geq 7\%$ were interviewed by special questionnaire, that was filled in by the medical staff of the clinic. The subjects analyzed in this study were adults (≥ 18 years old) with previously diagnosed diabetes ($n = 3522$). The duration of diabetes range from 1 to 30 years.

Results: Mean HbA1C was 8.4 ± 2 percent, with 835 (23.7%) patients with HbA1C less than 7% and 2688 (76.3%) equal to or more than 7%. Of 3522 studied patients, 46.6% were men and 51.5% were women, with mean age of 53.78 ± 12.81 year and age range 18–97 years. Patient opinion for not achieving good glycemic control among 2688 patients with HbA1C $\geq 7\%$ included the following. No drug supply from primary health care center (PHC) or drug shortage is a cause in 50.8% of cases, while drugs and or laboratory expense were the cause in 50.2%. Thirty point seven percent of patients said that they were unaware of diabetics complications and 20.9% think that diabetes is an untreatable disease. Thirty percent think that non-control of their diabetes is due to migration after the war. No electricity or erratic electricity, self-monitoring of blood glucose (SMBG) is not available, or strips were not available or could not be used, and illiteracy as a cause was seen in 15%, 10.8% and 9.9% respectively.

Conclusion: Our patients with diabetes mellitus declared that of the causes for poor glycemic control most of them related to the current health situation in Iraq.

1042

Improving the control of diabetes among Israeli Arabs

J. Khury, D. Kurzum, S. Abd elhadi, D. Besharat, I. Hilf

Family Medicine- Nazareth B' Clinic, Clalit Medical Services- Northern district, Nazareth, Israel

Background and aims: The prevalence of Diabetes Mellitus (DM) among Israeli Arabs (about 12%) is significantly higher than it is among Israeli Jews and other populations from other developed countries (6–8%). On the other hand, the percentage of controlled diabetic patient (HbA1C < 7) among this group (28%) is less than in Israeli Jewish population and populations from other developed countries (55%). It's also known that the incidence and severity of diabetic complication in Israeli Arabs is high especially among Arab women. Lastly DM was declared as a universal epidemic. It's widely proved that controlling DM markedly reduces the incidence of diabetic complications and death, what makes it worth to invest in the efforts to control this disease. The prevalence of DM among Nazareth B' Clinic patient is as high as 14% (1221 patients), only 38% of them were controlled. 21% of the patients were severely uncontrolled (HbA1C > 9).

Materials and methods: We conducted a study which aimed to achieve the goal of 45% controlled patients at the first year of intervention. DM "control" included desirable values of Blood Lipids, Blood Pressure, Proteinurea, BMI and eye examination. We randomly choused 184 uncontrolled patients with HbA1C > 9 , age between 20–65 years from the Electronic Medical Records (EMR). They were divided into sub groups of 8–10 patients. Each sub group was invited for follow by Family Physician, Diabetic Nurse, Dietitian and Social Worker every 3 months. The multidiscipline crew met once weekly to discuss the problematic issues that arise throughout the day work.

The intervention based on improving the

1- "Medication Adherence" and way of life which included encounter with dietitian, social worker, joining groups for physical activity and empowerment.

	fasting glucose	HbA1C	CHOL	LDL	HDL	TG	sys. BP	dias BP	BMI
prior intervention	257.2	11.7	174.6	112.1	44.1	215.2	129.7	75.9	34.3
after intervention	158.9	8.5	171.3	102.5	45.3	153.2	125.6	74.9	30.6
desired goal	110	7	160	100			120	80	25

2- "Clinical Interia" which included encounter with especially trained nurse and physician and recheck up by pharmacist for acknowledgment of medication usage.

3- "Treatment failure" by treating the treatment resistance with proper and effective medications.

Results: The results of the first year of interventions show a significant improvement of most of the control criteria of DM as shown in the following table.

Conclusion: Follow up and treatment of problematic and hard to control Diabetic populations should be carried out by a multidiscipline team of family physicians, especially trained nurses, dietitians and social worker:

Lipid management in type 1 and type 2 diabetes patients in Belgium - subject for quality improvement

N. Debacker¹, F. Nobels², C. Mathieu³, A. Scheen⁴, P. Van Crombrugge²

¹Epidemiology, Scientific Institute of Public Health, Brussels,

²Endocrinology, OLV Ziekenhuis, Aalst, Belgium, ³Endocrinology, UZ

Gasthuisberg, Leuven, ⁴Endocrinology, Centre Hospitalier Universitaire Sart Tilman, Liege, Belgium

Background and aims: In Belgium the Initiative for Quality improvement and Epidemiology for Diabetes (IQED) organised in all hospital-based multidisciplinary diabetes centres aims to improve quality of care. As a 2008 quality initiative blood lipid management is highlighted.

Materials and methods: In 2007 121 diabetes centres provided data on a random sample of 10% of their adult diabetes patients on ≥ 2 daily insulin injections. By using the IQED-software data on patient characteristics, glycemic control, cardiovascular risk profile, diabetes complications, blood glucose self-monitoring, follow-up procedures and treatment were obtained. LDL-cholesterol was calculated using the Friedewald formula.

	Type 1 diabetes	Type 2 diabetes
Number of patients	3186	7174
Median age (years)	44	69
Median duration (years)	17	12
% men	56	49
Median HbA1c (%)	7.8	7.4
Statin treatment		
% treated with statins	28	59
% treated with statins when presence of CVD	71	72
distribution across the centres (P10-P50-P90)	29-100-100	48-71-93
% treated with statins when microalbuminuria	35	56
distribution across the centres (P10-P50-P90)	0-31-100	25-53-88
% treated with statins when older than 40 years and ≥ 1 CV risk factor	37	58
distribution across the centres (P10-P50-P90)	0-25-56	30-57-85
Achievement of LDL-targets		
Statin treated patients reaching LDL-target		
- No CVD: % LDL < 100 mg/dl	46	66
distribution across the centres (P10-P50-P90)	0-25-67	0-37-68
- CVD: % LDL < 70 mg/dl	29	34
distribution across the centres (P10-P50-P90)	0-0-50	0-17-43

Results: Table: population characteristics, statin treatment, achievement of treatment goals and distribution of the results across the centres (percentile 10, 50 and 90) by type of diabetes.

Of DM1 and DM2 patients resp. 8 and 31% have cardiovascular disease (CVD: myocardial infarction, PTCA/CABG or stroke), 16 and 35% have microalbuminuria and 50 and 80% have at least one other CV risk factor (BMI > 30 kg/m²; blood pressure $> 140/90$ mmHg or smoking). Where in case of CVD an equal proportion of DM1 and DM2 patients are treated with statins, more DM2 than DM1 patients are treated in case of another risk profile. Compared to 2006, where 24% of DM1 and 50% of DM2 patients were treated, statin

treatment increased significantly (irrespective of age and diabetes duration). For treatment goal achievement we looked at LDL-cholesterol levels, available for only 51% and 55% of resp. DM1 and DM2 patients. Treatment goals are reached significantly more often in type 2 than in type 1 diabetes patients without CVD. Compared to 2006, where 23% of DM2 patients with CVD and 52% of DM2 patients without CVD reach the LDL-target, significantly more patients reach the target in 2007. The variations between the centres are large. Also regarding the determination of fasting lipids the variation between the centres is high: 10% of the centres have nearly no fasting lipid determinations and 10% have for nearly all their patients a fasting lipid profile.

Conclusion: The studied population has an important CV risk requiring appropriate treatment. Compared to 2006 more patients are treated and reach treatment goals. However, a large part of the patients remains without treatment and does not reach the treatment goals and this varies considerably between the centres. Moreover a fasting blood lipid profile is not available for a large part of the population, hampering the calculation of LDL-cholesterol. So room for improvement remains. To induce this we aim to bring cardiovascular risk and treatment to the attention of the centres by providing more specific feedback (benchmarks) concerning this aspect.

IDF quality assistance indicators based on metabolic control level in patients with DM2 in Spain

J.I. Diago, J. Reviriego, P. Polavieja, F. Chacon
Medical Research, Lilly Spain, Alcobendas, Spain

Background and aims: To evaluate the compliance level of measures of care recommended by IDF (International Diabetes Federation) in relation to metabolic control in non-insulin treated type 2 diabetes mellitus (DM2) patients, in standard clinical practice in Spain.

Materials and methods: A retrospective, observational, naturalistic and multicentre study, that reviews clinical records of a 2-year period previous to the inclusion of patients in the study. A total of 216 physicians participated (endocrinologists, internal medicine specialists and general practitioners). Sociodemographic, socioeconomic, clinical and assistance variables were collected. Indicators of quality of assistance provided to patients with DM2

according to the IDF 2005 were assessed (see Table 1). The 6th IDF indicator ("begin insulin therapy when optimized oral glucose-lowering drugs and lifestyle interventions are unable to maintain blood glucose control at target levels") was not applicable due to patients' inclusion criteria. Metabolic control was defined according to IDF and ADA (American Diabetes Association) criteria (good metabolic control = HbA1c ≤ 6.5; HbA1c < 7%, respectively). Group comparisons were done by means of Chi-square tests.

Results: Clinical records from a total of 2,266 patients were reviewed. Mean age (SD) was 64.4 (11.1) years. 47.2% were female; 7.7% of fertile age. Median time (IQR) of diagnosis was 5.9 (2.9–10.1) years. According to IDF and ADA criteria, 41.8% and 59.9% of patients had good metabolic control, respectively. Mean number (SD) of accomplished indicators was 6.7 (2.1), out of 12 selected for this population. There were no significant differences between good and poor metabolic control groups following IDF (6.6 (2.2) and 6.7 (2.1) respectively) or ADA criteria (6.7 [2.2] and 6.6 [2.1] respectively). Indicators number 2, 8, 9, 10 and 12 were the least followed ones (48.3%, 34.3%, 22.6%, 35.2% and 48.6% respectively). Their monitoring was slightly higher in patients with good vs. poor metabolic control ($p < 0.05$ for indicators 2, 9 and 10, following ADA criteria) (see Table 1). Indicators 4 and 5 were monitored more frequently in patients with poor control ($p < 0.01$).

Conclusion: Compliance of quality assistance indicators in clinical practice in Spain is low, although it is slightly higher in patients with good metabolic control. Some assistance indicators are more followed in patients with poor metabolic control, what probably indicates the more care that these patients need. Nevertheless, there is a need to improve both, number and frequency of these measurements of care, in daily clinical practice in Spain.

Improved HbA_{1c} and blood pressure values in 11752 patients with diabetes on the primary health care level ten years after initiation of a diabetes-check up programme by the “Deutsche BKK”

U.A. Müller¹, N. Müller¹, C. Kloos¹, G. Wolf¹, R. Berner²

¹Funktionsbereich Endokrinologie und Stoffwechsel, University Hospital Jena, ²Controlling und Versorgungsmanagement, Deutsche BKK Stuttgart, Wolfsburg, Germany

Background and aims: The Deutsche BKK, the health insurance for employees of the Volkswagen AG and Deutsche Post AG, initiated and sponsored a diabetes quality assurance programme (“Diabetes TÜV”) in 1997. The intention of the programme was to improve the quality of primary care for insured patients with known diabetes by motivating local general physicians to perform standardized diabetes-related clinical examinations. HbA_{1c} and blood pressure (BP) could be evaluated now over a period of ten years.

Patients and methods: Participants were informed about the programme by Deutsche BKK and their local general practitioners twice by a mailing. Physicians were motivated to support the programme by a additional remuneration of 25 Euro for every examination performed. In order to improve the reliability of clinical examinations and data recording, patients' and physicians' signatures on the documentation of the results was a prerequisite for the remuneration. All patients with known type 1 or type 2 diabetes were eligible for the programme. Participants who agreed to participate were recruited in consecutive order as they were referred. The presence of diabetic late complications, cardiovascular events, HbA_{1c}, blood pressure, creatinine and microalbuminuria were documented once a year. 15111 documentation sheets of 11752 patients were provided by 351 practices in the periods 1997–2000 and 2002–2006. HbA_{1c} was adjusted to an upper normal range of 6.1% of total Hb.

Results: The mean systolic BP was 142.9, the mean diastolic BP pressure 81.0 mmHg and the mean HbA_{1c} 7.10% of total Hb over the whole period. There was a significant improvement of systolic BP (-10.5 mmHg), diastolic BP (-4.1 mmHg) and HbA_{1c} (-0.49% of total Hb) over the decade (Table). The decrease was continuous over the whole period (Bonferroni).

Conclusion: The quality of care of patients with diabetes mellitus insured by the Deutsche BKK improved over the period from 1997 to 2006. The decrease of BP was comparable to the intervention group of the UKPDS (BP systolic -10; diastolic -5 mmHg). The mean HbA_{1c} at the beginning of the programme was lower than the baseline HbA_{1c} of the UKPDS. The mean HbA_{1c} at the last observation year was comparable to the intervention group of UKPDS and DCCT. A yearly documentation was sufficient for the monitoring of changes in the quality of diabetes care.

Quality of care in the Diabetes-TÜV programme

Addressing the gap for diabetes education services in a rural US community

L.M. Siminiero¹, A. Uhler², A. Cook³, G. Piatt³, J. Zgibor⁴, K. Ruppert⁴

¹Endocrinology, University of Pittsburgh Diabetes Institute, ²UPMC, University of Pittsburgh Medical Center, ³UPMC, University of Pittsburgh Diabetes Institute, ⁴Graduate School of Public Health, University of Pittsburgh Diabetes Institute, United States

Background and aims: Healthy People 2010 is a comprehensive set of disease prevention and health objectives for the US. The goals are to increase quality within focused areas. Diabetes self-management education (DSME) is essential for the proper management of diabetes and ultimately prevention of complications. A Chronic Care Commission has been instituted in the US state of Pennsylvania (PA) to improve quality of care, specifically for diabetes. A Healthy People objective is to increase the proportion of persons with diabetes who receive education from 45 to 60%. Citizens residing in PA are lagging behind the target for education (50%). PA has the second largest senior population and largest rural population of any state accounting for 30% of its population. Evidence suggests that sub-optimal outcomes in people with diabetes in rural communities are due to limited preventive health services and access to specialists, like diabetes educators. Clinicians in rural settings also lack availability of clinical information systems and organizational support from larger health systems. Our aim was to use elements of the Chronic Care Model (health system, community, decision support, information systems, self-management, system redesign) as a framework to help clinicians meet Healthy People goals in rural PA.

Materials and methods: The Pittsburgh Regional Initiative for Diabetes Education (PRIDE) was developed to build a collaboration between the University of Pittsburgh Medical Center with outlying rural communities in an effort to gain organizational and community support for self-management services. ADA standards were used for decision support; an information system served as a registry for local primary care practices and educators to communicate data; and an education center was established to address system redesign. Our first objective was to examine all patients with a diagnosis of diabetes seen at the local primary care practices to determine characteristics of those who had not received DSME. A total of 844 patients were seen at these practices between 7/18/06 and 2/29/08. Of them, 566 (67%) patients had a complete education history and were included in this analysis.

Results: Mean age was 61.4, 48% were males, 82% had type 2 diabetes, with mean diabetes duration of 9 yrs. Risk factors for coronary artery disease (CAD)(hyperlipidemia, obesity BMI >30, reported smoking, and hypertension) were studied in this group. 49% had LDL ≥ 100mg/dL, 60% were obese, 25% were smokers, and 82% had some indication of hypertension. 94.5% of these patients had 2 or more risk factors for CAD. Co-morbidities included CAD (20%), retinopathy (2.5%), neuropathy (16%) and nephropathy (15.5%). 35% (n = 200) had not received DSME.

Conclusion: Despite high rates of obesity and risk factors for CAD, a large proportion of patients had not received DSME that includes nutrition therapy. As we quickly approach the 2010 milestone, US systems, like PA, would be wise to consider a paradigm of systematic approaches in support of clinicians in high risk rural communities. A critical first step is the identification of those people who are in greatest need for DSME.

Resource use associated with type 2 diabetes in 24 countries in Asia, Latin America, the Middle East and Africa

S. Mechiche¹, A. Ringborg^{2,3}, P. Lindgren^{2,3}, J. Bengt⁴, A. Ramachandran⁵, J.J. Gagliardino⁶

¹sanofi-aventis, Paris, France, ²Cardiovascular and Metabolic Diseases, i3 Innovus, Stockholm, ³Institute of Environmental Medicine, Karolinska Institute, Stockholm, ⁴Centre for Health Economics, Stockholm School of Economics, Sweden, ⁵Dr. A. Ramachandran's Diabetes Hospitals, India Diabetes Research Foundation, Chennai, India, ⁶Faculty of Medical Sciences, CENEXA (UNLP-CONICET), La Plata, Argentina

Background and aims: There is a paucity of data on the economic burden imposed by type 2 diabetes (T2DM) in the developing world. The aim of this study was to estimate average quantities of diabetes-related resource use among T2DM patients in 24 countries in Asia, Latin America, the Middle East and Africa and to investigate predictors of resource use in each region.

Materials and methods: Cross-sectional observational data on diabetes-related resource use were collected from 15,016 patients with T2DM within the second wave of the International Diabetes Management Practices Study (IDMPS). Mean (SD) and median (min-max) annual quantities were determined using a prevalence-based approach and predictors of diabetes-related resource use investigated using negative binomial regression. Analyses were conducted using available-case/complete-case methods as well as with missing values imputed.

Results: The mean (SD) age of study patients recruited in Asia (n=4678), Latin America (n=6090) and the Middle East & Africa (n=4248) was 57 (12), 60 (12) and 57 (11) years, respectively, and mean diabetes duration was 8 (7), 10 (9) and 8 (7) years. On average, patients made 3.4, 5.4 and 2.5 GP visits per year while the average number of specialist visits was 8.2, 6.3 and 5.0 per year in Asia, Latin America and the Middle East & Africa, respectively. Among patients visiting a GP during the 3-month recall period, the median (min-max) number of visits was 2 (1-20), 2 (1-24) and 1 (1-12) in the respective regions and among those visiting a specialist the median (min-max) number of visits per 3 months was 2 (1-30), 2 (1-12) and 1 (1-18). The frequency of hospitalisation was 8.5%, 6.5% and 8.8% and the mean (SD) number of inpatient days amounted to 3.8 (18.1), 2.2 (13.9) and 2.6 (13.5) per year in the respective regions. Results of the negative binomial regression models pointed to the major influence of diabetes-related complications on resource use. The proportion of patients with microvascular complications was 51% in Asia, 40% in Latin America and 40% in the Middle East & Africa and the corresponding proportions with macrovascular complications were 20%, 22% and 23%. In Asia, the presence of macrovascular complications was associated with a 5.5 times higher expected annual rate of inpatient days (incidence rate ratio (IRR) 5.5, 95% CI 2.8-10.9, n=3243). In the Middle East & Africa, the expected rate of inpatient days was 7.9 times greater for patients with macrovascular complications (IRR 7.9, 95% CI 3.9-15.8, n=2622) and 2.4 times greater for patients with microvascular complications (IRR 2.4, 95% CI 1.5-3.5, n=2630). The effect of complications on resource use was equally pronounced in Latin America, where inadequate glycemic control (HbA1c≥7%) was identified as an additional predictor of hospitalisation.

Conclusion: The status of micro- and macrovascular complications as major predictors of resource use in T2DM demonstrates the health economic importance of early diagnosis and treatment.

Cardiovascular risk targets in type 2 diabetes should be lower for patients of South Asian ethnicity: the United Kingdom Asian Diabetes Study (UKADS)

S. Bellary^{1,2}, N.T. Raymond³, J.P. O'Hare³, S. Mughal¹, K. Johal³, S. Kumar³, A.H. Barnett^{1,2}

¹Diabetes, Heart Of England NHS Trust, Birmingham, ²Medicine, University of Birmingham, ³Diabetes, Warwick Medical School, Coventry, United Kingdom

Background and aims: Management of cardiovascular risk in patients with diabetes in primary care is determined by targets set by national and international bodies. These targets are not ethnicity specific and may underestimate risk in certain population groups. We compared cardiovascular risk factors between patients of White European (WH) vs. South Asian (SA) ethnic background. Our study hypothesis was that patients of SA ethnicity would have

higher cardiovascular risk, reflected in elevated individual and combined risk factors

Materials and methods: The study was cross-sectional, with all data collected from 25 general practices in East Birmingham and Coventry during 2004-5, the baseline assessment phase of the main UKADS study. Demographic and clinical data, plus blood and urine samples were collected at diabetes research clinics, by a trained team including specialist nurses and Asian link workers. Individual risk factors and CHD risk estimated by the Framingham equation and using the UKPDS risk engine were analysed.

Results: A total of 1978 patients were recruited to the study, 1486 (75%) SA and 492 (25%) WH. The SA group, were younger (mean age 57.0 vs. 64.8 yrs, P<0.01), had longer duration of diabetes (mean 7.8 vs. 6.3, P<0.01) and included more women (48% vs. 41%, P=0.02).

Systolic blood pressure and HDL cholesterol were significantly lower in SA vs. WH: 140 vs. 144 mmHg, p<0.01 and 1.29 vs. 1.48, P<0.01 respectively. Total cholesterol and HbA1c were both significantly higher for SA (4.67 vs. 4.32, P<0.01 and 8.2 vs. 7.2, P<0.01). Diastolic BP was slightly but not significantly higher for SA. 15% of both groups were current smokers, but significantly more WH were ex-smokers 38% vs. 9% SA, $\chi^2=244.63$, 2df, P<0.01. Using both the Framingham equation and UKPDS risk engine to estimate 10 year CHD risk, no significant differences between the WH and SA groups were identified; Framingham 9.7% vs. 9.9% and UKPDS 17.9% vs. 17.5% respectively.

Conclusion: Significant differences in individual risk factor profiles comparing these two ethnic groups were identified in this study. No difference in CHD risk was found using one general and one diabetes specific method. Since SA with type 2 diabetes are widely acknowledged to have higher cardiovascular event rates, it is surprising that risk factor profiles compared to WH are not more clearly elevated. Lower and ethnicity group specific targets should be generated to address this imbalance.

The impact of ethnicity on quality of care for diabetes in primary care measured by process indicators and intermediate outcomes

A.T. Tran¹, A.K. Jenum¹, J.G. Cooper², T. Claudi³, M.F. Hausken⁴, W. Ingskog¹, J. Straand⁵

¹The Diabetes Research Center, Aker and Ullevål University Hospital, Oslo, ²Department of Medicine, Stavanger University Hospital, Stavanger, ³Department of Medicine, Nordland Hospital, Bodø, ⁴National Adult Diabetes Registry, Western Norway Regional Health Authority, Stavanger, ⁵General Practice Research Unit, Faculty of Medicine, University of Oslo, Norway

Background and aims: Norway has had updated guidelines for the care of diabetes in primary care since 1988. Surveys in 1995 (2 regions), 2000 (3 regions) and 2005 (4 regions) have shown that the quality of care has improved, measured both by process indicators and intermediate outcomes. The aim of the present study was, for the first time in Norway, to assess the impact on ethnicity on the quality of care for patients with type 2 diabetes (T2DM) treated in primary care. A list based system for general practitioners (GPs) has since 2001 provided the denominator of their population. Only data from the population in Oslo (the capital) reflects the recent immigration from non-western countries, as <2% were immigrants in the other regions in 2005.

Materials and methods: We used data from a retrospective cross-sectional study of electronic medical records of 58000 patients from 49 GPs in Oslo in 2005. 2064 patients with diagnosed diabetes were identified and the relevant data extracted by a computer program and manually validated by a research nurse. Ethnicity was self-reported from the medical records according to country of birth and categorized as follows: Westerners, South Asians, Middle East/North Africa (MENA), East Asians, South Sahara Africa (SSA), Eastern Europe (EE), Central and South America (CSA). All non-western (NW) groups were also merged. We excluded 128 patients with <6 months of follow-up, 264 with ≥2 visits to specialists in diabetes care, 2 with ethnicity status missing and 17 with T1DM.

Results: Of the 1653 T2DM study patients 524 (32%) were NW. Table 1 shows mean age for the ethnic groups, processes of care (% with recommended procedures recorded) and mean values for major risk factors. Mean age was substantially lower for NW (53.5 vs. 66.4 years), but mean diabetes duration was identical (6.6 years for both groups). Mean HbA1c was significantly higher for

NW (7.5 vs. 7.0%, $p<0.001$), and highest for South Asians (7.7%), but blood pressure significantly lower for NW. Only minor ethnic differences were found for process indicators. NW were treated more intensely with glucose-lowering drugs (18 vs. 28% were non-users), but in all treatment groups they had significantly higher HbA1c (7.4 vs. 7.1% for oral drugs only, 8.4 vs. 7.9% for oral drugs and insulin combined, and 8.6 vs. 7.7% for insulin alone).

Conclusion: NW immigrants were younger than westerners, but mean diabetes duration was identical. When measured by process indicators, only minor ethnic differences in the quality of care for T2DM patients were found. However, metabolic control was poorer in NW, despite more intensive treatment with glucose-lowering drugs.

Does screening work for the common good? ADDITION- Leicester: design of a multi-factorial intervention trial in an ethnically diverse population with screen-detected type 2 diabetes

M.J. Davies¹, D.R. Webb¹, B.T. Srinivasan¹, S. Hiles², J. Hill², S. Campbell², N.A. Taub³, A. Farooqi⁴, N. Wareham⁵, S. Griffin⁵, K. Khunti³

¹Department of Cardiovascular Sciences, University of Leicester,

²Department of Diabetes and Endocrinology, University Hospitals of

Leicester NHS Trust, ³Department of Health Sciences, University of Leicester, ⁴East Leicester Medical Practice, Eastern Leicester Primary Care Trust, ⁵MRC Epidemiology Unit, University of Cambridge, United Kingdom

Background and aims: Incentive-driven opportunistic screening for type 2 Diabetes Mellitus (T2DM) is now common UK clinical practice despite lack

of proven benefits. Doubts surrounding screening methodology, cost-effectiveness and cardio-protective efficacy remain. UK National Screening Committee guidelines advocate screening targeted to populations at risk. ADDITION-Leicester will evaluate the feasibility of screening a mixed ethnic UK population, quantify effectiveness of optimised treatments on modelled cardio-vascular risk and assess economic and psychological costs of screening.

Methods: The study is a pragmatic cluster RCT of screening and intervention in 20 general practices (total practice population 65,792). An Intensive group (I) will receive multi-factorial treatment (structured education, aspirin, protocol-driven tight control of blood pressure, glucose and lipids) from a hospital-based diabetes team, whilst a conventional group (R) will receive routine care according to national guidelines. People aged 40-75yrs (25-75 South Asian) will be offered fasting and 2-hr post-challenge glucose assessments, anthropometric measurements, Quality of Life / well-being questionnaires and other cardiovascular parameters (BP, %Body Fat, serum lipids, urinalysis, ECG, smoking status, alcohol consumption, medical history). Diabetes will be diagnosed using WHO criteria. We will require 308 participants (154 per arm) with screen-detected diabetes to detect a 6% difference (80% power, alpha 0.05) in modelled cardiovascular outcome (UKPDS CHD risk) between routine and intensive groups at one-year assuming an intra cluster correlation coefficient of 0.14 and allowing for a loss to follow-up of 15%. Assuming a prevalence of screen-detected diabetes of 4.5% in our mixed ethnic population, we will need to screen over 7000 (30%- 2100 South Asian) individuals over 2 years.

Preliminary Results: Optimisation of intensive multi-factorial treatment is associated with clinically important improvements in intermediate outcomes at 12 months (Tabulated). Whether such a program will be a cost-effective means of reducing CVD events over five years is being addressed in the

12 month data (n=150)

	Mean (sd) baseline (R)	Mean (sd) follow up (R)	Mean (sd) baseline (I)	Mean (sd) follow up (I)	Δ (IvsR)	95% CI	P
HbA1c (%)	7.15 (1.6)	6.71 (1.0)	7.1 (1.42)	6.35 (0.46)	-0.32	-0.72 to +0.11	0.14

Factors associated with receipt of appropriate care among patients with a prolonged and persistent period of hyperglycaemia: what matters when action is needed?

J.E. Lafata¹, E.A. Dobie¹, G. Divine², M. Ulcickas Yood³, B.D. McCarthy⁴

¹Center for Health Services Research, Henry Ford Health System, Detroit, ²Biostatistics and Research Epidemiology, Henry Ford Health System, Detroit, ³Medicine, Yale University, New Haven, ⁴Medicine, Allina Medical Clinic, Minneapolis, United States

Background and aims: To estimate the prevalence of prolonged and persistent periods of hyperglycaemia among patients with diabetes and the factors associated with receipt of appropriate care once A1cs are substantially and consistently above target levels.

Materials and methods: Using claims data, we identified insured patients with diabetes who initiated oral hyperglycemic monotherapy between 2000–2005 (N=5082). Actuarial methods were used to estimate time to a period of prolonged and persistent hyperglycaemia (2 A1c results over 8% at least 90 days apart, not yet dispensed insulin with no medication change in the preceding 90 days). Among those experiencing prolonged hyperglycaemia (N=1391) we estimate time to and factors associated with appropriate care defined as either a medication change (dose change, class change, or class addition) or achieving glycemic goal of A1c≤7%.

Results: At inception, mean age was 60.1 years, 48% were female, 37% African American, and mean A1c was 8.6%. Eight percent of patients faced prolonged hyperglycaemia within 1 year, and this proportion steady rises to 41% within 5 years. Among those with prolonged hyperglycaemia, 35% had been dispensed combination therapy, and 20% had no hyperglycemic medication on hand in the prior 90 days. Mean A1c was 9.7% (range 8.1–18.9). Mean time to appropriate care was 7.3 months, with 27% not receiving appropriate care within 1 year. Those with no medication on hand (hazard ratio=0.67, 95% CI=0.55–0.82), or on combination therapy (0.81, 0.71–0.93) faced longer delays. Longer delays were also associated with increasing drug co-payments (0.96, 0.93–0.98), while shorter delays were associated with increasing income levels (1.04, 1.01–1.07), and higher A1c levels > 9% (1.41, 1.08–1.83). Recent visits to primary care (4.22, 3.65–4.89) or endocrinology (3.66, 2.10–6.38) were associated with shorter delays.

Conclusion: Patients facing prolonged and persistent periods of hyperglycaemia are at risk of further delays in appropriate management. Our results

illustrate that when patients with diabetes face prolonged and persistent hyperglycaemia, the likelihood of receiving appropriate care is related to a combination of patient, physician, and system factors many of which are amenable to intervention.

Association of waist circumference, cardiometabolic risk factors and health care utilization in a German internet-based cohort study

N. Cadi Soussi¹, N. Finer², H. Hauner³

¹sanofi-aventis R&D, Paris, France, ²Wellcome Clinical Research Facility, University of Cambridge, United Kingdom, ³Klinik für Ernährungsmedizin, Klinikum rechts der Isar, Technical University of Munich, Germany

Background and aims: The association of obesity measured by Body Mass Index (BMI), and health care costs (HCC), is well established. Although abdominal obesity (AO) measured by waist circumference (WC) is an independent predictor for diabetes and cardio-vascular diseases, few real-life studies have evaluated its association with HCC. The association of WC, BMI and medical resource utilization of a large cohort of German adults were explored.

Materials and methods: PROCEED (Prospective Obesity Cohort of Economic Evaluation and Determinants) is an international longitudinal, observational cohort study of overweight/obese and control normal weight subjects recruited from an internet panel, stratified by BMI and gender. Past and current health conditions were collected through questions about several health disorders, symptoms, prescription drugs as well as resource utilization. Anthropometric data were validated in a 5% random sample of subjects during in-home visits. The prevalences of cardiometabolic risk factors, the indicators of inpatient and outpatient health care utilization (at least one event) and the use of any prescription medications (at least one) in the past 3 months for subjects above and below the gender specific median WC for each BMI class were compared with Fisher's and Mann-Whitney-Wilcoxon tests. All the tests were two-sided with a global type I error α , equal to 5%.

Results: 5,406 subjects (99% Caucasian) were recruited in Germany. In the normal weight, overweight and obese categories respectively: mean age was 43(±10), 45(±10) and 46(±9) years and gender specific median WC 88/79, 99/90 and 111/101 cm respectively (male/female). In the diabetic population, the prevalences of hypertension and dyslipidemia (defined by low HDL and/or high TG) were 27/33%, 53/60%, 60/65% and 0/50%, 35/39%, 53/38% respectively (above/below the gender specific median WC) in the normal, overweight and obese categories. In the non-diabetic population, the prevalences of hypertension and dyslipidemia were 15/21%, 21/28%, 30/42% and 3/12%, 9/12%, 15/17% respectively. The table shows the health care utiliza-

		Control BMI 20-24		Overweight BMI 25-29.9		Obese BMI ≥30

	Use of ≥ 1 prescription medication	41 (44.1%)	42 (45.7%)	989 (51.5%) μ	968 (68.5%)	309 (66.8%) ϵ	294 (67.1%)
	N	93	92	1922	1655	544	438

μ p<0.05 for WC median groups comparison in Control population

μ p<0.05 for WC median groups comparison in Overweight population

ϵ p<0.05 for WC median groups comparison in Obese population

tion outcomes in the diabetic, non-diabetic and overall populations by BMI and WC categories.

Conclusion: The increased of medical resource utilization observed with increasing BMI is consistent with the literature. In addition, within each BMI group, a higher waist circumference was associated with increased health care resource utilization. This trend was still observed after stratification for diabetes. Thus, it seems relevant to account for both BMI and AO when evaluating the burden of cardiometabolic risk factors.

Reasons for diabetes clinical inertia in primary care practice

P.J. O'Connor¹, J.M. Sperl-Hillen¹, W.A. Rush¹, P.E. Johnson², G. Biltz¹, H.L. Ekstrom¹

¹Research Foundation, HealthPartners Research Foundation, ²Carlson School of Management, University of Minnesota, Minneapolis, United States

Background and aims: Previous studies suggest clinical inertia, defined as lack of treatment intensification in a patient not at goal, is largely responsible for the slow improvement seen in population measures of diabetes care. It is controversial how much of the inertia problem is attributable to providers, care systems, or patient preference.

Materials and methods: An electronic visit-based decision support tool called Diabetes Wizard was successfully implemented in 6 HealthPartners Clinics from October 2006 through May 2007 as part of the NIDDK funded study entitled "Reducing Clinical Inertia in Diabetes Care (DK068314). The Wizard gave relevant clinical information and specific recommendations for treatment intensification for glycemia, BP, and lipids. In addition, 19 consented physicians in the clinics agreed to complete an electronic visit action resolution (VAR) form at each encounter if the patient was not at goal for glycemia, blood pressure, or lipids and treatment was not intensified. The VAR was completed by checking from a list of possible reasons or through free text.

Results: Out of 1639 encounters with patients not achieving A1C less than 7 percent, the WIZARD was used and VAR completed 831 times (51 percent). Inertia occurred in 258 (43 percent) of the VAR completed visits. Reasons that were specified by physicians for glycemia inertia were: (1) Choice of patient not to increase or add medications, 70 (19.6 percent), (2) Need for an updated A1C, 62 (17.3 percent), (3) Followed by endocrinology or diabetes nurse, 53 (14.8 percent), (4) Addressed dietary/lifestyle changes instead, 45 (12.6 percent), (5) Other problem/acute illness addressed, 17 (4.7 percent), (6) Not my patient, 13 (3.6 percent), (7) Addressed adherence problem, 13 (3.6 percent). Other reasons that were cited less frequently (less than 2.5 percent) were medication regimen already too complex, hypoglycemia concerns, drug intolerance, cost concerns, advanced age or severe co-morbidities, referred to endocrinology or diabetes educator, close to goal, and other miscellaneous reasons.

Conclusion: Only a relatively small amount, less than 20 percent, of total glycemia inertia at diabetes patient encounters is attributable to patient refusal or preference. The remaining reasons could potentially be addressed through care system changes, including point of care testing to assure up-to-date A1C test results are available at visits, provider training, and better coordination of care with the extended care team and primary provider colleagues.

Diabetes increases recurrences of acute urinary tract infections but does not lead to a different prescription pattern in primary care

K.J. Gorter¹, D. Van Oostveen¹, E. Hak¹, N.P.A. Zuithoff¹, A.I.M. Hoepelman², G.E.H. Rutten¹

¹Julius Center for Health Sciences and Primary Care, ²Division of Internal Medicine and Infectious Diseases, Utrecht, Netherlands

Background and aims: Women with diabetes have an increased risk of urinary tract infections, especially recurrences. The relation between characteristics of diabetes and the risk of recurrent UTIs is unclear. Most diabetes guidelines do not include a treatment advice in case of UTIs and most guidelines on UTIs do not offer a targeted approach for women with diabetes

Aim: To assess diabetes related risk of recurrent urinary tract infections (UTIs) in adult women with diabetes (DM) in primary care and to describe the pattern of prescribed antibiotics in case of UTIs in women. Retrospective cohort study

Materials and methods: Women of ≥ 30 years in two primary health care centres (n=7,063) in a large city in The Netherlands during a period of 43 months were the source population.

From these women with DM (n=340) and without DM (n=6,618) with uncomplicated UTI were studied. Main outcome measures were independent risk of diabetes and related characteristics for UTI recurrences (i.e. relapses and re-infections combined) [OR; 95% CI] and the DM associated pattern of antibiotic prescriptions for first episodes and recurrences of UTI.

Results: In women with diabetes relapses and re-infections were reported in 7.1% and 15.9% versus 2.0% and 4.2% in women without diabetes. Multi-variable logistic regression analysis showed a higher risk of a recurrent UTI in women with DM than in those without DM (OR 2.0; 95% CI 1.4-2.9). Especially women who used oral hypoglycaemic medication (2.1; 1.2-3.5), insulin (3.0; 1.7-5.1), who had >5 years diabetes (2.9; 1.9-4.4) and who had retinopathy (4.1; 1.9-9.1) were at risk. A different pattern of antibiotics was prescribed for recurrent versus first UTI episodes in women both with and without diabetes. However, diabetes did not influence this association.

Conclusion: Women with diabetes have an elevated risk of UTI recurrences, especially if their diabetes exists > 5 years, is treated with tablets or insulin or complicated by retinopathy. Diabetes does not lead to a difference in the pattern of antibiotic prescriptions. Research focusing on antibiotic treatment of UTIs is needed in women with DM.

Which blood glucose samples of the day predicts HbA_{1c}. Results from the ADAG (HbA_{1c} Derived Average Glucose) study

R. Borg¹, J.C. Kuenen², B. Carstensen¹, J. Nerup¹, H. Zheng³, D. Schoenfeld³, R.J. Heine², D.M. Nathan³

¹Steno Diabetes Center, Gentofte, Denmark, ²Dept of Endocrinology, VU Medical Center, Amsterdam, Netherlands, ³Harvard Medical School, Massachusetts General Hospital, Boston, United States

Background and aims: Intensive self-monitoring of blood glucose (SMBG) is necessary in insulin-treated diabetic patients. The benefit of regular use of SMBG in non-insulin-using type 2 diabetes (T2DM) is less clear. Earlier studies have tried to establish which measurements of the day have greatest impact on mean blood glucose levels (MBG). The ADAG study demonstrated that MBG derived from seven-point profiles predicts HbA_{1c} with a precision of $\pm 1.65\%$. There was no difference in this relationship for the two types of diabetes. The aim of this analysis is to examine which SMBG value(s) of the day provides the best prediction of MBG as measured by HbA_{1c}.

Materials and methods: The ADAG study established the relationship between MBG and HbA_{1c} levels by comparing the average glucose calculated from a combination of continuous glucose monitoring and frequent SMBG profiles during a 3-month period with the HbA_{1c} value at the end of the 3-months. From this intensive blood glucose monitoring, we examine the laboratory-quality Hemocue SMBG measurements performed for 8–10 days during the 12 week study period for each of 441 subjects. Multiple linear regression models were constructed using measurements at different times of the day as separate explanatory variables. Models were fitted separately for the T1DM (n=273) and T2DM (n=168) diabetic subjects.

Results: SMBG at particular times of the day were stronger predictors of HbA_{1c} than others, and this differed between T1DM and T2DM. In general, the combined pre-meal values predict HbA_{1c} better than combined post-meal values for both diabetes types and, in particular, for T2DM.

Conclusion: Pre-prandial glucose monitoring is generally more closely associated with HbA_{1c} than post-pandial glucose levels. For T1DM, pre-breakfast, pre-lunch, and post-dinner values predict HbA_{1c} the best, and for T2DM, the combination of pre-breakfast and pre-dinner values provides the best prediction. These findings provide insight for the patient and clinician who seek the optimal blood glucose monitoring at minimal expense and discomfort.

Table 1. Parameter estimates (in % HbA_{1c} per mmol/l) from the statistical model with all glucose variables. The combined mean pre- and post-meal values were evaluated in a separate model.

	T1DM		T2DM	
	Estimate* (SE)	P-value	Estimate* (SE)	P-value
Pre-breakfast	0.1010 (.0212)	<0.0001	0.1550 (.0302)	<0.0001
Post-breakfast	0.0059 (.0194)	0.759	0.0560 (.0236)	0.019
Pre-lunch	0.1327 (.0229)	<0.0001	0.0115 (.0319)	0.719
Post-lunch	0.1145 (.0230)	<0.0001	0.1064 (.0329)	0.002
Pre-dinner	0.0488 (.0221)	0.0291	0.1615 (.0313)	<0.0001
Post-dinner	0.0792 (.0214)	0.0003	0.0106 (.0317)	0.738
Residual SD	0.68% HbA _{1c}		0.56% HbA _{1c}	
Pre-meal mean	0.2729 (.0310)	<0.0001	0.3283 (.0387)	<0.0001
Post-meal mean	0.1966 (.0288)	<0.0001	0.1541 (.0338)	<0.0001
Residual SD	0.70% HbA _{1c}		0.58% HbA _{1c}	

*% per mmol/l. For T1DM, step-wise addition of the individual timed samples revealed that the prediction obtained by pre-breakfast, pre-lunch, and post-dinner values (residual SD = 0.72%) was not substantially improved by adding further variables. For T2DM, the combination of pre-breakfast and pre-dinner values (residual SD = 0.61%) provide an adequate prediction, with little improvement by adding further glucose measures.

Computer-guided versus standard column-based intravenous insulin regimens: a comparison of insulin infusion protocols in the medical intensive care unit

C.A. Newton¹, D. Smiley¹, P.C. Davidson², B.W. Bode², R.D. Steed², S. Jacobs¹, A.E. Kitabchi³, F. Stentz³, P. Mulligan¹, A. Cleveland², G.E. Umperiez¹

¹Division of Endocrinology, Emory University School of Medicine, Atlanta,

²Endocrinology, Atlanta Diabetes Associates, ³Division of Endocrinology, University of Tennessee Health Science Center, Memphis, United States

A variety of continuous insulin infusion (CII) algorithms are available to improve and maintain strict glycemic control in the intensive care unit (ICU). To date, few have been prospectively evaluated against each other to determine if any differences exist. We conducted a multi-center, randomized trial (NCT#00394524) comparing the safety and efficacy of a computer-guided (Glucomanager) and a column-based paper protocol (Standard). 138 medical ICU patients with a mean age of 58.1 (range 19–80) years and a blood glucose (BG) >7.8 mmol/L were enrolled at 4 hospital centers. Patients were excluded if they were admitted for diabetic ketoacidosis or hyperglycemic hyperosmolar state or if they were anticipated to need surgery. Both protocols

Patient characteristics and glycemic control achieved and maintained with the CII protocols.

	Glucomanager (# patients = 69) (Total # BG tests = 2848)	Standard (# patients = 69) (Total # BG tests = 2578)	p-value
Initial glucose (mmol/L)	11.2 \pm 3.5	10.3 \pm 2.3	NS
Time to achieve target BG of 80–120 mg/dL (hours)	5.0 \pm 2.9	8.0 \pm 9.4	<0.01
Mean BG maintained once target achieved (mmol/L)	5.7 \pm 0.5	6.7 \pm 0.9	<0.0001
Insulin infusion rate (units/Kg/day)	0.67 \pm 0.2	0.48 \pm 0.16	0.03
Median (range) duration of CII (days)	2.0 (0.4 - 10)	2.7 (0.1 - 10)	NS
Hemoglobin A1c (%)	7.1 \pm 2.0	6.8 \pm 1.3	NS
Mortality	24.1%	20.3%	NS
# BG tests (%) within target range	1943 (68.2%)	1223 (47.4%)	<0.0001
Mild Hypoglycemia: BG <3.3 mmol/L	# BG tests (%) 78 (2.5%) # Patients (%) 29 (42.0%)	36 (1.2%) 21 (30.4%)	0.0002 NS
Severe Hypoglycemia: BG <2.2 mmol/L	# BG tests (%) 5 (0.16%) # Patients (%) 2 (2.9%)	2 (0.07%) 2 (2.9%)	NS NS
Hyperglycemia (BG >11.1 mmol/L)	# BG tests (%) 20 (0.7%) # Patients (%) 7 (10.1%)	57 (2.2%) 17 (24.6%)	<0.0001 0.02

used glulisine (Apidra) insulin and targeted BG to 4.4–6.7 mmol/L for up to 10 days. Assessments were made for differences in mean daily BG, number of hypoglycemic events (BG <3.3 mmol/L and <2.2 mmol/L), number of hyperglycemic episodes (BG >11.1 mmol/L), and insulin infusion rates. Gender, ethnicity, diabetes history and admitting diagnoses were similar for the Glucommander and Standard groups. Efficacy and safety differences between the groups in terms of CII parameters and glycemic control are outlined in the table.

Ten (14.5%) patients in the Standard group failed to achieve or to maintain glycemic targets despite progression to the column with maximum infusion rates. These patients remained on the standard protocol for 26.25 hours with average glucose levels of 9.1 ± 2.7 mmol/L before being transitioned to an alternative treatment option with glucose levels at the time of withdrawal from the study of 9.5 ± 3.3 mmol/L. In conclusion, the computer-guided protocol achieved BG control faster and maintained BG within the targeted range of 4.4–6.7 mmol/L better than the standard algorithm. The Glucommander was associated with higher insulin delivery and higher rate of mild hypoglycemic events. The higher insulin doses were achieved because the computer has no limitation on dosing increments, which was made more evident by the Standard protocol treatment failures. Further studies are needed to determine if the more consistent BG control from computer-based titration protocols may have benefit on clinical outcomes.

Predictors of postprandial hyperglycaemia in patients with type 2 diabetes

C.A. Nita^{1,2}, A. Rusu¹, C.G. Bala^{1,2}, N. Hancu^{1,2}

¹Diabetes, „Iuliu Hațieganu” University of Medicine and Pharmacy, ²Clinical Center of Diabetes, Emergency County Hospital, Cluj Napoca, Romania

Background and aims: Growing evidence suggests that all aspects of glucose metabolism - glycated hemoglobin (A1c), fasting plasma glucose and postprandial glycemia (PPG) - are clinically relevant parameters to be monitored. PPG, in particular, appears to be related to the cardiovascular disease. Although measurement of PPG has not yet been adopted as part of the routine diabetes management, it may be more accurate indication of overall glycemic control than FPG or A1c.

The objective of this study was to investigate the factors associated with postprandial glucose excursions in patients with type 2 diabetes (T2DM).

Materials and methods: We have evaluated the factors associated with postprandial hyperglycemia (>140 mg/dl at 2 hours after the meal), corrected for sex and treatment in 122 consecutive patients with T2DM attending the outpatient clinic from Clinical Center of Diabetes, Nutrition and Metabolic Diseases Cluj-Napoca, Romania. These patients were included in a larger epidemiological study aiming to assess the impact of postprandial hyperglycemia on cardiovascular risk in persons with type 2 diabetes. A complete medical history and physical examination were performed. Blood samples were collected in the overnight fasting state, and A1c, total cholesterol, HDL-cholesterol and triglycerides were assessed. A six points blood glucose profile (before and 2 h after meals) measured by patients at home, together with a meal questionnaire was performed for each patient. To determine variables associated with higher postprandial glycemic levels, factor analysis followed by linear regression model was performed.

Results: The study group had a median age of 58 years (min 29, max 77 years), 59.8% were males. The median duration of diabetes was 6 years (min 0, max 37 years). Stratification for antidiabetic treatment was as follows: 10.7% were on diet alone, 13.9% on metformin, 9% on sulfonylurea, 23% on combined oral therapy, 30.3% on insulin alone and 13.1% on insulin plus oral therapy. By factor analysis we have extracted 4 factors that explained 73% of the variance of postprandial glycemia [Factor 1 with positive loadings of weight and body mass index, Factor 2 with positive loadings of total cholesterol and LDL-cholesterol, Factor 3 with positive loadings of diabetes duration and age, Factor 4 with positive loadings of triglycerides and HDL-cholesterol]. In an unadjusted linear regression analysis with mean postprandial glycemia as a dependent variable, the model which included the above mentioned factors identified was significantly associated with postprandial glycemia ($r=0.392$, $p=0.002$). When individual regression coefficients were evaluated, that due to Factor 2 displayed a p value of 0.593 and was removed from the analysis. A second regression included Factor 1, 3 and 4, and the model remained statistically significant ($r=0.389$, $p=0.001$, F change=6.123, significance of F change= 0.001). After adjustment for sex and treatment, only Factor 1 and Factor 4 remained significantly associated with postprandial glycemic values

($p=0.025$, and 0.004), indicating that postprandial glycemia is best explained by a multiple regression that included Factor 1 and Factor 4 as independent variables ($r=0.422$, $p<0.001$).

Conclusion: The results of our study shows that weight, body mass index, triglycerides level and HDL-cholesterol are independently associated with postprandial glucose excursions.

Non-invasive monitoring of blood glucose in critically ill patients

A. Weinstein¹, O. Herzenstein¹, E. Gabis¹, P. Singer²

¹OrSense Ltd., Nes Ziona, ²ICU, Rabin Medical Center, Petach-Tikva, Israel

Background and aims: The purpose of this study is to evaluate the feasibility of the fully non-invasive NBM device (OrSense Ltd.) for continuous glucose monitoring in critically ill patients. Critically ill patients frequently experience abnormalities in carbohydrate metabolism and a severe insulin resistance state. Hyperglycemia is a negative predictor of outcome in these patients, as high blood glucose (BG) values are associated with an increased risk of morbidity and mortality. Current BG monitoring methods do not provide the continuous glucose monitoring (CGM) needed to implement tight glucose control protocols.

Materials and methods: The NBM uses a red/near-infrared sensor located at the finger's base. It performs a temporary occlusion of the blood flow, resulting in an enhanced, time dependent, optical signal which enables calculation of BG and hemoglobin concentrations. A study was conducted on 14 patients (7F, 7M, ages 34–92 years) in the intensive care unit (ICU) of the Rabin Medical Center, upon receipt of informed consent. The NBM probe was placed on patients' thumbs, where it performed non-invasive CGM for up to 24 hours, with readings every 10 minutes. The results obtained from the NBM device were compared to arterial blood samples taken through an arterial line every 30–60 minutes and analyzed with a blood gas machine (ABL 700, Radiometer, Copenhagen, Denmark).

Results: A total of 14 sessions were conducted, one from each subject. Patient compliance was good, and no adverse effects were identified. A prospective analysis based on a uniform model with personal calibration was performed on the NBM readings, for a total of 208 paired data points. The calibration phase lasted 3 hours, and utilized reference BG values taken at t_0+1 , t_0+2 , t_0+3 , and t_0+4 . An additional reference point was supplied every 8 hours thereafter (t_0+12 and t_0+20 , if available), in accordance with the ICU's internal protocol whereby blood samples are taken at these regular intervals. Reference BG range was 62–369 mg/dl. The resulting median relative absolute error was 7.3%, and the median absolute error was 8.6 mg/dl. A Clarke error grid analysis showed that 95.2% of the measurements fell within zones A (74.5%) and B (20.7%). Furthermore, we find that both the NBM and ABL 700 showed comparable estimates of time spent in hypoglycemia, mid-range, and hyperglycemia.

Conclusion: This study indicates the potential use of the non-invasive NBM for continual, accurate, safe, and easy-to-use BG evaluation in ICU. The device is of clinical utility for trend analysis, excursion alerts and closed-loop systems, enabling automatic glycemic control. It holds the promise of improving patients' care and survival, as well as reducing staff workload.

Blood glucose measurement techniques for hyperglycaemic clamp studies

T. Mura¹, S. Lepape¹, J.-L. Faillie¹, H. Chevassus¹, J. Cayuelas¹, A. Chalançon¹, I. Gabillaud¹, P. Petit^{1,2}, F. Galtier¹

¹Centre d'Investigation Clinique, CHRU Montpellier&Inserm CIC0001,

²Centre de Pharmacologie et Innovation dans le Diabète, Université Montpellier1 & CNRS UMR 5232, Montpellier, France

Background and aims: Because of the cost of glucose analyzers, glucose meters designed for self-monitoring are sometimes used to measure blood glucose during metabolic investigations.

However there have been debates on the analytical quality of glucose meters. For disease management, the ISO recommends less than 5 % errors, an error being defined as more than 20% discrepancy with reference value. But when glucose meters are used to adjust infusion rates during hyperglycemic clamps, even variations < 20 % may result in erroneous dextrose infusion rates.

The aim of our study was to compare the accuracy of 2 methods of glucose measurement and the frequency of errors in subsequent dextrose infusion rates, for blood glucose > 7 mmol/l.

Materials and methods: 242 blood glucose values > 7 mmol/l were obtained during 32 hyperglycemic clamps performed on 15 healthy men (age 20–34 years, mean BMI 22.3 kg/m²). Reference blood glucose values were obtained in the Biochemistry Laboratory, Olympus analyser (glucose oxydase). During the clamps, blood glucose was assessed with 2 methods:

-blood glucose analyzer 2300 Stat Plus, System Industry

-self-blood glucose monitoring system (SBGMs) Medisense Optium Xceed® with electrodes for venous samples

During the 10 mmol/l hyperglycemic clamp, Stat Plus analyzer glucose values were entered on a spreadsheet using de Fronzo formulas to calculate the 30% dextrose infusion rate. Blood glucose values obtained by the reference method and by the SBGMs were entered a posteriori in the same spreadsheet to calculate the respective infusion rates. Quantitative variables were compared with non parametric tests for paired data (Wilcoxon signed-rank test). Medians of differences are presented with 5th and 95th percentiles. Error rates, defined as discrepancies of $\pm 10\%$, $\pm 20\%$ and $\pm 30\%$ with reference values, were calculated for blood glucose values and dextrose infusion rates. Qualitative variables were compared using chi-2 test. Statistical analysis was performed using SAS 9.1 for Windows.

Results: For blood glucose, medians of differences between reference method and Stat Plus analyzer or SBGMs were 0.08 mmol/l (-1.19; +0.85; $P = 0.21$) and 0.27 mmol/l (-1.40; +1.62; $P = 0.0004$) respectively. For dextrose infusion rates, medians of differences between reference method and Stat Plus analyzer or SBGMs were -8 ml/h (-51; +62; $P = 0.0004$) and -13 ml/h (-82; +68; $P = 0.0004$) Error rates are depicted in the table.

Conclusion: The frequency of errors in the dextrose infusion rates is high with the 2 methods. However, the accuracy of the Stat Plus is better, and errors due to Stat Plus analyzer are random and not systematic, as shown by the lack of significant difference between medians with reference method. Our results are in favor of the use of a Stat Plus analyzer over SBGMs for high blood glucose measurements.

Comparison of error rates obtained with Stat Plus analyzer and SBGMs

		variable	N	errors (n)	error rate (%)	P value
blood glucose	error > 10 %	Stat Plus	242	23	9.5	< 0.0001
		analyser	242	71	29.3	
	error > 20 %	SBGMs	242	5	2.1	0.12
		Stat Plus analyser	242	11	4.6	
dextrose infusion	error > 10 %	Stat Plus	215	160	74.4	< 0.0001
		analyser	215	199	92.6	
	error > 20 %	SBGMs	215	123	57.2	< 0.0001
		Stat Plus analyser	215	171	79.3	
	error > 30 %	SBGMs	215	99	46.0	< 0.0001
		Stat Plus analyser	215	141	65.6

Whole 24-hour continuous glucose monitoring profiles with insulin glargine or oral antidiabetic drug therapy in patients with type 2 diabetes mellitus

J.-F. Yale¹, S. Harris², J.A. Stewart³, H.C. Gerstein⁴

¹McGill Nutrition Centre, McGill University Health Centre, Montreal, Canada, ²Family Medicine, University of Western Ontario, London, Canada, ³Biometrics, sanofi-aventis, Bridgewater, United States, ⁴Medicine, McGill University Health Centre, McMaster University, Canada

Background and aims: This analysis used data from the continuous glucose monitoring (CGM) portion of a randomized-controlled trial (RCT) in which adults with type 2 diabetes mellitus (T2DM) on stable therapy with 0, 1, or 2 oral antidiabetic drugs (OADs), HbA_{1c} 7.5%–11.0%, and not taking a thiazolidinedione were allocated to either the addition of evening insulin glargine (GLAR, initiated at 10 units/day and increased by 1 unit/day until targeted fasting plasma glucose [FPG] was achieved) or optimization of OAD, including the addition of metformin, sulphonylureas, repaglinide, nateglinide, or

a thiazolidinedione, if required, for the next 24 weeks. Both groups targeted FPG ≤ 5.5 mM. The main objective of this RCT was to assess the change in A1C between conventional therapy with physician adjustment of OAD agents and addition of nighttime insulin glargine with self-titration. (Gerstein et al, 2006) [Gerstein 2006] The current analysis was performed on a subset of data to characterize whole 24-hour CGM profiles by comparing both the estimated mean glucose function at week 24 to baseline for each study arm ($n=37$, GLAR; $n=39$, OAD) and the estimated mean glucose functions of the 2 arms at week 24.

Materials and methods: This study used a Fourier approximation to each 24-hour CGM curve as previously published. (Miller and Strange, 2007) [Miller 2007] Using model adjusted mean Fourier coefficient sets, continuous plots of blood glucose (BG) vs time were obtained by study arm and visit; comparisons with baseline and between study arms were made by plotting the difference curve and ± 2 standard errors (SEs).

Results: In the whole study, GLAR was associated with a greater decrease in A1C during the 24-week trial compared with adjustment of OADs (1.55% vs 1.25%, $P=0.005$, $N=405$), without differences in overall hypoglycemia (48.5% vs 42.2%, $P=0.23$). In the current analysis, a subgroup of patients who had CGMS data was examined. Assessments of 24-hour BG curves at week 12 and week 24 were combined and compared to baseline as only 56 subjects (28 each arm) had ≥ 1 complete 24-hour profile at baseline and week 12/24. GLAR mean BG profile at week 12/24 was lower than baseline by >2 SEs for most of the 24 hours; OAD arm had BG levels lower than baseline by 2 SEs except from 8–11 am and a short period around 7 pm. Both arms showed excellent reduction in mean A1C level (8.3% to 7.0% in the OAD arm, 8.4% to 6.8% for GLAR, $P=NS$ between groups in these subcohorts); however, only GLAR successfully controlled prandial breakfast BG levels from 8–11 am.

Conclusion: While in this subgroup analysis GLAR and OAD showed similar effects on mean HbA_{1c}, 24-hour CGM profiles revealed greater reductions for GLAR between midnight and noon.

Mean Continuous Glucose Monitoring System (CGMS) Profile (mg/dL): Comparison of GLAR and OAD at Week 12/24 Subjects With Complete Baseline and Week 12/24 CGM Profiles

The curves were estimated from one multivariate ANCOVA using a 12-cycle Fourier approximation applied to each 24-hour CGM profile. The model included study arm, strata, base FPG, base HbA_{1c}, base alanine aminotransferase (ALT), visit (baseline, week 12 or 24), interactions: study arm by strata.

Non-invasive system for continuous glucose monitoring

A. Karasik^{1,2}, O. Herzenstein³, E. Gabis³, A. Weinstein³

¹Endocrinology, Sheba Medical Center, Ramat Gan, ²Faculty of Medicine, Tel Aviv University, ³OrSense Ltd., Nes Ziona, Israel

Background and aims: Non-invasive glucose devices hold the promise of delivering painless and hassle-free continuous glucose monitoring (CGM). Such devices could assist subjects with diabetes in complying with the protocols known to prevent long and short-term complications; ultimately improving health and reducing the cost of diabetes. This study presents the use of the fully non-invasive NBM device (OrSense Ltd.) for CGM in subjects with type 1 and type 2 diabetes.

Materials and methods: The NBM uses a red/near-infrared sensor located at the finger's base. It performs a temporary occlusion of the blood flow, resulting in an enhanced, time dependent, optical signal which enables calculation of glucose concentration. The device was tested on 15 patients in sessions of

24 hours, with NBM measurement every 10 minutes. Reference values were measured every 30–60 minutes using a self monitoring glucometer (Abbott Freestyle).

Results: A total of 1068 paired glucose values (NBM vs. reference) from 25 sessions were produced, with a reference glucose range of 23–404 mg/dL. In the paired data set, the median relative absolute difference (RAD) was 12.3% and a Clarke EGA showed that 95.1% of the measurements fell within the clinically acceptable A+B regions (zone A - 66.7% and zone B - 28.4%). Use of the device did not cause any discomfort for subjects, was safe and well tolerated.

Conclusion: The RAD values obtained in the study are comparable to values reported for currently approved CGM invasive apparatus. The information gained was of clinical utility for trend analysis as it detected both peaks and troughs in blood glucose levels. This work substantiates the potential use of OrSense's NBM as a non-invasive sensor for continuous, safe and easy-to-use blood glucose evaluation, which holds the promise of improving blood glucose control in both type 1 and type 2 diabetes.

iSense Mastery™ CGM performance during in-clinic glucose clamping studies was found to track plasma glucose very closely

M.V. Rebec¹, W.K. Ward¹, J.L. House¹, E.M. Anderson¹, R. Bruce¹, H.M. Duman¹, B. Hernandez², M.S. Kipnes²

¹iSense Corp., Wilsonville, ²Research, DGD Research, San Antonio, United States

Background and aims: There is an increasing effort to control blood glucose levels so that long-term complications associated with diabetes can be reduced. A concern with that therapeutic approach is the higher incidence of hypoglycemic episodes. Continuous glucose monitoring (CGM) systems have the potential of reducing the frequency and severity of such hypoglycemic episodes. A key to the application of CGM technology in controlling hypoglycemia is the performance of CGM in the hypoglycemic region. Quantifying such performance requires well-designed clinical study protocols, such as ones that incorporate glucose clamping. The aim of this study was to evaluate the performance of the iSense Mastery™ CGM during a glucose clamping protocol that includes extensive hypoglycemic episodes.

Materials and methods: Ten subjects (five type I and five type II) were recruited to participate in the study. Infusions of insulin and dextrose were carried out to clamp four to five glucose levels during an eight-hour glucose clamping protocol that was conducted in an in-clinic setting. Each clamping level was maintained for 35 - 45 minutes depending on the targeted level chosen. Venous blood was drawn every five minutes and the plasma glucose concentration was determined using an Alanox GM9. Three iSense biosensors were inserted in the abdominal area of the subjects using a trocar-based insertion process. The trocar was then removed, leaving the iSense biosensor in the subcutaneous tissue. The glucose sensors were attached to a potentiostat, and the glucose related current readings were digitized. The digital signals were transmitted via RF to a receiving station attached to a laptop PC, where the data was logged. Glucose related data was stored every minute. An algorithm was applied to the digitized data to obtain retrospective glucose values. Performance assessments were made on data pairs of CGM glucose values and the reference glucose values obtained on the Alanox.

Results: A total of 30 sensors were inserted and 29 of them functioned for the duration of the study. A one point calibration was applied at the 300th minute of each study. All the digitized minute by minute current values were converted to glucose values from the 300 to 600 minute point of each study. The overall Mean Absolute Relative Difference for all the glucose values above 75 mg/dl (1087) was 14.4% and Median Absolute Relative Difference was 11.0%. The Absolute Differences were determined for all the glucose values that were 75 mg/dl or less (275). They had a mean of 17.3 mg and median of 12.9 mg/dl. The Clarke Error Grid analysis of all the data pairs (1354) showed 93.3% of the data points were in the A & B regions.

Conclusion: The iSense Mastery™ CGM demonstrated robust performance when tested using a demanding glucose clamping protocol that incorporates extended hypo testing and rapid changes in the glucose concentrations. It can be concluded that the iSense glucose sensors show very reliable performance, even at this development stage. The significant beneficial potential of the CGM system is clearly demonstrated by its performance in the hypoglycemia region.

1063

Correlations between plasma glucose (PG) measures and HbA_{1c} in insulin-treated patients (pts) with type 2 diabetes (T2D)

L. Ilag¹, S. Choi¹, M. Carey², D. Shrom¹, R. Heine¹

¹Lilly Research Labs, Eli Lilly & Co., Indianapolis, ²Medical Writing, i3 Statprobe, Cary, United States

Background and aims: A strong correlation has been demonstrated between HbA_{1c} and self-monitored PG values, especially fasting PG (FPG), in diet-treated T2D pts. PG correlations are weaker for pts treated with oral agents or insulin. As data on the relationship of PG values to HbA_{1c} in insulin-treated T2D pts are limited, the correlations between individual or mean of ≥ 2 PG values and HbA_{1c} were analysed in insulin-treated pts. The goal was to determine which PG values show strong correlation with HbA_{1c} and whether different insulin regimens affect those correlations in this patient group.

Materials and methods: Data were pooled from 5 randomised clinical trials (RCTs) in T2D pts treated with bedtime basal insulin glargine (G) or insulin lispro mixes (LM) [25% lispro/75% insulin lispro protamine suspension (ILPS) BID (2 studies); 50% lispro/50% ILPS TID (2 studies); 50% lispro/50% ILPS BID and 25% lispro/75% ILPS QD (1 study)]. HbA_{1c} data from the first 16-week period of crossover studies and the 24-week period of parallel studies were used as well as 7-point self-monitored PG profiles conducted in the 2 weeks prior to HbA_{1c} collection and the means of fasting and evening postmeal, all premeal, all postmeal and all 7 PG values. Pearson's correlation coefficients were calculated for PG values and HbA_{1c}. For combined analyses, partial correlation was used to remove treatment effect. Receiver-operating characteristic (ROC) curves were generated to analyse the sensitivity of PG values (FPG, pre- or postmeal PG) against HbA_{1c} above or below 7%.

Results: The mean \pm SE HbA_{1c} in combined dataset (LM, n=317; G, n=306) was 7.4 \pm 0.04%. The table shows correlation coefficients between HbA_{1c} and key PG values (individual or means). FPG had the lowest correlation with HbA_{1c} over-all and particularly in the G-treated pts. Among individual PG values, evening premeal and evening postmeal PG values had the highest correlation with HbA_{1c} in both G-treated and LM-treated pts. Higher correlations were generally seen between HbA_{1c} and PG values that were means of ≥ 2 PG measurements. The mean of all 7 values had the highest correlations in both groups and in the combined analysis. The areas under ROC curves were consistent with the correlation analyses.

Conclusion: The correlations between PG values and HbA_{1c} in insulin-treated pts in RCTs is consistent with previous studies, i.e. they were lower than reported in non-insulin treated T2D pts (r=0.75). Although correlations vary in each treatment group, FPG generally had a weaker correlation with HbA_{1c} compared to other PG values while evening premeal and evening 2-hr postmeal PG had stronger correlations. Means of ≥ 2 PG values had higher correlations to HbA_{1c}. These data suggest that FPG is not a reliable glycaemic indicator in insulin-treated pts and that checking ≥ 2 PG values during the day may better guide insulin intensification.

PG values	Correlation Coefficients*			Area under the ROC	
	Combined ^a	G	LM	G	LM
Fasting	0.40	0.39	0.41	0.64	0.67
Noon 2hr postmeal	0.44	0.47	0.41	0.70	0.69
Evening premeal	0.46	0.47	0.45	0.71	0.70
Evening 2hr postmeal	0.46	0.48	0.43	0.74	0.70
Mean of FPG and 2hr postmeal	0.52	0.53	0.51	0.76	0.72
Mean of 7-point PG	0.58	0.59	0.56	0.78	0.74

Meal size estimation using continuous glucose monitoring: towards a hybrid closed-loop artificial pancreas

B.W. Bequette¹, H. Lee¹, K. Caswell², E. Dassau³, F.J. Doyle III³, B.A. Buckingham²

¹Department of Chemical and Biological Engineering, Rensselaer Polytechnic Institute, Troy, ²Division of Pediatric Endocrinology and Diabetes, Stanford Medical Center, Stanford, ³Department of Chemical Engineering, University of California, Santa Barbara, United States

Background and aims: A hybrid closed-loop artificial pancreas, where an insulin bolus is delivered at mealtime, has the potential for significantly improved glucose regulation, compared to a feedback-only system. This “feed-forward” control strategy requires that an individual with type 1 diabetes be vigilant in estimating the amount of carbohydrates in their meals, and remember to bolus at mealtime. Unfortunately, juveniles forget to bolus, so it is desirable to have an automated system that detects when a meal has been consumed, and estimates the amount of carbohydrates in the meal to provide an appropriate meal bolus.

Materials and methods: In this presentation we develop such a meal detection and meal size estimation algorithm based on a continuous glucose monitoring, optimal estimation theory and signal processing techniques. A set of threshold values for the first and second derivatives of glucose with respect to time are found to detect a meal within 15–45 minutes of actual meal consumption. When a meal is detected, a finite impulse response filter, based on the estimated second derivative of glucose with time, is used to estimate the meal size (grams of carbohydrate). Results are presented based on both *in silico* and clinical studies. The clinical studies are based on continuous monitoring data from 19 subjects with type 1 diabetes mellitus, consuming a total of 25 meals (mean meal size of 53 grams of carbohydrates; range of 14 to 103 grams).

Results: While 4 meals were not detected (16%), the meal size estimation filter is trained using 5 meals from 4 individuals out of the 21 detected meals, with a median detection time of 42 minutes and a median absolute meal size estimation error of 3.7%. The algorithm was validated against the remaining 16 meals: the median detection time was 32 minutes, and the median absolute error in estimating the meal size was 24% with a mean absolute error of 32%. *In silico* closed-loop studies reveal a significant improvement glucose regulation performance using the proposed meal detection and meal size estimation algorithm in a hybrid closed-loop strategy, compared to feedback-only control. The postprandial mean glucose levels are reduced from 217 to 145 mg/dL and the maximum postprandial glucose is reduced from 333 to 232 mg/dL.

Conclusion: This meal detection and meal size estimation algorithm can be incorporated into: 1) a hybrid closed-loop algorithm allowing for a meal bolus even if the subject forgets to self-administer a meal bolus, and 2) a fully automated closed-loop system using model predictive control.

Does glucose variability influence the relationship between average glucose and HbA_{1c} levels?

J.C. Kuenen¹, R. Borg², H. Zheng³, D. Schoenfeld³, M. Diamant¹, R. Heine¹, D. Nathan³ on behalf of the ADAG Study Group

¹Diabetes Center, VU University Medical Center, Amsterdam, Netherlands, ²Steno Diabetes Center, Gentofte, Denmark, ³Diabetes, Harvard Medical School, Boston, United States

Background and aims: The HbA_{1c}-Derived Average Glucose (ADAG) study demonstrated a close linear relationship between average glucose (AG) during 3-months [derived from continuous glucose monitoring (CGM) and frequent self-monitored blood glucose (SMBG)] and HbA_{1c} at the end of 3 months. In this ADAG sub study, we examined the influence of glycaemic variability on the relationship between AG and HbA_{1c} levels.

Materials and methods: We analysed AG and HbA_{1c} data from 268 patients with diabetes mellitus type 1 (T1DM) and 159 with diabetes mellitus type 2 (T2DM) from 10 international centers. AG was calculated from 7-point SMBG collected during 3 days/week and CGM performed for 2–3 days on 4 occasions during a 12 week-period. From the CGM data we calculated 3 different measures of variability: the mean amplitude of glycaemic excursions (MAGE, measuring major swings in glucose), the standard deviation (SD) of all glucose levels, and the continuous overlapping net glycaemic action

(CONGA). The CONGA average or CONGA n=1–24h is measuring intraday variability. The MAGE, SD and CONGA average were subdivided according to tertiles of low, moderate and high glucose variability. We tested for differences in the relationship between AG and HbA_{1c} for all diabetic subjects pooled and for T1DM and T2DM separately, according to tertiles of the respective measures of glucose variability, adjusted for demographic variables.

Results: Approximately 2700 glucose values were obtained for each subject during the 3-month monitoring period. Linear regression analysis showed a correlation between HbA_{1c} and AG values ($AG_{mmol/L} = 1.59 \times HbA_{1c} - 2.59$, $R^2 = 0.84$, $P < 0.0001$). There was a significant difference in the relationship between AG and HbA_{1c} comparing the highest variable tertile vs the lower tertile for SD, MAGE and CONGA average for all patients and for T1DM and T2DM separately. The differences between high and medium tertiles for all measures of variability were only significant for the pooled analysis and in the T1DM. For T2DM, the high vs the medium variability tertiles for SD, and the medium vs the low variability for MAGE had a significant effect on the HbA_{1c}-AG relationship. (Table 1) The impact of this difference in the HbA_{1c}-AG relationship for high vs low glucose variability, defined by MAGE, in T1DM patients with HbA_{1c} levels of 7% and 9% would be a calculated difference in mean glucose of 1.8 mmol/L and 3.7 mmol/L, respectively.

Conclusion: Over most levels of glucose variability, but especially at higher variability levels, the relationship between HbA_{1c} and AG appears to be altered for the entire group and for T1DM only. For the T2DM, HbA_{1c}-AG relationship depends on the variability measure used. Although the differences in “interpretation” of HbA_{1c} are influenced by variability, the clinical impact is modest.

	Variability measure	High vs Low	Medium vs Low	High vs Medium
T1DM + T2DM N = 427	SD	0.002*	0.29	0.001*
	CONGA average	0.003*	0.11	0.04*
	MAGE	<0.001*	0.005*	0.005*
T1DM N = 268	SD	0.01*	0.39	<0.001*
	CONGA average	0.02*	0.33	0.008*
	MAGE	<0.001*	0.14	<0.0001*
T2DM N = 159	SD	0.008*	0.18	0.03*
	CONGA average	0.02*	0.10	0.41
	MAGE	0.006*	0.007*	0.24

Table 1: Differences in the relationship between AG and HbA_{1c} for all diabetic subjects pooled and for T1DM and T2DM separately, according to tertiles of the respective measures of glucose variability, adjusted for demographic variables. The reference range for the three tertiles of glucose variability for SD are: Low < 34, Medium 34–61 and High >61; for CONGA average: < 45, 45–80 and >80; and for MAGE: < 80, 80–144 and >144. P* is statistic significant different between the groups.

Significantly improved HbA_{1c} values with no increase in hypoglycaemia in pregnant women with type 1 diabetes using real-time continuous glucose monitors

M.K. Voelmlle, P.J. Ritchie, K.K. McFann, R.G. Naik, S.K. Garg

University of Colorado Denver, Barbara Davis Center for Diabetes, Aurora, United States

Background and aims: Optimizing glucose control in pregnant patients with diabetes continues to be a challenge. Intensive insulin management that includes increased glucose monitoring improves glycemic control. The purpose of this retrospective pilot study was to evaluate the glycemic control of pregnant patients with type 1 DM who used Real-time Continuous Glucose Monitors (RTCGM) in addition to self monitored blood glucose (SMBG) as compared to women who only performed SMBG. The secondary outcome was to evaluate hypoglycemia in patients with near-normal A1c.

Material and methods: A total of 13 patients used a DexCom STS or Medtronic Paradigm RT during pregnancy, initiating sensor use at 0–24 weeks gestation. A comparison group matched for age, duration of diabetes, ethnicity, and normal AERs (< 20 ug/min) was used for data analysis. Mean (\pm SD) age and duration of diabetes was 30.5 ± 4.4 yrs and 15.4 ± 6.5 for the RTCGM group. Baseline characteristics were similar in both groups. Baseline A1c values were 6.7 ± 1.1 and 6.9 ± 0.7 in the sensor and control groups respectively ($p > 0.05$).

Results: Reductions in mean A1c values were seen at all time points in the sensor group (Figure 1a). 8 women in the sensor group with available data significantly improved A1c over a three-month period from sensor initiation, without increasing percentage of time in hypoglycemic range. Of those 8, A1c's were improved from 6.6 ± 1.1 to 6.1 ± 1.0 ($p \leq 0.05$) without any increase in low blood sugar (Figure 1b).

Conclusion: We conclude use of real-time continuous glucose monitors in pregnant mothers with diabetes can significantly improve A1c values without changing the amount of time spent in hypoglycemia. This pilot study supports the need for larger randomized control trials to evaluate clinical implications of RTCGM in the management of pregnant women with type 1 DM and their fetal outcomes.

1067

Symptom attributions during hypoglycaemia and hyperglycaemia - a continuous glucose monitoring study

T. Kubiak¹, A. Wittig¹, B. Mraz², U. Herrmann³, W. Kerner³

¹Institute of Psychology, University of Greifswald, ²A. Menarini, Diagnostics, Berlin, ³Clinic for Diabetes and Metabolic Disorders, Klinikum Karlsburg, Germany

Background and aims: Symptoms of acute hypoglycaemia and hyperglycaemia often are ambiguous for people with diabetes, with incorrect symptom attributions and misinterpretations presumably being common. The aim of the present study was to investigate (1) the accuracy of detection of hypoglycaemia and hyperglycaemia in people with longstanding type 1 diabetes mellitus, and (2) determinants of correct and incorrect symptom attributions and attributional patterns depending on the type of symptoms, employing ambulatory assessment methodology (continuous glucose monitoring combined with electronic diaries).

Materials and methods: N = 12 type 1 diabetes patients (age M \pm SD: 47.7 \pm 11.5 years; duration of disease > 20 years, gender female 58.3 %) completed electronic diaries (Psion Series 3a hand-held computers) for two consecutive days, assessing self-reports on (a) perceived symptoms, (b) symptom attributions, and (c) estimated blood glucose levels. In addition, the participants were equipped with a continuous glucose monitoring system (GlucoDay S).

Results: A mean glucose monitoring time of 48.2 \pm 0.2 hours was achieved (sensor vs. reference: r = .81; ICC = .84; MAD % = 22.0 \pm 0.4; mean sensor glucose 7.8 \pm 1.5 mmol/L; SD sensor glucose 3.1 \pm 0.9). 7.6 \pm 6.5 hypoglycaemic (10.0 mmol/L) were captured. On average, 1.5 \pm 1.9 undetected hypoglycaemic events (blood glucose estimation vs. sensor glucose) and 7.5 \pm 7.0 undetected hyperglycaemic episodes occurred per participant. In case of hypoglycaemia, the most common incorrect attributions were of an unspecific nature (46.7%, e.g. being tired due to physical exhaustion); in case of hyperglycaemia cardiovascular attributions of symptoms were the most common misinterpretations with 35%. Mixed logit regressions revealed associations between incorrect attributions and neuroglycopenic symptoms for hypoglycaemia (b = 1.3, p < .05), and affective symptoms, such as depressed mood or irritability for hyperglycaemia (b = 1.2, p < .05).

Conclusion: Different types of symptoms are associated with different detection rates of hypoglycaemia and hyperglycaemia. Furthermore, this study provides initial evidence for distinct patterns of incorrect symptom attributions. As well, the findings are in line with clinical experience (e.g., ambiguity of neuroglycopenic symptoms). The results of this study could add new starting points to enhance established patient education interventions, such as programmes for improving hypoglycaemia awareness.

Non-invasive glucose monitoring in patients with type 1 diabetes: repeatability in the same subjects

A. Caduff¹, W.A. Stahel², C. Bull³, M.S. Talary¹, J. Klisic¹, M. Donath⁴, L. Heinemann⁵

¹Solanis Monitoring, Zurich, Switzerland, ²Seminar for Statistics, ETH Zurich, Switzerland, ³Centre for Clinical Research, University Hospital Zurich, Switzerland, ⁴Clinic for Endocrinology and Diabetes, University Hospital Zurich, Switzerland, ⁵Research, Profil Institute for Metabolic Research, Neuss, Germany

A non-invasive multisensor device (MD) for continuous glucose monitoring, based on dielectric spectroscopy, combined with additional sensors for optical, sweat/moisture and temperature measurement has been developed. The motivation for the MD is based on the understanding that various temporal fluctuations of the properties of skin, can introduce significant perturbations to the actual glucose related measurement. The aim of this study was to measure glucose excursions on different study days in the same subjects using an identical set of calibration parameters.

The multisensor system was worn on the upper right arm by 10 patients with Type 1 Diabetes (age 45 \pm 13 y, BMI 25.5 \pm 2.2 kg/m², duration of diabetes 22.5 \pm 10.5 y, HbA_{1c} 7.0 \pm 0.5%). Glucose was administered orally to induce two consecutive hyperglycemic excursions (12–15 mmol/L) within 8 hours. Euglycemia was re-established by i.v. insulin administration. Based on the sensor signals registered after the first study day, a global calibration model was derived, and the respective coefficients of the individual sensor signals were determined. The model included one coefficient specific to each run.

On the second study day, 5 of these patients were again administered glucose orally to induce a glucose profile with one hyperglycemic excursion. The coefficients from the first study day were re-applied to the 5 test runs of the second study day in order to study the prediction power of the model. Both study days for all subjects were performed within a period of two months. Application of the calibration model from day one to day two yielded an $R^2 = 0.68$ and $MARD = 27.3\%$. These data indicate that a global model can be derived using training runs and successfully applied to a set of test runs with a different glucose profile. The global parameterisation is shown to be transferable, leading to a successful tracking of glucose variations. Repeating this in a larger study group and under less experimentally controlled conditions, will be another important step towards non-invasive glucose monitoring.

Permanent use of a continuous glucose monitor significantly reduces hypoglycaemia and HbA_{1c} in type 1 diabetic patients treated by insulin pump with high occurrence of hypoglycaemia

R.P. Radermecker^{1,2}, A. Saint Remy³, J. Bringer^{1,4}, E. Renard^{1,4}

¹Endocrinology Department, CHU de Montpellier, Montpellier, France,

²Diabetes, Nutrition and Metabolic disorders Department, CHU Sart

Tilman, Liege, Belgium ³Nephrology Department, CHU Sart Tilman,

Liege, Belgium, ⁴Endocrinology Department, Université Montpellier 1, Montpellier, France

Background and aims: High occurrence of hypoglycaemia in type 1 diabetic (T1D) patients is a debilitating condition and has been shown to hamper the improvement of HbA_{1c}. We performed a prospective, randomized, controlled, cross-over study to assess the effectiveness of the permanent use of a continuous glucose monitor (CGM) for 12 weeks on glucose control in T1D patients presenting frequent hypoglycaemia while treated by insulin pump.

Materials and methods: 13 patients (5M, 8F), aged 47 \pm 10 (SD), with T1D since 25 \pm 15 years, under insulin pump since 5.5 \pm 7.0 years, showing > 6 recorded capillary blood glucose (CBG) values < 60 mg/dl in their meter memory for the last 14 days while performing daily 6.2 CBG tests on average, were randomized for permanent use of a CGM (Guardian RT[®], Medtronic, Northridge, CA, USA) or usual CBG testing (control arm) for 12 weeks, followed by a cross-over period for the next 12 weeks. A review of guidelines for adaptation of pump delivery according to CBG was performed in all patients at study inclusion, and a specific education for CGM management before CGM use. The sc glucose sensor, calibrated twice daily against CBG and replaced every 3 days, generates a continuous signal which is on line transmitted wirelessly to the monitor resulting in the presentation of blood glucose estimation every 5 min. Hypo and hyper alarms were set at 80 and 240 mg/dl, respectively. Patients were taught how to adapt insulin delivery and glucose intakes according to online CGM data while usual CBG testing was maintained. A CBG test was requested before action in case of hypo/hyper alarm. Outpatient visits were scheduled after 2 and 12 weeks of each study period. Glucose control was assessed at baseline (BL) and after 12 and 24 weeks from recorded CBG values < 60 mg/dl for the last 2 weeks in the meter memory and HbA_{1c}.

Results: From the 13 included patients, 4 dropped out during the first study period (3 while using CGM and 1 in the control arm). Among the 9 completers, while CBG testing remained similar during both study periods, occurrence of CBG values < 60 mg/dl per 14 days significantly decreased dur-

ing CGM use from 15.3 \pm 8.6 (BL) to 7.6 \pm 6.8 ($p=0.0076$), versus no significant change during the control period (11.1 \pm 4.5). During CGM use, HbA_{1c} (%) significantly decreased from 8.3 \pm 0.4 (BL) to 7.8 \pm 0.6 ($p=0.035$) versus no significant modification during control period (8.0 \pm 0.8). No 'period effect' was identified. Of note, the difference of CBG values < 60 mg/dl per 14 days between BL and end of study was significantly correlated with BL occurrence (Spearman $r = 0.95$, $p < 0.05$). No severe hypoglycaemia, ketosis or adverse event related to CGM use was reported.

Conclusion: Our data support the hypothesis that permanent use of a CGM for 12 weeks allows a significant reduction of hypoglycaemia in T1D patients treated by insulin pump who are prone to hypoglycaemia. Moreover, reduction of hypo occurrence is accompanied by a significant improvement of HbA_{1c}. Although these benefits should be confirmed on longer term, frequent occurrence of hypoglycaemia under insulin pump therapy may represent a sound indication for CGM. In such cases, permanent use appears as necessary.

Evaluation of microdialysis-based glucose monitoring in blood and subcutaneous adipose tissue in type 1 diabetic patients

J.K. Mader¹, F. Feichtner², S. Korsatko¹, G. Köhler¹, R. Schaller², J. Plank¹, T.R. Pieber^{1,2}, M. Ellmerer¹

¹Internal Medicine / Diabetes and Metabolism, Medical University Graz,

²Institute of Medical Technologies and Health Management, Joanneum Research GmbH, Graz, Austria

Background and aims: Tight glycaemic control (TGC) is beneficial for critically ill patients at a cardiac and medical ICU. In order to achieve TGC a continuous glucose signal could be helpful to decrease workload. Subcutaneous adipose tissue (SAT) has been suggested as an alternative site for continuous glucose monitoring and has extensively been tested in type-1-diabetic patients. In the critically ill patient, vascular access is granted, and thus, continuous blood glucose monitoring might be preferable. The aim of the present study was to test a microdialysis-based technique for peripheral venous glucose monitoring and compare the technique with SAT glucose monitoring in type-1-diabetic patients.

Materials and methods: 21 type-1-diabetic patients (age: 31.9 \pm 3.1 years; BMI: 25.1 \pm 8.1 kg/m²) were investigated over a period of 26 hours. SAT microdialysis (MDs) was performed using a standard CMA60 catheter (CMA microdialysis, Sweden), for vascular microdialysis (MDv), a conventional double lumen catheter (mtb Zier, Germany) with a planar flow-through microdialysis unit was used. Microdialysis samples were collected in 15 to 30 minutes intervals and analyzed for glucose with a standard laboratory analyzer. Microdialysis samples were prospectively calibrated to reference glucose by applying a one-point calibration. MDs and MDv glucose levels were compared against arterialized-venous reference blood measurements (Beckman Glucose Analyzer).

Results: Both microdialysis techniques could be applied without restrictions and all 21 patients completed the trial period of 26 hours. Mean glucose difference [2SD] between reference blood glucose and glucose readings obtained from microdialysis were as follows: MDs 5.0 [40.3] %, and MDv 8.9 [32.8] %, respectively. Mean absolute relative difference (MARD) [\pm SD] was 15.7 \pm 7.8 % (MDs), and 15.9 \pm 10.8 % (MDv), respectively. Clarke Error Grid analysis indicated 71.5% in A, 25.6% in B, 2.3% in C and 0.6% in D for MDs and 68.1% in A and 31.9 % in B for MDv, respectively.

Conclusion: Glucose monitoring from SAT and blood using a microdialysis-based approach indicated similar performance when investigated in type 1 diabetic patients for a period of 26 hours.

What is the best way to analyse glycaemic variability using continuous glucose monitoring data?

B.C. Whitelaw, P. Choudhary, D. Hopkins

Department of Diabetes, King's College Hospital, London, United Kingdom

Background and aims: Continuous glucose monitoring (CGM) provides detailed information about glucose fluctuations and is often used in the clinical and research setting to evaluate glycaemic variability. Glycaemic variability can contribute to risk of micro and macrovascular complications and also to the risk of severe hypoglycaemia. Most methods currently used to evaluate glycaemic variability were developed for use with frequent capillary glucose sampling but are now being applied to CGM data. There is currently no consensus as to the best method of assessing glycaemic variability from CGM data. The aim of this project is to apply the different methods of assessing glycaemic variability to a range of CGM data to assess both their validity and their correlation with a clinical assessment of glycaemic variability. A subsequent aim is to make an assessment as to which method has the strongest correlation with a clinical assessment.

Materials and methods: We analysed 48 continuous hours of CGM data from 22 subjects, 7 non-diabetic controls and 15 with type 1 diabetes. The subjects with diabetes were purposively sampled to reflect a wide range of duration of diabetes (17 +/-10yrs) and hypoglycaemia experience. Mean age was 48+/-12yrs and mean HbA1c was 7.3% +/- 1.1. Replicating methodology used by Ryan et al in development of the lability index, we compared established measures of glycaemic variability with a clinical lability score derived from blinded review of CGMS traces by two independent clinicians. Several indices of glycaemic variation were calculated including: standard deviation (SD), Mean Amplitude of Glycaemic Excursion (MAGE), Average Daily Risk Range (ADRR), Glycaemic Risk Assessment Diabetes Equation (GRADE) and Continuous Overall Net Glycaemic Action (CONGA). CONGA was calculated using 1, 2 and 4 hour intervals, giving three separate indices CONGA1, CONGA2 and CONGA4. Each method of assessing glycaemic variability was then correlated with the clinical lability score, using Spearman's rank correlation.

Results: Correlations of different measures of glycaemic variability are shown in table 1. All measures of glycaemic variability gave a statistically significant correlation with clinical assessment, confirming their validity for use with CGM traces. CONGA2 and CONGA4 provide the strongest correlations (0.96 for both).

Conclusion: Our data shows that even though many of these indices of glycaemic variability were originally developed for use with capillary glucose values, they have a close correlation to a clinical assessment of variability when used with continuous data obtained from CGM. CONGA2 and CONGA4 have the strongest correlation with glycaemic variability. They are the standard deviations of the differences between the any individual glucose value and the value 2 or 4 hours previously respectively. This suggests that CONGA2 or CONGA4 should be used when analysing CGM traces to determine glycaemic variability.

Table 1: Correlation between clinical assessment and different indices of glycaemic variability

Index	Correlation Coefficients	p value
ADRR	0.57	0.007
GRADE	0.88	<0.001
MAGE	0.91	<0.001
SD	0.95	<0.001
CONGA1	0.91	<0.001
CONGA2	0.96	<0.001
CONGA4	0.96	<0.001

Impact of an algorithm guiding patient responses to real-time continuous glucose monitoring (CGM) in type 1 diabetes managed with continuous subcutaneous insulin infusion (CSII)D.N. O'Neal¹, B. Krishnamurthy¹, F.J. Cameron², P.G. Colman³, S. Hamblin⁴, M.A. O'Connell⁵, C. Rodda², H. Teede², J.D. Best¹, A. Jenkins¹

¹University of Melbourne Department of Medicine, St Vincent's Hospital, Fitzroy, ²Department of Endocrinology and Diabetes, Royal Children's Hospital, Melbourne, ³Department of Endocrinology and Diabetes, Royal Melbourne Hospital, Melbourne, ⁴Department of Endocrinology and Diabetes, Western Hospital, Footscray, ⁵Department of Endocrinology and Diabetes, Monash Medical Centre, Clayton, Australia

Background and aims: The Australian Sensor Augmented Pump Study demonstrated that use of Real-Time CGM reduced HbA1c by 0.4% in type 1 diabetes (T1D) CSII patients. This study may underestimate the potential benefit CSII-CGM technology as subjects were not advised how to respond to CGM data. Aims are to develop and test a decision support tool for T1D patients using CSII-CGM technology.

Materials and methods: Algorithms were developed providing guidelines for both reactive and proactive responses to Real-Time CGM information. Sixty (38 female/22 male) CSII using T1D patients were recruited in pairs matched for age, gender and HbA1c. All were commenced on Real-Time CGM (Paradigm MMT722, Medtronic, Minimed, Northridge, CA) and randomised to Algorithm: (Baseline:Age 29.8(13.3)Y; HbA1c7.9(0.7)% or no Algorithm (Baseline:Age 27.4(16.2)Y; HbA1c 7.8(0.8)% for 16 weeks. HbA1c was measured at baseline and completion. A 6-day masked CGM trace was performed pre-Real-Time CGM initiation and 1 week prior to study-end. Analysis was by paired t-test and ANOVA.

Results: Algorithms have been developed. As of 3/08 HbA1c of the 11 completed subjects fell: 7.5(0.5)% to 7.0 (0.5)%; p=0.006. For Algorithm-users (n=6): 7.6(0.4)% to 6.9(0.7)%; mean change 0.7%, range of change -1.2% to +0.1%; 5/6 reached HbA1c<7.1%. For non-Algorithm users (n=5): HbA1c 7.4(0.5)% to 7.2(0.3)%; mean change 0.2%, range of change -0.8% to +0.4%; 1/5 achieved HbA1c<7.1%. CGM data did not differ significantly between the two groups. In particular there was no difference in time spent in hypoglycaemia (<4.0mmol/L).

Conclusion: Preliminary results suggest that patient education may improve benefit of Real Time- CGM use in CSII treated T1D patients.

The effect of preprandial vs. postprandial administration of rapid-acting insulin analogue on continuous glucose monitoring in type 1 diabetic patientsA. Gelber¹, I.F. Liberty², Z.H. Perry³, E. Botach², I. Harman-Boehm²

¹Goldman Medical School, Ben-Gurion University Faculty of Health Sciences, ²Diabetes Unit, Soroka University Medical Center, ³Department of Surgery A, Soroka University Medical Center, Beer-Sheva, Israel

Background and aims: Rapid acting insulin analogs have an onset of action 15 minutes after injection and peak action at 30-120 minutes. It is recommended that they be injected 10-15 minutes prior to meals. Several studies have found that preprandial injection of analog is preferable but concluded that postprandial injection can provide adequate glucose control. The aim of our study was to examine whether postprandial administration of the meal-time insulin bolus is as effective as preprandial administration in controlling glycemia in type 1 diabetic patients using an insulin pump or multiple daily injections and to assess patient satisfaction of both methods.

Materials and methods: Twelve subjects with type 1 diabetes- 6 on multiple injections and 6 on insulin pumps- were studied in two separate time periods. During the first three day time period the patients injected the meal rapid analog insulin bolus within 15 minutes before the meal, and during the second three day period, immediately after the meal. The patients were monitored by a Continuous Glucose Monitoring System (CGMS) for both time periods. The data was derived from the Minimed CGMS Solutions software and analyzed using SPSS. Mean blood glucose, nadir and peak values, 2 hour postprandial glucose, 2 hour AUC, standard deviation of mean glucose and time spent above 180 mg% or below 70 mg% were calculated. Analytical statistics were done using parametric measures (paired-sample T test P<0.05)

Results: Patients ranged in age from 23-71years with HbA1c values ranging from 5.7-7.6%. Mean BMI 26.97±3.72. Mean basal insulin dose18.86±11.48 units and mean daily bolus of 22.36±14.38 units. In the postprandial injection period, there was a significantly higher percentage of time during which the

subjects using an insulin pump compared to MDI were above the recommended upper glucose limit of 180 mg/dl (26.5 ± 13.35 vs $8.46 \pm 11.00\%$ respectively $p=0.037$). In addition, in the same time period there were significantly higher maximal glucose values two hours post prandial in the patients using an insulin pump (139.74 ± 26.12 vs 119.91 ± 17.99 mg%, $p=0.038$). There were no other significant differences seen in any of the parameters used to assess glycemic control between the two time periods nor were there any other significant differences seen between patients on multiple injection or pump therapy. Patient satisfaction scores were similar in the two periods but more patients preferred post-prandial injections citing improved flexibility and decreased fear of hypoglycemia.

Conclusion: The current study which did not find a significant advantage for pre-prandial injection makes it is reasonable to instruct type 1 diabetes patients using multiple daily injections to administer the insulin bolus immediately after the meal, if this timing better suits their life style. Patients on pump therapy may need to increase their mealtime bolus when switching from pre to postprandial timing of the bolus. The greater flexibility in the timing of mealtime injections and decreased fear of hypoglycemia may improve adherence to treatment.

1074

Continuous glucose monitoring system compared to self blood glucose monitoring in type 1 diabetics at haemodialysis

P.T. Monteagudo¹, M.S.M. Marrocos², C. Bittencourt¹, M.D.F. Neves¹, C. Stella¹, E.B. Rangel³, C. Melaragno³, J.O.P. Medina³, S.A. Dib¹, A.R. Chacra¹, J.R. Sa¹

¹Medicine, Division of Endocrinology, Federal University of Sao Paulo,

²Nephrology, Servidor Publico Estadual Hospital, ³Medicine, Division of Nephrology, Federal University of Sao Paulo, Sao Paulo, Brazil

Background and aims: The better glycemic control during dialysis periods, the better clinic conditions patients will have for an eventual transplantation. But diabetics with renal insufficiency are at risk for hyper and hypoglycemic episodes, and usually have instable diabetes. The continuous glucose monitoring (CGM) is a device that allows a better glycemic evaluation. The objective was to compare glycemic behavior at CGM and the auto monitoring results in 11 type 1 diabetics (DM1) (6 men) at renal replacement therapy.

Materials and methods: They were submitted to CGM for 3 days. We analyzed the 24h before hemodialysis and 24h during and after dialysis, each 4 hour. Patients had 38.7 ± 11.9 y of age; 17.7 ± 4.0 y of diabetes duration; 25.7 ± 20.2 months in dialysis; 22.2 ± 3.5 kg/m² of body mass index. Basal insulin was glargine in 5, detemir in 2 and NPH in 4 patients, 37.6 ± 21.4 UI in the dialysis day and 31.6 ± 21.4 UI in the non dialysis day (*ns*). Glycated hemoglobin was $9.0 \pm 1.4\%$. They realized 4 capillary glycemia each day, and ultra rapid insulin replacements were performed by 10 patients, and 9 counted carbohydrates. All had advanced diabetic retinopathy (2 amaurotic) and peripheral neuropathy (2 with neuropathic pain), 9 had autonomic neuropathy (8 with postural hypotension) and 6 had macroangiopathic disease (2 with coronary insufficiency).

Results: Table shows CGM results, and in the 3 last lines the glucometer values. T test was performed for continuous variables, and “compare two proportions” for statistical analyses; * $p<0.005$ vs. 24h Before dialysis and & $p<0.03$ vs. total CGM value.

Periods	n	Glycemias mg/dl	% Glycemias ≤70	70<Glyc<140	≥140	≥180
24h Before dial	3070	207±97	5.6	23.2	71.2	57.5
Day of dialysis	2831	234±100 *	3.9*	16.4*	79.7*	71.1*
TOTAL-CGMS	5901	220±99	4.7	19.8	75.5	64.0
Glucometer-pre	47	203±118	17.2	10.6	72.3	44.7
Glucometer-post	44	226±114	6.8	20.5	72.7	59.1
Glucometer-total	91	214±116	12.1&	15.4	72.5	51.7&

Conclusion: Our type 1 diabetic patients in chronic hemodialysis, although using basal/bolus insulin treatment, are in bad glycemic control. Especially in the day of dialysis, when mean CGM glycemia was significantly greater compared to the day before dialysis (234 ± 100 vs. $\pm 207 \pm 97$ mg/dL), with lesser hypoglycemia frequency (3.9 vs. 5.4%), 16.4 vs. 23.2% within normal values and 71.1 vs. 57.5% with hyperglycemia ≥ 180 mg/dl ($p<0.05$ in all). When we compared the glucometer values with the CGM, the proportion of hypoglycemia at self-blood glucose monitoring was more prevalent (12.1% vs.

4.7% respectively), and hyperglycemias ≥ 180 mg/dl was less prevalent (51.7% vs. 64.0%). These findings suggest that a more frequent self blood glucose monitoring might improve glycemic control in type 1 diabetic patients in hemodialysis.

Evaluating the effect of the FreeStyle Navigator® Continuous Glucose Monitoring System in diabetes self-management

T. Danne¹, T. Kracht¹, K. Walte¹, B. Aschemeier¹, R. Geldmacher², L. Sölter², W. von dem Berge², J.R. Bugler³, Z. Welsh³, C. Jones³, R. Hartmann¹, O. Kordonouri¹

¹Diabetes Center for Children and Adolescents, Kinderkrankenhaus Auf der Bult, Hannover, Germany, ²Schwerpunktpraxis, Diabetes-Zentrum Hannover-Nord, Germany, ³Research, Abbott Diabetes Care, Oxon, United Kingdom

Background and aims: This study was designed to investigate the use and impact of the FreeStyle Navigator Continuous Glucose Monitoring System (FSN-CGM) under home use conditions in self-management of diabetes.

Materials and methods: The study was for 60 days of continuous sensor wear (arm or abdomen) in patients with type 1 diabetes at home. The patients performed sensor insertions and calibrations. Real-time data and alarms were not available for the first 20 days (masked phase). Real-time data, trend arrows and threshold alarms for hypo- and hyperglycaemia were un-masked for the next 40 days. For the masked phase, patients were instructed to make all treatment decisions based on capillary BG tests only and to perform BG tests with the built-in FreeStyle BG meter. In the un-masked phase, subjects were instructed to make treatment decisions based on FSN-CGM except during hypoglycaemia or rapidly changing glucose values when confirmatory capillary BG test was performed prior to self-management decisions. The primary endpoint was to demonstrate a reduction in time spent outside euglycaemia (70–180mg/dL) between the first 20 days (phase A) and last 20 days (phase B) of the study. Both phases were compared for a number of specified measures of glycaemic variability by paired t-test. HbA1c was recorded by DCA 2000 at the start and end of the study.

Results: Twenty-seven adult patients with type 1 diabetes (male/female ratio 14/13) were included and completed the study (mean age 33.0 ± 10.3 , range 18–55 yrs; diabetes duration 18.2 ± 10.9 yrs). The average baseline HbA1c was $7.3 \pm 1.0\%$ with 21/27 patients on CSII therapy, the remaining on MDI. Mean baseline glucose was 169 ± 27 mg/dL for phase A. During the study, two adverse events occurred for an adhesive reaction and bleeding/pain on sensor insertion; no serious adverse events were reported. Comparing phase A and phase B, patients had a significant reduction of the time spent outside euglycaemia from 10.2 to 8.8 hrs/day ($p<0.05$). Furthermore, there were significant reductions in glucose SD from 61 to 55 mg/dL ($p<0.01$), hyperglycaemic time (>180 mg/dL) from 9.5 to 8.2 hrs/day ($p<0.05$), and the High Blood Glucose Index1 (HBGI; Kovatchev BP et al, *Diabetes Technol Ther* 4:295–303, 2002) risk score from 9.0 to 7.6 ($p=0.025$). Hypoglycaemic time (<70 mg/dL) decreased from 0.74 to 0.59 hrs/day without statistical significance ($p>0.05$). Mean HbA1c fell from $7.3 \pm 1.0\%$ at baseline to $6.7 \pm 0.7\%$ at the end of the study ($p<0.001$).

Conclusion: Data of this study indicate that the use of the FreeStyle Navigator Continuous Glucose Monitoring System has a positive effect on self-management of diabetes concerning glycaemic control and glycaemic variability. These findings are encouraging and supportive of similar data reported by other continuous glucose monitoring utilization studies.

Use of real time continuous glucose monitoring in type 1 diabetes patients on intraperitoneal insulin (CIPII). A feasibility study

H.J.G. Bilo^{1,2}, K.H. Groenier³, N. Kleefstra^{1,4}, S.J.J. Logtenberg¹

¹Diabetes Centre, Isala Clinics, Zwolle, ²Internal Medicine, UMCG, Groningen, ³General Practice, UMCG, Groningen, ⁴Medical Research Group, Langerhans, Zwolle, Netherlands

Background and aims: Continuous intraperitoneal insulin infusion (CIPII) is used in patients with poorly controlled diabetes. Real time continuous glucose monitoring (CGM) can provide continuous information about current glucose values without the need for multiple invasive measurements. A

prospective CGM system might be a valuable addition to CIPII, especially in those patients still experiencing frequent and/or unexpected hyper- or hypoglycemic episodes. Our aim was to investigate the effectiveness and safety of real time CGM in patients treated with CIPII.

Materials and methods: Open label, cross-over, randomized, controlled trial. A baseline phase of 72 hours, in which blinded CGM data were collected, was followed by 2 study phases in which subjects used either blinded or open CGM for 2 x 72 hours with a one-week crossover period in between. In the open phase the CGM system would alert whenever a glucose level fell below or rose above preset values (3.9 and 11.1 mmol/L, respectively). The primary efficacy endpoint was percentage of time spent in euglycemia. A secondary endpoints was patient satisfaction as measured with the User Acceptance Questionnaire (UAQ) for CGM. Device accuracy was evaluated using median relative absolute difference (RAD) of continuous glucose values to paired SMBG meter readings.

Results: *Baseline characteristics:* 6F/4M type 1 diabetes patients, median (IQR) age 43.8 (31.8–50.6) years, median (IQR) duration of diabetes 20.5 (14.7–35.3) years, mean (SD) HbA_{1c} 8.5 (1.4) %. *Outcomes:* Median RAD of sensor values compared to SMBG values was 14.0%.

Figure 1. presents an example of CGM data in 1 subject.

Percentage of time in euglycemia (4.0–10.0 mmol/L) was 68% and 64% in the open and blind phase, respectively ($p=0.41$). Looking at a more narrow range (4.0–8.7 mmol/L) these percentages were 54% and 48% ($p=0.37$). Percentage of time in hyperglycemia (>10.7 mmol/L) was 25% and 29% ($p=0.25$) in the open and blind phase, respectively. The mean (SD) UAQ scores regarding comfort, sensor operation, alarm and overall assessment (range 0–100) were 73.9 (14.4), 61.0 (18.9), 54.4 (7.8) and 60.8 (22.5), respectively, indicating satisfaction with CGM.

Conclusion: Patient satisfaction and user acceptance with the CGM system were generally high. However, efficacy on glycemic control should be evaluated in a sufficiently powered trial of longer duration. CIPII combined with CGM could serve as the next step to the development of a closed loop system.

Glycaemic profile by continuous glucose monitoring system in a cohort of adolescents treated with continuous subcutaneous insulin infusion or long acting insulin analogues

M. Anzellotti, A. Di Stefano, S. Carinci, F. Chiarelli, S. Tumini
Departement of Pediatrics, University of Chieti, Italy.

Background and aims: The purpose of the study was to analyze daily glycemic trend in a cohort of adolescents on “basal-bolus” insulin regimen with continuous subcutaneous insulin infusion (CSII), glargine and detemir compared with a control group of healthy adolescents using continuous glucose monitoring system (CGMS). It was analyzed if CGMS could reveal different glycemic pattern in these groups of patients with similar metabolic control. Numbers of boluses, number of hypoglycemia and its duration, ketoacidosis and accuracy of CGMS were also evaluated.

Materials and methods: The 45 adolescents with type 1 diabetes who participated in the study had median age 17.08 ± 3.21 yrs old, mean duration of diabetes 8.77 ± 4.82 yrs, mean HbA_{1c} $7.84 \pm 0.95\%$, and mean BMI 25.69 ± 4.71 Kg/m². Fifteen patients were on CSII with rapid insulin analogue, 15 patients on glargine and rapid analogue at meals, 15 patients on detemir and regular insulin at breakfast and lunch and rapid analogue at dinner. Eligibility criteria for patients with T1DM included: treatment with basal bolus regimen at least from 6 months, duration of diabetes more than 2 years and similar BMI and HbA_{1c}. Ten healthy adolescents were enrolled as control group.

Results: The accuracy of CGMS was evaluated by linear regression of 704 data pairs recorded during the study. The correlation coefficient was $r=0.94$

($p<0.0001$). The glycemic profile was divided in daily glycemic profile from 8.00 am to 24.00 pm and in night glycemic profile from 00.00 am to 8.00 am. During the night there weren't statistical significant difference between the 3 insulin regimens versus healthy subjects. During the day the glycemic profile revealed statistical significant difference between patients treated with CSII versus other insulin regimens (detemir from 11.00 to 12.00 am ($p<0.001$), from 12.00 to 1.00 pm ($p<0.01$), from 1.00 to 2.00 pm ($p<0.0001$), from 3.00 to 6.00 pm ($p<0.05$); glargine from 11.00 am to 1.00 pm ($p<0.01$), from 1.00 to 2.00 pm ($p<0.0001$), from 3.00 to 4.00 pm ($p<0.0001$), from 4.00 to 5.00 pm ($p<0.001$) and from 5.00 to 6.00 pm ($p<0.01$). It was also evaluated glycemic variability by the absolute value of measured glucose minus 5.5 mmol/l that revealed statistical significant difference between patients in treatment with CSII in comparison with patients in treatment with glargine ($p<0.37$). The area under the curve (AUC) was calculated but it wasn't statistical significant difference between the 3 groups. The 45 patients with T1DM had 83 episodes of glucose level below 60 mg/dl (3.25 mmol/l) measured by CGMS. The number of daily hypoglycemia were 52 episodes. The number of night hypoglycemia were 31. There weren't statistical significant difference between groups in number and mean duration of hypoglycemia during the day and during the night. It was also noted that patients on CSII grant a mean of 5 boluses a day (43.5%) versus 3.5 in patients on glargine (30.5%) and 3 boluses in patients on detemir (26%). No severe hypoglycemic or ketoacidosis events occurred in either groups.

Conclusion: The CGMS is useful to identify glycemic variability that are not evident with routine monitoring. Basal-bolus treatment with CSII seemed to be associated with better daily glycemic control. Patients on CSII grant more boluses and present less glycemic variability during daily time than other groups.

The use of basal/bolus insulin regimen in the management of patients with diabetic ketoacidosis (DKA)

D. Smiley¹, S. Jones², P. Mulligan¹, A. Temponi¹, C. Semakula², T. Keyler², D. Umpierrez¹, S. Nazarian², N. Tesfaye², M. Ceron¹, G. Umpierrez¹;

¹Division of Endocrinology, Emory University, Atlanta, ²Division of Endocrinology, University of Minnesota, Minneapolis, United States

Background and aims: The traditional treatment of DKA includes the intravenous (IV) infusion of regular insulin until resolution of hyperglycemia/ketosis, followed by subcutaneous (SC) injections of split-mixed or multi-dose regimen of NPH/regular insulin. The aim of this randomized controlled study (NCT00590044) was to compare the safety and efficacy of the traditional approach (NPH/regular) versus a basal/rapid-acting insulin analog (glargine/glulisine) regimen both during the acute IV phase and during the SC transition to maintenance period.

Materials and methods: A total of 60 patients with DKA were randomized to receive a continuous IV infusion of regular or glulisine insulin (starting dose 0.1 U/kg/hr) until the resolution of DKA. Following resolution of DKA, patients were transitioned to a split-mixed (NPH/regular) insulin (n=30) or to glargine/glulisine (n=30) at a starting dose of 0.6 U/kg/day for lean and 0.8 U/kg/day for obese subjects. NPH and regular were given as 3/5 of the total daily dose in the morning and 2/5 in the evening. Glargine was given once daily as 1/2 of the total daily dose and the remaining 1/2 was given as glulisine in equally divided doses before meals.

Results: There were no differences in the admission BG: 29 ± 7 mmol/L vs. 33 ± 10 mmol/L, pH: 7.18 ± 0.1 vs. 7.19 ± 0.1 , HCO_3^- 13 ± 5 mmol/L vs. 14 ± 5 mmol/L, BOHB: $(768 \pm 288 \text{ } \mu\text{mol/L})$ vs. $(864 \pm 288 \text{ } \mu\text{mol/L})$ between groups (p=NS). The mean time to resolution of DKA was similar between patients treated with IV regular (11.4 ± 8 hrs) and those treated with IV glulisine insulin (8.6 ± 4 hrs, p=NS). There were no differences between groups in the total amount and/or rate of insulin infusion until resolution of DKA. There was no significant difference in mean BG level during the hospital stay between the NPH/regular (11 ± 3 mmol/L) and the glargine/glulisine (12 ± 3 mmol/L) groups, p=0.08. NPH/regular insulin, however, was associated with a higher rate of mild (BG < 3.3 mmol/L) and severe hypoglycemia (BG < 2.2 mmol/L) during the hospital stay. In the NPH/regular group, a total of 8 patients (27%) had 15 episodes of mild hypoglycemia, and 2 patients (6.6%) had 2 episodes of severe hypoglycemia. In the glargine/glulisine group, only four patients (13%) had a single episode of mild hypoglycemia and no patient in this group had severe hypoglycemia.

Conclusion: Our results indicate that the use of basal/bolus insulin regimen in the management of DKA resulted in improvement in glycemic control and a lower rate of hypoglycemia during the SC maintenance period. Our study indicates that the use of glargine and glulisine insulin regimen is as effective and safer compared to the traditional NPH and regular insulin for the management of diabetes following resolution of DKA.

Postprandial urinary glucose may be useful for preventing arteriosclerosis with PWV data

M. Kato¹, N. Kato¹, H. Fujii², Y. Watanabe², T. Miyakawa²

¹Internal Medicine, Kato Clinic of Internal Medicine, Takasago, Katsushika,

²Internal Medicine, Tama-Center Mirai Clinic, Tokyo, Japan

Background and aims: Japanese diabetics are more likely to develop insulin deficiency compared with Caucasian type 2 diabetic patients. In this study, the usefulness of measuring postprandial urinary glucose as a marker of postprandial hyperglycemia was investigated by urinary glucose levels during the 75-g oral glucose tolerance test (OGTT). The aortic pulse wave velocity (PWV) is an independent marker of cardiovascular risk, so the relationship between PWV and blood or urine glucose levels was investigated in patients who underwent both the OGTT and PWV measurement.

Materials and methods: Japanese diabetics are more likely to develop insulin deficiency compared with Caucasian type 2 diabetic patients. In this study, the usefulness of measuring postprandial urinary glucose as a marker of postprandial hyperglycemia was investigated by urinary glucose levels during the 75-g oral glucose tolerance test (OGTT). The aortic pulse wave velocity

(PWV) is an independent marker of cardiovascular risk, so the relationship between PWV and blood or urine glucose levels was investigated in patients who underwent both the OGTT and PWV measurement.

Results: Among 306 patients, 160 had diabetes according to the result of the OGTT. However, a diagnosis of diabetes was missed in 33% of patients when judged from the FPG alone. When a 2-hr urinary glucose level ≥ 100 mg/dL was used as a screening criterion, it was found to be elevated in 156 out of 160 patients (98%). In the subjects with a normal, borderline, and diabetic OGTT pattern, the mean PWV was 13.7, 15.8, and 15.9 m/s, respectively. It showed differences between the normal pattern and the borderline or diabetic patterns, but not significant. When the PWV was compared with the blood glucose level after OGTT, the mean PWV was 14.8, 15.9, and 16.1 m/s when the fasting blood glucose was less than 110, 110–125, and over 126 mg/dL, respectively. It showed no significant differences between the three groups. However, it was 13.7, 15.9, and 16.3 m/s when the blood glucose level at 60 min after the OGTT was less than 180, 180–199, and over 200 mg/dL, respectively, with a significant difference (p<0.05) between the first and third group. There was also a difference (p<0.1) between the groups in which urinary glucose was 100 mg/dL or more and less than 100 mg/dL from 60 min after the OGTT (the mean PWV was 14.2 and 16.0 m/s, respectively). Although the PWV is known to increase with age, there were no significant age differences between the groups for which these significant differences of PWV were noted.

Conclusion: Postprandial hyperglycemia is a factor that promotes the development of arteriosclerosis. In the present study, the PWV was also more closely related to the blood glucose level at 60 min after the OGTT than to the fasting or 120 min glucose levels. Urinary glucose is an important parameter for screening, because it reliably detects patients with postprandial hyperglycemia. The PWV showed a significant difference in relation to the time of measurement after the OGTT (from 60 min), so measurement of postprandial urinary glucose may be useful for preventing arteriosclerosis, as is measurement of blood glucose, while also being more economical.

1080

Impact of hyperglycaemia on morbimortality, length of hospitalisation and rates of rehospitalisations in a general hospital setting in Brazil

S.A.O. Leite, S.B. Locatelli, A.R.F. Oliveira, D. Tockus, S.P. Niece, T. Tosin
Internal Medicine, Universidade Positivo, Curitiba, Parana, Brazil

Background and aims: It is already known that hyperglycemia in hospitalized patients is related to a higher incidence of clinical and surgical complications and to worse outcomes. Adequate glycemic control and earlier diagnosis of type 2 diabetes during hospitalization are cost-effective measures.

Material and methods: This study was designed to determine the impact of hospital hyperglycemia on morbimortality in a university hospital setting during a 3 month period by reviewing patients' records. The primary purposes of this trial were to verify if hyperglycemia is properly and early diagnosed, how it is managed during the hospitalization and also to evaluate the relationship between control of hospital hyperglycemia and outcomes such as complications during hospital stay, extent of hospitalization, frequency of rehospitalizations, death rates and number of days at the ICU (Intensive Care Unit) after admission. The secondary objective was to evaluate the medical management of hyperglycemia. Statistical analysis utilized Kruskal-Wallis and "a posteriori" d.m.s. to complement, Spearman and Qui-square test with a level of significance of 5% (p<0.05).

Results: 779 patient records fulfilling inclusion criteria were reviewed. They were divided into 5 groups: 1-)diabetics with normal blood glucose (n=123); 2-)diabetics with hyperglycemia (n=76); 3-)non diabetics with hyperglycemia (n=225); 4-)persistent hyperglycemia during 3 consecutive days (n=57) and 5-)normal glucose control (n=298). Patients in groups 2, 3 and 4 compared groups 1 and 5 had significantly higher mortality rates (17.7% vs. 2.8 %) and ICU admissions with complications (23.3% vs 4.5%). Group 4 had longer hospitalization (mean 15.5 days) and group 5 had the lowest rate of rehospitalizations (mean of 1.28). Only 152 hyperglycemic patients were treated. Insulin "sliding-scale" alone was the most frequent treatment used with wide variations in glucose target medical prescriptions. Insulin IV infusion was used in 3,8% of patients at the ICU. A1c was measured in 11 patients.

Conclusion: There is a correlation between hospital hyperglycemia and morbimortality, length of hospitalization and number of re-hospitalizations, among other parameters. Most of patients do not have their blood glucose assessed at hospital, despite of high number of patients with hyperglycemia without diagnosis of diabetes, A1c was not measured. Even when patients were assessed for hyperglycemia, they are not treated properly.

1081

Practical knowledge and confidence in the management of diabetes is lacking amongst hospital doctors

P. Muthusamy, E. Ejenavi, S.M. Rajbhandari

Diabetes Dept, Lancashire Teaching Hospital, Chorley, United Kingdom

Background and aims: One of the reasons why diabetic patients who are hospitalised have prolonged length of stay is due to the suboptimal management of their diabetes during admission. Day to day management of glycaemic control has been increasingly delegated to diabetes specialist (nurses or doctors) despite 20% of all in-patients having diabetes. In order to assess whether this is due to lack of knowledge or due to lack of confidence we conducted an audit amongst hospital doctors of all grades and specialties.

Materials and methods: This was a prospective study using anonymous multiple-choice questionnaires. Out of 16 questions, 6 assessed factual knowledge of oral hypoglycaemic agent, insulin and treatment targets, 5 assessed hypothetical case scenario such as adjusting insulin doses and oral hypoglycaemic agents and 5 questions assessed self-reported confidence. Questionnaires were sent by e-mail and letters to all grades of doctors working in 2 hospitals. A reminder was sent to all doctors after 3 weeks.

Results: Out of 115 questionnaires sent 44 (38.3%) replies were obtained. All answers were anonymous so it was not possible to pursue individuals for reply. We found that basic knowledge of HbA1c and blood glucose targets were known to 80% of doctors. Regarding various insulin preparation available, only 60% could correctly identify if the particular insulin was long acting, short acting or mixture of insulin. When asked about how familiar were they with commonly prescribed insulin in the hospital, around 50% felt that these were well known to them. In a hypothetical case scenario of persisting hyperglycaemia on insulin treated patient, 70% of replies correctly adjusted the dose of insulin but only 45% felt confident in doing so. On the other hand 80% had self-reported competency in managing metabolic emergencies such as ketoacidosis, hyperosmolar state or hypoglycaemia. The most common in-patient clinical scenario of uncomplicated hyperglycaemia was correctly managed only by 25% of subjects and hypoglycaemia by 79%. Most (80%) of the doctors stated that they would like further training in the management of diabetes for in-patient.

Conclusion: Our study suggests that there is a lack of practical knowledge amongst hospital doctors in the management of diabetes. Following this audit we have developed a case based teaching tool, which has been highly appreciated by trainee doctors.

In-patient prevalence of diabetes in an Irish teaching hospital: resource implications?G. Moloney¹, R. Connolly¹, A. Egan¹, E. Higgins¹, F. Waldron-Lynch¹, F. Dunne^{1,2}¹Endocrinology, University College Hospital Galway, ²Department of Medicine, National University of Ireland, Galway, Ireland

Background and aims: Patients with diabetes mellitus are acknowledged to be at higher risk of an in-patient hospital admission and to experience a greater length of hospital stay. Several bodies of research have shown that good glycaemic control as an in-patient improves the clinical outcome. One of the key strategies in improving the quality of in-patient management of diabetes is the provision of specialist diabetes services. The aim of this study was to assess the point prevalence of diabetes in the general adult wards of a major teaching hospital, with comparison of the demographics of diabetic patients to those of the general patient population and analysis of the use of multidisciplinary diabetic services.

Materials and methods: A cross-sectional study at a tertiary centre was undertaken during a defined 24 hour period. A list of all in-patients was compiled and those with a diagnosis of diabetes identified using data from the Hospital In-Patient Enquiry scheme (HIPE). A chart review was undertaken to identify specific patient characteristics, and referral pattern to the diabetes services.

Results: There were 340 in-patients during the defined period, 19 (5.6%) of whom had diabetes mellitus. 13 (68%) of these patients were male and 6 (32%) were female. Type 2 diabetes was present in 13 (68%). The mean age of the diabetic cohort was 68 years compared to 58 in the non-diabetic population. The median length of stay (LOS) was 18 days for diabetic patients compared to 11 days for the non-diabetic population. The mean LOS for patients >66 years was 28 days, compared to 15 days for patients <66 years. 15 patients

(78.9%) were admitted to services other than diabetes, and 8 (42%) were admitted because of a vascular complication. All diabetic patients survived to discharge. Of the non-diabetic patients, the mortality was 5% (16 out of 321). 10 of 15 patients on general wards were reviewed by diabetes services during their hospital admission.

Conclusion: Our study population followed established trends regarding age, gender and type of diabetes. The main reason for admission of diabetic patients was management of vascular complications. Diabetes services were utilised for two thirds of patients. The length of stay for patients with diabetes was greater compared to background patient population with significant resource implications.

Difference between insulin sensitivity expressed by ability to lower plasma glucose concentration and to keep plasma glucose concentration stable during medical treatment

M. Matsuda, Y. Hisano, N. Hayakawa, M. Shigeto, Y. Akiyama, M. Masuzawa, T. Okabe

Diabetes and Endocrine Department, Kameda Medical Center, Kamogawa, Japan

Background and aims: Insulin sensitivity has been expressed mainly by two ways, ability to lower BG (blood glucose) and to keep BG constant. To understand the difference between these two kinds of parameters, we applied insulin infusion analysis which was used to stabilize plasma glucose conc. after acute phase of critically ill diabetic patients.

Materials and methods: Insulin sensitivity is defined as a decremental conc. of BG by a fixed increment of insulin (or delta insulin) (ISI-delta [mg/dl per U]). On the other hand, whole body insulin resistance (IRI-abs [U/hr]) can be defined as an absolute amount of insulin to keep fixed glucose turnover and keep BG constant. These two parameters were analyzed by plotting insulin infusion rates on x-axis, and the differences of BGs on y-axis. BG was measured from 1 to 6 hrs intervals. GIR (Glucose infusion rate [g/hr]) is converted to the theoretical increase of BG [mg/dl per hr] in glucose distribution space, and is added on the graph to estimate the next BG value, and insulin infusion rate was adjusted to achieve the desired BG. BG was measured by PCx (Abbott, USA), and human regular insulin (1 U/ml saline) and glucose were infused by infusion pumps for clinical use calibrated routinely. Data during 15115 hours from 139 subjects (M/F = 80/59, age = 60 ± 16 y.o., BMI = 24 ± 5 kg/m²) were analyzed in this method. After connecting two consequent observed points, reading X (U/hr) on X-axis (Y=0: to cancel the effect of glucose infusion) was used to calculate IRI-abs. ISI-delta was the slope of the line, when IRI-abs became fixed. When IRI-abs was not stable, ISI-delta was calculated by the least square method to minimize the error between the expected points and actual observed points. An average IRI-abs and ISI-delta were calculated every 24 hours starting next day after initiation of insulin infusion. Only when GIR was more than 2.2mg/kg per min and insulin infusion rate was more than 1 mU/kg per min, the calculation was made to avoid the influence of residual endogenous glucose production and insulin secretion. GIR during 1mU insulin clamp was simulated by IRI-abs and ISI-delta. Calculation was made by EXCEL application.

Results: Total number of sampling of BG was 6405. BG before insulin infusion was 220 ± 187 mg/dl, and the average BG was 154 ± 57 mg/dl, achieving final BG of 130 ± 48 mg/dl. During 15115 hours, BGs less than 50mg/dl were occurred only 5 times; 3 incidental halts of glucose infusion, one incident of wrong insulin preparation, and one patient with a pancreatic tumor. ISI-delta and IRI-abs were calculated from data of 377 days. Average ISI-delta was 57 ± 10 mg/dl per U per hr. IRI-abs was shifted from -0.8 ± 2.6 to 4.2 ± 4.9 U/hr in one subject, and the average IRI-abs was 1.0 ± 2.9 U/hr. Significant correlation between ISI-delta and IRI-abs was not demonstrated. However, a simulated GIR during 1 mU insulin clamp was correlated with ISI-delta ($r=0.7$, $p<0.05$), and inverse of IRI-abs ($r=0.7$, $p<0.05$).

Conclusion: We have calculated two types of insulin sensitivity indices, IRI-abs and ISI-delta. Insulin clamp can detect the change of both IRI-delta and IRI-abs, while the ISI-delta cannot detect the change of IRI-abs. Since both IRI-abs and ISI-delta affect insulin requirement during real clinical settings, it is possible to conclude that insulin sensitivity is better approximated by insulin clamp technique, rather than the other methods which calculate indices like ISI-delta only.

Glycaemia variability in acute myocardial infarction goes undetected despite intensive capillary glucose monitoring

J. Baptista¹, D.R. Franco^{1,2}, C.R. Sampaio³, M.C. Alves⁴, D.J. Goldberg¹, F.G. Eliaschewitz^{1,5}

¹Clinical Research, CPCLIN, ²Endocrinology, Intermédica Saúde,

³Cardiology, H. SEPAO, ⁴Fac. Public Health, Un. São Paulo, ⁵Internal Medicine, H. Heliópolis, São Paulo, Brazil

Background and aims: Acute changes in glycemia can cause oxidative stress and lead to endothelial dysfunction. Therefore, reducing the variability of glucose levels is increasingly recognized as an additional target in diabetes control. Variability can be quantified by mean amplitude of excursions, MAGE, or quantified above certain thresholds as AUC or rate of excursions per time. Our aim was to compare control and variability parameters obtained by intensive capillary glycemia (CAPG) measurements with continuous glucose monitoring systems (CGMS), in hyperglycemic acute myocardial infarct (AMI) patients followed 3-4 days in Intensive Care Unit (ICU) that were included in a randomized study comparing glucose control between insulin Glargine (IG) and standard care (StC) therapy.

Materials and methods: Hyperglycemic patients (207 ± 73 mg/dl) admitted at the ICU within 24 h of AMI were randomized to receive basal-bolus regimen with IG and Regular Insulin (RI) (N=10), or StC (N=10), which comprises glycemia control by continuous insulin infusion (CII) for 24-48 h followed by control with NPH insulin and RI (Fig 1). After a period of stabilization with RI, CGMS was installed. Groups were comparable in onset of AMI, age, gender, weight, duration of diabetes, previous treatment, complications, and glycemia at the beginning of CGMS. CGMS data were analyzed in blind fashion and compared with CAPG parameters. Mann-Whitney and T tests were used.

Results: Mean glycemia by CGMS and CAPG was comparable. Mean exposure to hyperglycemia in the IG group was 4 times lower measured by CGMS and 60% less by CAPG, but without reaching significance. CGMS and CAPG data in the same treatment group show similar values for all parameters, with the exception of CGMS data on mean exposure and excursion rates < 70 mg/dl, higher for IG in the first 48 h compared to StC. The main difference was a consistently increased rate of excursions > 140 mg/dl/day measured by CGMS (Table 1).

Conclusion: CAPG during ICU allows us to obtain glycemic control data similar to those measured by CGMS, excepting the rate of excursions to hyperglycemia. Capillary monitoring detects only 25-50% of excursions. Thus, if variability in glycemia levels is an important component of diabetes control, it is being missed even if intensive capillary glycemia control is employed.

Do patients with diabetes and those without react differently to hyperglycaemia in the hospital?

R. Juneja¹, Q. Zhang², V. Abad³, A. Golas¹, J. Carroll¹, S. Flanders¹, C. Roudebush¹

¹Med, Indiana U, Indianapolis, ²sanofi-aventis, U.S., Bridgewater, ³Diabetes, Epsilon Grp Virginia, Charlottesville, United States.

Background: Inpatient hyperglycemia is a contributing factor to morbidity and mortality. Little is known about the levels of blood glucose (BG) at which mortality becomes most prevalent

Methods: We analyzed data from the SUGAR™ (Systematic Utilization of Glucose Assessment and Response) program implemented at two large academic medical centers. SUGAR is a process improvement program centered around Tight Glycemic Control (TGC) that includes the Clarian GlucoStabilizer (CGS™) computerized insulin administration systems, education on principles of TGC and its importance, and electronic data collection. This study focused on the relationship of mean BG for the entire hospital stay to in-hospital mortality for patients with and without diabetes. The primary outcome measure was a standardized mortality ratio (SMR) calculated as the actual mortality rate divided by an expected mortality rate provided by the University HealthSystem Consortium. We examined 36,404 patient encounters from June 2003 - Sept 2007 (10,988 for patients with diabetes and 25,416 without preexistent diabetes). All encounters included at least one day in the Intensive Care Unit (ICU). We generated locally smoothed curves of the SMR versus mean BG for patients with and without diabetes to portray in a continuous way the dependence of the SMR on mean BG. The value of SMR at a BG value is the SMR for all patients whose mean BG was within 0.3 mmol/L of that value.

Results: Table 1 presents actual mortality, expected mortality, and SMR for patients across discrete ranges of mean BG. Patients *without* diabetes appear to derive maximum benefit when their mean BG is in the neighborhood of 5.0-7.2 mmol/L with a pronounced trend of increased SMR either above or below this range. Patients *with* diabetes appear to derive maximum benefit when their mean BG is in the 5.0-10.0 mmol/L range with worsening outcomes as BG level moves away from this range in either lower or higher direction.

Conclusion: Current treatment guidelines recommend a blood glucose of <6.1 mmol/l for ICU patients and <10 mmol/l for non-ICU patients. Our findings suggest that patients with diabetes appear to be tolerating a wider range of blood glucose in the hospital. Further analysis is planned to examine relationships between BG variability and hospital outcomes by controlling for patient characteristics, antidiabetic medications prior to hospital admission and insulin therapy during hospital stay.

Table 1. Actual mortality, expected mortality, and standardized mortality ratio for patients with and without diabetes by blood glucose range.

Mean BG (mmol/L)	Patients with Diabetes				Patients without Diabetes			
	n	Actual Mortality Rate (%)	UHC Expected Mortality Rate (%)	SMR (%)	n	Actual Mortality Rate (%)	UHC Expected Mortality Rate (%)	SMR (%)

A prospective audit of glucocorticoid-induced hyperglycaemia in non-diabetic hospital in-patients

G. Daniels, J. Kaye

Endocrinology and Diabetes, Sir Charles Gairdner Hospital, Perth, Australia

Background and aims: Glucocorticoids are commonly prescribed in a wide variety of clinical situations and in people with established diabetes, worsening of glycaemic control is a well-recognised side effect. Glucocorticoids administered to non-diabetic patients may be associated with transient hyperglycaemia or new-onset diabetes, however, there have been very few studies that have accurately described the prevalence on glucocorticoid-induced hyperglycaemia, its predictors or its impact or consequences on hospitalised patients not otherwise known to have diabetes.

Materials and methods: This study, over a 3 month period, examined glucocorticoid-induced hyperglycaemia in patients receiving >25mg prednisolone; or >8mg dexamethasone; or equivalent, for any indication (apart from palliative care use or use as part of an organ transplantation or chemotherapy regime). Two definitions of hyperglycaemia were considered. The first required 2 or more glucose levels within the *diabetic range* (fasting ≥ 7.0 or random ≥ 11.1 mmol/L). The second required 2 or more glucose levels within the range considered appropriate for *therapeutic* intervention for hyperglycaemia in hospital in-patients (fasting ≥ 6.0 or random ≥ 10.0 mmol/L).

Results: 64 consecutive in-patients were studied. All had fasting and pre-prandial capillary glucose levels measured for 48 hours. Admission diagnoses were grouped as respiratory (53%), intra-cranial pathology (19%) or other (28%). 14 had a known diagnosis of diabetes. Of the remaining 50, based on a diabetic range definition, 15 (30%) were hyperglycaemic. These patients were older (68.3 ± 16.4 vs 55.2 ± 21.2 years; $p=0.04$), were more likely to have respiratory disease (80% vs 46%; $p=0.04$) and less likely to have received dexamethasone (0% vs 37%; $p=0.005$) therapy. There was a non-significant trend toward longer hospital length of stay however, only 2 (13%) received any form of hypoglycaemic therapy. Prior glucocorticoid use did not influence risk of hyperglycaemia. Glucose levels peaked prior to lunch (10.6 ± 5.0 vs 7.4 ± 2.7 ; $p<0.0001$), however, unexpectedly, fasting glucose levels were significantly elevated in the glucocorticoid treated group (7.7 ± 1.6 vs 6.0 ± 1.7 ; $p<0.001$) with 60% having both fasting levels greater than 7.0 mmol/L. Nearly half (47%) of patients admitted with a respiratory illness were hyperglycaemic. They had longer hospital stays (11.5 ± 9.2 vs 6.1 ± 5.1 days; $p=0.04$), however age; gender and prior glucocorticoid use did not differ significantly between those with or without hyperglycaemia. Considering a therapeutic range definition, prevalence increased to 50%.

Conclusion: In this prospective study, the prevalence of significant hyperglycaemia in glucocorticoid treated non-diabetic inpatients was 30% with up to 50% of patients having some degree of abnormal glucose regulation. Significant fasting hyperglycaemia was an unexpected feature. Glucocorticoid-induced hyperglycaemia was associated with an older age, prednisolone (as opposed to dexamethasone use), and admission with a respiratory illness but not with prior glucocorticoid use. It also predicted a longer length of hospital stay. Despite this, very few patients received any form of glucose lowering therapy.

1087

Should the diabetes team be involved in the first line for hyperglycaemic crises?

S.M. Nguyen¹, G. Waeber², M.-D. Schaller³, L. Trueb⁴, R.C. Gaillard¹, J. Ruiz¹

¹Endocrinology, Diabetology and Metabolism, CHUV, ²Internal Medicine, CHUV, ³Intensive Care, CHUB, ⁴Emergency Medicine, CHUV (Centre Hospitalier Universitaire Vaudois), Lausanne, Switzerland

Background and aims: Diabetes mellitus affects about 7.5% of the adult population. Diabetic keto-acidosis (DKA) and the hyperglycemic hyperosmolar state (HHS) are the most serious acute complications of diabetes. They are frequent within the diabetic population and tend to increase with the growing diabetes pandemic. These acute complications remain associated with a high mortality rate (<5% for DKA and 15% for HHS) despite an optimal care. The aim of the study was to analyze the precipitating factors, complications, treatment, length of stay (LOS) and mortality of these hyperglycemic crises in the university hospital of Lausanne.

Materials and methods: This study describes a retrospective analysis of 173 patients admitted for DKA, HHS or both in the department of Internal Medicine (Emergency Room, Intensive Care Unit, Ward) between 1995 and 2006. Demographic factors, admission diagnoses and laboratory data were examined. The acute hyperglycemic crises were defined according to the 2006 ADA criteria, i.e. DKA as a plasma glucose ≥ 13.9 mmol/L, an arterial pH ≤ 7.30 with the presence of either blood or urine ketones; HHS as a plasma glucose ≥ 33.3 mmol/L together with an effective serum osmolality ≥ 320 mOsm/kg. We defined mixed DKA-HHS crises as the combination of both.

Results: Median age of the study population was 50 (33.5–67.8) years, 61% were males. At the admission, 32% of cases presented ACD, 32% HHS and 35% mixed DKA-HHS. The main precipitating factors were non-adherence (49%), infections (26%), inaugural diabetes (24%), idiopathic (8%) and cardiovascular (4%). The median LOS was 9 (6–15) days, type 2 diabetic patients had a longer LOS (14 vs. 6 days, $p<0.0001$). DKA patients had a shorter median hospital LOS than other patients (7 vs. 10 days, $p=0.022$). In-hospital mortality was the highest in mixed DKA-HHS (8.2%), followed by DKA (5.4%) and HHS (3.6%). Older age was a predictive factor for mortality (77 vs. 53 years, $p=0.011$), as well as in multivariate analysis ($p<0.0001$). Consultation by a diabetes team was associated with much lower mortality rates (1.8% vs. 58.3%, OR=0.04, $p<0.0001$). A consultation by a specialized diabetes team during the first 3 hospitalization (early) days significantly reduced LOS in both univariate (7 vs. 15.5 days, OR=0.35, $p<0.0001$) and multivariate analyses ($R^2=0.46$, $p<0.0001$).

Conclusion: Patient's non adherence with their diabetes treatment and inaugural diabetes are the major precipitating factor for DKA, HHS and mixed DKA-HHS crises, which was never previously described in HHS or mixed DKA-HHS crises. We observe a shift in the distribution of the precipitating factors, which were previously outlasted by infections. Mortality was highest in the mixed DKA-HHS crises group, a situation that can be accounted for by the greater metabolic imbalance in this group. We highlight that an early consultation by a diabetes team highly decreases the LOS. Thus, we suggest that diabetic patients' education be reinforced, the diabetes team be involved as soon as the first hospitalization days and patient's education program for emergency team could be useful.

PS 102 Costs of diabetes

1088

Long-term consequences on annual earnings of the onset of type 1 diabetes in young adults. Longitudinal analysis of annual data 1990–2005 for persons born 1949–1970

K. Steen Carlsson¹, M. Landin-Olsson², L. Nyström³, S. Gudbjörnsdóttir⁴ for the DISS Group

¹LUCHE, Lund University, ²Dpt Clinical Sciences in Lund, Lund University, ³Dpt Public Health and Clinical Medicine, Umeå University, ⁴NHV, Nordic School of Public Health, Göteborg, Sweden

Background and aims: The tools to study long-run labour-market consequences caused by the onset of diabetes have not been available earlier. The availability of high-quality register data for research and a unique civic registration number for each individual used in all Swedish administrative population registers have changed this. Our aim was to quantify the long-term consequences on annual earnings of the onset of diabetes for persons aged 15–34 years old using data from the national longitudinal database LISA at Statistics Sweden.

Materials: Based on the Diabetes Incidence Study in Sweden DISS which since 1983 prospectively registers all incident cases of diabetes in young adults aged 15–34 years old (400/year; total 9,298 for 1983–2005), and control persons (N=37,192) from LISA matched for age, sex and municipality of residence at the time of diabetes onset, we constructed a longitudinal socio-economic database, Econ-DISS. It contains annual information on demographics, education, profession, income, work place, unemployment, sick-leave and early retirement for the period 1990–2005. For persons with diabetes onset after 1990, data include also the pre-diagnosis phase. There is also annual socio-economic information on parents through record linkage using the Multiple Generations Register at Statistics Sweden. From Econ-DISS, we selected all individuals diagnosed with type 1 diabetes (N=3,650) and their controls (N=14,629) born 1949–1970 as the youngest were potentially active in the labour market in 1990.

Methods: Non-parametric comparisons of cases and controls (Pearson's χ^2 and Kruskal-Wallis tests) before and after onset of diabetes; and longitudinal regression methods accounting for known correlates of earnings: own and parent's education, sex, business cycle, region of residence, the presence of young children in household, age at onset and duration of diabetes.

Results: We found no statistical differences in annual earnings *before* diabetes onset. *After* onset, persons with diabetes gradually lag behind (Fig 1). Equality of median earnings was rejected for each year 1995–2005 ($p<0.01$). Equality of populations was rejected for each year 1993–2005 ($p<0.01$). In 2005, the median annual earnings were EUR 1,390 (5%) lower for persons with diabetes. For the 1st quartile, the difference was even greater, EUR 2,760 (18%). The longitudinal regression analysis showed that differences were greatest for persons with compulsory level of education, all else equal. Each additional year of diabetes duration reduced earnings by 1% for women and by 0.4% for men, all else equal.

Conclusion: Persons with diabetes have significantly lower earnings, and these differences were most pronounced for persons with less education.

Annual earnings 1990–2005

Persons born 1949–1970. Sample after diabetes onset
Median, 1st and 3rd quartiles

Note: Annual average exchange rate 2005: SEK 1,000 = EUR 108

Risk of diabetes is spreading to all socio-economic groups: a prospective childhood study

L.D. Voss, J. Hosking, B.S. Metcalf, A.N. Jeffery, T.J. Wilkin
Endocrinology and Metabolism, Peninsula Medical School, Plymouth, United Kingdom

Background and aims: In today's rapidly changing society, the relationship between socio-economic status and diabetes merits re-examination. Lifestyle interventions to prevent type 2 diabetes continue to target areas of relative deprivation, based on the assumption that this is where the greatest prevalence of obesity and metabolic disturbance will be found. However, the evidence is largely historical. We have re-examined the question, cross-sectionally and longitudinally, in a contemporary cohort of healthy young children to establish whether adiposity and metabolic risk are still linked to deprivation, and whether deprivation is associated dynamically with change in adiposity or metabolic risk from 5 to 8 y.

Materials and methods: Subjects: Earlybird is a prospective, non-intervention cohort study of 300 healthy UK children, recruited from randomly selected city schools representing a wide socio-economic range. Deprivation: a postcode-based Index of Multiple Deprivation (IMD) was used to assess material living conditions. The higher the score, the higher the deprivation. Mean IMD score of the total cohort at baseline was 21.7, close to the UK mean of 26.3, but covered a substantial range (6.5–73.0). Measures of adiposity: body mass index (BMI) sds using 1990 UK norms, waist circumference, and sum of 5 skinfolds (biceps, triceps, subscapular, supra-iliac and umbilical) at 5y and 8y. Metabolic Risk: a composite metabolic risk z-score (MetRisk) was derived from mean arterial blood pressure, and HOMA-IR, triglycerides, cholesterol/HDL ratio from fasting venous blood. We report on 266 subjects (146 boys, 120 girls) with complete data sets.

Results: In boys, mean BMI sds was 0.21 ± 1.08 at 5y, increasing to 0.30 ± 1.10 at 8y. Unexpectedly, BMI was inversely related to IMD score at 5y ($r = -0.18$, $p = 0.04$) and again at 8y ($r = -0.17$, $p = 0.05$). Waist circumference was also inversely related to IMD score at 5y ($r = -0.21$, $p = 0.01$) and at 8y ($r = -0.20$, $p = 0.02$). Sum of skinfolds was not significantly related to IMD score at either age (both $p > 0.12$). Importantly, changes in all measures of adiposity from 5–8y were unrelated to IMD score (all $r < 0.14$, $p > 0.10$). There were no significant associations between MetRisk and IMD score at 5y ($r = -0.05$, $p = 0.59$) nor at 8y ($r = -0.15$, $p = 0.08$). Change in MetRisk from 5–8y was not significantly related to IMD score ($r = -0.14$, $p = 0.10$). In girls, mean BMI sds was 0.51 ± 0.98 at 5y, increasing to 0.55 ± 1.10 at 8y. No measure of adiposity was related to IMD score at any age (all $r < 0.10$, all $p > 0.31$). Again, changes in all measures of adiposity from 5–8y were unrelated to IMD score (all $r < 0.15$, $p > 0.11$), and there were no significant associations between MetRisk and IMD score at any age ($r < 0.1$, $p > 0.27$). Change in MetRisk from 5–8y was unrelated to IMD score ($r < 0.1$, $p > 0.27$).

Conclusion: Our data do not support the popular assumption that obesity and metabolic disturbance remain more prevalent among poorer children in an urbanised population. Indeed, we found evidence to the contrary in boys, making lack of power an unlikely cause. Findings were consistent when using three alternative measures of socio-economic status: entitlement to free school meals, parental income and occupation, suggesting robust data. Any relationship between deprivation, obesity and metabolic risk appears to have been lost. With all neighbourhoods affected by an increasingly obesogenic environment, all children may now be vulnerable, with population-wide implications for public health policy.

1090

Cost and resource use associated with different insulin regimens initiated in 5 European countries in the 6 months following initiation of insulin

H. Smith¹, A. Simpson¹, A. Tynan¹, C. Nicolay², A. Goday³, A. Liebl⁴, M. Benroubi⁵, S. Jones⁶

¹Eli Lilly, Surrey, United Kingdom, ²Eli Lilly, Bad Homburg, Germany, ³Endocrinology, Hospital Del Mar, Barcelona, Spain, ⁴Centre for Diabetes and Metabolism, Fachklinik Bad Heilbrunn, Germany, ⁵Diabetes Centre, General Hospital, Athens, Greece, ⁶The Academic Centre, James Cook University Hospital, Middlesbrough, United Kingdom

Background and aims: INSTIGATE is a prospective observational study in 5 European countries (France, Germany, Greece, Spain, UK) investigating patients with type 2 diabetes initiating insulin during usual care. Data are collected over 24 months following insulin initiation. The primary objective

of the study is to assess the direct costs of care for type 2 diabetes before and after insulin initiation.

Materials and methods: Direct costs of diabetes care were calculated by collecting data on individual resource use and assigning local unit costs (from 2006). Reported costs and resource use are for the 6 months prior to insulin initiation at baseline (BL) and the 6 months after insulin initiation (6m).

Results: Data were collected from 1153 patients at BL and 1051 patients at 6m. With the exception of France, patients had more frequent contact with health care professionals (HCP) at 6m than BL (Figure 1), although the types of HCP and type of contact (visit or phonecall) varied between countries.

Figure 1. Total number of contact with HCPs per patient, by country

Median total costs of diabetes care were €512 BL and €725 6m. The total costs in the 5 countries are reported in table 1.

Within regimens the largest differences in median costs were seen in basal bolus (€481 BL and €888 6m) and short acting insulin regimens (€453 BL and €771 6m). Further analysis is needed to assess the impact of insulin regimen changes on the cost of diabetes care.

There were some changes in type of resource use and associated costs from BL to 6m. Median cost of general practice care fell (€54 BL, €38 6m), while median cost of specialist care for glycaemic control increased (€53 BL, €105 6m). As expected the median cost of oral antidiabetic medications fell (€138 BL, €37 6m), and median cost of insulin medication increased (€1 BL, €189 6m). Median costs of blood glucose monitoring also increased (€60 BL, €184 6m).

Table 1: Total cost (euros) of diabetes care by country

Country	Visit	N	Min.	Q1	Median	Q3	Max.	Mean
Germany	Baseline	256	0	237.2	407.8	676.6	11532	605.0
	6 month	233	257	741.7	895.6	1114.7	3270	961.3
France	Baseline	177	23	421.0	647.3	1372.5	6570	1317.5
	6 month	152	207	579.0	805.2	1213.3	22660	1449.0
United Kingdom	Baseline	251	101	431.7	593.6	812.0	5495	697.9
	6 month	222	156	528.3	712.0	893.3	6963	772.5
Greece	Baseline	262	1	224.0	436.1	659.8	2549	497.2
	6 month	256	101	369.9	537.9	717.6	2124	577.2
Spain	Baseline	207	1	323.9	514.7	730.2	8041	630.9
	6 month	188	84	518.0	698.9	1042.7	19341	1109.7

Conclusion: After insulin initiation the costs of diabetes care increased. Except in France, contact with HCPs also increased. Costs associated with care from HCPs for diabetes shifted from primary care to specialist care after insulin initiation and the cost associated with blood glucose monitoring increased.

The relationship between socioeconomic deprivation, educational attainment and clinical outcomes in type 2 diabetes: a cohort study

M.J. O'Kane¹, M. McMenamin², J. Innes³, A. Moore⁴, B. Bunting³, V. Coates⁵

¹Clinical Chemistry Laboratory, Altnagelvin Hospital, Londonderry,

²Institute of Nursing Research, University of Ulster, Coleraine,

³School of Psychology, University of Ulster, Londonderry,

⁴Causeway Data Communications Ltd, Innovation Centre, Coleraine,

⁵Institute of Nursing Research, University of Ulster, Londonderry, United Kingdom

Background: Socioeconomic deprivation may be associated with worse outcomes in type 2 diabetes. An understanding of this relationship would allow more appropriate and targeted intervention to improve care.

Aim: To study the relationship between socioeconomic deprivation, educational attainment and clinical outcomes in type 2 diabetes.

Methods: A random sample of 457 patients with type 2 diabetes [57% male, age 64.7 (11.5), mean (SD) years, duration of diabetes 11.2(6.2) years] stratified by Noble Index of Deprivation measure was selected from a hospital diabetes service database. Information on patient specific socioeconomic status, educational attainment, behaviour and attitudes was gathered by patient interview. Clinical outcome data were extracted from the hospital diabetes database. Data analysis was by multivariate logistic and linear regression with correction for age, gender and duration of diabetes.

Results: Cohort Descriptive data Antidiabetic treatment: diet alone 7.4%, oral agents alone 54.3% and insulin 38.3%. Other treatments: antiplatelet agents 78%, lipid lowering agents 90.1%, antihypertensive agents 86%. Metabolic indices: BMI 32.3 (6.0) kg/m², HbA1c 7.6 (1.4) %, total cholesterol 4.0 (0.9) mmol/L, systolic BP 134.2 (20.6) and diastolic BP 72.7 (11.2) mmHg. The breakdown by deprivation [in quintiles of the N Ireland population as a whole] was: Group 1 [least deprived] 8.7%, group 2 18.6%, group 3 20.9%, group 4 22.4% and group 5 [most deprived] 29.6%. Complication prevalence: hypertension 82%, myocardial infarction 11%, angina 18.2%, claudication 7.2%, stroke 2.3%, any retinopathy 22%, proteinuria 25.6%, renal impairment 14.3%.

Data analysis Hypertension [adjusted OR 1.2] and coronary angioplasty [adjusted OR 3.3] were more prevalent in the most deprived v. least deprived groups [p<0.05]. Higher educational attainment [A level equivalent or above] v. lower educational attainment [no qualification and GCSE / trade] was associated with reduced BMI [adjusted slope -0.13, p = 0.01].

Conclusion: Although deprivation and low educational attainment were associated with adverse outcome indicators the effects were small. It is possible that any detriment associated with deprivation is minimised by aggressive management of modifiable risk factors.

Economic cost associated with type 1 and type 2 diabetes in the United States

T. Dall¹, S. Mann¹, Y. Zhang¹, W. Quick²

¹The Lewin Group, The United HealthCare Service, Inc., Falls Church, ²Research, The United HealthCare Service, Inc., Morristown, United States.

Background and aims: Estimate the economic cost associated with diagnosed type 1 diabetes (T1DM) and type 2 diabetes (T2DM) in the United States in 2007

Materials and methods: Medical claims and national surveys were analyzed to estimate the proportion of diagnosed diabetes cases and excess medical costs associated with T1DM and T2DM. The economic value of lost productivity associated with T1DM and T2DM were estimated using findings from the literature and presented as ranges based on alternate assumptions of productivity loss per case of T1DM and T2DM. The primary sources used to develop the model are the Census Bureau's population estimates for 2007; the 2004-2006 National Health Interview Survey (NHIS) to estimate diagnosed diabetes prevalence, work days absent, inability to work because of permanent disability, and rates of insulin and oral agent use; the 2003-2005 Medical Expenditure Panel Survey (MEPS) to estimate average medical cost per health care event (e.g., per visit) or per annum usage per person (e.g., annual cost for insulin, home health services, podiatry, ambulances, and other medical supplies); the 2004-2005 Nationwide Inpatient Sample (NIS) to estimate total inpatient days and hospital costs by chronic condition category; the 2003-2005 National Ambulatory Medical Care Survey (NAMCS) and

National Hospital Ambulatory Medical Care Survey (NHAMCS) to estimate total emergency and ambulatory visits; the 2000 National Home and Hospice Care Survey (NHHCS) to estimate hospice visits; and the 2004 National Nursing Home Survey (NNHS) to estimate total resident days in nursing facilities and the prevalence of diagnosed diabetes among the population in long-term care. The Ingenix MCURE database, containing medical claims for 16.2 million insured people under age 65 in 2006 (683,000 with a diagnosis of diabetes), was used to determine the proportion of diagnosed diabetes cases that are T1DM and how patterns of health care use for the population under age 65 differ by diabetes status (no diabetes diagnosis, diagnosed T1DM, or diagnosed T2DM or type unknown). A similar analysis for the 65 and older population was conducted with the 2006 Medicare 5% Sample File (which contains claims records for approximately 17.95 million people age 65 and older, of which 1.03 million have a diagnosis of diabetes). Analysis of the NHIS shows that approximately 40% of diagnosed diabetes cases are under age 65 and commercially insured, and approximately 37% of cases are age 65 and older and insured by the government. Medical costs are estimated by demographic (age and sex), health care delivery setting, and complication/comorbidity group. Non-medical costs are estimated by demographic, and include absenteeism, presenteeism, inability to work because of long term disability, and mortality.

Results: Previous research estimates that the economic burden of diagnosed diabetes in 2007 is US\$174 billion. The preliminary estimates from this study suggest that approximately \$16.2 billion (9%) of this economic burden is associated with the T1DM. This estimate includes medical costs of \$11.2 billion for T1DM and \$105.0 billion for T2DM. Lost productivity is estimated at \$5.0 billion for T1DM and \$53.1 billion for T2DM.

Conclusion: The economic burden per case of diabetes is larger for T1DM, but the majority of cases and economic costs are associated with T2DM and therefore might be largely preventable.

1093

Economic cost associated with pre-diabetes and undiagnosed diabetes in the United States

Y. Zhang¹, A. Baldwin², Y. Chen¹, W. Yang¹, W. Quick³, T. Dall¹

¹The Lewin Group, The United HealthCare Service, Inc., Falls Church,

²i3 Pharma Informatics, The United HealthCare Service, Inc., Cary, ³i3 Research, The United HealthCare Service, Inc., Morristown, United States.

Background and aims: Build on recent cost of diabetes study, this study estimates health care use and costs associated with undiagnosed diabetes mellitus and pre-diabetes mellitus

Materials and methods: We analyzed medical claims data for a commercially insured population (continuously insured during 2004, 2005 and 2006, N=3,232,134).

A population with pre-diabetes in 2004 was identified using existing test results from Fasting Plasma Glucose (FPG) and Oral Glucose Tolerance Test (OGTT). We used multivariate regression analyses to compare health care use patterns for this population during 2005 and 2006 with those of (1) people with a FPG or OGTT result of no pre-diabetes in 2004, and (2) all people for whom there is no evidence of diabetes or pre-diabetes (including people who did not receive a FPG or OGTT in 2004). A proxy for the population with undiagnosed diabetes was constructed by identifying people who are on the verge of first diagnosis for diabetes: those who had diagnoses for diabetes in 2006 medical claim records but none in 2004 and 2005. We use multivariate regression analyses to compare health care use patterns during the 2004 to 2005 period for this “undiagnosed” diabetes population to patterns for a population with no indication of diabetes between 2004 and 2006. Using nationally representative data sources, we estimate the prevalence of pre-diabetes and undiagnosed diabetes, and total physician office visits, outpatient visits, emergency visits, and hospital inpatient days for seven categories of complications typically associated with diabetes: neurological, peripheral vascular, cardiovascular, renal, endocrine, ophthalmic, and other complications. We combine pre-diabetes and undiagnosed diabetes prevalence rates with health care use patterns to calculate etiological fractions. Multiplying these fractions by total national healthcare use by complication group provides estimates of health care use associated with pre-diabetes and undiagnosed diabetes.

Results: Preliminary estimates suggest that approximately 36.8 million (12%) Americans have pre-diabetes and 5.1 million (1.7%) have undiagnosed diabetes. Compared to their counterparts with no diabetes diagnoses, those who had undiagnosed diabetes had increased use of health care services for hospital inpatient days (adjusted rate ratio, aka. RR=1.50), emergency

room visits (RR=1.30), outpatient visits (RR=1.25) and physician office visits (RR=1.11); the increase in risk varies by complication categories. Compared to their counterparts with no indication of diabetes, undiagnosed or pre-diabetes, those who had pre-diabetes had increased outpatient visits (RR=1.30) and physician office visits (RR=1.12) but no increase risk of emergency visits and hospital inpatient days. Sensitivity analyses suggest a consistent dose response in increased risk over the spectrum of diabetes prognosis. Full results will be available by May, 2008.

Conclusion: Both pre-diabetes and undiagnosed diabetes are associated with increased use of health care services (and costs), and there is a consistent dose-response relationship between use of health care services and the presence of normal glucose levels, pre-diabetes, undiagnosed diabetes, and diagnosed diabetes.

1094

Bedside monitoring of blood β -hydroxybutyrate shortens hospitalisation for diabetic ketoacidosis in children and lowers the cost

A. Rewers¹, K. McFann², M. Rewers³

¹Department of Pediatrics, ²Department of Preventive Medicine, ³Barbara Davis Center for Childhood Diabetes, University of Colorado, Aurora, CO, United States

Background and aims: Bedside monitoring of blood β -hydroxybutyrate (B-OHB) has been used in treatment of diabetic ketoacidosis (DKA). Previously, we demonstrated that the levels of B-OHB correlate closely with time-dependent levels of venous pH, bicarbonate, and pCO_2 . The purpose of this study was to evaluate the effect of bedside monitoring of blood B-OHB levels on duration of hospital stay and the cost of admission for DKA.

Materials and methods: All children admitted to our hospital for DKA during a period of 20 months were treated using a standard treatment protocol. DKA and its severity were defined using the 2007 ISPAD criteria. Bedside monitoring of blood B-OHB, on average every 2 hours, using the Precision Xtra™ (Abbott Diabetes Care, Abbott Park, IL) was added to the protocol in 53 randomly selected patients with type 1 diabetes admitted for DKA. Patients who received IV fluids or insulin prior to admission to our hospital were not included. The direct hospital cost and the length of admission in the B-OHB group were compared to those of 53 DKA control patients treated concurrently but without B-OHB monitoring (no B-OHB). Controls were frequency matched on age (median 12 y vs. 12 y in the B-OHB group), severity of DKA (pH 7.17 vs. 7.16) gender (female 60% vs. 57%) and duration of diabetes (newly diagnosed 57% vs. 51%).

Results: The cost of hospitalization was borderline lower in patients whose B-OHB levels were monitored at the bedside. The median cost of hospitalization was 10,657 US\$ (range 1,581–31,983) in the B-OHB group vs 14,358 US\$ (range 2,154–40,657) in the control group ($p=0.11$) and the mean cost of hospitalization in the B-OHB group was 11,526 US\$(SD 6,301) vs 14,441 US\$(SD 8,738) ($p=0.05$) in the control group. The length of hospital stay was slightly shorter in the B-OHB group, compared to the No B-OHB group, but the difference did not reach the level of statistical significance with the median hospital stay of 24h (range 4–106) in the B-OHB group vs 26h (range 4–145) in the control group ($p=0.21$) and the mean hospital stay of 29h (SD 21) vs 36h (SD 31) ($p=0.17$), respectively. While this preliminary evidence suggests benefit, the exact mechanisms of lower cost are unclear. The B-OHB results were not part of routine hospital documentation and sometimes unknown to the provider who ordered laboratory tests, treatment and the timing of discharge.

Conclusion: The results of this unmasked intervention suggest that addition of blood B-OHB monitoring to standard DKA treatment protocol may reduce the length and the cost of hospitalization. Future randomized trials should evaluate overall cost-effectiveness and outcomes of such a modification.

Cost-effectiveness of adding sitagliptin vs. an sulfonylurea in Swiss patients with type 2 diabetes inadequately controlled on metformin monotherapyM. Brandle¹, J. Chen², E. Alemas³, D. Yin³, J. Cook², T. Szucs⁴¹Head of Endocrinology and Diabetology, Cantonal Hospital of St. Gallen, Switzerland, ²Health Statistics and Economics, Merck & Co., Upper Gwynedd, United States, ³Global Outcomes Research, Merck & Co., Whitehouse Station, United States, ⁴Head of Medical Economics, Institute of Social- and Preventive Medicine, University of Basel, Switzerland

Background and aims: Sitagliptin (Sita) is an oral antihyperglycemic agent that inhibits the dipeptidyl peptidase (DPP-4) enzyme. It is licensed in Europe as a treatment adjunct to metformin (Met), diet and exercise in the management of type 2 diabetes mellitus. The objective of the study was to determine the cost effectiveness of adding Sita vs adding sulfonylurea (SU) to drug regimens of patients inadequately controlled on Met monotherapy.

Materials and methods: A discrete event simulation model (JADE), which employed the United Kingdom Prospective Diabetes Study (UKPDS) Outcomes Model risk equations for predicting risks of diabetes related complication, was used. Lifetime costs and outcomes were projected for alternative treatment strategies of adding Sita, compared with adding SU to Met in patients not at hemoglobin A1C (HbA1c) goal on Met monotherapy. Changes in HbA1c as well as side effects associated with these different treatment strategies were based on clinical trial data. Mean baseline values for age, duration of diabetes, % HbA1c, systolic blood pressure and other risk factors of diabetes complications were obtained from a local epidemiologic study involving patients with type 2 diabetes not at HbA1c goal on Met monotherapy. Direct medical costs associated with treatment regimens (based 2008 values), diabetes complications and adverse events were accounted in 2007 values based on Swiss-specific unit costs. UKPDS based utility weights associated with diabetes complications were incorporated. Utility decrements associated with medication side effects were based on published data. All future costs and outcomes were discounted at 3% according to local guidelines on cost-effectiveness analysis. One-way sensitivity analyses were conducted by varying key input parameters.

Results: Drug costs of adding Sita vs. adding SU to Met was CHF 15,325 and CHF 14,411 respectively over a lifetime horizon. However, diabetes complication costs and adverse event costs were lower with Sita compared to SU, resulting in a total incremental cost of CHF 204 per patient with Sita compared to SU over life time. The quality adjusted life years (QALYs) gained due to adding Sita vs. adding SU was 0.066 thus providing an incremental cost per QALY of CHF 3,091 (Table). In the one way sensitivity analysis, the results were robust to changes in the model input parameters.

Conclusion: This cost-effectiveness analysis demonstrates that adding Sita to Met compared to adding SU to Met is a cost-effective treatment option in patients failing Met therapy in the Swiss setting.

Table: Direct medical Costs, QALYs, and ICERs for Sita vs. SU in Patients Failing Met

	Sita	SU	Sita - SU
Medication Costs (CHF)	15,325	14,411	+ 914
Diabetes Complication Costs (CHF)	52,696	53,090	-394
Adverse Event Costs (CHF)	1,129	1,447	-318
Total Costs (CHF)	69,152	68,948	204
QALY (years)	6.323	6.257	+ 0.066
Cost per QALY (CHF) -			3,091

1 CHF = 0.643 Euro

1096

Short-term economic benefits of self monitoring blood glucose (SMBG) in type 2 diabetes for health maintenance organisations (HMOs)F.D. Mataveli^{1,2}, L. Turatti³, A. Pimazoni Netto⁴¹Internal Medicine, Federal University of São Paulo, ²Lifescan, Johnson & Johnson, ³Endocrinology, State University of São Paulo, ⁴Hospital do Rim, Federal University of São Paulo, São Paulo, Brazil

Background and aims: Acceptable HbA1c levels may be associated with lower costs in the management of type 2 diabetes. This study was aimed to evaluate the association between SMBG and healthcare costs, according to HbA1c value, under the Brazilian Managed Care perspective.

Materials and methods: An economic model based on data published in 2006 by the Brazilian Regulatory Agency for Managed Care (ANS) was developed to evaluate the 3 years impact of SMBG in a hypothetical HMO cohort of 1,000 pharmacologically treated patients with diabetes type 2. HbA1c changes due to SMBG were based on the results of a large cohort study of patients with type I and type II diabetes, designed to assess the correlation between SMBG frequency and HbA1c changes over a 1-year period. Daily SMBG frequency was associated with a 0.6 % HbA1c reduction in the pharmacologically treated type 2 diabetes patients group. Estimates for medical care charges were based on a study standardized 3-year estimate, in which successive 1% increases in HbA1c resulted in cumulative increases, starting from HbA1c value of 6%, of 4, 10, 20 and 30% in medical care charges. The average cost of an individual enrolled in a HMO was set as the value for a 6% HbA1c individual. Increases of 1% in HbA1c followed the criteria for cumulative costs, being the average cost multiplied by 1.04, 1.1, 1.2 and 1.3. Average annual costs per patient were calculated based on total medical charges and enrolled population for 3 different Brazilian HMOs: an Insurance Company (IC) - R\$ 2,858; a Medical Cooperative (MC) - R\$ 1,365 and a Medicine Group (MG) - R\$ 1,134 (R\$ 1 = 0.37 €). HbA1c distribution in a HMO population in Brazil was based on literature and adapted locally by a board of specialists. Distribution of HbA1c range values was presented as follows: 30% HbA1c 7-8; 30% HbA1c 8-9; 30% 9-10; 10% HbA1c >10. Total costs in diabetes management were observed to increase up to 400% due to coexisting clinical complications and comorbidities in comparison to patients with diabetes only. A cost complication factor varying from 1.2 to 1.8 was then assigned to different levels of HbA1c (< 7 to >10 HbA1c) and average costs to reflect this variation in costs. Individual changes of 0.6 % in HbA1c obtained with 1-year SMBG resulted in change for the next lower HbA1c level at the end of the 3-year period. Patients not under SMBG change for the next higher level of HbA1c during the 3-year period. Costs were considered and calculated according to the individual HbA1c level at the end of the third year of the analysis. SMBG costs were based on 1 strip daily dispensation for 3 years. Strip average unit cost is R\$ 1.10. Costs were discounted at 5% annual rate.

Results: Over a 3-year period, daily SMBG frequency (1strip/day) was associated with significant savings compared to no SMBG at all in all three Brazilian HMOs: IC (R\$ 3,265,561), MC (R\$ 884,077) and MG (R\$ 649,767). Sensitivity analyses on complication cost factor varying from 1.4 to 2.0 and from 1.0 to 1.6 resulted in savings of: R\$ 3,499,280 and R\$ 3,031,842 (IC); R\$ 1,100,102 and R\$ 772,451 (MC); R\$ 743,232 and R\$ 556,302 (MG), respectively.

Conclusion: SMBG may have a positive economic impact in the management of patients with diabetes type 2 under the perspective of the Brazilian Managed Care System.

1097

Cost-effectiveness of a computerised decision support diabetes management program that improves diabetes controlF.G.W. Cleveringa¹, P.M.J. Welsing², M. van den Donk¹, K.J. Gorter¹, L.W. Niessen³, G.E.H. Rutten¹, K. Redekop³¹General Practice, Julius Center for Health Sciences and Primary Care, Utrecht, ²Public Affairs, Pfizer B.V., Capelle a/d IJssel, ³Institute for Medical Technology Assessment, Erasmus Medical Center, Rotterdam, Netherlands

Background and aims: Costs related to diabetes are high; countries in Europe spent 2.5 - 6.5% of their total health care budget on type 2 diabetes (DM2) and the United States 10%. Improvements in diabetes health outcomes are possible by strict control of glucose, lipids and blood pressure, as recommended in the guidelines. Guidelines-based care can also reduce the costs of DM2 related complications. However it is difficult to implement and adhere to guidelines; at least 30% of DM2 patients do not achieve the strict targets for glycaemic and cardiovascular control. Information technology enabled

diabetes management has the potential to improve care, delay diabetes complications and lower health care costs, but most evaluations of these programs have not included a proper cost effectiveness analysis.

The Diabetes Care Protocol (DCP), which consists of task delegation, decision support and benchmark information, has been shown to improve patient outcomes, but the cost-effectiveness of DCP is unknown. We therefore aim to study the cost effectiveness of DCP from a Dutch health care perspective.

Materials and methods: In a cluster randomised trial, 55 primary care practices were assigned to usual diabetes care (control group), or the DCP (intervention group). Baseline and one year follow-up measurements (i.e. HbA1c, blood pressure, total cholesterol, HDL cholesterol, medication etc) were performed by practice nurses (intervention) and research assistants (control). The one year follow-up data of individual patients in both groups are used to compute lifetime disease outcomes (cardiovascular disease and other DM2 related complications) and direct medical costs using a validated probabilistic Dutch diabetes model and the UKPDS risk engine. The costs of implementing and maintaining DCP and medication use are also included. Incremental costs per quality-adjusted life year will be calculated and probabilistic sensitivity analyses performed. Correction for clustering (usually neglected in cost-effectiveness analyses) is performed using generalized linear models.

Results: 3391 patients participated in the trial (intervention group, 1699; control group, 1692). Baseline characteristics of both groups were comparable. No statistically significant difference was seen in HbA1c reduction at 1-year (intervention group vs. control group; 0.2% vs. 0.1%). However, statistically significant between-group differences were seen for reduction in systolic blood pressure (2.6 mmHg vs. 0.5 mmHg), total cholesterol (0.3 mmol/L vs. 0.1 mmol/L), and 10 year UKPDS coronary heart disease risk (1.9% vs. 0.3%). Overall costs and health outcomes and the incremental cost-effectiveness ratio of the DCP versus usual care will be presented, including the relative contribution of diabetes control and reduction in cardiovascular disease risk. Results of sensitivity analyses are expressed using a cost-effectiveness plane and acceptability curve.

Conclusion: Delegation of routine diabetes care to a practice nurse combined with computerised decision support and benchmark information improved patient outcome and reduced cardiovascular risk for DM2 patients. The long-term cost-effectiveness of DCP will be presented at the EASD.

The equivalency of diabetes distress

K. Glaister

Faculty of Health, Curtin University, Perth, Australia

Background and aims: The nature of diabetes is generally considered pervasive, such that many feel its impact on their quality of life. The emotional distress generated may be considered minor, presenting transient hassles, or significant, presenting major obstacles in life pursuits. The aim of the study was to determine the level of distress experienced by people with diabetes and to explore if gender differences of reported measures of distress existed.

Materials and methods: A cross-sectional survey involving a representative sample of people (N = 940) with diabetes in Western Australia, was conducted in 2007. The inclusion criteria were: adults, over 18 years of age; diagnosis of diabetes and English literacy. To measure distress the relatively new Diabetes Distress Scale, developed by Polonsky and colleagues was used. This scale is a 17-item scale, with four subscales representing *emotional burden*, *physician related distress*, *regimen-related distress* and *interpersonal distress*. Distress was measured using Likert ratings from 1 'serious problem' through to 4 'not a problem'.

Results: Findings suggest that the cohort did not perceived their condition to be causing significant levels of distress in their life (M = 3.4, SD \pm 0.21, range = 0.63). Least problematic were *physician related distress* (M = 3.6, SD \pm 0.01), followed by *interpersonal distress* (M = 3.4, SD \pm 0.15), *regimen-related distress* (M = 3.3, SD \pm 0.17) and *emotional burden* (M = 3.2, SD \pm 0.12); a pattern consistent with that found by the instrument developers. Three of the four sub-scales confirmed a gender difference in responses. Females (M = 3.13, SD \pm 0.77) reported more difficulties with dealing with the *emotional burden* of having diabetes than males (M = 3.27, SD \pm 0.73), $t(972) = 2.82$, $p = 0.005$. Furthermore, females (M = 3.22, SD \pm 0.74) reported more *regimen related distress* than males (M = 3.35, SD \pm 0.65), $t(942.93) = 2.84$, $p = 0.005$. Given the data for the *interpersonal distress* data violated the homogeneity assumption a Mann-Whitney U test was used, which indicated that females (Mean Rank = 436.12, n = 482) reported significantly more difficulties with interpersonal relationships as a result of having diabetes than that reported by male participants (Mean Rank = 507.63, n = 458), (U = 93806.50, $z = -4.22$, $p < 0.001$). Over half of the items in the DDS displayed a similar relationship with gender, the notable exceptions being the 4 *Physician related distress* items.

Conclusion: Distress associated with diabetes is undoubtedly present, but where support from a modern health care system exists it may be less pervasive. Distress eventuates more from the emotional stressors resulting from having the condition and the associated management regimen. However, this cannot be assumed to be a consistent reaction for all, clearly gender differences exist. The instrument used in this study is a comprehensive and relatively quick tool that could be used as a clinical assessment tool, however, it would be worth validating its construct further with other know groups.

The influence of family cohesion and adaptability on type 1 diabetes mellitus patients

E. Liouri¹, A. Koutsovasilis¹, K. Kounenou¹, N. Giannakopoulos¹, E. Fofopoulou¹, E. Karagiaouri¹, M.-P. Koukouli¹, S. Iraklianou¹, C. Karagianni², A. Melidonis¹

¹Diabetes Center, Tzanio General Hospital, Piraeus, ²Second Department of Pediatrics, Medical School, University of Athens, Greece

Background and aims: Type 1 diabetes mellitus appears in a young age and follows the patient changing not only his/her life, but also that of the family. With this study, we attempt to establish possible differences between families of children and adolescents with type 1 diabetes and those without it as to the adaptability, the cohesion and the type of family as defined by Olson.

Materials and methods: 66 patients with type 1 diabetes (Group A), and 44 without diabetes (Group B) of comparable age and gender filled out an approved questionnaire (FACES-III) of 40 questions determining the level of adaptability (rigid, structured, flexible, very flexible) and cohesion (disengaged, separated, connected, very connected) in a family, as well as its type

according to international literature where 4 types of family are specified (extremely imbalanced, moderately imbalanced, moderately balanced, balanced). HbA1c was recorded in type 1 diabetics while somatometric characteristics were recorded in both groups. Statistical analysis was carried out using SPSS 15.0. A p -value < 0.05 was considered significant.

Results: Concerning adaptability, a statistically significant difference was found between the two groups ($p=0.044$), with non-diabetics scoring better on the fourth level of adaptability (59.3% vs 32.5%). There is also a difference in cohesion, with diabetics showing the highest rates (38.5% vs 11.1% of non-diabetics) on the level of connected families ($p=0.016$), while non-diabetics show a higher level of cohesion (37% vs 23.1% $p=0.041$). Non-diabetics outnumber diabetics in the fourth type of family (81.5% vs 61.5%, $p=0.034$), without a statistically significant difference in other types of family. The level of adaptability, as well as the level of cohesion and the type of family, affect the regulation of diabetes mellitus. Children in families with the highest adaptability had $HbA1c=7.17 \pm 0.88$ (statistically significant difference vs rigid adaptability (8.2 ± 0.91), $p=0.010$); children in families with the highest cohesion had $HbA1c=6.67 \pm 0.59$ (statistically significant difference vs disengaged families ($HbA1c=7.68 \pm 1.07$), $p=0.014$) and children in balanced families had $HbA1c=7.16 \pm 1.08$ (statistically significant difference vs extremely imbalanced families (7.7 ± 1.04), $p=0.026$).

Conclusion: Families of children and adolescents with type 1 diabetes mellitus show a lower adaptability and cohesion compared to families of healthy controls of the same age. The findings are similar concerning the type of family. Family type, adaptability and cohesion play a crucial role in the regulation of diabetes mellitus during the first years of its emergence.

Depression, sense of coherence, and health related quality of life in patients with type 1 diabetes - association with diabetic nephropathy (The FinnDiane study)

A.J. Ahola¹, M. Saraheimo^{1,2}, C. Forsblom^{1,2}, H. Sintonen³, P.-H. Groop^{1,2}

¹Department of Diabetes Genetics, Folkhälsan Research Center, ²Division of Nephrology, Department of Medicine, Helsinki University Central Hospital,

³Department of Public Health, University of Helsinki, Finland

Background and aims: Patients with diabetes have an increased risk of psychological disturbances. Our aim was to evaluate depression, sense of coherence, and health related quality of life in a large sample of Finnish patients with type 1 diabetes and to assess whether these outcome measures were associated with the presence of diabetic nephropathy.

Materials and methods: Patients ($N = 956$, 45.6% men) were recruited from the Finnish Diabetic Nephropathy (FinnDiane) study. Beck Depression Inventory (BDI), Antonovsky's coherence test (SOC), and the 15D health-related quality of life (HRQoL) instrument were used as outcome measures. The χ^2 -test and the Kruskal-Wallis test were used in statistical analyses when appropriate. Logistic regression analysis was used to study independent variables associated with diabetic nephropathy. Cross-sectional data are presented.

Results: The overall prevalence of depression ($BDI \geq 16$) was 12.4%. Depression was found in 9.5%, 9.8%, 18.4% and 26.1% of patients with normo-, micro-, macroalbuminuria and ESRD, respectively ($p < 0.0001$). The median depression score increased from 4 to 8 with deteriorating renal status ($p < 0.0001$). Altogether, 21.3% of the patients had poor sense of coherence ($SOC < 60$). The prevalence of poor sense of coherence was 19.1%, 19.7%, 30.8% and 23.9% in patients with normo-, micro-, macroalbuminuria and ESRD, respectively ($p < 0.05$). In contrast, there was no difference in the median SOC score between the four groups. Median HRQoL score was highest in subjects with normoalbuminuria (0.9451) and decreased with deteriorating renal status ($p < 0.0001$), reaching the value of 0.8527 in subjects with ESRD. In a logistic regression analysis, duration of diabetes ($OR\ 1.025$; 95%CI 1.002-1.047), BMI (1.071; 1.008-1.138), smoking (2.709; 1.476-4.970), HbA_{1c} (1.538; 1.273-1.859), serum creatinine (1.055; 1.042-1.068), and the HRQoL score (0.020; 0.001-0.095) were independently associated with diabetic nephropathy. Of the other psychological measures, neither BDI nor SOC were associated with diabetic nephropathy.

Conclusion: Depression, poor sense of coherence, and poor health related quality of life are prevalent in type 1 diabetic patients with diabetic nephropathy. However, out of these psychological measures, only HRQoL was independently associated with diabetic nephropathy when adjusted for other confounding factors. Whether psychological disturbances are a primary feature or a consequence of diabetic complications remains to be established.

di Brescia, ⁸Dept. of Clinical Sciences, La Sapienza University, Roma, ⁹D.U.,

A.O. S. Camillo, Roma, Italy

Background and aims: Aim of this study was to explore patient characteristics associated with poor QoL perception among adults with T1DM using continuous subcutaneous insulin infusion (CSII).

Materials and methods: The study involved 472 patients aged between 18-55 yrs and treated with CSII, recruited by 43 diabetes clinics. During a routine visit, physicians collected clinical and sociodemographic data and patients completed the Diabetes Specific Quality of Life Scale (DSQOLS). The summary score of DSQOLS summarizes the daily burden and restrictions related to diabetes, with lower scores indicating a worse QoL perception. The main results were obtained by using a regression-tree technique (RECPAM), that permitted to identify homogeneous and distinct subgroups expressing a different likelihood of scoring in the lower tertile of the DSQOLS score. All the analyses were adjusted for patient age and number of diabetes complications.

Results: Overall, 57.2% of the patients were female, 38.4% had ≥ 1 diabetes complications, 25.2% reported ≥ 1 hypoglycaemic episodes (HEs) and 11.2% reported ≥ 1 ketoacidosis episodes (KEs) in the previous 12 months. The mean age was of 35.1 ± 10.9 yrs and the mean duration of diabetes was of 18.4 ± 10.2 yrs. Male patients not reporting KEs and using CSII for > 2 yrs had the lowest likelihood of scoring in the lower tertile of DSQOLS and thus represented the reference category. Patients who reported ≥ 1 KEs, independently of other characteristics, showed a five-fold risk of poor QoL as compared to the reference category ($OR=5.1$; 95% CI 2.3-11.6). These patients also showed the highest reported frequency of HEs. Among patients who didn't report KEs, females with a duration of diabetes of < 10 yrs represented the group of patients with the highest likelihood of poor QoL ($OR=6.2$; 95% CI 2.7-14.6), while for females with longer diabetes duration the likelihood of scoring in the lower tertile of the DSQOLS was two-fold as compared with the reference group ($OR=2.4$; 95% CI 1.3-4.7). Among males, those treated with CSII for ≤ 2 yrs showed a two-fold risk of poor QoL ($OR=2.3$; 95% CI 1.1-4.7) as compared to those treated with CSII for > 2 yrs. The extremely high risk of poor QoL among women with a diabetes duration < 10 yrs as compared to those with longer diabetes duration was associated with a significantly higher likelihood of wearing the pump for ≤ 2 yrs (75% vs. 45%).

Conclusion: Unstable diabetes (high frequency of KEs and HEs) is the most important clinical variable associated with poor QoL among patients treated with CSII. In both genders, being on treatment with CSII for ≤ 2 yrs represented an important correlate of poor QoL, thus suggesting that specific strategies are needed to help the patient to cope with this therapeutic modality, especially during the initial phase of the treatment.

Assessment of lower limb risk factors for falls in those with diabetes mellitus

C. MacGilchrist¹, L. Paul², B. Kennon³, A. McFadyen⁴, B. Ellis¹, T. Howe¹

¹School of Health and Social Care, Glasgow Caledonian University, ²Nursing and Health Care, Glasgow University, ³Centre for Diabetes and Metabolism, Southern General Hospital, ⁴School of Engineering and Computing, Glasgow Caledonian University, Glasgow, United Kingdom

Background and aims: People with Diabetes Mellitus (DM) are at an increased risk of falling with the incidence of falls within the elderly diabetic population estimated to be around 39%. Falls constitute a significant public health burden in terms of patient morbidity and mortality as well as economic cost. Accurately predicting which patients are at risk of falling is challenging. The aims of this study were to establish lower limb risk factors for falls in patients with DM.

Materials and methods: Sixty patients with DM, over 55 years old, were recruited from the Southern General Hospital, Glasgow, Scotland. Subjects were classified as fallers or non-fallers with 'fallers' defined as individuals who self reported at least one fall in the last year. The following risk factors, generally associated with falls, were assessed; presence of neuropathy [10g monofilament screening on ten sites], neuropathy disability score (NDS), neuropathy symptom score (NSS) and vibration perception threshold (VPT) bilaterally to the hallux, foot problems [the foot deformity score (FDS)], balance and gait [Tinetti Performance-Oriented Assessment of Mobility], mean ankle dorsiflexion strength (DF) [hand-held dynamometer], footwear suitability [Menz & Sherrington footwear assessment tool], spatial and temporal parameters - an average of 3 passes along a 61cm x 366cm walkway [GAITRite® System]. Multivariate discriminant analysis was performed to identify the variables most predictive of falls in this group.

Results: Thirty five percent (n=21) of the sample had fallen in the preceding year. The mean age of the 'fallers' (F) was 69.2yrs and the 'non-fallers' (NF) 65.9yrs. Forty percent were classified as neuropathic (diagnosis achieved using a combination of signs and symptoms of neuropathy). Eighty-six percent (n=18) of 'fallers' but only 56% (n=22) of 'non-fallers' had peripheral neuropathy. Gait analysis demonstrated that fallers walked with a significantly lower velocity (F=78.46cm/s, NF=108.46cm/s; $p<0.001$) and had smaller step length bilaterally (Right F=48.82cm NF=61.09cm, Left F=48.43cm NF=60.88cm; both $p<0.001$). The prevalence of foot deformity was high in both groups; 'fallers' (58%) and 'non-fallers' (54%). The mean Tinetti score classified 'fallers' as being at moderate risk (22.4) and 'non-fallers' as low risk (25.6). The mean ankle dorsiflexor muscle strength was significantly lower in 'fallers' than 'non-fallers' (2.4kg and 3.9kg respectively; $p<0.001$). Multivariate discriminant analysis identified velocity and DF strength as the variables with the best discriminating power and together, with cross-classification validation, they correctly classified ~76% of the 60 participants.

Conclusion: These novel findings highlight the lower limb risk factors in those with DM. Multivariate analysis suggests that walking velocity and dorsiflexor muscle strength may be useful in identifying those patients at risk of falling. Health Care Professionals could use these simple clinical measures to identify those at risk of falling and thus implement appropriate early preventative strategies.

Identifying depression in the diabetes clinic: how can we target this important co-morbidity?

L. Matone¹, R.P. Raghavan², T. Durston², J. Phull¹, P. Singhal²

¹Department of Psychiatry, ²Department of Diabetes, Weston General Hospital, Weston-Super-Mare, United Kingdom

Background and aims: The prevalence of depression in patients with diabetes is higher than in the general population. Depression is associated with personal suffering, reduced social functioning and emerging evidence indicates that patients with mental health conditions may receive poor quality medical care. Active screening/surveillance for depression is not routine in diabetic outpatient clinics. We set out to identify depression within a diabetes secondary care outpatient population, using self-administered questionnaires in order to establish current care and improve service provision.

Materials and methods: A prospective study of 100 consecutive patients with diabetes attending secondary care outpatients clinics, between January and May 2007 was undertaken. Anonymised data regarding patient demographics, diabetes history and management were collected using a questionnaire and pathology reports. In addition, patients were requested to complete a general questionnaire once and the Beck Depression Inventory (BDI) at presentation (while waiting to see the health professional) and again 6 weeks later.

Results: Subjects who returned both BDI questionnaires (74/100) were included. The composition of the respondents was 46%(n=34) female and 54%(n=41) male with a median BDI score of 7 (range 0 - 49). The median HbA1c was 7.95 (range 5.8 - 12.9). A target HbA1c ≤ 7 was only seen in 7% (n=1) with a BDI score ≥ 17 (n=13, indicating depression) versus 23% (n=14) out of 61 subjects with a BDI score <17 . 24% of the study group had a past history of depression, but only 54.2% (n=13) were receiving drug treatment for depression. Using the BDI, 18% scored positive for depression (BDI score ≥ 17), of whom 69% (n=9) were previously undiagnosed. Within the group that had known depression and were on treatment, The mean BDI score was 17.6. In this group 23.1% (n=3) had a depression score classed 'Severe / Extreme' (score ≥ 31). Another concern was that 18.2% (n=2) with a past his-

tory of depression were scoring Severe / Extreme on the BDI and were not receiving pharmacological treatment for depression. The mean BDI score was 15.9 in this group. Subjects older than 65 years of age were less likely to be significantly depressed. People suffering from depression were less likely to be employed compared to non-depressed group (20% vs. 37%).

Conclusion: Within this study, 17% of outpatients scored positive for depression using the BDI: over half of this group had not been previously diagnosed with depression. We have demonstrated that there is a high prevalence of concomitant depression in diabetic patients, and it may impact on glycaemic control. There is a need to create awareness and address this important comorbidity in diabetes. The identification of depression in diabetic outpatients could be substantially improved by the knowledge and use of the BDI screening tool. When the BDI score is >17 , it is suggested that a patient undergoes further evaluation to determine more precisely a diagnosis of depression. Depression is more likely in younger subjects a finding which has been noted in previous research on this subject. Our study shows that the BDI is very easy to use and could become part of the annual review process allowing health professionals to pinpoint those individuals who are in need of further psychological evaluation and support.

1104

Social, psychological, and health care factors associated with patient self-care success in the multi-national DAWN Youth Survey

M. Peyrot¹, H.-J. Aanstoot² on behalf of the DAWN Youth Survey Group
¹Sociology, Loyola College, Baltimore, United States, ²Diabetes Center for Children and Youth, Diabeter, Rotterdam, Netherlands

Background and aims: This study assessed the social, psychological, and health care factors associated with self-reported self-care success among young adults with diabetes.

Materials and methods: Data are from a cross-sectional internet survey of independent national samples of patients with diabetes aged 18-25 (N = 1905) from the Diabetes Attitudes, Wishes and Needs (DAWN) Youth Survey. Respondents from the US, Japan, Brazil and five countries in Europe provided self-report data for all measures. Self-care success was a 7-item scale measuring success in controlling blood glucose, taking medications, SMBG, diet and exercise ($\alpha = .81$). Hierarchical multiple regression was used to assess the associations of self-care success with country, respondent demographic and disease characteristics, aspects of healthcare provision and participation, perceived social support from family and friends, and patient psychological functioning (diabetes coping, subjective quality of life, and psychological well-being).

Results: All factors were significantly ($p < 0.05$) associated with self-care success, and together accounted for 42% of the variance. Success was higher in Denmark and Germany and lower in Japan; after adjustment for all covariates, success was lower in Brazil and Japan, and higher in Denmark. Males and those using insulin pumps reported more success; these relationships were mediated by psychological functioning. After adjustment for all covariates, respondents with type 1 diabetes and those diagnosed at older ages reported more success. More information at diagnosis and more communication among health care team members were associated with more success. Greater perceived physician support and understanding of the difficulties of living with diabetes, and patient involvement in decision making were associated with more success, and the physician factors mediated the relationships of success with information at diagnosis and health care team communication. Health care factors accounted for one-quarter of the model's explanatory power. Family and friend support were both associated with more success. Diabetes coping success, perceived quality of life, and psychological well-being were associated with more success and accounted for just over half of the model's explanatory power; these factors mediated the relationship of self-care success with family and friend support.

Conclusion: Self-care success is multi-factorially determined. Country of residence makes a contribution beyond the factors examined here. Some individual characteristics have indirect effects that are mediated by psychological factors, while others have effects that are masked by psychological factors. From the patient perspective, physician support and understanding of psychosocial issues are the most important aspects of health care. Social support contributes to good psychological functioning and in turn to more self-care success. Successful coping is the strongest correlate with self-care success, predicting both good quality of life and psychological well-being, and in turn more self-care success. Enhancing greater provider empathy, social support for the patient and patient psychological coping appear to be promising strategies for improving self-care outcomes.

Contribution of psychological symptoms on immediate and prolonged effects of diabetes self-management education

M. Pibernik-Okanovic, D. Ajdukovic, M. Prasek, Z. Metelko
Outpatient Clinic, Vuk Vrhovac Institute, Zagreb, Croatia

Background and aims: Depressive symptoms and diabetes-related distress may adversely interact with patients' effectiveness in the learning process during diabetes self-management education. This study was aimed at comparing baseline and follow-up indicators of diabetes knowledge and glycaemic control in patients with and without these symptoms who attended an educational course.

Materials and methods: One hundred and sixty-six patients (aged 48 ± 15 years, 52% female, 38% type 1, with diabetes duration of 10 ± 8 yrs, 78% insulin treated) who participated in a 5-day educational course were assessed for depression and diabetes-related distress using the Center for Epidemiological Studies-Depression scale (CES-D) and the Problem Areas in Diabetes (PAID) scale. The CES-D score >15 and the PAID score >40 were considered indicative of severe depressive symptoms and high distress caused by diabetes. Diabetes knowledge was assessed at the beginning and at the end of the course using parallel forms of the Diabetes Knowledge Test (DKT). Indicators of glycaemic control as measured by HbA1c were assessed at the beginning of the course and after 3, 6 and 12 months. Baseline and follow-up indicators of diabetes knowledge and glycaemic control were compared in the subgroups of depressed-distressed, depressed, distressed and symptom-free individuals using the Kruskal-Wallis ANOVA.

Results: Thirty-two percent of patients attending the educational course reported elevated depressive symptoms and high diabetes-related distress, 9% expressed elevated depressive symptoms, 10% high diabetes distress and 49% reported none of these symptoms. The four subgroups differed with respect to diabetes knowledge assessed at the beginning of the course ($H=11.2$ $p=0.01$), with depressed-distressed individuals having poorer knowledge as compared to the symptom-free individuals ($p=0.02$). Diabetes knowledge did not differ across the subgroups after the course ($H=6.2$ $p=0.10$), indicating comparable improvement in all participants. Depressed-distressed, depressed, distressed and symptom-free individuals had comparable baseline HbA1c values ($H=3.6$ $p=0.31$), which improved correspondingly after 3 and 6 months ($H=3.2$ $p=0.36$ and $H=6.7$ $p=0.08$ respectively). Differences in HbA1c values across the subgroups were observed at 12-month follow-up assessment ($H=7.7$ $p=0.05$), indicating poorer control in depressed-distressed vs depressed individuals ($p=0.04$).

Conclusion: The benefits of a five-day educational course defined as improvements in diabetes knowledge and long-term diabetes control were shown to be comparable in patients reporting depressive symptoms and diabetes-related distress as compared to patients without these symptoms. Patients with double symptoms have greater difficulties in maintaining an acceptable long-term glycaemic control, suggesting a need for a more intensive follow-up.

Quality of life, coping ability and metabolic control in patients with type 1 diabetes followed by group care with a carbohydrate counting programme

M.E. Basile¹, M. Trento¹, E. Borgo¹, C. Kucich¹, P. Passera¹, A. Trinetta¹, G. Grassi¹, F. Cavallo², M. Porta¹

¹Laboratory of Clinical Pedagogy, Internal Medicine, University of Turin,

²Department of Public Health and Microbiology, University of Turin, Italy

Background and aims: Patients with type 1 diabetes (DM1) must adapt their daily life to therapeutic changes and modify insulin dosages according to the Carbohydrate (CHO) content of their meals. We have validated a process to train patients to carbohydrate counting (CCHO) within the clinical-pedagogic Group Care (GC) approach, in order to verify its additional effects on quality of life, knowledge of diabetes, coping ability (problem solving, social support seeking, avoidance) and metabolic control.

Materials and methods: Out of 56 patients with DM1 followed by GC, 27 were randomized to attend the CCHO programme and 29 controls continued GC without CCHO. The two groups were similar by age, duration of diabetes, years of attendance in clinic, years in GC, schooling, occupation, family history of diabetes, HbA1c, BMI, mean insulin dosage and blood lipids. The CCHO programme included 8 sessions, lasting 1 hour each and held every

3 months. At the beginning and after 30 months 3 questionnaires were administered to verify quality of life (DQOL), knowledge and coping. Every 3 months HbA1c, body weight, blood glucose, blood pressure, number of hypoglycaemic episodes and insulin dosage were measured. At the beginning, after 1 year and at the end of the study blood lipids were measured.

Results: DQOL improved significantly ($p<0.0001$) in both patients followed by CCHO (88.7 ± 9.2 vs 78.0 ± 9.9) and Controls (88.7 ± 12.5 vs 80.4 ± 1.7) and remained so after adjustment for age ($p<0.02$). Knowledge (9.3 ± 1.7 vs 10.6 ± 0.6 , $p<0.0001$) and the 3 coping areas (problem solving: 28.0 ± 1.9 vs 30.0 ± 1.5 , $p<0.0001$; social support seeking: 18.0 ± 4.4 vs 17.0 ± 5.1 , $p<0.02$; avoidance: 16.7 ± 3.5 vs 14.8 ± 3.5 , $p<0.001$) improved only in the patients followed by CCHO. The improvement in knowledge remained significant after adjusting for age ($p<0.001$), with a linear trend in favour of patients with poor schooling, and in the problem solving ($p<0.0001$) and avoidance ($p<0.003$) areas of coping. HbA1c showed a non significant divergent trend between patients followed by CCHO (from 7.56 ± 1.26 to 7.33 ± 1.03) and controls (from 7.73 ± 1.24 to 7.89 ± 1.42). There were no modifications in insulin mean dosage, hypoglycaemic episodes or blood lipids.

Conclusion: This study confirms that GC improves quality of life in people with DM1 but suggests that, to modify adaptation to their disease, they need more specific educational and cognitive support. The carbohydrate counting programme we developed appears effective in promoting change especially in people with poor schooling.

1107

Marked improvement of quality of life and treatment satisfaction with intraperitoneal insulin (CIPII) compared to CSII in type 1 diabetes

N. Kleefstra^{1,2}, S.J.J. Logtenberg¹, S.T. Houweling^{1,2}, K.H. Groenier³, H.J.G. Bilo^{1,4}

¹Diabetes Centre, Isala Clinics, Zwolle, ²Medical Research Group, Langerhans, Zwolle, ³General Practice, UMCG, Groningen, ⁴Internal Medicine, UMCG, Groningen, Netherlands

Background and aims: To report about the effects of intraperitoneal (IP) insulin delivered with an implantable pump on Health Related Quality of Life (HRQOL) and treatment satisfaction as compared to intensive subcutaneous (SC) insulin therapy in poorly controlled type 1 diabetes patients.

Materials and methods: Open-label, randomized controlled cross-over trial. After a 3-month qualification phase, during which optimization of insulin therapy was targeted, patients who had a HbA_{1c} $>7.5\%$ and/or ≥ 5 hypoglycemic events/week, were randomized to receive either 6 months IP insulin (CIPII) followed by 6 months SC insulin by CSII or vice versa, with a 4-week washout phase in between. Treatment adjustments were done according to protocol. IP insulin was delivered through an implantable pump (MIP 2007C, Medtronic), SC insulin was delivered with continuous subcutaneous insulin infusion (CSII). HRQOL was assessed with the SF-36 and the WHO-5 (range 0-100); Treatment Satisfaction was assessed with the DTSQ (range 0-36) at baseline and at the end of both treatment phases. General linear models were used to test differences, taking treatment order into account.

Results: *Baseline characteristics:* 11 males, 13 females; mean (SD) age 43.6 (11.8) years; mean diabetes duration 22.6 (10.6) years; mean HbA_{1c} 8.6 (1.1) %. After randomization groups were comparable regarding clinical characteristics. One subject was lost to follow-up (start IP insulin).

Outcomes: Scores at end of both treatment phases on the SF-36 subscales are shown in Figure 1; With IP insulin scores are significantly higher on 6 out of the 8 subscales. The Mental and the Physical component summary score of the SF-36 were also higher with IP ($p=0.002$ and $p=0.006$, respectively). The total DTSQ score at the end of the IP-phase was 32.6 (3.9) as compared to 23.3 (9.2) at the end of the SC treatment phase ($p<0.001$). The WHO-5 score at the end of the IP treatment phase 64.9 (22.7) compared to 45.2 (22.7) at the end of the SC treatment phase ($p<0.001$).

Conclusion: In a selected group of patients, CIPII significantly improves HRQOL and Treatment Satisfaction as compared to CSII, despite having to undergo a surgical procedure to have the IP-pump implanted.

Figure 1: Scores on the SF-36 subscales after 6 months of CIPII and CSII in type 1 diabetes patients (n=23).

Legend: IP=IntraPeritoneal, SC=Subcutaneous. PH=Physical Functioning, SF=Social Functioning, RP=Role Physical, RE=Role Emotional, VT=Vitality, BP=Bodily Pain, GH=General Health, MH=Mental Health.

Clinical efficacy and cost-effectiveness of a brief educational intervention for self-efficacy in type 1 diabetes: results from the BITES randomised controlled trial

J.T. George¹, A. Peña², S. Lomax¹, P. Droomgoole¹, D.J. Torgerson³, J.C. Thow¹

¹Diabetes and Endocrinology, York Hospital, United Kingdom,

²Coordinación de Políticas de Salud, Instituto Mexicano del Seguro Social, Mexico, ³York Trials Unit, University of York, United Kingdom

Background and aims: Educational interventions providing self-management skills for type 1 diabetes have been shown to improve glycaemic control. Although intensive 5-day educational interventions like have been shown to be effective in European setting (Düsseldorf, DAFNE and Bucharest- Düsseldorf studies), resource pressures demand brief interventions that are clinically and economically effective. We evaluated the biophysical and psychological effectiveness of a brief (2.5 day) psycho-educational intervention with integrated cost-effectiveness analysis.

Materials and methods: Our randomised controlled clinical trial in secondary-care setting had HbA1c and severe hypoglycaemia as primary endpoints with blood pressure, weight, height, lipid profile and composite psychometric scores as secondary outcomes. BITES curriculum was delivered in groups using pre-approved material. Assessments were done at baseline, 3, 6 and 12 months. We calculated incremental cost-effectiveness ratios (ICER) and confidence limits for the ICER were estimated using non-parametric approach of bootstrapping.

Results: 54 and 60 adult participants (type 1 diabetes for longer than 12 months, multiple injection therapy for at least 2 months) were allocated to intervention or control groups. HbA1c showed no statistically significant change at 3 months (difference = 0.01 95% confidence interval (CI) (-0.23 to 0.26, p = 0.92), 6 months (difference = -0.06 95% CI -0.32 to 0.20 p = 0.67) and 12 months (difference = 0.01 95% CI -0.30 to 0.32, p = 0.94). Incidence of severe hypoglycaemia (per patient per year) in the intervention group (0.41) and control group (0.48) was not statistically different. Lipids, blood pressure, use of insulin and body mass index demonstrated no statistical significance between the two groups.

Diabetes Knowledge Test, Illness Perception Questionnaire, Hypoglycaemia Fear Scale and Short Form 36 showed no change. Diabetes treatment satisfaction improved at 3 months (difference = 9.4 95% CI 5.2 to 13.6) p = 0.0005, 6 months (difference = 10.4 95% CI 6.0 to 14.8 p = 0.0005) and 12 months (difference = 7.1 95% CI 2.1 to 12.1 p = 0.006). Significant improvement was seen in Diabetes Empowerment Scale, 3.6 points more on average in the intervention group (95% CI: 0.65 to 6.6). There were no significant differences between groups in QALY at 3, 6 and 12 months. An ICER of £ 38,400 (USD 76,000, Euro 38,400) per QALY was obtained, including in loss of productivity.

Control group had more visits to primary-care physician (average: 6.3 visits in intervention group; 7.3 in control group) and specialist services (average: 1.9 visits in intervention group; 3.2 in control group). Intervention group reported less sick days (average: 0.85 days per patient in the intervention group vs 5.1 days in the control group) though statistically insignificant.

Conclusion: Dietary liberalisation did not lead to decline in HbA1c or increase in serious hypoglycaemic episodes. Although improvements in treatment satisfaction and empowerment were achieved even in absence of any statistically significant glycaemic improvement, cost-effectiveness has to be interpreted in context of the local health economy.

Predictors of insulin requirement in the early days after diagnosis of type 1 diabetes

S. Pilacinski, A. Gawrecki, D. Zozulinska-Ziolkiewicz, B. Wierusz-Wysocka

Department of Internal Medicine and Diabetology, Poznan University of Medical Sciences, Poland

Background and aims: In the majority of patients with newly diagnosed type 1 diabetes dose of insulin is reduced shortly after introduction of treatment.

Low insulin requirement in the initial course of diabetes reflects partially preserved insulin secretion and high insulin sensitivity, being associated with good metabolic control and prolonged clinical remission of diabetes. Data on direct predictors of insulin requirement in the early postinitial period of diabetes are inconclusive. Therefore, aim of this study was to determine predictors of insulin requirement at the end of initial hospitalization after diagnosis of type 1 diabetes.

Materials and methods: We followed prospectively 279 consecutive patients (111 women and 168 men, aged 16–34, mean age 24.8 ± 5.0), admitted to the Department with newly diagnosed type 1 diabetes. 34 patients presented with diabetic ketoacidosis. Mean glycaemia at diagnosis was 22.7 ± 8.0 mmol/l, HbA_{1c} 11.0 ± 2.5 % and BMI 21.7 ± 3.1 kg/m². In all patients intensive functional insulin treatment in multiple injections was introduced. Mean hospitalization time was 7 ± 2 days. The group was divided according to the daily insulin dose at discharge from the hospital (median value 0.21 U/kg/24h). Statistical analysis was performed using Statistica 5.1 software. Mann-Whitney U test and multivariate logistic regression were used.

Results: In the group with lower insulin requirement, lower initial glycaemia (21.3 ± 8.1 vs. 24.1 ± 7.7 mmol/l), HbA_{1c} value (9.9 ± 2.3 % vs. 12.0 ± 2.2 %, $p < 0.0001$), serum total cholesterol concentration (4.42 ± 1.11 vs. 4.79 ± 1.30 mmol/l, $p < 0.05$) and lower serum triglyceride concentration (1.26 ± 1.09 vs. 1.79 ± 1.50 mmol/l, $p < 0.0001$), higher serum HDL concentration (1.27 ± 0.35 vs. 1.19 ± 0.40 mmol/l, $p < 0.05$) and higher capillary blood bicarbonate concentration (25.2 ± 4.6 vs. 20.7 ± 6.9 mmol/l, $p < 0.0001$) were recorded, when compared with subjects with insulin requirement above 0.21 U/kg/24h. There was also a tendency towards increased age (25.3 ± 5.0 vs. 24.2 ± 5.0 years, $p = 0.053$) and BMI (22.0 ± 2.9 vs. 21.3 ± 3.3 kg/m², $p = 0.068$) in the group with lower insulin requirement. In the multivariate logistic regression model, lower initial HbA_{1c} (OR: 1.43; 95%CI: 1.13–1.81, $p < 0.01$), lower white blood cell count (OR: 1.12; 95%CI: 1.01–1.26, $p < 0.05$), lower erythrocyte sedimentation rate (OR: 1.07; 95%CI: 1.01–1.13, $p < 0.05$), absence of clinically evident infection (OR: 1.81; 95%CI: 1.07–3.07, $p < 0.05$) and higher capillary blood bicarbonate concentration at diagnosis (OR: 1.18; 95%CI: 1.07–1.30, $p < 0.001$) were predictors of lower (< 0.21 U/kg/24h) insulin dose at discharge from hospital, independently from age, gender and BMI.

Conclusion: Mild initial metabolic decompensation and absence of acute inflammation may be considered as predictors of low insulin requirement in the early days after diagnosis of type 1 diabetes.

18 years after first ambulatory flexible intensified insulin therapy: current impact on metabolic control in 227 consecutive type 1 diabetic patients

D. Albrecht, U. Keller, H. Zulewski

Division of Endocrinology and Diabetes, University Hospital Basel, Switzerland

Background and aims: Good metabolic control in type 1 diabetic patients is crucial for prevention of diabetes complications. Achievement of HbA_{1c} values below 7.0% is a very difficult task as shown by various studies including the recent DCCT update with mean HbA_{1c} around 7.8%. Flexible intensified insulin therapy was introduced in our institution in 1990 as standard of care for patients with type 1 diabetes. The ambulatory training program teaches the patient to apply long and short acting insulins according to certain rules and algorithms in order to cover the insulin needs in fasting state as well as in response to meals or during physical activity. Here we analyzed the impact of such therapeutic approach on blood glucose control in 227 consecutive type 1 diabetic patients followed routinely at our outpatient clinic.

Methods and results: Using a computerized database we screened in a cross-sectional study 237 patients with type 1 diabetes of whom 227 were finally included because 10 patients missed follow up appointments. The median age was 46.3 years, median duration of diabetes 19.0 years, 56 % were male, 33% smokers. In 58% of the patient flexible intensified insulin therapy was taught in a formal group-based ambulatory training program. The other patients were taught individually during the ambulatory visits. Insulin analogues were used in 96% of the patients. Metabolic control was similar in patients treated in a group-based program or individually. The median HbA_{1c} (measured by DCA 2000+ analyzer, Bayer Inc.) of the last available value was 7.1% (6.6% – 7.8%, lower quartile – upper quartile). Patients with diabetes duration < 5 years ($n = 31$) had a median HbA_{1c} of 6.6 % (5.8 – 7.6) most likely due to preserved endogenous insulin secretion. In patients with diabetes duration of 5 years or more ($n = 196$) the median HbA_{1c} value was 7.1% (6.7 – 7.8). 44.1%

achieved the therapeutic target of $HbA_{1c} < 7\%$, 64.8% $< 7.5\%$ and 79.7% $< 8\%$. Thus 20.3% showed HbA_{1c} values $\geq 8\%$. Similar to published data, smokers had worse HbA_{1c} values: median HbA_{1c} 7.4% (6.7 – 8.3) in smokers vs. 7.1% (6.6 – 7.6) in non-smokers ($p = 0.026$, Mann-Whitney U-Test). As compared to men, women had a higher HbA_{1c} : women median HbA_{1c} 7.1% (6.8 – 7.8) vs. men 6.9% (6.5 – 7.7) ($p = 0.014$, after exclusion of patients with eating or psychiatric disorders ($n = 15$)). Severe hypoglycaemia requiring assistance from another person was rare and observed in about 6 patients per year.

Conclusion: Ambulatory training in flexible intensified insulin therapy for diabetes mellitus type 1 is associated with a diabetes control that was equal or better as compared to published data. Such treatment strategy increases patient's responsibility for good metabolic control and may diminish the rate of complications.

Do teenagers and young adults agree to clinical contact by text or email messaging?

T. Koko, J. Bodansky, R. Parslow

Diabetes Center, Leeds General Infirmary, United Kingdom

Background and aims: Many teenage and young adult patients have unacceptable levels of glycaemic control, evidenced by high HbA_{1c} values. This usually emanates from poor adherence to insulin injections, self monitoring of blood glucose (SMBG) values, diet and exercise. However, patients are reluctant to admit to non-adherence. New technology could promote adherence by prompting patients to perform SMBG, exercise and take their insulin using mobile text and email messaging. SMBG results can be returned to clinicians by Bluetooth/mobile phone and email. Prior to evaluation of these technological innovations in a clinical setting, this study aimed at assessing their availability in a clinic cohort of 16–25 year old patients, and whether they were willing to use them for this purpose.

Materials and methods: Consecutive patients attending a teenage/young adult teaching hospital clinic were invited to self complete a structured questionnaire.

Results: 52 consecutive patients (29M, 21F, 2 unknown sex; mean age 18, range 14–24; mean duration of diabetes 12, range 1–22 years) agreed to complete the questionnaire. All had a mobile phone, 87% of them Bluetooth enabled. 88% had computer access at work, school or college, and 92% had access at home. 58% possessed a laptop or PDA (personal digital assistant). All but one patient had internet access; 87% at home, 27% at school and 38% at college. Only 58% were willing to have their SMBG results monitored, while 42% were either unwilling or unsure about this. Only 48% were agreeable to receive text messages to remind them to adhere to their treatment, but 46% would not agree to this and 2 were unsure. Regarding advice via email, 67% were in favour of this, but the remainder were against this or unsure.

Conclusion: The teenagers and young adults surveyed here had a high availability of access to communication by mobile phone and email, thus potentially enabling easy transfer of SMBG results to clinicians, advice to patients and messaging reminders to adhere to their treatment plan. However, about half the subjects were unwilling to have their SMBG values monitored or receive prompting to adhere to their therapy. This may reflect a reluctance to be repeatedly reminded about their condition or provide information about their adherence to their treatment and their glycaemic control.

1112

Optimising basal plus insulin therapy in type 2 diabetes by telecare assistance for self-monitoring of blood glucose - the ELEONOR study

S. Del Prato¹, A. Nicolucci², G. Vespasiani³

¹Department of Endocrinology and Metabolism, University of Pisa,

²Department of Clinical Pharmacology and Epidemiology, Consorzio Mario Negri Sud, Santa Maria Imbaro, ³Diabetology and Metabolic Disorders Center, Madonna del Soccorso Hospital, San Benedetto del Tronto, Italy

Background and aims: Evaluate whether a Telecare programme facilitates optimisation of basal (glargine; GLAR) followed by the addition of one insulin bolus injection (glulisine; GLU) in T2DM patients (pts) with secondary failure to oral hypoglycaemic agents (OHAs). We present preliminary results of 200 (out of 240) pts.

Materials and methods: 200 pts (54% male; mean \pm SD age 58.9 ± 8.2 yrs, BMI 29.9 ± 4.3 kg/m², diabetes duration 10.9 ± 6.9 yrs) with poor glycaemic

V5					

Active treatment phase and Telecare/SMBG was performed between V2 and V5; GLAR was started at V2 (baseline); GLU was started at V3. V2–V3: 8–16 weeks; V3–V4: 12 weeks; V4–V5: 12 weeks. Analysis of covariance or Chi square test were used as appropriate. Results are means ± SD unless otherwise stated. FBG=fasting blood glucose; GLAR=insulin glargine; GLU=insulin glulisine; SMBG=standard blood glucose monitoring; V=visit

control (HbA_{1c} 8.9±0.9%) on one or more OHAs participated in this open-label, multicentre, randomised, controlled, parallel-group study. After a 4-wk run-in, all pts were started on GLAR (Visit 2) and titrated to achieve FBG ≤5.5 mmol/L. At GLAR initiation (baseline), pts were randomised to either Telecare (allowing electronic transfer of blood glucose [BG] readings, n=91) or standard BG monitoring (SMBG; n=109) to identify the highest postprandial peak and glargine dose adjustment by phone, as deemed necessary by the investigators, or dose adjustment at each visit, respectively. After 8–16 wks of GLAR, pts with FBG ≤7.0 mmol/L in both groups (n=91 and 109, respectively) added one dose of GLU at the meal with the highest postprandial BG; this treatment was maintained for 24 wks. The primary objective was to compare Telecare with SMBG in terms of HbA_{1c} change. The primary endpoint was change in HbA_{1c} from baseline to endpoint. Secondary endpoints included BG profiles, weight change, insulin doses and safety (including hypoglycaemia). Preliminary results are reported without lifting the study blinding.

Results: During GLAR titration, HbA_{1c} improved with both BG monitoring approaches by 1% (Table). One GLU injection was added to 83% of pts reaching target FBG (Breakfast 12; Lunch 39; Supper 43%), resulting in a further 0.7–0.8% HbA_{1c} drop in both groups (endpoint HbA_{1c}: 7.1±0.7 vs 7.0±0.7%; both p<0.0001 vs GLAR) with 50.6 and 54.6% of pts, respectively, reaching HbA_{1c} ≤7.0% at endpoint. With GLAR, FBG decreased in both groups (from 11.7±3.1 to 6.0±1.0 and from 11.6±3.3 to 6.1±1.1 mmol/L, respectively; both p<0.0001) with no further change after GLU initiation (6.4±1.6 vs 6.3±1.6 mmol/L). There was no difference in weight changes (+0.4±3.0 vs +0.1±5.0 kg) and GLAR (29±16 vs 28±17 U/d) or GLU (8.3±7.1 vs 8.1±8.1 U/d) dose. 5 episodes of severe hypoglycaemia were experienced by 4 pts.

Conclusion: GLAR plus one bolus GLU injection at the time of the meal with the highest BG peak results in marked improvement of glycaemic control and achievement of glycaemic targets (HbA_{1c} ≤7%), with low risk of severe hypoglycaemia, in a large proportion of pts with secondary failure to OHA. Telecare and SMBG are equally effective for initiation and titration of the basal plus strategy.

Diabetes knowledge among children and adolescents in Germany: unfamiliarity with risk factors and concealment of own illness

K. Kempf^{1,2}, R. Landgraf¹, S. Martin^{1,2}

¹Nationales Aktionsforum Diabetes mellitus, NAFDM, ²Westdeutsches Diabetes- und Gesundheitszentrum, Sana Kliniken Düsseldorf GmbH, Düsseldorf, Germany

Background and aims: There is a growing epidemic of type 2 diabetes mellitus (T2DM) worldwide and it is estimated that 7–8 million people suffer from T2DM in Germany. Studies have shown that the manifestation of T2DM in high risk populations can be prevented by lifestyle modifications but prevention programs can only be promising if basics about, symptoms of and risks for T2DM are well known. Nevertheless, data about T2DM knowledge, especially among children and adolescents, are rare worldwide and so far only available from one cross-sectional study in Mexico. Therefore, it was the aim of this study to determine the knowledge about T2DM among students in Germany.

Materials and methods: We developed a questionnaire for students (class levels 5–13) including 12 questions about T2DM knowledge and 2 questions about awareness about and the attitude towards diabetes within the family and social environment. Differences between T2DM knowledge were analyzed by chi square test and odds ratios (OR) were determined using logistic regression with adjustment for school type, class level, sex, diabetes within family and social environment.

Results: Including complete age-groups within schools 4383 questionnaires have been filled out by students of grammar and secondary schools (e.g. German Gymnasium, Realschule and Hauptschule, 3 each) in the region of Düsseldorf. Comparable to the results from the Mexican study 92% of the students knew that in case of diabetes blood glucose levels are elevated but only 27% were able to define thirst and urgency (21%) as typical symptoms for diabetes. More important, only 12% of the students were aware of the fact that overweight, lack of physical activity and fat-rich diet are risk factors for T2DM. In total, the chance for adequate diabetes knowledge was depending on class level (OR 2.5 [2.1–2.9] for class level 11–13 and 2.6 [2.0–3.2] for class level 8–10 vs. 5–7), school type (OR 1.4 [1.2–1.6]), female sex (OR 1.4 [1.1–1.7]) and diabetes within the family or social environment (OR 1.5 [1.2–1.9]). Indeed, 66% of the students were acquainted with someone with diabetes,

nevertheless 12% would not inform classmates about their own illness (8% from grammar school vs. 19% from secondary school, $p < 0.001$).

Conclusion: The data demonstrate that the knowledge, especially about risk factors for T2DM, is insufficient among children and adolescents in Germany. To enable effective diabetes prevention the knowledge about diabetes should be increased and diabetes concealment reduced. Education about healthy diet and risk of overweight and lack of physical activity in context with diabetes should not only be intensified in curricula but also implemented in schools.

European implications of the READ (Ramadan focused Education and Awareness in Diabetes) programme

V. Bravis^{1,2}, E. Hui¹, S. Salih³, S. Mehar³, M. Hassanein⁴, D. Devendra^{1,3}

¹Jeffrey Kelson Diabetes Centre, Central Middlesex Hospital, London,

²Investigative Sciences, Imperial College, London, ³Brent Integrated Diabetes Pathway, Brent tPCT, London, ⁴Diabetes, Glan Clwyd Hospital, North Wales, United Kingdom

Background and aims: Europe has one of the highest prevalence of diabetes, an estimated 53 million people according to IDF data in 2007. There are 14 million Muslims living in Europe and approximately 1 million suffer with diabetes. During Ramadan, Muslims fast from dawn to dusk for the duration of one lunar month. The majority of Muslim patients with diabetes are unaware of the complications associated with fasting, like hypoglycaemia, and are passionate about the Ramadan fast. The EPIDIAR study showed that 79% of patients with type 2 diabetes fast in 13 Muslim nations during Ramadan. Their risk of severe hypoglycaemia during this fasting period increased by five-fold. The safety of fasting has not been studied in the European Muslim population with Type 2 diabetes. Our Ramadan-focused, structured education programme aimed to meet the unfulfilled patient need for education to allow for safer fasting for people with diabetes who choose to fast during Ramadan. It was based on the ADA consensus statement for management of diabetes during Ramadan. The impact of the programme on weight and hypoglycaemic episodes (HE) during Ramadan in a UK Muslim population with Type 2 diabetes was evaluated.

Materials and methods: In the READ (Ramadan focused Education and Awareness in Diabetes) programme, 57 patients (Group A) took part in a structured education programme about meal planning, physical activity, glucose monitoring, hypoglycaemia, dosage and timing of medications. Group B did not (66 patients). HE (capillary blood glucose ≤ 3.5 mmol l⁻¹ and/or symptoms) and mean weight were measured before and after Ramadan. Group A patients filled in standardised educational session feedback forms, where patients reported satisfaction levels by use of numbers (1 strongly agree, 5 strongly disagree).

Results: After Ramadan, there was a mean weight loss of 0.7 kg in group A ($p < 0.001$), compared to a 0.6 kg increase in group B ($p < 0.001$). The weight changes observed were independent of the class of hypoglycaemic agents used. There was a significant decrease in the total number of HE in group A, from 9 to 5, compared to a four fold increase in group B from 9 to 36 ($p < 0.001$). The majority were in patients treated with short-acting sulphonylureas (group A=100%, group B=94%). Education feedback was very positive demonstrating that overall attendees had learnt a great deal and as a result would be likely to change their behaviour.

Conclusion: Ramadan-focused education in diabetes empowers patients to change their lifestyle during Ramadan. It minimises the risk of HE and prevents weight gain during this festive period for Muslims. We encourage all healthcare providers in Europe to implement this novel education programme, which is the first to study outcomes of fasting in the European Region. The intervention is pragmatically designed; hence it is generalisable and potentially replicable for the rest of Europe. Currently, there is no European or EASD consensus available for managing Muslims with diabetes during Ramadan. This study provides a template for a larger randomised control trial, the results of which could have significant impact for the Muslim population of Europe affected by diabetes.

An intake of fat is a major factor which affects on basal insulin dose in type 1 diabetes patient

T. Hashimoto¹, T. Kawamura¹, M. Hirose¹, H. Fujimoto², K. Yoshida², C. Takemura¹, T. Higashide¹, K. Kimura¹, H. Inada¹, S. Niihira¹, S. Aono¹, T. Yamano¹

¹Pediatrics, Osaka City University Graduate School of Medicine, ²Nutrition/Dietary Section, Osaka City University Hospital, Osaka, Japan

Background and aims: Recently, the rapid acting insulin analogues, the long-acting insulin analogues, and pump therapy have made the roles of basal insulin and bolus insulin clear in the insulin therapy of type 1 diabetes patients. The dose of bolus insulin is depended on carbohydrate counting. However, it is not known what is responsible for the dose of basal insulin. In this study, we have focused on the factors which might affect the dose of basal insulin in type 1 diabetes patients.

Materials and methods: Type 1 patients who were visiting to our clinic, had been on multiple daily insulin (MDI) injection using rapid-acting insulin and long-acting insulin ($n = 111$: male 50, female 61) (7–34 yr, average 18.4 yr) or continuous subcutaneous insulin infusion using rapid acting insulin ($n = 46$: male 10, female 36) (4–33 yr, average 15.2 yr) were enrolled as the subjects of the study. The enrollment criteria included the disease duration more than 2 years, a daily insulin requirement of 0.5 to 1.5 U/kg/day, and HbA1c less than 9 %. The dose of bolus insulin was adjusted by carbohydrate counting. The basal insulin dose was adjusted according to the stability of blood glucose level without meal and correction insulin. The various factors, including age, sex, body weight, BMI, HbA1c, disease duration, total daily dose of insulin (TDD), adipocytokines (adiponectin, resistin, and leptin), and the meal contents of daily food, have been analyzed their relationships with the dose of basal insulin. The meal contents were analyzed using the photographs which were taken with the digital cameras of daily foods on subjects.

Results: The ratios of basal insulin to TDD (B/T ratio) were 35% and 40% in MDI and CSII, respectively. The B/T ratio and basal insulin dose (U/kg) were not related with age, sex, body weight, BMI, HbA1c, disease duration, TDD, adiponectin, leptin either. The level of serum resistin was weakly related with the B/T ratio ($p < 0.05$). The accuracy of our food analysis using the photographs was confirmed by three experienced dietitians and sample meals. The food analysis has revealed that an intake of fat in daily meals was strongly related to the B/T ratio and basal insulin dose (U/kg) ($p < 0.05$).

Conclusion: The B/T ratio of our Japanese patients was lower than that reported in the western countries. Neither age nor sex nor obesity nor puberty was related to the B/T ratio and the basal insulin dose (U/kg) in this study. The serum resistin levels were related to the B/T ratios. It is known that resistin is a maker of insulin resistance. However, the puberty was not related to resistin and the B/T ratio in this study. The further investigation will be needed to know the relationships among them. The meal content, especially an intake of fat seemed to be a major factor of affecting on the basal insulin doses in type 1 diabetes. This evidence may explain the lower B/T ratio of our Japanese type 1 diabetes patients.

Development of training and education for people with a diagnosis of pre-diabetes in culturally diverse communities

J. Troughton¹, S. Amin², H. Daly¹, L. Martin- Stacey¹, N. Patel³, M.A. Stone³

¹Diabetes Research Department, University Hospitals of Leicester NHS Trust, ²Diabetes, University Hospitals of Leicester NHS Trust, ³Department of Health Sciences, University of Leicester, United Kingdom

Background: The prevalence of pre-diabetes (impaired glucose tolerance, impaired fasting glucose or both) is increasing. This condition is associated with an increased risk of type 2 diabetes (2–10% progression per annum) and cardio-vascular endpoints. Lifestyle modifications have been shown to be effective in delaying progression, suggesting the need for effective educational interventions to encourage and empower people with this condition to change their lifestyle behaviour. In an action research project based on diabetes education, we have previously developed a methodology for modifying education programmes to be fit-for-purpose for specific groups including people from black and minority (BME) ethnic groups.

Methods: In order to develop training and education programmes designed for people who have received a diagnosis of pre-diabetes, we have applied the methodology previously developed, using the newly diagnosed DES-MOND (Diabetes Education and Self Management for Ongoing and Newly

Diagnosed) education module and training programme for educators as our starting point. This methodology involves an iterative process similar to the 'audit cycle' and includes the use of data collection and analysis using rigorous qualitative methods to gather and consider the implications of feedback from key stakeholders including health care users (patients attending education sessions) and providers and facilitators (trainers, educators and interpreters). Each 'cycle' involves identification and implementation of modifications needed; piloting including data collection using observation, interviews and focus groups; collation and analysis of data collected; interpretation and reflection; and identification of further changes needed. The cycle is repeated until piloting suggests that a fit-for-purpose model has been developed. Our previous experience of modifying the DESMOND newly diagnosed programme for people from BME groups has enabled us to use our methodology to concurrently develop pre-diabetes training and education for people with language and cultural needs.

Results: During the first 'cycle' of modifications and qualitative data collection, feedback and observational data indicated good levels of acceptability and effectiveness for the training and education including, in patients, increased understanding of the nature and implications of their diagnosis and assimilation of messages about lifestyle changes. Some further modifications were also suggested, including resource and curriculum changes relating to methods of conveying key messages about physical activity and to information given about the differences between complications of diabetes and pre-diabetes. Following a further cycle, it was felt that, with very minor additional modifications, training and education schedules were ready for implementation and evaluation in a larger sample.

Conclusion: The methods used have enabled us to develop a fit-for-purpose model for the provision of training and education relevant to people with a diagnosis of pre-diabetes from culturally diverse populations. The effectiveness of the education module now requires formal evaluation.

Efficacy of intensive multi-factorial intervention for cardiovascular disease prevention in high-risk type 2 diabetes: 2-year interim analysis of the MIND.IT study

A.A. Rivelles¹, O. Vaccaro¹, D. Ardigo², M. Trovati³, F. Cavalot³, R. Miccoli⁴, L. Franzini², C. Di Loreto³, P. De Feo⁵, G. Derosa⁶, A. Damato⁷, D. Zavaroni⁸, I. Zavaroni²

¹Dept of Clinical/Experimental Medicine, Federico II University, Napoli, ²Dept of Internal Medicine, Parma University, ³Dept of Clinical/Biological Sciences, Turin University, San Luigi Gonzaga Hospital, ⁴Dept of Endocrinology, Pisa University, ⁵Dept of Internal Medicine, Perugia University, ⁶Diabetes Center, Pavia University, ⁷Dept of Endocrinology, Bari University, ⁸Piacenza Hospital, Diabetes Unit, Italy

Background and aims: The Multiple Intervention in type 2 Diabetes. Italy (MIND.IT) study is a multi-centric randomized, controlled trial in type 2 diabetic patients at high cardiovascular (CVD) risk (2 or more CVD risk factors). The study compares the Usual Care (UC) of CVD prevention with a multi-factorial treat-to-target Intensive Care (IC) strategy as implemented according to national/international guidelines. The study has a planned follow-up duration of 5 years and a combined primary end-point of CVD morbidity and mortality. This report gives the results of the pre-planned ad-interim analysis after 2 years of follow-up to assess middle-term efficacy of the intervention on CVD risk factors.

Materials and methods: Ten large diabetes clinics were randomized to carry on their usual clinical practice for CVD primary prevention (UC group) or to perform an intensive program of lifestyle and pharmacological intervention aiming at the following targets: weight loss > 5% (if overweight), HbA1c < 7%, LDL-cholesterol (LDL-c) < 100 mg/dL, blood pressure (BP) < 130/80 mmHg, and anti-platelet treatment implementation. IC operators were asked to implement a pre-determined step-wise treat-to-target intervention program. Laboratory analyses were performed in each centre; an external quality control system was implemented and systematic differences between laboratories were corrected before statistical analysis.

Results: A total of 1461 type 2 diabetic patients (759M/702F, age 61±5 years) free of previous CVD was enrolled. In two years the drop-out rate was 17.1% for the IC and 23.2% for the UC group. A statistically significant, and clinically relevant, decrease in HbA1c (mean±SD from 7.7 ± 0.05 % to 7.0 ± 0.01 %, p<0.0001) and BMI (from 30.4± 0.3 to 29.7±0.1, p<0.0001) was observed in the IC group, whereas no differences were detectable in the other. In addition, BP and LDL-c decreased significantly in both groups, but more in the

IC group (systolic BP from 144±13 to 132±14 vs 148±15 to 147±19 mmHg, diastolic BP from 85±8 to 79±7 vs 86±8 to 82±10 mmHg, LDL-c from 144±35 to 108±31 vs 142±28 to 118±32 mg/dL; p for interaction intervention arm*time" < 0.0001 for all comparisons). Accordingly the proportion of patients achieving the treatment goals was significantly higher in the IC than in the UC group: HbA1c 51% vs 27%, LDL-c 43% vs 27%, systolic BP 41 vs 11%, diastolic BP 41 % vs 28% (p<0.001 for all).

Conclusion: The application of a multi-factorial treat-to-target intervention strategy is associated with a significant improvement in all major CVD risk factors and the efficacy of this approach after two years of treatment is far beyond what achieved in the usual practice in diabetes care. In addition, data demonstrate, for the first time, that a significant improvement in metabolic control (HbA1c) can be achieved without a concomitant body weight increase.

A diabetic foot screening programme in primary care

A. Macleod¹, M. McCarthy^{1,2}, A. Tahrani¹, S. Wooton-Whiting³

¹Hummingbird Centre, Royal Shrewsbury Hospital, ²Belvidere Medical Practice, Shropshire County PCT, ³Podiatry, Shropshire County PCT, Shrewsbury, United Kingdom

Background and aims: In 2002 a project was commenced to look at the feasibility of providing foot screening for people with diabetes in primary care. Chiropody services were restricted and there was the impression that diabetic foot lesions were referred late. We now describe the results of this project.

Materials and methods: A local Primary Care Trust (PCT) agreed to fund a pilot study which could be expanded if found useful. The Podiatry Department and the Diabetic Clinic formulated a template that was downloaded onto primary care computer systems and which recorded peripheral pedal pulses, as measured by palpation and Doppler, and nerve function, measured by vibration threshold (Neurothesiometer) at the great toe pulp. Practices are visited in rotation by accredited podiatrists so that each patient is screened annually. Screening visits are also used to update patients regarding footcare. A recall system is run by the Podiatry Department and updated by practices.

Results: Initially the scheme involved twelve practices within the county town and environs. With the advent of the new General Practice Contract in 2004 the Foot-Screening programme expanded and now serves two PCTs and all 66 practices within the county of Shropshire. Patients are categorised as low or high risk and the latter are referred into the hospital Diabetic Foot Clinic. Percentages of patients screened in the programme are given in the table. There has been a marked increase in screening from baseline in 2003 to 2007, which is statistically significant (p<0.001 for both neuropathy and peripheral circulation screening). Eighty six percent of the 18,614 patients with diabetes in Shropshire County have been screened over the last year, and the details and action documented on the computer system.

Conclusion: Since the start of the pilot programme, the community Foot-Screening programme has achieved near maximal coverage of people with diabetes in Shropshire. It is valued as much for its input into foot education as for its detection of high risk patients and their swift referral into the Diabetic Foot Clinic.

Foot screening of Diabetic Patients: Percentage of patients screened

Year	2003	2004	2005	2006	2007
Total Number of Patients with Diabetes	14,203	15,628	16,121	16,867	17,853
Peripheral Pulses Recorded	12%	22%	79%	81%	87%
Neuropathy Testing Recorded	12%	22%	78%	81%	86%

Factors that can influence adherence to an Education Program for Preventive Diabetic Foot Self-care

A.M. Caetano, A. Gonçalves, A. Valongo, I. Lessa, A. Recto, R. Oliveira,

A. Castela, R. Duarte, J.-M. Boavida, J. Raposo

Diabetic Foot, APDP, Lisbon, Portugal

Background and aims: Therapeutic education represents a vital tool in the prevention of major complications of the diabetic foot. The aim of this study was to identify some factors that can influence adherence to an Education

Program for Preventive Diabetic Foot Self-care in a Portuguese Diabetic Foot Clinic.

Materials and methods: A retrospective case-control study based on clinical data collected from diabetic patients that attended a Diabetic Foot Clinic between January and December 2007. From a total total population of 1048 diabetic patients who were invited to attend a structured and free Education Program for Preventive Diabetic Foot Self-care we have studied some clinical and social-economic factors including demographic variables, metabolic control and foot ulcer risk factors in all the patients that attended the Education Program (134 Patients) - group A and in a random sample of those who did not attend the Education Programme (n= 134) - group B. Statistical analysis was performed through SPSS (Statistical Package for the Social for science).

Results: The comparative analysis between the two samples showed statistic significant differences in gender (group A: 70,90% vs group B: 45,52%) for male and (29,10% vs 54,48%) for female; $p < 0,001$; with mean age 49,30 vs 64,20 years old. The average duration of the disease: group A: 9 years vs group B: 12 years; $p < 0,001$. The last HbA1c patients with $\leq 6,5\%$: 12,69% (group A) vs 15,67% (Group B) $p < 0,05$. In Group A, the majority of patients lived in Lisbon metropolitan area where the Diabetic Clinic is located were unemployed (8,2%), retired (38,1%). 64,2% had high school degree. 14,2 % of the patients were accompanied by another person. Type 2 Diabetes was less prevalent in group A (70.1%) than in group B (74.5%). There were no significant differences regarding foot ulcer risk between both groups

Conclusion: Factors that can positively influence adherence to an Education Diabetic Foot Prevention programme include: male gender, less duration of disease, worse metabolic control, higher school degree and professional inactivity. This study also shows a low adherence to the education program (12% of the total population). We believe that this study provided some clues in order to improve the future adherence to the educational programs.

PS 105 Pregnancy in type 1 diabetes mellitus

1120

Pregnancy outcomes in women with type 1 diabetes treated with long-acting insulin analogues. A case control study

K. Todorova - Ananieva¹, M. Genova²

¹High-risk Pregnancy Department, University Hospital of Obstetrics and Gynaecology, ²Department of Clinical Laboratory and Immunology, Medical University, Sofia, Bulgaria

Background and aims: The aim was to evaluate and compare the pregnancy outcomes in women with type 1 diabetes (T1D) intensively treated with long-acting human or analog insulin.

Materials and methods: A prospective two years case control study in ninety pregnant women with T1D. The intensified treatment consisted of insulin aspart as bolus insulin and long-acting insulin as basal. Women were divided into three groups according to the basal insulin: $n_1 = 30$ treated with NPH insulin, $n_2 = 30$ treated with insulin detemir and $n_3 = 30$ treated with insulin glargine. Participants were matched for age, duration of diabetes, BMI, HbA1c before pregnancy, parity, number of previous pregnancies and abortions. Metabolic control, diabetic complications, severe hypoglycemic episodes and pregnancy induced hypertension and preeclampsia were registered. Perinatal mortality, stillbirth, macrosomia, weeks at and route of delivery were also recorded. Statistical methods: ANOVA - with multiple comparisons and chi square test have been used.

Results: No statistically significant difference in mean values for age, diabetes duration, BMI, parity and number of previous pregnancies. No differences were observed in pre-prandial, postprandial glucose and HbA1c levels in early pregnancy (HbA1c $n_1 = 7.3 \pm 0.8\%$, $n_2 = 6.9 \pm 0.7\%$, $n_3 = 7.1 \pm 0.8\%$, $p = 0.7$). No differences were observed in postprandial glucose and HbA1c levels in late pregnancy (HbA1c $n_1 = 7.8 \pm 0.3\%$, $n_2 = 7.1 \pm 0.6\%$, $n_3 = 7.3 \pm 0.7\%$, $p = 0.06$) as well. The level of pre-prandial glucose in late pregnancy was lowest in the first group ($n_1 = 4.5 \pm 1.4$ mmol/l, $n_2 = 6.6 \pm 1.1$ mmol/l, $n_3 = 6.9 \pm 0.8$ mmol/l, $p = 0.0001$). The dose of short-acting insulin was significantly higher in the first group in early ($n_1 = 25.9 \pm 34.9$ U/kg, $n_2 = 17.0 \pm 25.3$ U/kg, $n_3 = 19.6 \pm 26.7$ U/kg, $p = 0.004$) and in late pregnancy ($n_1 = 41.1 \pm 20.0$ U/kg, $n_2 = 26.1 \pm 12.9$ U/kg, $n_3 = 21.9 \pm 10.1$ U/kg, $p = 0.0001$). There was no difference in the dose of long-acting insulins in early pregnancy between the groups, but in late pregnancy the dose in n_1 group was statistically lower in comparison to the other two groups ($n_1 = 16.0 \pm 6.8$ IU/kg, $n_2 = 21.4 \pm 8.2$ U/kg, $n_3 = 29.7 \pm 6.6$ U/kg, $p = 0.001$). Severe hypoglycemic episodes in the first group was observed at rate of 16% ($p = 0.03$). There was no difference in the frequency of hypoglycaemic episodes between groups n_2 and n_3 . Caesarean section was the main choice in all groups. There was statistically significant difference in the time of delivery in the third group compared to other two groups ($n_1 = 36.7 \pm 1.1$ week, $n_2 = 36.2 \pm 1.2$ week, $n_3 = 37.5 \pm 0.7$ week, $p = 0.001$). The newborns body weight in the third group was statistically higher than the other two groups ($n_3 = 3623.9 \pm 527.8$ g, $n_1 = 3364.3 \pm 662.4$ g, $n_2 = 3076.7 \pm 798.7$ g, $p = 0.02$). The incidence of Respiratory Distress Syndrome was higher in the first group ($p = 0.04$). The frequency of neonatal hypoglycaemia was higher in the third group ($p = 0.003$). The incidence of spontaneous abortion and stillbirths was higher in the third group, but without statistical significance. The evaluation of risk factors could not establish relationship between the observed foetal complications and the insulin treatment.

Conclusion: The treatment with long-acting insulin analogs during pregnancy has similar maternal efficacy and safety. In terms of foetal complications and safety the conduct of more long-treatment trials in larger groups are needed.

1121

The efficacy of continuous subcutaneous insulin infusion and multiple daily injections of insulin in pregnant women with type 1 diabetes

A. Hebda-Szydło¹, K. Cyganek¹, M.T. Małecki¹, I. Trznadel-Morawska¹, B. Katra¹, T. Klupa¹, I. Kaim², A. Reroń², J. Sieradzki¹

¹Department of Metabolic Disease, ²Department of Obstetrics and Perinatology, Jagiellonian University, Krakow, Poland

Background and aims: The risk of complications for the mother and infant in pregnancy complicated by type 1 diabetes mellitus (T1DM) can be reduced by a strict glycemic control. To achieve this goal two insulin regiments are

commonly used: multiple daily injections (MDI) and continuous subcutaneous insulin infusion (CSII) via an insulin pump.

The purpose of this study was to assess metabolic control of pregnant women with T1DM treated by CSII and MDI and to compare the pregnancy outcomes in both groups.

Materials and methods: We included 216 pregnant women with T1DM in this observational study. Among them, there were 142 women on MDI, while 74 subjects were on CSII. We analysed HbA1c level and mean blood glycaemia (MBG) in each trimester of pregnancy, as well as the pregnancy outcomes for both groups.

Results: MDI and CSII groups did not differ in terms of age (mean 28.4 years \pm 6.0 vs. 29.0 \pm 4.0, respectively) and duration of diabetes (mean 12.0 \pm 7.3 years vs. 10.8 \pm 7.0, respectively). They also had a similar degree of metabolic control at the study entry as measured by HbA1c (7.0 \pm 1.6 vs. 6.9 \pm 1.2; $p=0.7$, respectively) and MBG (114.4 \pm 38.0 mg% vs. 105.5 \pm 12.4; $p=0.07$, respectively). However, we observed a lower level of HbA1c in the second trimester in CSII than in MDI (5.7 \pm 0.7 vs. 6.0 \pm 1.0; $p=0.03$); no difference was seen for MBG (105.6mg% \pm 20.0 vs. 102.6 \pm 20.0; $p=0.3$). In the third trimester, we did not find differences between CSII and MDI groups in respect to the level of HbA1c (5.7 \pm 1.1 vs. 5.9 \pm 0.9; $p=0.2$) and MBG (106.7 \pm 20.2 vs. 106.2 \pm 48.9; $p=0.9$, respectively). There was a tendency for slightly better pregnancy outcomes in CSII group as compared to MDI in respect to infant deaths (4.1% vs. 4.9%), stillbirths (5.4% vs. 7.0%), and congenital malformations (5.4% vs. 6.3%), although at this sample size this was not significant ($p=0.7$ for combined outcomes). Unexpectedly, we found higher frequency of newborns with LGA (Large for Gestational Age) in CSII group (40.5% vs. 23.9%; $p=0.01$ respectively).

Conclusion: In this large observational study, the CSII model showed some evidence of superiority over an MDI regimen in respect to metabolic control in women with T1DM. The observation, concerning more frequent LGA births in CSII group warrants further confirmation.

Continuous subcutaneous insulin infusion and multiple dose insulin injection in type 1 diabetic pregnant women: a case control study

F. Pancani, C. Lencioni, M. Aragona, A. Bertolotto, A. Ghio, I. Cuccuru, V. Resi, S. Del Prato, L. Volpe, G. Di Cianni
Endocrinology-Metabolism, University of Pisa, Italy

Background and aims: Optimal glycemic control before and during pregnancy is essential to reduce the health risk for both the mother and the foetus in diabetic women. Recently, subcutaneous insulin infusion (CSII) has been used during pregnancy as an alternative to multiple dose insulin injection (MDI), but results concerning CSII effectiveness in pregnancy are not conclusive. The aim of this study was to evaluate the effects of CSII on glycaemic control, insulin requirement, maternal and foetal outcomes in type 1 diabetic pregnant patients.

Materials and Methods: We retrospectively evaluated 42 type 1 diabetic pregnancies, divided in two groups: CSII (including 20 women transferred on CSII therapy 3-6 months before pregnancy) and MDI (including 22 women with short insulin analogues before each meal and NPH insulin 2-3 times daily). Safety and efficiency of CSII versus MDI was evaluated by HbA1c, maternal hypoglycaemia, insulin requirement and pregnancy outcomes.

Results: The two groups were comparable for age (CSII: 31 \pm 3 vs MDI 29.8 \pm 6.3 years), diabetes duration (CSII: 16 \pm 8.2 vs MDI: 12 \pm 7.7 years), and pre-pregnancy BMI (CSII: 23 \pm 2.8 vs MDI: 23.7 \pm 4.3 Kg/m²). CSII women (according to White's classification: 5 in B, 3 in C, 9 in D and 3 in F) planned pregnancy in 50% of cases, whereas only 18% of the pregnancies were planned in MDI women (9 in B, 7 in C, 6 in D of White's classification). At the first evaluation during pregnancy (6 \pm 2.2 weeks), HbA1c values (CSII: 6.98 \pm 0.7 vs MDI: 7.4 \pm 1.3%) and daily insulin doses (CSII 0.62 \pm 0.1 vs MDI 0.69 \pm 0.21 IU/kg) were similar in the two groups. Pregnancy was interrupted by miscarriage during first trimester in 4 CSII and 2 MDI patients. At the end of the pregnancy there were no differences for weight gain (CSII: 13.4 \pm 5.4 vs MDI: 11.5 \pm 3.7 kg) and HbA1c values (CSII: 6.3 \pm 0.6 vs MDI: 5.8 \pm 2.1%). On the contrary, insulin requirement resulted significantly lower in CSII than in MDI (0.76 \pm 0.3 vs 1.1 \pm 0.3 IUI/kg, $p<0.009$). We recorded only one severe hypoglycaemic episode in both groups. No ketoacidosis episodes were observed. The delivery occurred at 36.4 \pm 2.2 weeks of gestation with caesarean section in 95% of cases; time of the delivery, rate of pre-term deliveries and caesarean section were similar between two groups. Birth weight was similar in both groups (CSII 3541 \pm 757 g vs MDI 3100 \pm 719 g), and LGA were 53% in CSII, 27.5% in MDI ($p=0.08$). No differences concerning foetal morbidity were observed in either of two groups (10 newborns by CSII mothers and 8 by MDI had transitory neonatal hypoglycaemia and/or hyperbilirubinemia).

Conclusion: CSII and MDI insulin therapy are both effective in improving metabolic control, but CSII therapy is associated with a lower insulin daily requirement. However, no clinical advantages appear for maternal and foetal outcome

1123

Reduced need for intensive care in newborns of women with type 1 diabetes - is routine admission to neonatal intensive care unit still necessary?

E. Stage¹, P.B. Emmersen¹, E.R. Mathiesen², C. Mester³, G. Greisen³, P. Damm¹

¹Gynaecology and Obstetrics, ²Endocrinology, ³Neonatology, Rigshospitalet, Faculty of Health Sciences, Copenhagen, Denmark

Aims: Neonatal morbidity is increased in infants of women with type 1 diabetes (T1DM) compared with infants of healthy women, and the infants are routinely admitted to neonatal intensive care unit (NICU) after delivery in many centres. In our centre all infants of women with T1DM were previously admitted to the NICU for observation the first 24 hours after delivery, but on May 1st 2006 our routine was changed to improve the early mother-infant bonding. The newborns now follow their mothers to the maternity ward shortly after delivery. The outcome of this changed routine is evaluated.

Methods: The study included an old cohort of 102 consecutive infants born between May 1st 2001 and January 31st 2003 all admitted to the NICU immediately after delivery. The new cohort included 103 consecutive infants born between May 1st 2006 and October 31st 2007. Infants in the new cohort were routinely admitted to a specialised maternity ward together with their mothers and only transferred to NICU if requested by the pediatric team. All infants had their plasma glucose measured 2 hours after delivery and were treated with early feeding by cup with manufactured milk every third hour during the first 24 hours. Gastric tube was used when necessary. In the maternity ward frequent skin-to-skin contact and breastfeeding were encouraged. Clinical data were drawn retrospectively from the medical records.

Results: After delivery 84 (82%) infants from the new cohort were transferred directly together with their mothers to the maternity ward and 19 were transferred directly to the NICU mainly due to prematurity and/or respiratory problems. Ten (12%) infants were later transferred from the maternity ward to the NICU for various reasons, only 4 of these due to hypoglycaemia. All infants survived in good health except one who died immediately after delivery in the NICU. In the new cohort the first nursing was initiated earlier and the percentage of neonatal hypoglycaemia reduced. Gastric tube feeding and CPAP treatment of respiratory distress were used less frequently (Table 1).

Table1. Pregnancy outcome and infant morbidity in the new cohort compared with the old cohort among infants born to women with type 1 diabetes.

	New cohort Mainly admission to maternity ward 2006-2007	Old cohort Routine admission to NICU 2001-2003	pvalue
Number (%)	103	102	–
Maternal HbA1c before delivery (%)	5.9 (0.5)	6.3 (0.6)	<0.0001
Gestational age (days)	261 (11)	258 (18)	NS
Preterm delivery (< 37 weeks of gestation)	28 (27%)	33 (32%)	NS
Weight (grams)	3,487	3,540	NS
First nursing < 2 hours after delivery	78 (76%)	48 (47%)	0.0005
Plasma glucose < 2,5 mmol/l two hours after delivery	42 (41%)	64 (63%)	0.0027
Gastric tube feeding	33 (32%)	88 (87%)	< 0.005
Intravenous glucose therapy	11 (11%)	31 (30%)	0.00053
Phototherapy of icterus	12 (12%)	18 (18%)	NS
Continuous positive airway pressure (CPAP)	16 (16%)	31 (30%)	0.014

Data are given as numbers (%) and mean (SD)

NICU: neonatal intensive care unit

Conclusion: Observation in a maternity ward facilitating early mother-infant bonding seems safe in newborns of women with T1DM. These infants had less hypoglycaemia and received less treatment for respiratory problems compared with a historical cohort of infants routinely transferred to NICU. The demonstrated reduced need for neonatal intensive therapy in the new cohort may be related to early mother-child bonding, but improved metabolic control during pregnancy may also play a role.

Poor pregnancy outcome in women with type 1 diabetes is predicted by HbA_{1c} and spikes of high glucose values in the third trimester

P. Damm¹, H. Mersebach², P. Brown², R. Kaaja³, M. Hod⁴, E. Mathiesen¹
¹Center for Pregnant Women with Diabetes, Rigshospitalet, Copenhagen, Denmark, ²Novo Nordisk A/S, Bagsvaerd, Denmark, ³Department of Obstetrics and Gynaecology, Helsinki University Central Hospital, Helsinki, Finland, ⁴Division of Maternal Fetal Medicine, Tel Aviv University, Petah-Tiqva, Israel

Background and aims: Strict glycaemic control during pregnancy in type 1 diabetes is necessary to reduce the risk of adverse maternal and perinatal outcomes. Data from a randomised, controlled study of a rapid-acting insulin analogue (prandial insulin aspart versus human insulin) in pregnant women with type 1 diabetes (n=322) were analysed for potential factors affecting outcome in late pregnancy. The trial included subjects who were pregnant or planning on becoming pregnant at enrollment. NPH was used as basal insulin.

Materials and methods: This post-hoc analysis included 259 subjects with known pregnancy outcome and excluded subjects with congenital malformations and/or foetal loss before gestational week 22. Two outcomes were examined: 1) composite outcome: poor outcome in late pregnancy (n=78) including pre-eclampsia (n=12), pre-term delivery (n=53), both pre-term delivery and pre-eclampsia (n=10) and perinatal death (n=3); 2) excessive foetal growth (large for gestational age [LGA]/macrosomia) (n=88).

Results: HbA_{1c} and at least one plasma glucose (PG) measurement >11 mmol/L (198 mg/dL) (taken from 1 day's 8-point profile performed within 1 week prior to the third trimester visit) were found to be significant predictors for poor outcomes (see table). Other potential predictors (blood pressure, albuminuria and retinopathy in early pregnancy) did not predict any of the three outcomes ($p>0.10$). **Conclusions:** These results suggest that both elevated HbA_{1c} and spikes of high glucose levels impact on poor pregnancy outcomes; our findings therefore support the recommendation for achieving optimal glycaemic control also in late pregnancy in women with type 1 diabetes.

An audit of pregnancy outcomes in type 1 diabetes comparing continuous subcutaneous insulin infusion with multiple daily injections

P.J. Hammond¹, S. Ray¹, J. Carling¹, S. Dudley¹, L. Dinning¹, K. Johnson¹, A. MacDonald²

¹Diabetes Centre, Harrogate and District Foundation Trust, Harrogate,

²Medtronic Diabetes, Watford, United Kingdom

Background and aims: The benefits of continuous subcutaneous insulin infusion (CSII) over multiple daily injections (MDI) in terms of improvement in HbA_{1c} and reduced hypoglycaemia frequency are now well-established in non-pregnant individuals with type 1 diabetes. However findings in pregnancy are inconsistent despite the fact that benefits of improved control would be expected to translate into improved fetal outcomes. The aim of this audit was to determine whether use of CSII was more effective than MDI at delivering target outcomes for mother and baby.

Materials and methods: We audited a total of 73 pregnancies in women with type 1 diabetes between 1999 and 2007, during which time all women were offered CSII as an alternative to MDI in pregnancy. Outcomes audited were HbA_{1c} preconceptionally, in each trimester and post-partum; intra-partum maternal glucose; subjective reporting of hypoglycaemia severity; fetal growth and birth weight; neonatal morbidity; maternal weight gain and insulin requirements.

Results: 39 used CSII, 9 switching from MDI in early pregnancy, with 34 live births; 34 used MDI alone, with 30 live births. HbA_{1c} was significantly better in CSII users preconceptionally (7.3 ± 1.2 vs $8.2 \pm 2.0\%$) and in the first trimester (6.9 ± 1.1 vs $7.7 \pm 1.7\%$). However there were no significant differences through the remainder of the pregnancy, although mean HbA_{1c} during pregnancy was lower in those women who switched to CSII during pregnancy than those who used either CSII or MDI alone (6.6 ± 0.9 vs 6.8 ± 0.8 vs $7.0 \pm 1.0\%$). Reported hypoglycaemia severity was significantly reduced in CSII users. There was no impact of CSII use on fetal growth or birth weight. Only one CSII user did not continue on CSII during the intrapartum phase, and those who continued CSII had a significantly lower intrapartum glucose than women on MDI who used intravenous insulin infusion (5.6 ± 2.3 vs 7.0 ± 2.8 mmol/l). There was a corresponding reduction in frequency of neonatal hypoglycaemia, with a significantly higher mean neonatal glucose for those born to CSII users (2.4 ± 0.9 vs 1.7 ± 1.0 mmol/l). There was significantly less weight gain, lower insulin requirements and better post-partum HbA_{1c} for mothers who used CSII.

Conclusion: Pregnant women with type 1 diabetes using CSII rather than MDI can achieve better glycaemic control, particularly preconceptionally and in early pregnancy, experience less severe hypoglycaemia, and realise benefits to themselves in reduced weight gain and to the neonate in reduced hypoglycaemia frequency.

Outcome 1: Composite endpoint: poor outcome in late pregnancy		Successful outcome in late pregnancy (n=181)	Poor outcome in late pregnancy (n=78)	*Odds ratio (95% CI)	p-value
One measurement of PG >11 mmol/L, n (%)	Yes	35 (19%)	27 (35%)	2.17 (1.18, 3.98)	0.012
	No	145 (81%)	51 (65%)		
HbA _{1c} %, mean \pm (SD)		6.0 (0.6)	6.2 (0.7)	1.68 (1.08, 2.61)	0.022

Nitrosative stress and poly (ADP-ribose) polymerase activation in healthy and gestational diabetic pregnancies

E.M. Horvath^{1,2}, R. Magenheimer^{3,4}, E. Kugler⁵, G. Vacz⁵, A. Szigethy⁴, C. Szabo^{1,2}, Z. Lacza⁵

¹Department of Surgery, University of Medicine and Dentistry of New Jersey, Newark, United States, ²Cell Screen Center for Applied Research, Semmelweis University, Budapest, Hungary, ³School for Doctorial Studies, Semmelweis University, Budapest, Hungary, ⁴Department of Obstetrics and Gynecology, St. Margit Hospital, Budapest, Hungary, ⁵Institute of Human Physiology and Clinical Experimental Research, Semmelweis University, Budapest, Hungary

Background and aims: Oxidative stress increases during the course of normal pregnancy with a further elevation at the onset of labour and in various pathological conditions such as gestational diabetes (GDM) and preeclampsia. Hyperglycemia leads to increased generation of reactive oxygen and nitrogen species and subsequent DNA single-strand breakage, which in turn activate the nuclear enzyme poly (ADP-ribose) polymerase (PARP). PARP uses NAD⁺ as substrate to form poly (ADP-ribose) (PAR). Its overactivation leads to the rapid depletion of NAD⁺ and ATP causing cell dysfunction and necrotic cell death. Activation of PARP also leads to the translocation of apoptosis inducing factor (AIF) from the mitochondria to the nucleus, activating apoptotic pathways. Oxidative-nitrosative stress and PARP activation plays an important role in the formation of type 1 and type 2 diabetes and its complications. In the current study the presence and severity of these phenomena were examined in healthy and GDM pregnancies.

Materials and methods: Blood samples (16–29th, 36–40th week; n=25;22;5), placental and umbilical cord tissues (n=6;9;5) were collected from healthy volunteers and diet or insulin treated GDM patients. Immunohistological staining was performed on leukocyte smears and tissue sections using anti-nitrotyrosine (NT), anti-PAR and anti-AIF antibody.

Results: In healthy pregnancies there is a linear correlation between the number of NT positive leukocytes and their PARP activation and gestational week ($b=1.22\pm0.35$, $R^2=0.43$, $b=0.12\pm0.01$, $p=0.0033$; $R^2=0.49$, $p=0.0008$). In diet treated GDM patients the PARP staining was already strong on the 16–29th week ($p\leq0.001$ vs control) and did not increase further on. On the 16–29th week there was correlation between PAR staining and the 2 hour value of the oGTT ($b=0.63\pm0.14$, $R^2=0.49$, $p=0.0002$). While insulin therapy decreased the intensity of NT ($p\leq0.05$ vs control (36–40th week)) and PAR staining ($p\leq0.05$ vs diet (16–29th week)), in circulating leukocytes, it increased these parameters (NT: $p\leq0.001$ vs control and diet; PAR: $p\leq0.01$ vs diet, $p\leq0.05$ vs. control) and also AIF translocation ($p\leq0.05$ vs. control) in placental tissues.

Conclusion: While the continuous elevation of tyrosine nitration, PARP activation is physiological during pregnancy, the earlier elevation of PARP activity in GDM might contribute to the increased prevalence of pre-term deliveries and pre-eclampsia. The longer duration of the increased PARP activation may also explain the higher frequency of diabetes and cardiovascular diseases observed years after pregnancies complicated with carbohydrate intolerance. The highest PARP activity was observed in case of the most severe GDM, represented not only with the highest diagnostic oGTT results but also the later need of insulin treatment. Hence, PARP activation may be used as a potential marker to identify high-risk patients. While insulin has beneficial effects on the immune cells function, it may induce adverse reactions on the placenta.

1127

Proinflammatory cytokines are up-regulated in gestational diabetes

M. Kuzmicki¹, J. Szamatowicz², B. Telejko³, N. Wawrusiewicz-Kurylonek³, A. Nikolajuk³, A. Kretowski³, M. Gorska³

¹Department of Pathophysiology of Pregnancy, ²Department of Gynecology, ³Department of Endocrinology, Diabetology and Internal Medicine, Medical University of Białystok, Poland

Background and aims: Pro-inflammatory cytokines, including interleukin-6 (IL-6), interleukin-8 (IL-8) and interleukin-18 (IL-18) through their ability to interfere with insulin signaling, can contribute to the development of insulin resistance and the disturbances of glucose metabolism. In this study we examined whether serum IL-6, IL-8 and IL-18 levels, as well as their genes expression

in adipose and placental tissue are elevated in patients with gestational diabetes (GDM) and related to the metabolic factors conferring insulin resistance

Materials and methods: Serum IL-6, IL-8 and IL-18 concentrations were measured in 58 patients with GDM and 62 women with normal glucose tolerance (NGT) between 24 and 28 weeks of gestation, using immunoenzymatic method. IL-6, IL-8 and IL-18 mRNA expression in maternal subcutaneous adipose tissue (SAT), visceral adipose tissue (VAT) and placental tissue were evaluated in 15 women with GDM and 12 healthy pregnant women at term, using quantitative real time RT-PCR.

Results: Serum IL-6, IL-8 and IL-18 levels were significantly elevated in the GDM subjects as compared with the non-diabetic women [0.97 (0.66–1.49) pg/ml vs 0.77 (0.50–1.07) pg/ml, $p=0.006$, 2.03 (1.15–4.17) pg/ml vs 0.73 (0.39–0.94) pg/ml, $p<0.0001$ and 249.2 (188.5–318.7) pg/ml vs 179.4 (133.7–243.9) pg/ml, $p<0.0001$, respectively]. Serum IL-6 concentrations correlated significantly with current BMI ($R=0.31$, $p=0.0007$), fasting glucose ($R=0.33$, $p=0.0003$) and HOMA-IR ($R=0.20$, $p=0.02$). Serum IL-8 levels were associated significantly with current BMI ($R=0.34$, $p=0.0002$), glucose ($R=0.19$, $p=0.04$), insulin ($R=0.44$, $p<0.0001$) and HOMA-IR ($R=0.47$, $p<0.0001$), as well as with gestational age ($R=0.34$, $p=0.0002$). Serum IL-18 concentrations correlated with insulin ($R=0.24$, $p=0.0091$) and HOMA-IR values ($R=0.24$, $p=0.008$). IL-8 mRNA expression in VAT was markedly higher in GDM than in NGT subjects [1.88 (0.61–2.24) vs 0.48 (0.27–0.98) AU, $p=0.004$], whereas the expression of IL-6 and IL-18 genes in adipose and placental tissue did not differ between the two groups of pregnant women. IL-8 mRNA expression in SAT correlated significantly with fasting glucose ($R=0.47$, $p=0.02$). There were also significant correlations between IL-8 and IL-18 mRNA expression in SAT ($R=0.63$, $p=0.001$) and placental tissue ($R=0.43$, $p=0.04$).

Conclusion: Our results indicate that circulating proinflammatory cytokines are up-regulated in patients with GDM, potentially linking chronic subclinical inflammation with insulin resistance in GDM women.

1128

Early pregnancy C-reactive protein in the prediction of gestational diabetes mellitus

N. Fatema¹, S. Akter², F. Jebunnesa², A. Akhter², N. Sultana², T. Wahed², R. Helal², L. Ali²

¹Dept of Obstetrics and Gynecology, Square Hospital, ²Dept of Biochemistry and Cell Biology, BIRDEM, Dhaka, Bangladesh

Background and aims: Gestational diabetes mellitus (GDM) is a common medical disorder of pregnancy and is a leading cause of poor pregnancy outcome. The pathophysiology of GDM is complicated and still poorly understood. Low-grade systemic inflammation has been found to be associated with insulin resistance as well as with GDM, but the causal relationship between inflammation and GDM has not yet been established. The present study was undertaken to explore this relationship with C-reactive protein as a marker of chronic subclinical inflammation.

Materials and methods: A total 297 pregnant mothers of 6–16 weeks of pregnancy were enrolled in this study. All the patients were followed till delivery for the development of GDM. Fifty nine patients were lost in the follow-up and 31 (21.4%) women developed GDM. By a nested case-control design the 28 GDM cases were compared with 71 Controls with non-GDM pregnancy. Controls and cases were matched with each other in respect of age and gestational weeks. Serum C-peptide was measured by chemiluminescence based ELISA and serum high sensitivity C-reactive protein (hsCRP) was measured by immunonephelometry. Insulin secretory capacity (HOMA%B) and Insulin sensitivity (HOMA%S) was assessed by Homeostasis Model assessment. McNemar test was done to calculate sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of the parameters.

Results: The erythrocyte sedimentation rate (ESR) was highly significant in GDM as compared to Control (ESR, mm in 1st hr (wg) 82.32 ± 30.1 vs 61.38 ± 31.2 , $p=0.003$). The high sensitivity C-reactive protein (hsCRP) level of GDM was 6.82 ± 2 and that of the Control was 4.04 ± 1.93 . The CRP level in the GDM group was significantly higher compared to the Control group ($p<0.001$). The GDM subjects had significantly higher serum c-peptide (ng/ml, $M\pm SD$, 2.77 ± 0.57 vs 1.70 ± 0.46 , $p<0.001$) higher HOMA%B [median (range) 336 (155–498) vs 312 (59–474), $p=0.013$] and lower HOMA%S [22.2 (13.10–55.60) vs 31.8 (16.4–183.3), $p<0.001$] as compared to Control. On Pearson's correlation analysis hsCRP level had a highly significant positive correlation with BMI, gestational age, C peptide and HOMA%B ($p<0.001$) and it had an inverse correlation with HOMA% S ($p<0.001$). On binary logistic regression GDM was found to be associated with hsCRP after adjustment of the effects of the potential confounders. With a cut-off value at the 50th percentile (de-

terminated from on ROC curve) fasting C-peptide level showed a sensitivity of 72%, specificity 93%, PPV 58% and NPV 96% for the prediction of GDM. The corresponding values for hsCRP were 61%, 83%, 59% and 84%. Combination of C-peptide and hsCRP increased the PPV to 83% and NPV to 83%.

Conclusion: Subclinical chronic inflammation seems to have a causal association with insulin resistance in GDM and early pregnancy hsCRP appear to have role in predicting the development of GDM at the later stages of pregnancy.

1129

Association of high-sensitive C-reactive protein with the degree of hyperglycaemia in gestational diabetes mellitus

N. Sultana¹, N. Rosy², F. Jebunnesa¹, A. Akhter¹, T. Wahed¹, R. Helal¹, L. Ali¹

¹Dept of Biochemistry & Cell Biology, ²Dept of Obstetrics & Gynecology, BIRDEM, Dhaka, Bangladesh

Background and aims: Gestational diabetes mellitus (GDM) complicates about 3–5% of pregnancies and is a risk for pregnancy related maternal and neonatal morbidities. GDM, like Type 2 DM, is now increasingly recognized as an inflammatory condition, but the characteristics and determinants of the inflammatory process in GDM still need further investigation. The present study was undertaken to explore the association of high-sensitive C-reactive Protein (hsCRP), a reliable marker of low grade systemic inflammation, with the degree of glycemic status in GDM.

Materials and methods: A total of 110 GDM cases, along with 102 Controls, aged between 18–37 years, were studied for glycemic status and inflammatory markers. Erythrocyte sedimentation rate (ESR) was determined by standard technique, and serum hsCRP was measured by immunonephelometry. HOMA%B and HOMA%S were calculated by Homeostasis Model Assessment and those were used as markers of insulin secretory capacity and insulin sensitivity respectively.

Results: The age and gestational weeks of the study groups were found to be matched. HbA_{1c} level was significantly higher in GDM group (% M±SD; 5.96±0.78) as compared to Control (5.25±0.43, p<0.001). Serum C-peptide was also significantly higher in the GDM group (ng/ml, M±SD 3.82±0.95 in GDM vs 1.93±0.46 in control, p<0.001), but the insulin secretory capacity (HOMA% B) did not differ significantly between the two groups [HOMA% B, Median (range), in GDM 141.4(34.0–464.7) and in Control 139.1(66.1–339.4)]. HOMA% S was significantly lower in GDM group [64.3(25.7–90.5) compared to control 124.5(49.03–299.5), p<0.001]. There was significant difference in HOMA% S level between the two groups in all trimesters of pregnancy (p<0.001). ESR (mm in 1st hour, M±SD) was higher in GDM compared to control groups (90.88±12.56 vs 48.74±18.20, p<0.001). The hsCRP was significantly higher in GDM group compared to control [hsCRP, mg/l, M±SD, 9.56±1.99 vs 2.19±0.95, p<0.001]. The hsCRP level was about 5 times higher in GDM group in all trimesters of pregnancy (p<0.001). The hsCRP levels of the GDM subjects having HbA_{1c} levels below and above 6.0% respectively were as follows: HbA_{1c} %, median (range) 8.53(2.31–18.30) and 10.73(4.19–19.50). There was significant difference in hsCRP levels between the two groups (p<0.001). hsCRP had a significant positive association with HbA_{1c} (p=0.005) in Pearson's correlation analysis. Multiple linear regression analysis showed significant independent association of HbA_{1c} with hsCRP level (P=0.017).

Conclusion: Serum hsCRP is a highly sensitive marker for low grade systemic inflammation in GDM and its rise is strongly associated with the degree of hyperglycemia.

Monocyte-chemoattractant-protein-1 is elevated in gestational diabetes mellitus

J. Brix¹, K. Klein², M. Satler³, M. Elhenicky³, K. Krzyzanowska¹, G. Scherthaner¹, P.W. Husslein², G.-H. Scherthaner³

¹Medicine I, Rudolfstiftung Hospital, ²Obstetrics and Fetomaternal Medicine, Medical University of Vienna, ³Medicine II, Medical University of Vienna, Austria

Background and aims: Gestational diabetes mellitus (GDM) is defined as carbohydrate intolerance of variable severity, with onset/first recognition during pregnancy. GDM complicates about 7% of all pregnancies, and its

prevalence is increasing. Experimental studies in animals and evidence from prospective and longitudinal studies in humans are consistent with an etiologic role of subclinical inflammation in the pathogenesis of T2DM. Inflammatory alterations, being involved in “type 2 diabetic” atherosclerosis, might be as well associated with GDM. Therefore we investigated whether GDM is associated with Monocyte-chemoattractant-protein-1 (MCP-1) and soluble CD40 Ligand (sCD40L), functional relevant proteins in the inflammatory process.

Materials and methods: The study population consisted of 3 groups: Patients with GDM (n= 32; mean age 33±6 years, mean HbA_{1c}: 5.6±0.7%), pregnant women without GDM (non-GDM, n=18; mean age 31±7 years, mean HbA_{1c}: 5.1±0.5%) and non pregnant controls (CO, n= 40; mean age 30±8 years; mean HbA_{1c}: 5.1±0.3%) were included in a cross-sectional and longitudinal design. In the second trimester the diagnosis of gestational diabetes was secured by a 75 g oral glucose tolerance test. Blood samples for MCP-1 and sCD40L were obtained at 25±5 and 33±4 weeks of gestations, as well as 2±1 months postpartum. HbA_{1c} and Insulin levels were measured by standard laboratory procedures and HOMA was calculated.

Results: In controls (n=40), MCP-1 levels were 157±63 pg/ml and sCD40L levels were 17.2±8.2 ng/ml. Values of sCD40L did not differ between GDM, non-GDM at all time points investigated and controls. In contrast, MCP-1 was elevated in the third trimester in patients with GDM (300±115 pg/ml) compared to the second trimester (227±89 pg/ml; p=0.003) and post partum (218±111 pg/ml; p=0.001) to non-GDM in the second trimester, in the third trimester (209±72 pg/ml; p=0.007) and post partum, and to controls (p<0.001). To study the associations three multivariate regression analysis were applied: first, we tried to identify predictors of MCP-1 in the third trimester in all participants. Multiple regression analysis in the third trimester revealed that only BMI was associated with MCP-1 values (beta=0.523; p<0.001). In a separate analysis of pregnant women with GDM and without (non-GDM) we could not obtain a significant association of BMI prepregnancy and BMI at diagnosis of GDM (= time of OGTT) with MCP-1 values. Second, we investigated, which variables were able to predict MCP-1 values in the third trimester in pregnant women. Of all variables tested only the diagnosis of GDM was associated with MCP-1 values (beta=0.402, p=0.007). Third, we studied which variables that are associated with insulin resistance and sensitivity in T2DM, were related to MCP-1 values in the third trimester of our patients. Only glucose 1 hour was associated with MCP-1 values (beta=0.307; p=0.043).

Conclusion: The significant elevation of MCP-1 in the third trimester in GDM suggests an association between inflammation and GDM. Since MCP-1 was elevated in all pregnant women compared to controls, inflammation may have a physiological role in the normal pregnancy but could have pathophysiological effect in GDM.

Amniotic fluid adipokines in diabetic pregnancy: a snap-shot of foetal environment

M. Stojkovic

School of Biological Sciences, Auckland University, New Zealand

Background and aims: A number of different circulating markers of inflammation are produced by different tissue and cells such as the endothelial cells, white blood cells, liver and adipose tissue. In pregnant individuals the placenta also synthesises a variety of signalling proteins, adding an additional level of complexity to the immune-metabolic network. Cytokine (and adipokine) patterns during normal pregnancy are still not fully understood, although a number of studies have reported elevations in cytokines in conjunction with normal labour onset. In pregnancies complicated by diabetes there is a further dysregulation of the metabolic, vascular and inflammatory pathways, supported by an increase in the circulation of inflammatory molecules. While the influence of direct infectious or immune stimuli on cytokine levels has been documented, it is unknown whether in pregnancy, adipokine levels in amniotic fluid (AF) vary and if they do, to what degree. Our aim was to compare AF concentrations of adipokines in pregnancies complicated by diabetes with the levels in healthy controls at comparable maternal and gestational age.

Materials and methods: AF samples were obtained by amniocentesis for fetal chromosome analysis performed between 16 and 20 weeks of gestation. Samples were matched for maternal age (≥35 years) and gestational age at the time of amniocentesis. Analysis was conducted on 17 diabetic pregnancy samples (n=7 Type1 DM, n=8 GDM and n=4 Type2 DM) and 18 control

samples. Using human serum adipokine kit (panel A and B; LINCOplex) we assayed for 11 different adipokines including IL-1 β , IL-6, IL-8, TNF α , MCP-1, HGF, NGF, adiponectin, resistin, active PAI-1, leptin as well as insulin.

Results: Except for IL-1 β whose level was below the detection range, the Linco-plex kit generated data for 10 adipokines and insulin in AF of which 4 showed statistical differences between controls and diabetics (Table 1): Interleukin-8 (IL-8) $p=0.03739$, Leptin $p=0.01088$, MCP-1 $p=0.07632$ and PAI-1 (active) $p=0.04677$ (Figure 1). Post hoc analysis (*Tukey test*) show that two adipokines IL-8 and MCP-1 are elevated in all the types of diabetes (GDM, Type 1 and Type 2 DM) compared to non diabetic controls, whereas PAI-1 (active) and leptin are observed to be significantly increased only in Type 1 DM compared to controls. Unexpectedly there was no significant difference in insulin AF levels between normal controls and diabetics.

Conclusion: We found that immunoregulatory mechanisms associated with normal pregnancy may be poorly developed in diabetics. Furthermore, we show that diabetes in pregnancy is characterized by a unique profile of AF adipokines. Whether this influence of fetus organs and if pancreatic β -cells are influence responsible for fetus development of diabetes is unknown and need to be elucidated.

Gestational diabetes has no impact on circulating apelin and apelin mRNA expression in fat and placental tissue

B. Telejko¹, M. Kuzmicki², J. Szamatowicz³, A. Zonenberg¹, N. Wawrusiewicz-Kurylonek¹, A. Nikolajuk¹, A. Kretowski¹, M. Gorska¹

¹Department of Endocrinology, Diabetology and Internal Medicine,

²Department of Pathophysiology of Pregnancy, ³Department of Gynecology, Medical University of Białystok, Poland

Background and aims: Apelin is a 36-amino-acid bioactive peptide identified as the endogenous ligand of the orphan G-protein coupled receptor (APJ). Although its physiological functions have not yet been clarified, apelin has been recently described as a novel adipokine, produced and secreted by human mature adipocytes and up-regulated in various states of hyperinsulinemia/insulin resistance, such as obesity and type 2 diabetes. The aim of the study was to compare serum apelin concentrations and apelin gene expression in subcutaneous adipose tissue (SAT), visceral adipose tissue (VAT) and placental tissue from pregnant women with normal glucose tolerance (NGT) and gestational diabetes (GDM).

Materials and methods: Serum apelin concentration was measured in 101 patients with GDM and 101 women with NGT between 24 and 31 weeks of gestation, as well as in 15 women with GDM and 12 subjects with NGT at term (RIA). Apelin mRNA expression was measured in 12 women with NGT and 15 subjects with GDM, using quantitative real-time PCR.

Results: Median apelin concentrations did not differ significantly between the women with GDM and NGT, both - in the subjects between 24 and 31 weeks of gestation (1656.5 [1430.2-1852.1] vs 1555.6 [1281.2-1804.2] pg/ml) and at term (1607.9 [1453.4-1768.7] vs 1493.8 [1316.8-1956.7] pg/ml). No association between circulating apelin and glucose, insulin, HOMA-IR or BMI was found in both groups. Apelin gene expression did not differ significantly between SAT and VAT, but was markedly lower than in placental tissue ($p<0.0001$). There were no significant differences in apelin mRNA expression in SAT (0.204 [0.132-0.28] vs 0.112 [0.036-0.184] AU), VAT (0.233 [0.151-0.42] vs 0.29 [0.05-0.307] AU) and placental tissue (1.93 [0.522-3.18] vs 1.29 [0.495-2.44] AU) between the women with NGT and GDM. Apelin gene expression in placental tissue correlated with the expression of interleukin-6 ($R=0.53$, $p=0.007$), interleukin-6 receptor ($R=0.52$, $p=0.007$), tumour necrosis factor- α ($R=0.51$, $p=0.009$) and visfatin ($R=0.73$, $p<0.0001$) genes. There was also a correlation between apelin mRNA expression in SAT and VAT ($R=0.83$, $p=0.04$).

Conclusion: No association between apelin and GDM or the indices of insulin resistance was observed in our study. The placenta might be a substantial source of apelin in pregnant women, irrespective of their glucose tolerance status.

Foetal programming of hypertension and kidney disease in adult rats exposed in utero to maternal diabetes

M. Lelievre-Pegorier, C. Fassot, J.-P. Duong Van Huyen, M. Viltard, N. Freund, T. Nehiri, P. Bruneval, S. Laurent

Centre de Recherche des Cordeliers, INSERM U872, PARIS, France

Background and aims: Epidemiological and experimental studies have led to the hypothesis of fetal origin of adult diseases. We have previously demonstrated in the rat that in utero exposure to maternal diabetes impairs renal development leading to a 30% reduction in nephron number. The aim of the present study was to assess in the rat long-term effects of in utero exposure to maternal diabetes on arterial blood pressure (BP) and arterial and renal function.

Materials and methods: Diabetes was induced in pregnant rats by streptozotocin on day 0 of gestation. In the offsprings of control (CMO) and diabetic mothers (DMO), from 1 to 18 months of age BP, plasma renin activity (PRA), renal function, proteinuria, kidney histopathology and histomorphometry, arterial structure, elastic properties and gene expression profile (oligonucleotides chips, 22 000 genes) were assessed on 3-month-old CMO and DMO rats.

Results: After 6 months of age, in DMO rats, BP was higher, creatinin clearance was impaired and associated with proteinuria. At the pre-hypertensive stage, PRA was similar in CMO and DMO, then after the onset of hypertension, PRA decreased in DMO. High salt intake given at the prehypertensive stage induced an increase in systolic BP in DMO.

In DMO, subunits of P450 (Cyp4f4, Cyp4f2, Cyp8b1) are over-expressed and prostacyclin receptor is under-expressed contributing to vasoconstriction. Surprisingly, there is no difference in arterial structure between the 2 groups. This could be due to the under-expression of genes coding for protein interact with myofibres (Evl, Ckap4, Dcamk1l).

Conclusion: In utero exposure to maternal diabetes induces salt-sensible hypertension and impairs kidney function at adulthood. This may be due to the nephron deficit resulting from the in utero exposure to maternal diabetes associated to an abnormal vascular fetal programming in these rats.

Sex hormone binding globulin and urinary protein-creatinine ratio in the first trimester and subsequent development of pregnancy induced hypertension

R. Helal, F. Jebunnesa, N. Sultana, T. Wahed, L. Ali
Dept of Biochemistry & Cell Biology, Bangladesh Institute of Research & Rehabilitation in Diabetes, Endocrine and Metabolic Disorders, Dhaka, Bangladesh.

Background and aims: The causal association of insulin resistance and pregnancy induced hypertension is still uncertain due to lack of adequate prospective studies. Sex Hormone Binding Globulin (SHBG) has been shown to be a reliable marker for insulin sensitivity. We have used this marker to explore the association of PIH with insulin resistance in early pregnancy. Endothelial damage is another covariate of insulin resistance, and a marker of this damage, urinary protein-creatinine ratio (UPr/Cr), has also been investigated in this study under the same design. This may help to clarify temporal aspects of insulin resistance and hypertension in pregnancy, as well as to find suitable predictive markers in PIH.

Materials and methods: A total of 404 pregnant subjects, from different hospitals of Bangladesh, were followed up for the development of PIH until delivery. PIH (and subgroups PE and GH) was diagnosed by standard criteria. By matching the age- and gestational weeks with PIH cases a control group was defined out of the Non-PIH subjects following a nested case-control design. Serum insulin level was measured by microparticle enzyme immunoassay (EIA), serum SHBG by chemiluminescent immunometric assay and Insulin was measured by ELISA technique. Insulin secretory capacity (HOMA% β) and insulin sensitivity (HOMA%S) were assessed by Homeostasis Model Assessment (HOMA). McNemar test was done to calculate sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of the target parameters.

Results: On case-control comparison SHBG was found to be significantly lower in the PIH group compared to the Control [SHBG, nmol/l, 170 (10–198) in PIH vs 180 (103–219) in Control, $p=0.003$]. Among the covariates of insulin resistance BMI [23.7 ± 4.1 in PIH vs 22.4 ± 3.4 in control, $p=0.047$] and UPr/Cr [9.6 (3.48–20.5) in PIH vs 4.39 (1.1–15.5) in control, $p<0.001$] were higher in PIH compared to control. Correlation analysis between 3rd trimester blood pressure and 1st trimester SHBG as well as UPr/Cr indicated that PIH is associated with early pregnancy insulin resistance and endothelial damage. SHBG and UPr/Cr were found to be strongly correlated to each other. Logistic regression analysis provided more confirmatory evidence on the association of PIH with SHBG ($p<0.001$) and UPr/Cr ($p=0.013$) after adjusting the effect of the confounders. The value of the early pregnancy levels of these markers for predicting the development of PIH in the late pregnancy were explored. At an optimum cut-off value of 180 nmol/l (calculated from an ROC curve) the sensitivity, specificity, PPV and NPV of SHBG were found to be 63%, 80%, 39% and 80% respectively. At an optimum cut-off value of 6.79 the corresponding values for UPr/Cr were 65%, 78%, 55% and 84%.

Conclusion: Insulin resistance and endothelial damage seem to be causally associated with PIH. The present data also suggest that early pregnancy SHBG and UPr/Cr can be clinically useful in predicting future development of PIH in late stages gestation. Among these two options, UPr/Cr has a little better sensitivity and specificity and this can be preferred as it is technically much simpler (implementable even in rural settings) and cost-wise more economic.

Orosomucoid excretion in urine predicts preeclampsia in pregnant women with pregestational type 1 diabetes

M.S. Christiansen¹, P. Ekbom², D. Hesse¹, U. Hesse³, P. Damm⁴, E. Hommel⁵, B. Feldt-Rasmussen⁶, E.R. Mathiesen²

¹Department of Clinical Biochemistry, Amager Hospital, Copenhagen,

²Department of Endocrinology, Rigshospitalet, Copenhagen, ³National Institute of Public Health, University of Southern Denmark, Copenhagen,

⁴Obstetric Clinic, Rigshospitalet, Copenhagen, ⁵Diabetes, Steno Diabetes Center, Gentofte, ⁶Department of Nephrology, Rigshospitalet, Copenhagen, Denmark

Background and aims: Increased prevalences of preeclampsia (4-fold) and preterm delivery (8-fold) is common in pregnancies complicated by type 1 diabetes. Furthermore these complications are associated with increased perinatal mortality and morbidity. Increased urinary excretion of the inflammatory protein orosomucoid independently predicts cardiovascular mortality in patients with type 2 diabetes. The aim of the present study was to evaluate the predictive value of urinary orosomucoid excretion on development of preeclampsia and preterm delivery in women with type 1 diabetes.

Materials and methods: Women with pregestational type 1 diabetes and singleton pregnancies were consecutively included, if they had at least one urine sample collected before 17 gestational weeks. Frozen urine samples were thawed and analysed for orosomucoid by immunoturbidimetry. Women with macroalbuminuria (urinary albumin excretion > 300 mg/24 hours) or early abortion (before 22 gestational weeks) were excluded from the study. The clinical data were collected at the National University Hospital of Copenhagen from January 1996 to July 2002. The primary outcome measurements were development of preeclampsia (defined as blood pressure > 140/90 (three measurements) and proteinuria > 0.3 g/24 hours in 2 urine samples later than 20 weeks of gestation) and preterm delivery (defined as delivery before 37 weeks of gestation).

Results: 173 pregnant women with type 1 diabetes were included before 17 gestational weeks. Mean (SD) age was 30 (3.9) years, HbA1c was 7.1 (0.9) %, and median (range) duration of diabetes was 13 (0–35) years. The median (range) value of urinary orosomucoid was increasing during pregnancy (< 17 weeks: 0.45 mg/l (0.06–27.12); 17–27 weeks: 0.78 mg/l (0.06–14.46); > 27 weeks: 1.30 mg/l (0.09–28.90); $p < 0.0001$) by ANOVA. Development of preeclampsia was seen in 20 (12%) women and 65 (38%) women delivered preterm. Women developing preeclampsia had longer duration of diabetes, higher blood pressure, and higher excretion of urinary albumin and orosomucoid compared to women without preeclampsia. Using logistic regression analysis we found that urinary orosomucoid (collected < 17 weeks) higher than the 90. percentile (OR: 6.85 (95% CI: 1.97–23.88; $p < 0.003$)), nulliparity (3.88 (1.10–13.72); $p < 0.04$), systolic BP > 120 mm Hg (4.12 (1.35–12.59); $p < 0.02$) and duration of diabetes > 20 years (3.69 (1.18–11.52); $p < 0.03$) independently predicted the development of preeclampsia. The analyses were

adjusted for BMI, HbA1c, serum creatinine, smoking and microalbuminuria. Preterm delivery was independently predicted by duration of diabetes > 20 years (2.36 (1.07–5.20); $p < 0.04$) and HbA1c > 7 % at 10 weeks (2.18 (1.10–4.30); $p < 0.03$).

Conclusion: Increased urinary excretion of orosomucoid early in pregnancy predicts preeclampsia in women with pregestational type 1 diabetes. The pathophysiological link between increased urinary orosomucoid and preeclampsia is unknown but may be caused by increased inflammatory response and endothelial dysfunction.

Early pregnancy maternal serum PAPP-A and urinary calcium-creatinine ratio as predictive markers of pregnancy induced hypertension

B. Nasrin¹, F. Jebunnesa², A. Akhter², N. Sultana², T. Wahed², R. Helal², L. Ali²

¹Dept of Obstetrics and Gynecology, BSMMU, ²Dept of Biochemistry and Cell Biology, BIRDEM, Dhaka, Bangladesh

Background and aims: Preeclampsia (PE) and gestational hypertension (GH) are two hypertensive disorders of pregnancy (together termed as pregnancy induced hypertension or PIH) with involvement of both placental and maternal circulation. These are still called 'disease of theories' with considerable controversies, regarding causal agents and risk factors. The aim of this study was to investigate the possible causal association of PIH with serum PAPP-A and urinary calcium-creatinine ratio (UCA/Cr) as well as to evaluate the usefulness of maternal serum levels of these two variables as predictive markers of PIH.

Materials and methods: A total 200 women of 8–16 weeks of pregnancy were enrolled in this study. All the patients were followed till delivery for the development of PIH. Thirty patients were lost in the follow up, 3 (1.76%) developed PE and 14 (8.23%) GH. By a nested case-control design the 17 PIH cases were compared with 48 Controls with normal pregnancy outcome. Controls and Cases were matched with each other in respect of age and gestational weeks. Maternal serum pregnancy associated plasma protein-A (PAPP-A) was assessed by enzyme-labeled chemiluminescent immunometric assay, urine calcium was measured by colorimetric method and urine creatinine was measured by alkaline-picric methods. McNemar test was done to calculate sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of the parameters.

Results: UCA/Cr was significantly higher in the PIH group compared to Control [mg/mmol, median (range), 1.21 (0.35–1.98) vs 0.72 (0.21–5.07), $p<0.001$]. Maternal serum PAPP-A was significantly lower in the PIH group compared to Control [mIU/ml, median (range) 1.8 (0.70–4.1) vs 5.45 (2.7–10), $p<0.001$]. On logistic regression analysis only PAPP-A was significantly associated with PIH ($p=0.044$) when the effects of the confounders (BMI, TG, Cholesterol, HDL, UCA/Cr) were adjusted. When tested as a predictive marker of PIH the sensitivity, specificity, PPV and NPV of maternal serum PAPP-A in the lowest 25th percentile (selected from an ROC curve) were 82%, 95%, 87% and 93%. At 75th percentile the sensitivity, specificity, PPV and NPV of UCA/Cr were 41%, 79%, 41% and 79% respectively. An effort was made to see whether combination of other parameters (BMI, HDL and UPCr) with PAPP-A can increase the predictivity of PIH. The sensitivity, specificity, PPV and NPV of combined PAAP-A and BMI were 53%, 98%, 90% and 85% respectively; for PAPP-A and HDL the corresponding value were 47%, 100%, 100%, 84%; and for PAPP-A and UCA/Cr those were 41%, 97%, 87% and 82% respectively.

Conclusion: Maternal Serum PAPP-A has a causal association with the development of PIH and low PAPP-A in first trimester of pregnancy can be used as a predictive marker for later development of PIH.

Outcome of pregnancy in obese women after laparoscopic adjustable gastric bandingA. Lapolla¹, M. Dalfra¹, F. Favretti², G. Segato², M. Forletto³, M. Marangon¹, L. Busetto¹¹Medical and Surgical Sciences, University of Padova, ²Surgery, Ospedale Regionale San Bortolo, Vicenza, ³Clinical Surgical 2, University of Padova, Italy

Background and aims: Obesity is considered a risk factor for poor pregnancy outcome. Aim of our study was to evaluate pregnancy outcome in obese women after Laparoscopic Adjustable Gastric Binding (P-LAGB) and in Normalweight Pregnant Women (NPW).

Materials and methods: Sixtyone pregnancies in obese women after LAGB compared to 858 in lean women, as control group, were retrospectively analysed. We took into consideration age, prepregnancy BMI, weight gain during pregnancy, maternal morbidity (gestational diabetes, gestational hypertension, preeclampsia/eclampsia), abortions, timing and mode of delivery, fetal outcome (neonatal weight, adequate growth for gestational age, NICU admission, perinatal death).

Results: Age was not different in both groups, BMI was respectively 35.5 ± 7.3 in P-LAGB vs 22.2 ± 4 in NPW ($p < 0.001$) and weight gain 4.8 ± 11.3 kg vs 11.6 ± 5.2 kg ($p < 0.001$). As for maternal morbidity, GDM was diagnosed in 6.6% of obese women and in 6% in NPW, gestational hypertension respectively in 14.8% vs 2.4% ($p < 0.001$), pre-eclampsia/ eclampsia in 11.5% vs 2.4% ($p < 0.001$). As for pregnancy outcome, abortion was 9.8% in P-LAGB vs 8.5% in NPW, caesarean section 43.6% vs 28.2% ($p < 0.05$), preterm delivery 14.5% vs 3.6% ($p < 0.001$), no difference in average gestation week of delivery was found. As for fetal outcome, no different rate of SGA and LGA babies was found, mean neonatal weight was lower in P-LAGB than in NPW ones (3207 ± 694 g vs 3354 ± 443 g; $p < 0.05$). In a multiple regression analysis in P-LAGB prepregnancy BMI predicts gestational diabetes and LGA babies, furthermore weight gain predicts hypertensive disorders and LGA babies; when we considered separately obese women showing weight gain or weight loss during pregnancy, we found in weight loss group a reduction of GDM, hypertensive disorders and LGA babies rate, and an increase in preterm delivery frequency (21.4% vs 12.5%) with respect to obese women with weight gain, this difference is however of no statistical significance.

Conclusion: Obese women also after surgical treatment show a poor pregnancy outcome with respect to normalweight women.

Dysfunction of placental mitochondria in gestational diabetesP.G. Halvatsiotis¹, K. Patsouras², E. Delatola¹, E. Boutati¹, G. Salamalekis², E. Salamalekis², T. Economopoulos¹, S.A. Raptis^{1,3}¹2nd Dept of Int Med Propaedeutic, Athens University Medical School,²3rd Dept of Obstetrics and Gynecology, Athens University Medical School,³Hellenic National, Diabetes Center, Athens, Greece

Background and aims: Gestational diabetes mellitus (GDM) is a pathological state of carbohydrate intolerance beginning or first recognized during pregnancy, which when untreated increases the risk of adverse pregnancy outcome. Insulin resistance is widely accepted to be associated with increased morbidity, although its basis remains unclear. Decreasing activities of mitochondrial enzymes could be part of the pathogenesis of complications and thus the purpose of our study was to examine whether a decrease in placental mitochondrial function, is altered in GDM.

Materials and methods: Placental mitochondria from 6 women (GDM) ($30 \pm 2,46$ yo) and 5 matched to the BMI, race and age nondiabetic mothers (NGD) ($29,8 \pm 1,07$ yo) were isolated and gene transcripts were performed using a real-time QPCR technique for Citrate Synthase (CS), Cytochrome C oxidase I & III (COXI & COXIII), NADH and UCP2. All pregnancies were uncomplicated and normal newborns delivered through caesarean section. Statistical analysis performed with unpaired t-test.

Results: The GDM group demonstrated significantly higher serum insulin levels than NGD ($11,05 \pm 1,3$ vs $6,7 \pm 1,2$ μ U/ml) ($p = 0,04$), while at the same euglycemic levels indicating the presence of insulin resistance state for GDM mothers. GHbA1c levels of GDM were within normal limits ($5,6 \pm 0,5\%$). There was no difference in the BMI of GDM vs NGD before pregnancy ($28,43 \pm 3,9$ vs $26,26 \pm 4,6$) as well as for the weight gained during pregnancy between the groups ($12,75 \pm 1,5$ vs $17,5 \pm 1,9$ kg). Gene transcripts of CS ($0,26 \pm 0,06$ vs $0,5 \pm 0,08$ AU) ($p = 0,035$), COXI ($0,01 \pm 0,01$ vs $0,05 \pm 0,02$ AU) ($p = 0,05$), NADH ($7,49 \pm 4,1$ vs $28,51 \pm 0,3$ AU) ($p = 0,05$) were significantly lower in the GDM group than NGD, while UCPs showed to be higher in GDM ($0,22 \pm 0,04$ vs $0,11 \pm 0,01$ AU) ($p = 0,046$). There was not detected any difference for COXIII.

Conclusion: In conclusion these data indicate the existence of a placental mitochondrial dysfunction which might contribute to restricted fetal growth by limiting energy availability in cells. This bioenergetic failure may be attributed to the increased production of oxidative species while the up-regulation of UCPs indicates an activation of the mitochondrial defence mechanism compensatory to the increased redox state. Our findings support the notion that the decreased mitochondrial function may play a crucial role in the development of complications of pregnancy such as preeclampsia.

1139

Inverse correlation between vitamin D levels and glycosylated haemoglobin in a gestational diabetes clinic populationS. Lau¹, J.E. Gunton¹, N. Athayde², N. Cheung¹¹Diabetes & Endocrinology, ²Obstetrics and Gynaecology, Westmead Hospital, Westmead, Australia

Background and aims: Vitamin D deficiency during pregnancy is increasingly recognised, particularly in dark-skinned or veiled women. Both short and long-term neonatal effects have been studied, but few have considered a potential maternal detriment. A role for Vitamin D has been implicated in β -cell function. Deficiency during pregnancy could therefore also contribute towards gestational diabetes (GDM).

Materials and methods: In 2007, we initiated routine third trimester testing of 25(OH)vitamin D (25OHD), collected simultaneously with the HbA1c, in women attending a GDM clinic with a diverse ethnic population. The diagnostic criteria used for GDM were a fasting plasma glucose ≥ 5.5 mmol/L and/or 2 hour value ≥ 8.0 mmol/L on 75g oral glucose tolerance test. The IDS radioimmunoassay for measurement of 25OHD was used. We conducted a retrospective analysis to explore any relationship between vitamin D status and measures of glycaemia. Women with pre-gestational diabetes were excluded. Spearman Rank correlations were used to test the association between 25OHD, HbA1c and blood glucose values. Mean values of ethnic groups were

compared using ANOVA. A general linear model which included 25OHD, BMI at booking-in, ethnicity and age was tested for independent predictors of HbA1c. A p-value of <0.05 was considered significant for all tests.

Results: Results of the first 145 women are reported here. The average age was 32 yrs. 80% were insulin-requiring, reflecting the referral patterns to the clinic. The mean 25OHD levels for women from Caucasian (n = 27), East/South-East Asian (n = 43), Middle-Eastern (n = 15), Indian Subcontinental (n = 47) and other/non-specified (n = 13) backgrounds were 67.0, 66.5, 46.9, 49.1 and 41 nmol/L respectively (p-value for difference between groups <0.001). Overall, 40% of these women were classified as vitamin D insufficient / deficient, using a cut-off level of 50 nmol/L. 9% had values <25 nmol/L. There was a highly significant inverse correlation between 25OHD and HbA1c ($r = -0.316$, $p=0.001$). A weaker inverse correlation between 25OHD level and fasting blood glucose level at GDM diagnosis (on average 6–7 weeks before the time of collection of 25OHD) was also found ($r = -0.17$, $p = 0.038$). After adjusting for possible confounders, 25OHD was independently and inversely associated with HbA1c.

Conclusion: Despite our sunny climate, Vitamin D deficiency is common in an Australian multi-ethnic clinic population and may contribute towards glycaemic control in GDM. This is the first report of an association between 25OHD level and HbA1c in pregnancy. The precise contribution of vitamin D status to β -cell function or insulin resistance should be tested in prospective studies and clinical trials.

1-hr glucose level after 100 g OGTT as marker of disturbance of glucose homeostasis in pregnant women

C. Lencioni¹, G. Seghieri², I. Cuccuru¹, R. Anichini², A. De Bellis², A. Ghio¹, V. Resi¹, F. Tesi², L. Volpe¹, S. Del Prato¹, G. Di Cianni¹

¹Endocrinology-Metabolism, University of Pisa, ²Internal Medicine, Spedali Riuniti, Pistoia, Italy

Background and aims: We have recently shown that pregnant women with one abnormal value (OAV) during OGTT not meeting criteria for gestational diabetes (GDM) and women with GDM are clinically indistinguishable, with both groups exhibiting impaired insulin secretion and insulin sensitivity. Moreover, among OAV women, greater impairment occurred with 1-h OAV suggesting this value could provide further information of metabolic status in non-GDM women. Therefore, in order to gain further insight on the significance of milder alterations of glucose tolerance we have investigated to which extent 1-h OGTT maternal glycemic value can reflect alteration in insulin secretion and action.

Methods: A 3-hr 100-g OGTT was performed at 27±3.2 week of gestation in 4053 pregnant women (GDM: 18%; NGT: 63.3%; OAV: 18.7% - Fasting OAV: 28.8%, 1-h OAV 41.6%, and 2- or 3-h OAV: 29.5%) for determination of plasma glucose and insulin concentration, calculation of incremental area under glucose (AUCgluc) and insulin curves (AUCins), 1st- and 2nd-phase insulin secretion (using Stumvoll's formulae), and insulin sensitivity (ISI Matsuda). The insulin secretion-sensitivity index (ISSI) was calculated as the product of 1st-phase index and ISI. Data have been, then, analyzed as a function of 20mg/dl increments in 1-hr OGTT, resulting in 5 groups (G1: <120, G2:120-139, G3:140-159, G4:160-179, G5: ≥ 180 mg/dl).

Results: Prevalence of GDM (0.3, 1.8, 3.9, 13.7, 80.3%, respectively) and OAV (4, 8.7, 19, 26.7, 41.6 %, respectively) increased with raising 1-hr OGTT values. As expected, AUCgluc (from 8894 to 14493 mg/dl/min) and AUCins (from 6562 to 9150 10-3 pmol/L/min) both progressively increased over the 1-hr OGTT spectrum (both $p<0.0001$ for trend). On the contrary, ISI decreased in a linear manner from G1 to G5 (from 6.853 to 4.222, $p<0.001$). In particular, even within normal values of 1-hr OGTT (i.e. <180 mg/dl), ISI dropped by 29.3% ($p<0.001$). Along with the decline in insulin sensitivity, both 1st- and 2nd-phase insulin secretion progressively declined (both $p < 0.001$) over the entire spectrum, as well as within non-diagnostic 1-hr OGTT values. Moreover, a linear reduction in ISSI was apparent (G1: 8950, G2: 6866, G3: 5619, G4: 4607, and G5: 3524; $p<0.001$). Of note, even within non-diagnostic 1-hr OGTT values ISSI declined by 48.5% ($p<0.001$). Even when analysis was restricted to groups G1 - G3 with low GDM prevalence, the progressive nature of defects in insulin secretion (1st-phase: -10.9%; 2nd-phase: -8.6%), insulin sensitivity (ISI: -19.1%) was apparent accounting for a -40.2% reduction in ISSI (all $p<0.01$).

Conclusion: These results suggest, that in pregnant women, insulin secretion and insulin sensitivity progressively worsened on the basis of 1-hr glucose concentrations after a 100-g OGTT. Of note, a marked reduction in ISSI was already apparent even within non-diagnostic 1-hr OGTT values, suggesting

that loss of glucose homeostasis is an early and continuous process. These results should draw attention to the need for better understanding of the risk associated to increased maternal glycemia even in pregnancies considered metabolically normal.

Indices of beta cell function and insulin sensitivity in normal pregnancy

E. Qvigstad¹, N. Voldner², K.F. Frøslie³, C.M. Hoff², K. Godang¹, T. Henriksen², J. Bollerslev¹

¹Department of Endocrinology, Rikshospitalet University Hospital,

²Department of Gynecology and Obstetrics, Rikshospitalet University Hospital, ³Department of Statistics, University of Oslo, Norway

Background and aims: Gestational diabetes (GDM) is associated with increased risk of maternal and fetal morbidity and complications on short and long term perspective. The increasing incidence of obesity in fertile age influences insulin sensitivity and places extra demands on beta-cell function during pregnancy. The STORK-study follows healthy pregnant Norwegian women to investigate effects of metabolism, anthropometry, nutrition and physical activity on pregnancy outcome and complications.

Materials and methods: Inclusions were done in week 14-16, n=553. Oral glucose tolerance tests (OGTT) were performed at week 14-16 and 30-32, paralleled by anthropometry and obstetric data.

Results: Age 31.2 ± 1.2 years (mean ± SD), weight gain 10.6 ± 3.8 kg. 1.9 % had early onset GDM (GDM1) at week 14-16 and 10.6 % at week 30-32 (GDM2). The participants were stratified according to the OGTT results.

BMI, β cell function and insulin sensitivity indices, median (25th; 75th quartiles).

	NGT (n=460)	GDM1 (n=11)	GDM2 (n=49)
BMI (kg/m ²)	24,1 (22,0; 26,4)	28,3 (25,1;30,5)*	26,1 (22,0;28,8)
Insulin resistance week 14-16 (HOMA-IR)	5,0 (3,3;7,2)	10,7 (6,5;19,2)	7,1 (4,8;10,5)*
Insulin resistance week 30-32 (HOMA-IR)	8,1 (5,2;11,9)	13,8 (7,5;23,5)*	11,4 (8,3;16,2)*
Beta-cell function week 14-16 (HOMA-B)	807 (504;1464)	977 (600;1487)	874 (624;1233)
Beta-cell function week 30-32 (HOMA-B)	952 (640;1505)	682 (623;1692)	877 (693;1554)
Fasting insulin sensitivity (Quicki) week 14-16	0,49 (0,45;0,53)	0,44 (0,38;0,46)*	0,45 (0,42;0,49)*
Fasting insulin sensitivity (Quicki) week 30-32	0,44 (0,41;0,48)	0,40 (0,37;0,45)	0,42 (0,39;0,44)
Dynamic insulin sensitivity (OGIS) week 14-16	533 (485;593)	405 (313;429)*§	472 (433;524)*
Dynamic insulin sensitivity (OGIS) week 30-32	433 (388;486)	422 (383;466)	443 (405;487)
Kruska-Wallis test	* $p<0.01$ for difference vs NGT	§ $p<0.01$ for difference vs GDM2	Bonferroni correction for multiple tests.

Subdivision of OGTT groups by BMI demonstrated a preponderance of overweight (BMI > 25) in glucose intolerant states (NGT 38%, GDM2 58% and GDM1 82% respectively, Chi-squared test, $p<0.005$). OGIS decreased by 21 and 10% respectively in week 14-16 in overweight GDM1 and GDM2 ($p<0.01$ for comparison with NGT). At week 30-32 HOMA-IR increased by 32% in overweight GDM2 ($p<0.01$ vs NGT), and basal beta-cell function decreased by 7% in GDM2 vs NGT, $p<0.01$. Similar effects were not found in individuals with BMI ≤25.

Conclusion: In this prospective study of normal pregnancies, BMI was increased in individuals with GDM1, insulin sensitivity indices decreased early in pregnancy, but the increase in insulin resistance was a later event. In GDM2 we found similar effects on insulin sensitivity. For individuals with overweight, the GDM rates were significantly increased, and the deterioration of indices of insulin sensitivity and later beta-cell function in this group exposes maternal and fetal metabolism for an increased risk of morbidity and complications.

Deoxyfructosyl haemoglobin (beta) values in normal and gestational diabetic pregnancy

E. Anastasiou¹, K. Economou¹, G. Papageorgiou¹, M. Alevizaki¹, L. Spanou², I. Drakopoulos², K. Makris²

¹1st Endocrine Section - Diabetes Center, Alexandra Hospital, ²Clinical Biochemistry Department, KAT General Hospital, Athens, Greece

Background and aims: According to the work of the National Glycohemoglobin Standardisation Program the current HbA1c assay has been harmonised on reference methods that measure a mixture of glycated haemoglobins. The International Federation of Clinical Chemistry (IFCC) has recently approved a reference method for HbA1c that specifically measures the concentration of only one molecular species of HbA1c. A new name, deoxyfructosyl haemoglobin (beta) (DOFH) and measurement units (mmol/mol) were proposed to replace HbA1c (%). DOFH represents the fraction of the b-chains of hemoglobin that has a stable hexose adduct on the N-terminal amino acid valine. The aim of the study is (i) to examine the relationship of DOFH values with the traditional HbA1c measurements in pregnant women who underwent an OGTT and (ii) to relate the levels of DOFH values with the glucemic status of pregnant women.

Materials and methods: In 181 successive pregnant women, at the third trimester of pregnancy, who underwent an OGTT-100g, blood samples were collected for HbA1c and DOFH measurements. HbA1c was measured by an HPLC (HA8160 Menarini-Arkray), while DOFH was measured in another lab, also using an HPLC (HA8160 Menarini-Arkray) which was calibrated and traceable to the IFCC reference method. Pregnant women were divided into four groups, according to OGTT glucose values (ADA criteria) and the way of treatment, once diagnosed as Gestational Diabetes (GDM): (i) Normals, (ii) One Abnormal Glucose Value, (iii) GDM treated with Diet (GDM-D) and (iv) GDM treated with diet and Insulin (GDM-I).

Results: A very strong correlation was observed, between HbA1c (y) measured by the DCCT calibrated HPLC and HbA1c (x) calculated from DOFH which was measured by the IFCC calibrated instrument ($y=1.0218x-0.3124$, $r=0.935$, $p<0.001$). The DOFH values of the four groups are shown in the table. A positive correlation was observed between DOFH values and fasting glucose in the OGTT ($r=0.47$, $p<0.001$). Correlations with glucose values at 60, 120 and 180min were also positive but weaker.

Conclusion: The excellent correlation which was found between HbA1c (measured by the DCCT calibrated instrument) and HbA1c (calculated from DOFH), proves that both calibrations in instruments used in everyday practice can produce comparable results, although adoption of a new name and new measurement units requires education of both patients and health care providers. A further interesting finding of this study was that the DOFH values of pregnant women with one abnormal glucose value in the OGTT are similar to those of GDM women, an indirect indication that this group may need further attention, such as diet instructions.

DOFH Values Results

Groups	N	Gest. Age (Weeks)	Age (Years)	BMI (kg/m ²)	DOFH (mmol/mol)

The impact of recurrence of gestational diabetes (GDM) on glucose metabolism and subclinical inflammation

Y. Winhofer¹, A. Tura², T. Prikoszovich¹, A. Luger¹, G. Pacini², A. Kautzky-Willer¹

¹Department of Internal Medicine 3, Division of Endocrinology and Metabolism, Medical University of Vienna, Austria, ²National Research Council, Metabolic Modeling Unit, Institute of Biomedical Engineering, Padova, Italy.

Background and aims: GDM is often associated with obesity and subclinical inflammation and a major risk factor for the development of type 2 diabetes. When women do not regain normal glucose tolerance after delivery it

is unclear, whether impaired glucose tolerance (IGT) or even type 2 diabetes already existed at pregestational state or they were caused by GDM itself. Therefore we aimed to compare parameters of glucose metabolism and subclinical inflammation before pregnancy (bP), during pregnancy (P) and postpartum (pp) in women with recurrence of GDM.

Materials and methods: Women with prior gestational diabetes (pGDM, n=25) who participated in a prospective longitudinal observational study (Viennese Post Gestational Diabetes Project) and had recurrence of GDM in a subsequent pregnancy were included in this study. They were annually tested by an oral glucose tolerance test (oGTT), underwent an oGTT at 24 gestational weeks during pregnancy (P) as well as 4 months postpartum (pp). Follow-up data of the last examination prior to subsequent pregnancy served as pregestational data (bP). Metabolic parameters derived from plasma concentrations of glucose, insulin and C-peptide during oGTT (i.e. OGIS=insulin sensitivity; HIE=hepatic insulin extraction), Leptin as well as markers of subclinical inflammation (CRP, usCRP and IL-6) were assessed at all time points.

Results: Pregnancy was associated with a significant increase in areas under the curve (AUC) of glucose (+67%; $p<0.0001$), insulin (+42%; $p=0.03$) and C-peptide (+22%; $p=0.03$) under dynamic conditions while basal plasma concentrations did not rise significantly. Pregnancy induced insulin resistance was confirmed by a decrease of OGIS (bP: 407±91; P: 355±63, pp: 419±98 ml/min²; $p=0.0025$), but not HOMA-R. Hepatic insulin extraction (HIE) was decreased, resulting in a higher amount of insulin reaching the peripheral circulation (HIE: bP: 68±13; P: 62±10, pp: 69±10%; $p=0.04$). Disposition Index (OGIS^{dyn}·AUC_{insulin}), which characterizes the ability for compensating peripheral insulin resistance by modulating insulin release into systemic circulation, also increased during pregnancy (bP: 21±9; P: 27±8; pp: 20±8 nmol/m³; $p=0.03$). After pregnancy all parameters declined to values not different from those of pre-pregnancy, with the exception of BMI (bP: 28±7; pp: 29±6) and leptin (bP: 19,2±11,6; P: 31,2±13,3; pp: 24,6±15,5 ng/ml) which remained increased (both $p=0.03$). usCRP, but not CRP or IL-6, increased during pregnancy ($p=0.02$) and did not reach the pregestational value after delivery (bP: 0,51±0,53; P: 0,69±0,45; pp: 0,61±0,77; $p=0.02$).

Conclusion: Since the metabolic parameters that changed during pregnancy in pGDM returned to the pregestational state within 4 months after delivery, we conclude, that pregnancy itself does not alter the natural course of the development of diabetes after GDM. On the other hand, because BMI and leptin, as marker of body fat content, remained increased after pregnancy, regulation of bodyweight and postpartum weight retention seem to be the major problems for long-term maintenance of normal glucose tolerance in pGDM.

1144

Association of plasma individual NEFA with insulin sensitivity and /or insulin secretion in Bangladeshi GDM women

S. Murshed¹, M. Khatun², M. Rahman¹, S. Akter¹, T.A. Chowdhury², A.K. Azad Khan³, L. Ali¹

¹Dept of Biochemistry & Cell Biology, BIRDEM, ²Obstetrics and Gynecology, BIRDEM, ³Dept of Gastroenterology, Diabetic Association of Bangladesh, Dhaka, Bangladesh

Background and aims: GDM is associated with elevated NEFA and insulin resistance, but the causal relationship between the two events is not yet established. Recently association of reduced membrane omega-6 and omega-3 fatty acid with GDM has been reported in British and Korean population. The aim of the present study was to explore the relationship between plasma individual NEFA with insulin sensitivity and/or insulin secretion in Bangladeshi GDM women during 24-28 weeks of gestation (2nd trimester) and 29-36 wks of gestation (3rd trimester).

Materials and methods: A prospective study was performed with a total of 73 pregnant women. Among them 37 pregnant women with gestational diabetes mellitus (GDM) and 36 age and BMI matched nondiabetic healthy controls were collected from various hospitals during 24-28 wks of gestation (2nd tr) and asked for a 2nd visit during their 29-36 wks of gestation (3rd tr). Fasting Serum glucose, C-peptide, lipid profile, total NEFA were estimated by enzymatic-colorimetric method, HbA_{1c} was measured by HPLC method and individual NEFA were measured by gas chromatography.

Results: During 3rd tr HOMA S (%) in GDM [Median (range); 41.60 (14.60-91)] was significantly decreased ($p<0.006$) than in control [58.45 (12.30-92.20)]. Serum TG (mg/dl) were significantly increased ($p<0.001$) during 2nd and 3rd tr in GDM (Mean±SD; 222.65±16.36 and 255.24±9.69 respectively) than in control (189.47±3.22 and 237.86±18.45 respectively). Total NEFA

(mmol/l) was significantly increased ($p<0.001$) in GDM (0.99 ± 0.17) compared to control (0.82 ± 0.25) during 3rd tr. Only plasma stearic acid (%) in GDM was significantly increased ($p<0.001$) during 3rd tr (30.17 ± 5.54) compared to 2nd tr (24.17 ± 5.41). MUFA, palmitoleic acid, oleic acid were significantly decreased ($p<0.001$, 0.01 and 0.001 respectively) in GDM during 3rd tr (14.24 ± 3.93 , 2.06 ± 0.86 and 11.70 ± 5.16 respectively) compared to 2nd tr (25.04 ± 5.14 , 2.76 ± 0.37 and 20.53 ± 6.07 respectively). Among polyunsaturated fatty acids, arachidonic acid and docosahexaenoic acid were significantly decreased ($p<0.001$) in GDM at 3rd tr (2.20 ± 0.09 and 0.45 ± 0.25 respectively) compared to 2nd tr (2.90 ± 0.68 and 0.82 ± 0.10 respectively). During 2nd tr, arachidonic acid in GDM was positively correlated ($r=0.53$, $p=0.04$) with HOMA B. During 3rd tr, eicosapentaenoic acid in GDM was inversely correlated ($r=-0.52$, $p=0.05$) and in control directly correlated ($r=0.57$, $p=0.02$) with HOMA B. During 2nd tr, eicosadienoic acid in GDM was positively correlated ($r=0.69$, $p=0.00$) with HOMA S. During 3rd tr, linoleic acid, linolenic acid, PUFA and $\omega 6$ FA in GDM were inversely correlated ($r=-0.66$, $p=0.01$; $r=-0.66$, $p=0.01$ and $r=-0.65$, $p=0.01$ respectively) and eicosadienoic acid eicosapentaenoic acid were directly correlated ($r=0.54$, $p=0.04$ and $r=0.60$, $p=0.02$) with HOMA S.

Conclusion: The data suggest that GDM is associated with hypersecretion of insulin which may be positively modulated by arachidonic acid and negatively modulated by eicosapentaenoic acid. GDM is also associated with decreased insulin sensitivity which may be positively modulated by eicosadienoic acid, eicosapentaenoic acid and negatively modulated by linoleic acid, linolenic acid, total PUFA and $\omega 6$ fatty acids.

Influence of pre-pregnancy body mass index, physical activity and dietary habits on glucose tolerance during pregnancy

A. Bertolotto, L. Volpe, S. Vignali, A. Calianno, M. Pugliese, C. Lencioni, M. Corfini, V. Resi, L. Benzi, G. Di Cianni
Endocrinology-Metabolism, University of Pisa, Italy

Background and aims: Abnormal glucose tolerance (AGT) during pregnancy, including all conditions from minor degree of glucose tolerance to overt gestational diabetes, increases the risk of maternal morbidity and adverse pregnancy outcome. Pre-pregnancy over-weight and obesity are considered the most important risk factors for AGT. To date, other factors that may influence glucose tolerance during pregnancy, such as physical activity and dietary habits are not considered as risk factors for AGT. The aim of the present study is to investigate the relative contribution of physical activity, dietary habits, pre-pregnancy body mass index (BMI) and other traditional risk factors on glucose tolerance during pregnancy.

Materials and methods: A 1-hr 50-g Glucose Challenge Test (GCT) was performed at 27 ± 6.9 week of gestation in a cohort of pregnant women. On the morning of the test, demographic, anthropometric and clinical data (age, family history of diabetes, obstetric history and pre-pregnancy BMI) were recorded. To assess physical activity, women were invited to fill the short form of the International Physical Activity Questionnaire (IPAQ) and we calculated the average amount of time per week spent during 7 days before the test (MET h/week). Moreover, to evaluate dietary habits, all women answered to a food frequency questionnaire; the energy intake and dietary nutrient content were calculated by a computerized program (MetaDieta*).

Results: We studied 268 pregnant women (age 33.3 ± 4 years; primiparous 58%; positive family history of diabetes mellitus 13%; pre-pregnancy BMI 22.6 ± 3.8 Kg/m²; weight gain 8 ± 3.7 Kg). The mean physical activity was 18.5 ± 14.8 MET h/week and the mean daily energy intake of the cohort was 2145 ± 395 Kcal (carbohydrates 48%, total fats 36%, proteins 16%, cholesterol intake 243 ± 82 mg/d and fibres 19.5 ± 5.7 g/d). Women with GCT positive (GCT+: glycaemia ≥ 140 mg/dl) were 105 (39%) and GCT negative (GCT-) 163 (61%). No difference between these two groups resulted in demographic and clinical data, excluding pre-pregnancy BMI (GCT+ 23.5 ± 4 Kg/m² vs GCT- 22 ± 3.6 Kg/m², $p=0.02$) and weight gain (GCT+ 8.5 ± 4.3 vs GCT- 7.6 ± 3.3 Kg, $p=0.03$). GCT+ was observed in 54% of overweight/obese (BMI ≥ 25 kg/m²) and 36.8% of normal weight (BMI <25 kg/m²) ($p<0.002$). All parameters referring to physical activity energy and diet (Kcal and diet components) were not statistically different between GCT+ and GCT- groups. In joint analyses of BMI and physical activity, we divided the population into 4 groups: normal weight active (MET h/week ≥ 20) and inactive (MET h/week <3) and overweight/obese active and inactive; we didn't observe any difference about 1-hr glucose values and GCT+ prevalence among the 4 groups. Finally, after a multivariate analyses including pre-pregnancy BMI, weight

gain, MET h/week and Kcal/day, only pre-pregnancy BMI (F-value 9.264 $p=0.002$) resulted an independent predictor of 1-hr plasma glucose.

Conclusion: Our study confirms the importance of pre-pregnancy BMI as a risk factor for abnormal glucose tolerance during pregnancy. Although physical activity and diet are both well known factors to prevent glucose intolerance in general population, their contribution during pregnancy should be better evaluated.

1146

Comparability of an European guideline and American Diabetes Association protocol in identifying high risk patients for gestational diabetes

L. Varadhan¹, S. Bikmalla¹, D. Radford^{2,3}, D. Barton^{1,4}

¹Department of Diabetes and Endocrinology, Princess Royal Hospital NHS, Telford, ²Obstetrics and Gynaecology, Princess Royal Hospital NHS, Telford, United Kingdom, ³Obstetrics and Gynaecology, Royal Shrewsbury Hospital NHS, ⁴Department of Diabetes and Endocrinology, Royal Shrewsbury Hospital NHS, United Kingdom

Background and aims: Gestational diabetes (GDM) complicates about 4% of all pregnancies in the UK. Screening for this condition is essential in high risk patients. The recent NICE guidelines (National Institute of Clinical Excellence) released in March 2008 recommends screening of pregnant women at 24-28 weeks, only if they have one of the risk factors-BMI >30 kg/m², previous macrosomia >4.5 kg, previous GDM, family history of diabetes or belonging to an ethnic group with high risk of diabetes. This guideline does not recommend using age as a factor as this would involve most pregnant patients. However the American Diabetes Association(ADA) guidelines suggest screening all pregnancies unless they have all of the following low risk features-Age <25 , pre pregnancy weight normal, belonging to an ethnic group with low prevalence of diabetes, no family history, no history of abnormal glucose tolerance in past and no history of poor obstetric outcome. The aim of our study was to assess the comparability of the NICE and ADA criteria in risk-stratifying patients to subject to GTT, based on phenotypes of GDM patients at our hospital

Materials and methods: We conducted a retrospective analysis of case notes of all patients diagnosed and treated as GDM in the previous three years. The hospital protocol was to subject all pregnant women with glycosuria on more than 2 occasions to a random plasma glucose testing. Patients with values ≥ 6.5 mmol/L were then subjected to a standard 75gm GTT with plasma glucose taken at 0,1 and 2 hours. GTT was done ideally at 24-28 weeks, but earlier if risk factors existed. GDM was diagnosed based on WHO criteria (1999) if fasting plasma glucose(FPG) ≥ 7 mmol/L and/or 2h post glucose(2h PG) ≥ 7.8 mmol/L. Comparative analysis was then made on the ability of the NICE and the ADA criteria to risk predict these patients.

Results: 172 patients were diagnosed with GDM in the past 3 years. Based on the NICE guidelines, 144 patients (83.7%) had at least one risk factor for GDM, 83% of whom had more than one risk factor. Twenty eight patients (16.3%) did not have any risk factors at all, and could have been missed if the screening was based on the current guideline. The sensitivity of the NICE risk assessment guideline was 83.7%. Screening based on ADA guidelines would have missed only 4 / 172 patients, this being more comprehensive due to the inclusion of age criteria. The sensitivity of the ADA risk assessment guideline was 97.7%. However if the ADA guidelines for diagnosis of GDM had been used on these patients (FPG ≥ 5.3 mmol/L, 1hr PG ≥ 10 mmol/L, 2h PG ≥ 8.6 mmol/L, 2 of these values being positive), the sensitivity will reduce significantly to 50.6%

Conclusion: The ADA guidelines are more sensitive in stratifying risk for GDM than the current NICE recommendations. This would proportionately increase the number of pregnant women undergoing GTT done. However this approach would be beneficial in decreasing morbidity perinatally due to fetal macrosomia and would potentially identify patients at risk of development of future diabetes or gestational diabetes.

PS 109 Gestational diabetes: outcomes

1147

Pregnancy outcomes in metformin-treated women with gestational diabetes

J. Balani, S. Hyer, A. Rodin, H. Shehata

Diabetes, St Helier University Hospital, Surrey, United Kingdom

Background: Preliminary evidence from on-going prospective studies suggests that Metformin may offer advantages over insulin in the management of gestational diabetes.

Objective: To compare maternal and neonatal outcomes in women with gestational diabetes treated in our institution with either Metformin or insulin

Methods: We prospectively studied 100 consecutive women with gestational diabetes attending our Diabetes Antenatal clinic who were not adequately controlled by dietary measures. They were treated with Metformin 500mg bd and the dose was titrated up to a maximum of 2500mg/day to achieve target home blood glucose monitoring values (fasting <6mmol/l, 1h post-prandial <8mmol/l, 2h post prandial <7mmol/l). 11 women stopped taking Metformin (intolerance in 4, refusal to continue in 7) and 9 required additional insulin. Pregnancy outcomes in the 80 women who remained exclusively on Metformin until delivery were compared with a cohort of 80 women with gestational diabetes attending our clinic, matched for BMI and ethnicity, who were treated with basal-bolus human insulin.

Results: Women treated with Metformin gained less weight compared with the insulin group (mean (SEM) weight gain (kg): 0.3 ± 0.03 v 1.4 ± 0.15 ; $p < 0.01$). There were no significant differences in the occurrence of hypertension or pre-eclampsia. Neonatal morbidity was significantly improved in the Metformin group with less prematurity (0% v 11%; $p < 0.01$), less jaundice (9% v 43%; $p < 0.01$) and fewer admissions to the neonatal unit (5% v 19%; $p < 0.01$). No significant differences were found in the rate of Caesarean delivery, birth weight, number of babies with macrosomia, incidence of shoulder dystocia, congenital malformations or abnormalities in the post-natal glucose tolerance test.

Conclusion: These findings, taken together with accumulating evidence from larger trials, suggest that Metformin is beneficial in the management of gestational diabetes and may offer advantages over insulin.

1148

Glycaemic control during labour in gestational diabetes: easy management with fair outcomes

J.A. Flores, J.J. Chillarón, J. Puig, M. Fernández Miró, D. Benaiges, M. Prados, J.F. Cano

Endocrinology, Hospital del Mar, Barcelona, Spain

Background and aims: Several studies in patients with type 1 diabetes have demonstrated the importance of tight glycaemic control during labour on the development of neonatal hypoglycemia. Nevertheless, few studies have evaluated the importance of intrapartum glycaemic control in patients with gestational diabetes (GDM) and simple guidelines for its management are needed. The aims of our study were to evaluate metabolic control during labour using a simple protocol in women with GDM and to assess the impact of maternal factors during labour on the development of neonatal hypoglycemia.

Materials and methods: A prospective study was carried out in patients with GDM admitted for delivery between October 2006 and October 2007. A new protocol for glycaemic control during labour was applied which included iv glucose and insulin infusions. Capillary blood glucose (CBG) and ketone were monitored every 2 hours. Glucose infusion was adjusted according to fasting hours and development of ketosis. Insulin infusion was started if CBG was >130mg/dl. Ketosis was defined as ketonemia >0.5 nmol/l. Newborn management included serial CBG measurements during the first 24 hours of life. Hypoglycemia was defined as a CBG < 35mg/dl for term babies of appropriated weight and <20mg/dl for preterm babies or small for gestational age (SGA).

Results: 73 women with GDM were included, with an average age of 31 ± 5.3 years, a pre-gestational BMI of 27.5 ± 5 , 47.1% were nuliparus, and 18% had previous GDM. 35% required insulin treatment during pregnancy. Gestational age at delivery was 39.06 ± 1.67 weeks. Delivery was induced in 36% and 35% underwent caesarean section. Mean CBG during labour was $99.3 \pm$

23.6 mg/dl and 14.7% required insulin infusion (average dose 2.2 u/hour). 16.6% developed minor ketosis (mean ketonemia 0.83 ± 0.57 nmol/l) which was corrected in less than four hours. There were no maternal hypoglycemic episodes. Mean newborn weight was 3372 ± 537 gr, 8% were macrosomic and 7% SGA. The incidence of neonatal hypoglycemia was 5.8%. Development of neonatal hypoglycemia was unrelated to all maternal variables studied (mean CBG, maximal CBG, insulin use or dose, ketosis).

Conclusion: The use of a simple intrapartum management protocol achieved a satisfactory level of metabolic control, with only 15% of patients requiring insulin infusion. Further, there were no maternal hypoglycemic episodes and the incidence of minor ketosis was low. The incidence of neonatal hypoglycemia was 5.8% and it was unrelated to glycaemic control during labour and to other maternal variables studied.

1149

Obesity and caesarean delivery in gestational diabetes mellitus

B. Barquiel, L. Herranz, P. Martín-Vaquero, I. Castro, J.A. Rosado, L.F. Pallardo

Department of Diabetes, Hospital Universitario La Paz, Madrid, Spain

Background and aims: Gestational diabetes mellitus (GDM) is associated with a higher incidence of Caesarean Delivery (CD). We aimed to assess the relative effect of obesity and glycaemic control on CD in women with GDM.

Materials and methods: Retrospective cohort study. A total of 1960 GDM patients were included during a follow-up period from 1987 through 2006 in the Diabetes Department. Their mean age was 33 ± 4 years old, their mean prepregnancy BMI 24.8 ± 4.7 kg/m² and their mean gestational age at delivery 38.8 ± 1.1 weeks. Obesity was considered as a BMI ≥ 30 kg/m². Good glycaemic control was defined as A1C < 5.4% during the third trimester of pregnancy (this cut-off value corresponded to the p_{70} of the A1C distribution of the sample). We compared the CD rate among non-obese and obese women, and between women with good and poor glycaemic control. X² test was used for statistical analysis. Subjects were divided by pregravid BMI into normal (BMI < 25 kg/m²), overweight (BMI 25-30 kg/m²) and obese subgroups. Logistic regression analysis was run to determine the risk of CD in overweight and obese compared to normal prepregnancy BMI. For CD, Attributable Risk Percent (AR%) in overweight and obese women was calculated. This parameter estimates the excess of CDs that could be explained by overweight and obesity among GDM women exposed to these respective risk factors.

Results: 236 (12%) women were obese and 584 (29.8%) had poor glycaemic control. Prevalence of CD was 22.1%. The CD rate was higher in obese diabetic women compared to non-obese (32.6% vs 20.6%, $p = 0.000$). In contrast, CD was no different between poor and good glycaemic control groups (23.7% vs 21.4%, $p = 0.263$). For the subgroups defined, we found an enhanced CD risk in overweight [OR 1.61 (CI 95%: 1.26 - 2.07)] and in obese [OR 2.03 (CI 95%: 1.49 - 2.77)] compared to normal-weight women ($p = 0.000$). The CD AR% was 38.0% for being overweight and 50.8% for obesity.

Conclusion: In women with GDM, poor glycaemic control is not associated with a higher CD rate. Pregravid BMI is confirmed as a risk factor for CD, with an enhanced impact as prepregnancy BMI increases. In conclusion, overweight and obesity but not glycaemic control could explain the higher CD rate in GDM.

1150

Pregnancies in prediabetic women

U. Moll¹, M. Landin-Olsson¹, H. Olsson²

¹Department of Endocrinology, ²Department of Oncology, Institution of Clinical Science, Lund University, Sweden

Background and aims: Diabetes that occurs during pregnancy (gestational diabetes) can result in diabetic fetopathy, which is characterized by high birth weight and various postnatal complications. Elevated blood glucose during early pregnancy can lead to malformations and miscarriage. For the mother there is also an increased risk of developing type 2 diabetes later in life. We have studied characteristics during pregnancy in women who later in life developed diabetes.

Materials and methods: The Swedish birth registry (Medicinska föderseregistret MFR) started 1973 and contains data of the health of the mothers during pregnancy and peri- and postnatal status of the babies. In a population based large cohort study including 23 524 women aged 35-75 yrs from the southern part of Sweden we have identified 802 women with diabetes. In the

MFR we identified 30 559 pregnancies related to the women in our cohort. By merging data from the Swedish birth registry and this cohort we have studied if pregnancies of diabetic women, women developing diabetes later in life (after their pregnancy) and women without diabetes differ from each other.

Results: In MFR we found that 110/30559 (0, 4%) pregnancies of the women in the cohort was complicated by diabetes. Among the women who later developed diabetes we found that they had a higher weight (70, 2 vs. 63, 2 kg $p<0,001$) at the beginning of the pregnancy and a higher weight at delivery (82, 7, vs. 76,1 kg $p<0,001$) but they had less weight-gain (12, 9 vs. 14, 1 kg, $p=0,005$) during pregnancy than non-diabetic women. The weight gain of the “prediabetic” women was negative correlated to the pre-pregnancy weight. No correlation was found in the other studygroups. The babies of the “prediabetic” women had a higher birth weight (3624 vs. 3506 g $p<0,001$) and were more often large for gestational age, LGA. They also had a lower Apgar score after 1 minute (8, 7 vs. 8, 9 $p=0,001$).

Conclusion: The pregnancies of “prediabetic” women differ regarding weight and weight gain during pregnancy. These women gave birth to larger babies, the deliveries were more complicated and the children had lower Apgar-score at 1 minute compared to non-diabetic pregnancies.

The cases of “prediabetic” pregnancies in this study are most likely undiagnosed cases of gestational diabetes, since the frequency of gestational diabetes in the study is low. Better diagnostics and better care of the women with gestational diabetes would probably improve pregnancy outcome in these cases.

1151

Correlates of postpartum glucose testing after gestational diabetes mellitus in 14,486 racially/ethnically diverse women, 1999–2006

J.M. Lawrence¹, J. Liu¹, W. Chen¹, D.A. Sacks²

¹Research & Evaluation, Kaiser Permanente, Pasadena, ²Obstetrics & Gynecology, Kaiser Permanente, Bellflower, United States

Background and aims: While glucose testing is recommended at 6–12 weeks postpartum (PP) after gestational diabetes mellitus (GDM), data on the correlates of PP glucose testing in large diverse populations are limited. The aim of this study was to examine the prevalence and correlates of PP glucose testing from hospital discharge to 6 months PP.

Materials and methods: From 1999–2006, there were 14,486 singleton births to women with GDM based on the 100-g OGTT results using ADA criteria in a large managed care organization with GDM prevalence of 7.1–8.2/100 per year. Data were obtained from birth certificate (maternal/infant characteristics), pharmacy (GDM treatment; insulin or glyburide vs. neither), and laboratory (PP testing by fasting plasma glucose [FPG] test or a 75-g 2-hour OGTT) databases. Adjusted ORs and 95% CI were calculated using multiple logistic regression analysis for the outcome glucose testing (yes/no).

Results: Of 14,486 women (age 31.8 ± 5.5 years), 49.5% ($n=7,165$) had PP glucose testing from discharge–6 months (87% FPG, 13% OGTT) and 23.4% ($n=3,393$) were tested from 6–12 weeks PP (82% FPG, 18% OGTT). Mean and median # of days to testing were 53 and 42, respectively. After adjusting for the 11 delivery medical centers, age, race/ethnicity, parity, GDM treatment, any health care visit from discharge–6 months, mode of delivery, infant birthweight (BW), and year of delivery were associated with PP testing (all $p<0.0001$ except BW, $p<0.05$) while maternal education, household income, and gestational age at delivery were not. Women age 34–39 (3,629) and ≥ 40 years (1,137) were more than twice as likely to be tested as women 20–24 years (1,166); 13–19 year olds (186) were 45% less likely to be tested. Asian and Pacific Islander women (2,790) were 29% more likely (aOR 1.29; 1.14–1.50) and Hispanic women (7,623) were 19% more likely (aOR 1.19; 1.08–1.32) to be tested compared with non-Hispanic White (NHW) women (2,982), while Black women (930) and other women (161) did not differ from NHWs. Compared to primiparas, women with one (aOR 0.82; 0.74–0.90) and ≥ 2 two previous deliveries (aOR 0.67; 0.60–0.74) were less likely to be tested. Women treated with insulin or glyburide while pregnant (24% of sample) were 23% more likely to be tested (aOR 1.23, 1.12–1.36) than those who were not. Women without a health care visit (25% of sample) in the 6-months after delivery were 60% less likely to be tested; those with a cesarean delivery were 16% less likely to be tested than those with a vaginal birth; and women whose infant weighed < 2500 g were 15% less likely to be tested than those with infants 2500–3999g; testing did not differ for mothers of macrosomic (>4000 g) infants, which constituted 12% of these births. Women giving birth in 2006 being 3.84 (CI 3.26–4.53) times more likely to be tested than in 1999; 34% were tested in 1999 vs. 53% in 2006. Of the women with PP glucose test results available (7,014), 0.9% (61) had diabetes (DM) and 12.6% (881) had pre-DM based on ADA criteria.

Conclusion: Women at higher risk for DM, including minority women, older women, and those requiring pharmacological treatment for GDM, were more likely to be tested, although many were tested outside the 6–12 week window. As type 2 DM is being diagnosed at younger ages and among women in all racial/ethnic groups, it has become increasingly important to conduct PP glucose testing to identify women with DM or pre-DM after a GDM pregnancy. Glucose tolerance at follow up in women with previous gestational diabetes with or without metabolic syndrome

T. Prikoszovich¹, G. Pacini², A. Tura², O. Wagner³, C. Winzer¹, A. Luger⁴, A. Kautzky-Willer⁴

¹Department of Internal Medicine III, Division of Nephrology and Metabolism, Medical University of Vienna, Austria, ²Institute of Biomedical Engineering, CNR, Padova, Italy, ³Department of Medical and Chemical Laboratory Diagnostics, Medical University of Vienna, Austria, ⁴Department of Internal Medicine III, Division of Endocrinology and Metabolism, Medical University of Vienna, Austria

Background and aims: Gestational Diabetes (GDM) is characterized by impaired glucose metabolism during pregnancy. After pregnancy these women do not completely normalise their metabolism and maintain an increased risk of later maternal Type 2 diabetes mellitus (T2DM) and vascular disease.

Materials and methods: We investigated 119 women (Age: 33.76 ± 0.73 yrs, BMI: 27.65 ± 0.52 kg/m²) with a history of gestational diabetes (pGDM) 3 months after delivery with an intravenous (FSIGT) and an oral glucose tolerance test (75g-oGTT, 3h) and reinvestigated them annually up to 5 yrs post partum with an oGTT to evaluate their glucose tolerance. Furthermore parameters of endothelial dysfunction were evaluated. We defined the subgroup of women showing the metabolic syndrome (MS) according to WHO criteria early after delivery. Insulin resistance (Insulin sensitivity SI < 0.85 , hypertriglyceridemia (≥ 150 mg/dl), low HDL-cholesterol (< 39 mg/dl), high blood pressure ($\geq 140/90$ mmHg) and impaired glucose metabolism (IFG, IGT, T2DM) as well as microalbuminuria (Albumin to creatinine ratio: 30 mg/g) characterized the women with a MS.

Results: According to the WHO-criteria we identified 42 pGDM (35%) with a metabolic syndrome (MS) at baseline. 90% of pGDM with MS already had impaired glucose metabolism 3 months after pregnancy, but no pGDM without MS ($p<0.0001$). Women with MS were older, had elevated concentrations of inflammation parameters (sCRP: $p<0.01$, PAI-1: $p<0.0001$) and higher levels of circulating adhesion molecules (ELAM: $p=0.04$, ICAM-1: $p<0.05$), leptin ($p=0.008$) and lower concentration of adiponectin ($p<0.008$) compared to pGDM without MS. pGDM with MS also developed or retained impaired glucose metabolism at the follow-up visits more frequently than those without metabolic syndrome at baseline (69% vs. 31%; $p<0.0001$). pGDM with MS showed a nearly 5-fold higher risk to develop diabetes or retain impaired glucose metabolism (OR: 4.9 [2.2–11.1]; $p<0.0001$).

Conclusion: Women with a history of gestational diabetes who feature the metabolic syndrome (WHO) early after delivery are at a very high risk to develop overt diabetes or retain impaired glucose metabolism five years after delivery and to develop cardiovascular disease.

1153

Postpartum reversibility of impaired incretin effect in patients with gestational diabetes mellitus

M. Kosinski¹, F.K. Knop^{2,3}, K. Cypryk¹, J.J. Holst³, T. Vilsbøll²

¹Department of Endocrinology and Metabolic Diseases, Polish Mother's Memorial Hospital, Lodz, Poland, ²Department of Internal Medicine, Gentofte Hospital, Copenhagen, Denmark, ³University of Copenhagen, Department of Biomedical Sciences, Denmark

Background and aims: The incretin effect accounts for approximately 50–60% of the beta-cell secretory response (as assessed by C-peptide responses) following oral ingestion of glucose in healthy individuals. The incretin effect is severely reduced in patients with diabetes mellitus (DM).

Materials and methods: To establish the reversibility of this pathophysiological phenomenon we investigated 13 women with gestational diabetes mellitus (GDM); fasting plasma glucose (FPG): 5.0 (3.6–6.4) mM (mean (range)); HbA_{1c}: 5.4 (5.3–5.9)%; plasma glucose (PG) 120 min following 75-g oral glucose tolerance test (OGTT): 10.0 (7.9–11.6) mM). The incretin effect

was measured over 2 days by means of 4-hour 50-g OGTT and isoglycemic intravenous (*iv*) glucose infusion during pregnancy (third trimester) and again 2–3 months post partum.

Results: In order to obtain isoglycemic conditions 33 ± 1 g (mean \pm SEM) of glucose were infused intravenously during pregnancy as compared to 23 ± 3 g following delivery ($P < 0.05$). The incretin effect ($100\% \times (AUC_{C-pep,OGTT} - AUC_{C-pep,iv}) / AUC_{C-pep,OGTT}$) was reduced to 'diabetic' levels in women with GDM ($30 \pm 5\%$ (mean \pm SEM)) but significantly ($P < 0.05$) increased to normal levels following delivery ($54 \pm 9\%$).

Conclusion: Our results suggest that the reduced incretin effect in GDM is a consequence of the diabetic state and can be reversed as hyperglycemia ceases following delivery.

1154

Influence of maternal obesity on insulin sensitivity and secretion in the offspring

G. Mingrone¹, A. Mari², C. Guidone¹, A. Iaconelli¹, L. Leccesi¹, D. Gniuli¹, C. Chiellini¹, A. Favuzzi¹, M. Manco³

¹Internal Medicine, Università Cattolica S. Cuore, ²Institute of Biomedical Engineering, National Research Council, ³Liver Unit, Bambino Gesù Hospital and Research Institute, Rome, Italy

Background and aims: To clarify the effects of maternal obesity on insulin sensitivity and secretion in the offspring.

Materials and methods: Fifty-one offspring of both sexes of obese (Ob) and 15 offspring of normal weight (C) mothers were studied. Plasma glucose, insulin and C-peptide were measured during an OGTT. Insulin sensitivity was calculated using the Oral Glucose Insulin Sensitivity (OGIS) index and insulin secretion and beta-cell glucose sensitivity were computed by a mathematical model. Fasting leptin and adiponectin were also measured. Body composition was assessed by Dual-X-ray Absorptiometry.

Results: No birth weight statistical difference was observed in the two groups. Sixty-nine % of the Ob offspring were obese and 19% were overweight. Ob were more insulin resistant than C subjects (398.58 ± 79.32 vs. 513.81 ± 70.70 ml·min⁻¹·m⁻² in women, $P < 0.0001$ and 416.42 ± 76.17 vs. 484.24 ± 45.76 ml·min⁻¹·m⁻² in men $P < 0.05$). Insulin secretion after OGTT was higher in Ob than in C men (63.94 ± 21.20 vs. 35.71 ± 10.02 nmol·m⁻², $P < 0.01$), but did not differ significantly in women. Beta-cell glucose sensitivity was not statistically different between groups. A multivariate analysis of variance showed that maternal obesity and offspring gender concurred together with BMI and beta-cell glucose sensitivity to determine the differences in insulin sensitivity and secretion observed in the offspring.

Conclusion: Obese mothers can give birth to normal birth weight babies who later develop obesity and insulin resistance. The maternal genetic/epigenetic transmission shows a clear sexual dimorphism, with male having a higher value of insulin sensitivity (although not statistically significant) associated with a significantly higher insulin secretion than female offspring.

Inducible overexpression of sflt-1 in podocytes ameliorates glomerulopathy in diabetic mice

L. Gnudi¹, C.-H. Ku¹, K.E. White², A. Dei Cas¹, A. Hayward¹, Z. Webster³, R. Bilous², S. Marshall², G. Viberti¹

¹Cardiovascular Division, King's College, London, ²Diabetes and Metabolism, University of Newcastle, ³MRC Clinical Sciences Centre, Imperial College, London, United Kingdom

Background and aims: *In vivo* podocyte-specific doxycycline (DOX)-inducible overexpression of the soluble VEGF receptor-1 (sFlt-1) in mice was used to gain insights into the role of VEGF-A upregulation in diabetic glomerulopathy.

Materials and methods: Experiments were conducted in non-diabetic and diabetic transgenic mice and wild type controls, treated with vehicle (VEH) or DOX for 10-weeks. Blood glucose was measured by a glucose-oxidase method and blood pressure by a non-invasive technique. sFlt-1, VEGF-A, VEGF receptor-2 (VEGFR2), and nephrin protein expression in renal cortex were determined by western immunoblotting; urine sFlt-1 and free VEGF-A protein levels, and albuminuria by ELISA; glomerular ultrastructural morphology by electron microscopy, VEGFR2 cellular localization with immunogold techniques.

Results: Non-diabetic DOX-treated transgenic mice showed a 2-fold increased in renal cortex sFlt-1 expression and 4-fold increase in sFlt-1 urine excretion ($p < 0.001$), coupled with a 50% decrease in free urine VEGF-A and a 30% upregulation of renal cortex VEGF-A expression ($p < 0.04$); albuminuria, glomerular ultrastructural morphology, and cortex VEGFR2 expression were similar among groups; VEGFR2 was localised on podocytes.

DOX-treated transgenic diabetic mice were characterized by a 60% increase in 24 h urine sFlt-1 excretion paralleled by a ~70% decrease in urine free VEGF-A when compared to VEH-treated diabetic mice ($p < 0.04$). DOX-treated diabetic animals had lower urine albumin excretion at 10-weeks than VEH-treated diabetic mice (D-VEH vs D-DOX: $117.5[69-199]$ vs $43[26.8-69]$ µg/24h, geometric mean [CI], $p = 0.003$). Diabetes-induced mesangial expansion, glomerular basement membrane thickening, and foot-process fusion were ameliorated in DOX-treated diabetic animals ($p < 0.05$ for all). Diabetes-induced upregulation of VEGF-A and nephrin were not affected in DOX-treated mice.

Conclusion: In summary podocyte-specific sFlt-1 overexpression ameliorates diabetic glomerulopathy, presumably by modulating the autocrine/paracrine actions of VEGF-A on podocytes and other neighboring glomerular cells, and directly implicates VEGF-A in the pathogenesis of this complication.

Microvascular reactivity in painful and painless peripheral diabetic neuropathy

J. Doupis, T.E. Lyons, T. Dinh, A. Veves

Foot Center and Microcirculation Lab, Joslin - Beth Israel Deaconess Medical Center, Boston, United States

The pathogenesis of pain in diabetic neuropathy is not known. We investigated the differences in microvascular reactivity between DM patients with painful and painless neuropathy. We studied four groups matched for age and gender: healthy control subjects [C, $n = 47$, age 54 ± 14 years (mean \pm sd), 21 M], non-neuropathic DM patients [NND, $n = 97$, 56 ± 13 yrs, 48 M], patients with painless neuropathy [PDN, $n = 26$, 57 ± 10 yrs, 18 M] and patients with painful neuropathy [PLDN, $n = 76$, age 59 ± 9 years, 48 M]. We measured the foot skin vasodilator responses to the iontophoresis of acetylcholine (ACH, endothelium dependent) and sodium nitroprusside (SNP, endothelium independent) using a Laser Doppler Perfusion Imager and the nerve axon reflex-related vasodilation (NARV) that measures the C nociceptive fiber action using a single laser Doppler probe. The Neuropathy Disability Score was similar in PDN (12 ± 6) and PLDN (11 ± 7) but was higher comparing to NND (1.2 ± 1.5) and C (0.3 ± 0.8) $p < 0.0001$. The Neuropathy Symptom Score was similar in C (0.2 ± 0.5), NND (1.5 ± 1.8) and PDN (1 ± 0.9) but higher in PLDN (6 ± 2.7) ($p < 0.0001$). The response to ACH-induced vasodilation was similar

in PDN ($14.9 \pm 11.6\%$) and PLDN ($17.7 \pm 17.2\%$) and lower in both groups when compared to NND ($25.5 \pm 28.5\%$) and C ($25.6 \pm 20.9\%$) ($p < 0.05$). Similar differences were found in SNP induced vasodilation. The vibration perception threshold measurements (large myelinated fiber function) were equally elevated in both PDN (42 ± 11 V) and PLDN (34 ± 15 V) when compared to NND (13 ± 7 V) and C (10 ± 7 V) ($p < 0.0001$). Similar results were observed in Semmes-Weinstein monofilament measurements (small fiber function) [PDN (5.5 ± 1), PLDN (5.4 ± 1), NND (3.9 ± 0.5), and C (3.8 ± 0.5), $p < 0.0001$]. NARV was higher in PLDN [$29.6 (10.6 \pm 58.5\%)$] (median Q1:Q3 percentiles)] when compared to PDN [$8.9 (-0.4:35.5\%)$], ($p < 0.05$). NARV was also lower in both PDN and PLDN compared to NND [$50 (9:118.1\%)$] and C [$43.6 (9.2:133.3\%)$] ($p < 0.01$). We conclude that both endothelium dependent and independent skin vasodilation are equally impaired in patients with painful and painless neuropathy. However, the c-nociceptive fiber action was less impaired in patients with painful neuropathy despite the fact that the function of large myelinated fibers and small A δ fibers were equally impaired.

Abnormal retinal autoregulation during visual stimulation with flicker light in well-controlled type 1 diabetes without diabetic retinopathy

A. Mandelka¹, J. Dawczynski², M. Blum³, N. Müller¹, C. Kloos¹, W. Vilsér⁴, G. Wolf¹, U.A. Müller¹

¹Internal Medicine III, Friedrich Schiller University Jena, ²Department of Ophthalmology, Friedrich Schiller University Jena, ³Department of Ophthalmology, Helios Klinikum, Erfurt, ⁴IMEDOS, Jena, Germany

Background and aims: Stimulation of the retina with flicker light increases retinal arterial and venous diameters in humans. Nitric oxide is a mediator of the retinal vasodilation to flicker light. The reduction of vasodilation is considered as a marker of endothelial dysfunction. We investigated the response of retinal vessels to flicker in type 1 diabetic patients without diabetic retinopathy (DR) and with well-controlled diabetes mellitus. Additionally the static vessel analysis was done by measuring of central retinal arterial equivalent (CRAE) and central retinal venous equivalent (CRVE).

Materials and methods: 18 normotensive patients with type 1 diabetes without retinopathy and 19 age and sex matched healthy subjects were included. DR was classified according to the Early Treatment Diabetic Retinopathy Study criteria. The diameter of retinal vessels was measured with a Dynamic Vessel Analyzer. Changes in vasodilation after stimulation with flickering light are expressed as percent change over baseline values. Parameters were compared between diabetic and control participants using the non-paired *t* test after checking for normal distribution with the Kolmogorov-Smirnov test.

Results: HbA(1c) was $7.5 \pm 1.0\%$ and blood glucose 6.6 ± 1.9 mmol/l in type 1 diabetic patients, indicating relatively good glycaemic control. In arteries, the response to flicker was significantly diminished in diabetic patients compared to healthy volunteers ($p < 0.023$). In diabetic patients flicker stimulation increased arterial diameters by $+2.7\%$ in contrast to $+4.4\%$ in controls. The venous vasodilation was significantly reduced in diabetic patients compared to healthy controls. Venous vessel diameter increased by $+3.1\%$ in diabetic individuals and by $+5.3\%$ in the control group ($p < 0.002$). The static vessel analysis, showed greater central retinal artery equivalent (CRAE) in diabetic patients in comparison to controls, but the difference did not reach statistical significance ($204.7 \mu\text{m}$ vs. $198.2 \mu\text{m}$, $p = 0.245$). The central retinal vein equivalent (CRVE) did not differ in diabetic patients compared to healthy participants ($228.6 \mu\text{m}$ vs. $229.2 \mu\text{m}$, $p = 0.943$).

Conclusion: Type 1 diabetic patients without retinopathy with relatively good glycaemic control show reduced retinal vasodilation after stimulation with flicker indicating dysfunction in retinal autoregulation, likely endothelial dysfunction. There were no differences in static vessel analysis between healthy people and diabetic patients. Our study implies that the use of provocation test in conjunction with retinal vessel analysis together with the conventional methods used to detect retinopathy could lead additional information regarding abnormal retinal autoregulation.

Lower interphotoreceptor retinoid-binding protein is an early event in the human diabetic retina

M. García-Ramírez¹, M. Villarroya¹, J. Matesanz¹, M.A. Alonso², R. Fortuna³, L. Masmiquel⁴, C. Hernández¹, R. Simó¹

¹Diabetes and Metabolism Research Unit, Institut de Recerca Hospital Universitari Vall d'Hebron, Barcelona, ²Ophthalmology Department, Hospital Son Llàtzer, Palma de Mallorca, ³Biochemistry Department, Hospital Son Llàtzer, Palma de Mallorca, ⁴Endocrinology Division, Hospital Son Llàtzer, Palma de Mallorca, Spain

Background and aims: Interphotoreceptor retinoid-binding protein (IRBP) facilitates the transport of retinoids between the photoreceptor outer segments and retinal pigment epithelia (RPE) and, therefore, plays a major role in the visual cycle. In addition, it is essential to the maintenance of photoreceptors. A reduction in IRBP has been related to several degenerative retinal diseases in animal models. Recently we have reported a lower content of IRBP in the vitreous fluid from patients with proliferative diabetic retinopathy (PDR), by means of proteomic analysis. The aims of the present study are: 1) To confirm that intravitreal levels of IRBP are decreased in PDR. 2) To determine whether the decrease in IRBP production (mRNA levels and protein content) is found in the early stages of diabetic retinopathy. 3) To evaluate whether the loss of IRBP expression is associated with photoreceptor damage.

Materials and methods: Samples of vitreous from 9 type 1 diabetic patients with PDR and 7 non-diabetic patients with macular hole (control group) were selected from our vitreous bank. Both groups were closely matched by age. Human postmortem eyes ($n=18$) were obtained from 9 diabetic donors with mild non-PDR or even without clinically detectable retinopathy. Fourteen eye cups obtained from 7 non-diabetic donors matched by age were used as the control group. IRBP mRNA levels were quantified by quantitative real-time PCR (Q-RT-PCR). IRBP protein content in the neuroretina was determined by Western blot (WB) and confocal microscopy. IRBP in the vitreous fluid was assessed by WB. Neuroretinal rhodopsin content was measured by WB and confocal microscopy. The results of Q-RT-PCR and WB are expressed in arbitrary units after correction for beta-actin. Measurements of IRBP by confocal laser scanning are expressed as fluorescence intensity units.

Results: IRBP levels were significantly lower in the vitreous fluid of PDR patients in comparison with the control group (6.29 ± 2.48 vs. 10.36 ± 4.49 ; $p=0.04$). Retinas from diabetic donors showed significantly lower IRBP mRNA levels (1.15 ± 0.93 vs. 2.48 ± 2.11 ; $p=0.04$) and lower protein content in confocal laser scanning measurements (5788 ± 4532 vs. 10173 ± 3459 ; $p=0.003$). IRBP levels were also lower in neuroretinal extracts and in the vitreous fluid from diabetic donors than in non-diabetic donors, but the differences were not statistically significant. It should be noted that in all the retinas from diabetic donors (including those without vascular abnormalities in the preceding ophthalmologic examination) we found typical features of neurodegeneration (apoptosis and glial activation), thus proving that diabetic damage was present. Loss of IRBP production was neither associated with a significant decrease of rhodopsin expression nor with a higher rate of apoptosis in the photoreceptor layer.

Conclusion: Lower production of IRBP not only exists in PDR but also in the early stage of diabetic retinopathy. At this stage, the loss of IRBP is not associated with a significant reduction of photoreceptors. The meaning and clinical consequences of low IRBP production observed in diabetic patients deserve further investigation.

Vitreous levels of tumour necrosis factor- α , interleukin-6 and interleukin-1 β in patients with proliferative diabetic retinopathy

C. Gustavsson^{1,2}, C.-D. Agardh¹, B. Beding-Barnekow², E. Agardh^{1,2}

¹Unit on Vascular Diabetic Complications, Clinical Sciences,

²Ophthalmology, Clinical Sciences, Malmö, Sweden

Background and aims: There is increasing evidence for an inflammatory contribution to the pathogenesis of diabetic retinopathy, with tumour necrosis factor- α (TNF- α), interleukin-6 (IL-6) and IL-1 β as important mediators. The purpose was to study associations between serum and intravitreal levels of these cytokines and proliferative diabetic retinopathy compared with non-diabetic patients.

Materials and methods: Twenty-four patients with proliferative diabetic retinopathy (PDR) with vitreous bleeding and 27 non-diabetic subjects who underwent vitrectomy for other reasons (haemorrhage $n=1$, retinal detachment $n=16$, macular hole $n=7$, epiretinal membrane $n=2$, or cataract debris $n=1$) were included in the study. Serum and vitreous levels of TNF- α , IL-6

and IL-1 β were measured by an ELISA-mimicking method and analyzed by non-parametric testing and multivariate logistic regression analysis.

Results: Vitreous levels of TNF- α were high in both patient groups, although lower in PDR patients (18.0, (8.0–45.0) pg/ml and 22.0, (13.0–47.0) pg/ml, median, (min–max), respectively, $p=0.013$). TNF- α was detectable in serum from in all diabetic patients and 24/27 non-diabetic patients (88.9%). Serum TNF levels were higher in diabetic than in non-diabetic patients (9.0, (5.0–53.0) pg/ml and 6.7, (3.0–11.0) pg/ml, respectively, $p=0.001$). Vitreous levels of IL-6 were higher in diabetic than in non-diabetic patients (173.5, (25.0–1401.0) pg/ml and 44.0, (5.0–4425.0) pg/ml, respectively, $p=0.017$), but serum levels did not differ ($p=0.982$). IL-1 β was undetectable in all samples. Cytokine levels were not dependent on co-morbidity or medication ($p\geq 0.180$).

Conclusion: Intravitreal cytokine levels were high both in diabetic and non-diabetic subjects with retinovascular diseases necessitating vitrectomy. The relationship between serum and intravitreal cytokine levels in proliferative diabetic retinopathy is probably complex. Comparatively higher cytokine levels in the vitreous may support an intraocular production, and TNF- α and IL-6 can contribute to an inflammatory process in diabetic retinopathy.

Glucotoxicity and lipotoxicity in kidney cells: role of oxidative and endoplasmic reticulum stress

E. Katsoularis, J.G. Mabley, C.P.K. Chatterjee

Pharmacy and Biomolecular sciences, University of Brighton, United Kingdom

Background and aims: We are investigating glucotoxicity and lipotoxicity in vitro in NRK-52E proximal tubular cells. Our particular interest is in kidney cell killing by reactive oxygen species (ROS) and endoplasmic reticulum (ER) stress.

Materials and methods: Cytotoxicity assays used are MTT reduction, LDH release or Hoechst-propidium iodide (HPI) staining for apoptosis and necrosis determination. Reactive oxygen species were measured using nitroblue tetrazolium salt (NBT) reduction into blue formazan. ER stress was evaluated by Western blotting against the markers CHOP and protein chaperones glucose regulated protein 78 and 94.

Results: Direct application of oxidative stress inducers (0.5mmol/L paraquat and 0.3mmol/L hydrogen peroxide) was toxic to cells by both apoptotic and necrotic pathways. In a similar manner, high glucose and saturated fatty acid (palmitic) were toxic in a dose-dependent and time-dependent manner. Cell death due to 35mmol/L glucose was by both necrosis and apoptosis, while 300 μ mol/L palmitic acid caused apoptosis, predominantly. Oxidative stress (NBT reduction) due to 24h treatment with palmitic acid was similar to that following 72h treatment with 25mmol/L glucose. The antioxidants EUK-134 and tempol inhibited NBT reduction due to high glucose by 30% and 60% respectively ($P<0.01$) and in case of palmitic acid, EUK-134 returned superoxide to basal levels, while reducing cell killing and ER stress protein levels. One day treatments with paraquat (0.5mmol/L) and hydrogen peroxide (1mmol/L) increased CHOP levels by 200% ($P<0.05$) and 450% ($P<0.01$) respectively. Treatment with high glucose (25–35mmol/L) significantly increased GRP94 and phosphorylated CHOP, which was increased at 1, 3 and 7 days. Similarly, 24-hour treatments with palmitic acid caused significant concentration-dependent increases in both GRP78 (135%, $P<0.05$) and CHOP expression (266%, $P<0.01$).

Conclusion: We propose that rat kidney proximal tubular cells are subject to gluco and lipotoxicity. Cell death is mediated by oxidative stress, which, in part, induces ER stress.

Experimental diabetes induce changes in adenosine receptors expression and adenosine availability in rat kidney glomeruli

R. San Martín, C. Gajardo, T. Sotelo, E. Troncoso, C. Quezada, C. Escudero, L. Sobrevia

Instituto de Bioquímica, Universidad Austral de Chile, Valdivia, Chile

Background and aims: Glomerular expression and activity of vascular endothelial growth factor (VEGF) have been shown to be relevant for main-

taining the filtration barrier and cellular functions, but the regulation of the pathologic VEGF over production has not been clearly recognized. Adenosine A_{2B} receptor mediates an increases in the expression and release of VEGF from glomeruli in response to high glucose concentration exposure *ex vivo* (Valladares et al. 2008). In contrast adenosine A₁ receptor inhibits VEGF release *ex vivo*. Our objectives are determine the effects of diabetes in the expression of adenosine receptors and adenosine extracellular bioavailability in rat glomeruli.

Materials and methods: Diabetes was induced in male rats (Sprague dawley) by intravenous streptozotocin injection (65 mgr/Kg). This study has been carried out along the "Principles of laboratory animal care" (NIH Publication no. 85-23, revised 1985). After 15 days post induction glomeruli were isolated by a differential sieving method. For determine extracellular adenosine contents, the glomeruli were incubated for 1 hour in tyrode buffer at 37°C and 5% CO₂. Adenosine concentrations were quantified in supernatants using High Performance Liquid Chromatography (HPLC). The adenosine A₁ and A_{2B} receptors, equilibrative nucleoside transporters 1, 2 and 3 (ENT1, ENT2 and ENT3), and 5'-ectonucleotidase (CD73) mRNA were quantified by real time PCR. The adenosine receptors expression was evaluated by immunohistochemistry in kidney section of rats.

Results: An increase in adenosine A_{2B} receptor mRNA ($P<0.05$, $n=5$) and protein contents were detected in glomeruli from diabetic rats. While adenosine A₁ receptor was no changed by this experimental condition. The extracellular adenosine content in isolated glomeruli from diabetic rats was higher ($P<0.05$, $n=3$) than controls. The ENT1, ENT2 and ENT3 mRNA were not altered by diabetes but CD73 transcript level was increased ($P<0.05$, $n=5$).

Conclusion: Diabetes induces an increase in the low affinity adenosine A_{2B} receptor expression in kidney glomeruli which is accompanied for a rising in the extracellular nucleoside availability in this compartment, probably due to a higher activity of synthesis by CD73. Due to A_{2B} receptor increase the production of VEGF by podocytes, our finding may be relevant for explain a higher glomerular VEGF activity that occur as a remarkable feature at the onset of diabetic nephropathy.

Orally administered microencapsulated lysozyme downregulates AGE formation and prevents the early stage of diabetic nephropathy

R. Candido¹, B. Toffoli², S. Bernardi², M. Cocchiello³, L. Zorzin³,

R. Carretta², G. Sava³, B. Fabris²

¹Diabetic Centre D3, A.S.S. 1 Triestina, Trieste, ²Department of Clinical Medicine and Neurology, University of Trieste, ³Callario Foundation Onlus, Institutes of Biological Researches, Trieste, Italy

Background and aims: Diabetic nephropathy is the leading cause of end-stage kidney disease in the developed countries and is correlated to chronic hyperglycaemia. An increased production and deposition of advanced glyated end-products (AGEs) is known to play a major role in the pathogenesis of diabetic kidney damage. This study was undertaken to determine if lysozyme (LZ), microencapsulated in orally administrable chitosan-coated alginate microspheres (MS), is effective in preventing the early stage of diabetic nephropathy.

Materials and methods: Four groups of Wistar rats ($n=10$) were studied for 7 weeks: 1. Non-diabetic control rats (C), 2. Untreated streptozotocin-induced (50 mg/kg) diabetic rats (D), 3. Diabetic rats treated orally with microencapsulated LZ (MSLZ), and 4. Diabetic rats treated with non-encapsulated LZ. Serum and kidney AGEs levels, microalbuminuria, glomerular and tubular area and receptor for AGE (RAGE) gene expression were evaluated.

Results: Microencapsulated LZ treatment significantly reduces the concentration of serum AGEs in the diabetic animals (MSLZ: 128 ± 37 ng/ml vs D: 296 ± 64 ng/ml; $p<0.01$) and their kidney deposition. Correspondingly, MSLZ significantly prevented the development of microalbuminuria as compared to untreated diabetics rats (MSLZ: 3.47 ± 1.12 mg/24 hours vs D: 0.95 ± 0.54 mg/24 hours; $p<0.01$). Furthermore, MSLZ significantly prevented the development of glomerular (MSLZ: 6401 ± 591 μ m² vs D: 7448 ± 273 μ m²; $p<0.01$) and renal hypertrophy (kidney-to-body weight ratio MSLZ: 8.9 ± 0.9 g/mg vs D: 10.5 ± 0.8 g/mg; $p<0.01$) as well as RAGE gene overexpression (MSLZ: 1.21 ± 0.12 vs D: 1.89 ± 0.26 arbitrary units). An equidose of free LZ was less effective or totally ineffective.

Conclusion: The present study shows that orally administered LZ, and, even more, microencapsulated LZ, exerts a renoprotective effect in experimental diabetic nephropathy by inhibition of AGEs production and deposition.

Association of single nucleotide polymorphisms within intron 2 of vascular endothelial growth factor gene with early progression of retinopathy in type 1 diabetes

K. Nakanishi^{1,2}, C. Watanabe^{1,2}

¹Dept. of General Internal Medicine and Metabolism, Toranomon Hospital, Kawasaki, ²Dept. of Metabolism, Okinaka Memorial Institute for Medical Research, Tokyo, Japan

Background and aims: Vascular endothelial growth factor-A (VEGFA) is an endothelial cell-specific mitogen and implicated in the progression to proliferative diabetic retinopathy (PDR). Association of polymorphism in VEGFA gene and retinopathy has been investigated in several studies. However, because almost all studies were designed as case-control cross-sectional study, time to the development and progression of retinopathy was not addressed. We have recently done longitudinal observation of optic fundus in the cohort of type 1 diabetes [Diabetologia 50 (Suppl. 1) S448]. Using this cohort, we evaluated the influence of multiple single nucleotide polymorphisms (SNPs) across VEGFA gene on the development and progression of retinopathy.

Materials and methods: Subjects were 175 patients with type 1 diabetes (men/women: 94/81, age at onset: 34 ± 14 years, mean \pm SD). Seven SNPs across VEGFA gene (rs699947 in 5' promoter region; rs833068, rs833070, and rs2146323 in intron 2; rs3025010 in intron 5; rs3025021 in intron 6; rs3025035 in intron 7) were genotyped using TaqMan assays. Optic fundi were evaluated longitudinally 22 ± 18 times during 18 ± 9 years. Outcomes were mild nonproliferative diabetic retinopathy (NPDR), severe NPDR, and PDR. Mean HbA_{1c} value during entire illness was calculated as index of long-term glycemic control.

Results: Although cumulative incidence of mild NPDR did not differ among genotypes in any SNP, that of severe NPDR differed among genotypes in rs833070 [$p=0.037$; incidence rate (IR): 2.25, 2.68, and 4.30/100 patient-years in CC ($n=93$), CT ($n=65$) and TT ($n=11$) genotype] and rs2146323 [$p=0.036$; IR: 4.14, 2.69, 2.22/100 patient-years in AA ($n=12$), AC ($n=62$), and CC ($n=94$) genotype]. Cumulative incidence of severe NPDR was higher in AA ($n=14$) than other genotypes ($n=154$) in rs699947 ($p=0.031$; IR: 3.87 vs. 2.41/100 patient-years), TT ($n=11$) than other genotypes ($n=158$) in rs833070 ($p=0.010$; IR: 4.30 vs. 2.44/100 patient-years), AA ($n=12$) than other genotypes ($n=155$) in rs2146323 ($p=0.011$; IR: 4.14 vs. 2.40/100 patient-years). Although mean HbA_{1c} value was higher in AA (9.3 ± 1.6 %) than other genotypes (8.1 ± 1.2 %, $p=0.015$) in rs699947, it did not differ between TT (9.2 ± 1.8 %) and other genotypes (8.2 ± 1.2 %, $p=0.09$) in rs833070, and between AA (9.1 ± 1.8 %) and other genotypes (8.2 ± 1.2 %, $p=0.14$) in rs2146323. All patients who had TT in rs833070 also had AA in rs69947 and AA in rs2146323. Cumulative incidence of PDR did not differ among genotypes in any SNP. After adjusting possible confounders (sex, mean HbA_{1c} value, hypertension, age and BMI at the onset) by Cox's proportional hazards model, TT genotype in rs833070 and AA genotype in rs2146323 were marginally insignificant as risk factors for severe NPDR [HR (95%CI): 1.66 (0.93–2.73), $p=0.084$; and 1.65 (0.92–2.74), $p=0.088$, respectively], whereas, when mean HbA_{1c} value was withdrawn from this model, TT genotype in rs833070 and AA genotype in rs2146323 were significant risk factors for severe NPDR [HR (95%CI): 1.67 (1.01–2.54), $p=0.047$; and 1.67 (1.01–2.74), $p=0.047$, respectively].

Conclusion: Our longitudinal study of optic fundus in type 1 diabetes demonstrated that SNPs in VEGFA genes, especially within intron 2, associates with early progression of retinopathy in type 1 diabetes under the influence of glycemic exposure.

1164

Genetic factors have a major impact on nephropathy leading to haemodialysis than drinking alcohol, hypertension and smoking in Japanese type 2 diabetic patients

M. Hattori¹, H. Ueshima², T. Okamura², T. Fujii¹, S. Kono¹, Y. Furuichi¹, M. Imura³, Y. Noto⁴, K. Koyama⁵, K. Yamada⁶, T. Oura⁷, K. Kaneko⁸, A. Shimatsu¹, H. Kuzuya¹, K. Kogawa¹

¹Diabetes, National Hospital Organization Kyoto Medical Center, Kyoto,

²Health Science, Shiga University of Medical Science, Otsu, ³Diabetes and Endocrinology, Yaizu City General Hospital, Shizuoka, ⁴Diabetes, Kanazawa Medical Center, Kanazawa, ⁵Diabetes, Tokyo Medical Center, ⁶Diabetes, Yamada Kennichi Naika Clinic, Tagajyo Miyagi, ⁷Diabetes and Kidney, Oura Clinic, Naha Okinawa, ⁸Medicine, Kasumigaura Medical Center, Tsuchiura, Japan

Background and aims: Diabetic nephropathy is the primary cause leading to hemodialysis in Japan. Genetic factors and daily habits (drinking alcohol, smoking cigarettes, excessive intake of salts, greasy food and carbohydrates) are considered as risk factors for developing diabetic nephropathy. Our study aims to examine which factors are more influential for the development of the end stage of renal diseases resulting in hemodialysis.

Materials and methods: We recruited age- and sex-matched: group 1) 618 type 2 diabetic patients with nephropathy (273 on hemodialysis) (duration of diabetes ≥ 10 years, presence of retinopathy and neuropathy, urine alb/cre ≥ 30 mg/gCre, alb ≥ 30 mg/24h), group 2) 280 type 2 diabetic patients without nephropathy (duration of diabetes ≥ 10 years, negative microalbuminuria), and group 3) 312 healthy subjects (absence of diabetes and kidney diseases in the past and family history). The average age was 61 ± 12 (mean \pm SD) years old. Individual subjects in the three groups signed the informed consents, answered questionnaires on daily habits and provided blood samples for genetic analysis. We performed the whole genome mapping on using microsatellite markers at 1–20cM intervals. The data were evaluated by analysis of variance among the three groups, and multivariate logistic analysis for relative risk for hemodialysis, and Chi-square test for association study of the genetic mapping analysis.

Results: The analysis of variance among the three groups showed that blood pressure (both systolic and diastolic), the number of smoking cigarettes and alcohol consumption were risk factors for diabetic nephropathy in addition to hyperglycemia. The genome scanning revealed that five markers were associated with diabetic nephropathy. Of the five, marker D showed a prominent significance in association with diabetic nephropathy ($P=10^{-16}$). In the multivariate logistic analysis of the marker D and the above risk factors for hemodialysis in the type 2 diabetic patients (vs. healthy control subjects), the relative risk was 8.51 for marker D-homozygote ($P=0.000$, 95% Confidence Interval: 3.63 to 19.97), 6.63 for marker D-heterozygote ($P=0.000$, 95%CI: 3.57 to 12.32), 1.01 for drinking 1g of alcohol ($P=0.006$, 95%CI: 1.00 to 1.03), 1.01 for smoking 1 cigarette/day ($P=0.665$, 95%CI: 0.98 to 1.03), 1.07 for 2 mmHg increase of systolic blood pressure ($P=0.000$, 95%CI: 1.05 to 1.09), and 0.87 for BMI ($P=0.009$, 95%CI: 0.79 to 0.97). Age and sex difference were insignificant factors. The total cholesterol and HDL-C levels remained unclear for risk factors in the present study.

Conclusion: Genetic factors have a major impact on diabetic nephropathy leading to hemodialysis in Japanese type 2 diabetic patients despite a significant contribution of daily habits, especially drinking alcohol.

Background and aims: Poly (ADP) ribose polymerase (PARP-1) is a key enzyme in diabetic complications activated by oxidative stress-induced DNA

damage. We hypothesised that PARP-1 polymorphism is linked to the presence of diabetic nephropathy in patients with type 2 diabetes.

Materials and methods: We studied 3 different SNP, tagging the haplotypic structure of the PARP-1 gene. The genetic variants were studied according to the presence/absence of diabetic nephropathy in a case-control design. Setting: French multicentre collaborative study (15 diabetics clinic and 5 nephrology clinics). Patients: Diabetic nephropathy status was classified by an adjudication committee: nephropathic cases had retinopathy associated with microalbuminuria or proteinuria, regardless estimated glomerular filtration rate (eGFR), non nephropathic controls had normoalbuminuria assessed in the absence of ACE-I or ARB prescription, with eGFR higher than or equal to 30 ml/min, and either diabetic retinopathy regardless diabetes duration or long-term diabetes duration (20 years or more).

Results: A total of 1200 caucasian patients were included: 797 cases (528 men/279 women) and 403 non-nephropathic controls (221 men/182 women). The PARP-1 genetic variants were in Hardy-Weinberg equilibrium. The association between PARP-1 polymorphism and diabetic nephropathy is summarized in table regarding genotypic and haplotypic analyses.

Conclusion: PARP-1 genetic variants seem to play a weak role in the genetic susceptibility to diabetic nephropathy in type 2 diabetic people.

PARP-1 polymorphisms and diabetic nephropathy

The Q121 variant of ENPP1 (PC-1) gene is associated with chronic kidney disease among patients with type 2 diabetes

S. De Cosmo¹, A. Minenna¹, Y.-Y. Zhang², R. Thompson², G. Miscio¹, M. Vedovato³, A. Raoult⁴, A. Saller⁴, S. Mastroianno¹, F. Pellegrini⁵, R. Trevisan⁶, P. Fioretto⁴, A. Doria², V. Trischitta^{1,7}

¹Endocrinology, Scientific Institute "Casa Sollievo della Sofferenza", San Giovanni Rotondo (FG), Italy, ²Research Division, Joslin Diabetes Center, Boston, United States, ³Chair of Metabolic Diseases, University of Padova, Italy, ⁴Department of Medical and Surgical Sciences, University of Padova, Italy, ⁵Department of Clinical Pharmacology and Epidemiology, Consorzio Mario Negri Sud, S. Maria Imbaro, Italy, ⁶Unit of Diabetes, Ospedali Riuniti di Bergamo, Italy, ⁷Department of Clinical Sciences, "Sapienza" University, Rome, Italy

Background and aims: Insulin resistance plays a role in diabetic kidney complications. The ENPP1 K121Q polymorphism has been repeatedly associated with insulin resistance, type 2 diabetes (T2D) and related vascular complications. This study investigated whether the ENPP1 Q121 variant is associated with chronic kidney disease (CKD) in T2D

Materials and methods: Three sets of patients with T2D were studied: one from Gargano (360M/324F), one from Boston (M361/F222) and one from Padua (M100/F25). In all sets glomerular filtration rate (GFR) was estimated (e-GFR) with the abbreviated MDRD formula.

Results: In the Gargano and Boston populations, according to dominant model of inheritance, Q121 carriers (i.e. individual with either KQ or QQ genotype) had an increased risk of having CKD: ORs=1.69 (95%CI 1.1-2.6) and 1.50 (95%CI 1.0-2.2), respectively. In the Padua set the association was in the same direction though not reaching a formal statistical significance

(OR=1.77, 95%CI 0.7-4.5). When the three studies were pooled, the risk of CKD in Q121 carriers was highly significant (OR=1.58, 95%CI 1.2-2.1). Also pooled mean differences of absolute GFR values were different across genotype groups with Q121 carriers showing lower GFR, as compared to KK individuals (74±20 vs 71±21 ml/min/1.73m² KK vs Q121, respectively; p=0.04).

Conclusion: Our data indicate that patients with T2D carrying the ENPP1 Q121 variant are at increased risk of CKD. If this finding is confirmed in prospective studies, the Q121 variant might be useful to identify patients at high risk of developing renal dysfunction, who can be targeted with specific preventive and therapeutic strategies.

¹Department of Diabetes Genetics, Folkhälsan Research Center, Helsinki, ²Department of Medicine, Helsinki University Central Hospital, ³Department of Clinical Microbiology, University of Kuopio, ⁴Immunogenetics Laboratory, University of Turku, Finland

Background and aims: The human leukocyte antigen (HLA) class II locus on chromosome 6p21.3 is a known susceptibility locus for type 1 diabetes (T1D) and other autoimmune diseases. However, its potential role in the development and progression of diabetic nephropathy (DN) is still poorly understood. The locus contains numerous genes with multiple alleles and recently there have been suggestions that HLA DRB1*04 alleles would protect from nephropathy.

Materials and methods: 1935 well-characterised Finnish patients with T1D were grouped into patients with normoalbuminuria (n=674), microalbuminuria (n=459), macroalbuminuria (n=567), and end-stage renal disease (ESRD; n=235) based on their urinary albumin excretion rate in at least two out of three timed urine collections. Of the 1935 patients there were 1434 with prospective data and of these 206 progressed. The HLA genotyping was performed with commercial kits and haplotypes were constructed using known linkage disequilibrium patterns. The statistical analyses were performed with SPSS 13.0 using χ^2 tests for categorical variables and Kaplan-Meier and/or Cox-regression for progression and survival analyses.

Results: We identified 26 HLA haplotypes and 101 different HLA genotypes. The most common genotype was the T1D susceptibility genotype (DR3)-DQA1*05-DQB1*02 / DRB1*0401-DQB1*0302 with more than 20% of patients carrying it, however 80.9% (n=1565) of the patients carried one of the two haplotypes. In cross-sectional analyses (DR11/12/13)-DQA1*05-DQB1*0301 was enriched in patients without DN (58.8% vs. 41.5%, p=0.056, n=53). The uncommon (DR7)-DQA1*0201-DQB1*02 haplotype was enriched in macroalbuminuric patients compared to ESRD patients (86.8% vs. 13.2%, p=0.025, n=38). (DR3)-DQA1*05-DQB1*02 was found to be protective against the progression from macroalbuminuria to ESRD (p=0.01). Patients with at least one copy of the DRB1*0401-DQB1*0302 haplotype showed a trend for enhanced survival compared to patients without this haplotype. There were, however, no trends for the progression of kidney disease with DRB1*0401-DQB1*0302.

Conclusion: We found suggestive enrichment of certain HLA haplotypes regarding renal status. The effect of HLA haplotypes was more evident on the progression of DN as well as on patient survival. Interestingly, the haplotypes which showed a trend for enhanced survival or protection against the progression of DN, were the two major risk haplotypes for developing T1D.

Haptoglobin genotype and renal disease progression in type 1 diabetes

T. Costacou¹, R.E. Ferrell², T.J. Orchard¹

¹Department of Epidemiology, ²Department of Human Genetics, University of Pittsburgh, United States

Background and aims: Haptoglobin (Hp) is a plasma protein that binds free hemoglobin, thereby inhibiting hemoglobin-induced oxidative damage. Hp genotype influences the risk of vascular complications in type 2 diabetes and we have recently demonstrated an association with cardiovascular disease among individuals with childhood-onset type 1 diabetes. Here, we investigated whether Hp genotype is associated with renal disease progression in type 1 diabetes.

Materials and methods: Participants from the Epidemiology of Diabetes Complications Study with DNA available were studied for the incidence of microalbuminuria (MA), overt nephropathy (ON), end-stage renal disease (ESRD) and low estimated glomerular filtration rate (eGFR). MA was defined as albumin excretion rate $>20 \mu\text{g}/\text{min}$, ON as albumin excretion rate $>200 \mu\text{g}/\text{min}$ in multiple timed urine specimen, ESRD as renal dialysis or transplantation, and low eGFR as $<60 \text{ mL}/\text{min}/1.73 \text{ m}^2$ by the Cockcroft-Gault equation.

Results: The proportions of the cohort with the Hp 2/2, 2/1 and 1/1 genotypes were 47.2%, 41.3% and 11.5%, respectively. During 18 years of follow-up, there were 111 incident MA cases (41.1%), 61 incident ON cases (16.8%), 59 incident ESRD cases (12.4%), and 82 incident cases of low eGFR (16.2%). Univariately, no significant differences were observed in the proportion of cases by Hp genotype for MA and ON. However, the proportion of events was higher among those with the Hp 2/2 compared to Hp 2/1 or 1/1 for ESRD (17.0 vs. 7.7 and 10.5%, respectively, $p=0.01$). Cumulative incidence (including 9 prevalent cases) was also higher in the Hp 2/2 (19.1%) than the Hp 2/1 (8.6%) or Hp 1/1 (12.1%) ($p=0.007$). In multivariable Cox proportional hazard models, adjusting for known predictors in this population (diabetes duration, HbA1c, lipids, hypertension, eGFR) the Hp 2/2 genotype remained associated with increased ESRD incidence compared to the Hp 1/1 genotype (HR=3.53, 95% CI=1.41–8.82) whereas the Hp 2/1 genotype risk, though increased, did not reach statistical significance (HR=2.37, 95% CI=0.88–6.40). Associations were similar for progression to ESRD from MA (HR for Hp 2/2 to 1/1=3.29, 95% CI=1.34–8.09) and to ESRD from ON (HR for Hp 2/2 to 1/1=3.53, 95% CI=1.43–8.72), as well as for the incidence of low eGFR (HR for Hp 2/2 to 1/1=2.66, 95% CI=1.38–5.13). However, the Hp genotype was not a determinant of either MA (HR for Hp 2/2 versus Hp 1/1=1.31, 95% CI=0.58–2.95) or ON (HR for Hp 2/2 versus Hp 1/1=0.72, 95% CI=0.33–1.58) incidence in multivariable models. Adjustment for cardiovascular disease status did not alter these findings.

Conclusion: These data suggest that although Hp genotype is not related in this cohort of type 1 diabetes to the incidence of renal damage (micro- or macroalbuminuria), contrary to findings in type 2 diabetes, it may be a determinant of worsening of renal function (eGFR) and progression to ESRD.

Implication of superoxide dismutase 1 gene in the type 1 diabetic nephropathy: the SURGENE Study

K. Mohammadi^{1,2}, N. Bellili², S. Maimaitiming², C. Abi Khalil^{1,2}, F. Travert¹, N. Emery², F. Fumeron², G. Velho², R. Roussel^{1,2}, M. Marre^{1,2}

¹Endocrinologie Diabétologie et Nutrition, Assistance Publique des Hôpitaux de Paris, ²Xavier Bichat School of Medicine, INSERM, U695, Paris, France,

Background and aims: Oxidative stress has been involved in the pathophysiology of diabetic nephropathy. Antioxidant enzymes counteract oxidative stress. Several polymorphisms in antioxidant enzymes genes have been associated with diabetic nephropathy. In the DCCT/EDIC study, rs17880135 polymorphism of the superoxide dismutase 1 (SOD1) gene was associated with persistent microalbuminuria and severe nephropathy. We studied the impact of rs17880135 in SOD1 gene on the development and progression of diabetic nephropathy.

Materials and methods: We studied 310 type 1 diabetic (T1D) subjects included in the Survival Genetic Nephropathy (SURGENE), a prospective observational study designed to analyse the genetic determinants of diabetic nephropathy. At inclusion, there were 56% of males and 44% of females, mean age was 34 years, 81% were normoalbuminuric. Patients were compared to 310 non-diabetic age- and sex - matched subjects. The genotypes for rs17880135 were determined by the Taqman process. Renal events were defined as a change to the next nephropathy stage (absence, microalbuminuria, macroalbuminuria, renal failure, end-stage renal failure). We tested the association of genetic variations with albuminuria, hemodynamic parameters and renal events.

Results: Minor allele frequency was 11% for cases and 8% for controls ($p=0.27$). Genotypes frequencies were in Hardy-Weinberg equilibrium. In T1D subjects, 53 renal events occurred during follow-up. There was no significant association between this polymorphism and albuminuria (TT 64.5 \pm 12.6 vs G+ 29.9 \pm 26.1 mg/l, $p=0.45$), blood pressures or progression of nephropathy (renal events). In healthy controls, allele G carriers had higher SBP levels (G+ 136.8 \pm 2.5 mmHg, TT 129.3 \pm 1.0, $p=0.04$). In the pooled populations, rs17880135 G allele carriers had higher risk for hypertension [OR=2.29 (1.14–4.57), $p=0.02$].

Conclusion: rs17880135 polymorphism in SOD1 gene was not associated with type 1 diabetic nephropathy in SURGENE study. However, this gene could be a candidate gene for hypertension.

1170

ADMA and chronic renal failure in type 2 diabetic subjects: role of DDAH-1151 A/C polymorphism

I. Testa¹, M. Marra¹, A. Ceriello¹, F. Marchegiani², C. Sirolla³, M. Boemi¹, A.R. Bonfigli¹, M. Cucchi¹, R. Testa¹

¹Diabetology Unit, ²Center of Molecular Biology and Genetics, ³Center of Epidemiology and Biostatistic, INRCA, Ancona, Italy

Background and aims: To investigate whether the genetic polymorphism of Dimethylarginine Dimethylamino hydrolase (DDAH2) gene at the position -1151 A/C, an enzyme which degrades asymmetric dimethylarginine (ADMA) to citrulline and dimethylamine, regulates ADMA levels in type 2 diabetic patients (T2DM) with chronic renal failure.

Materials and methods: Two groups of carefully selected subjects of both sexes were enrolled and compared. The first group (control group) comprised 120 T2DM subjects without complications (mean age 70.0 \pm 8.0 years) whereas the second (CRF group) comprised 50 T2DM patients (mean age 75.2 \pm 7.0 years) with chronic renal failure. The -1151 A/C DDAH2 promoter polymorphism was determined by a polymerase chain reaction-restriction fragment length polymorphism approach.

Results: Significant differences between control and CRF group in plasma levels of ADMA (0.35 \pm 1.86 versus 0.42 \pm 1.94 $\mu\text{mol}/\text{l}$, $p=0.048$, respectively), symmetric dimethylarginine (SDMA) (0.32 \pm 1.62 versus 0.42 \pm 1.81 $\mu\text{mol}/\text{l}$, $p=0.002$, respectively) was found. Whereas no differences in L-arginine plasma levels was found. No differences in the frequency of DDAH2 1151 A/C polymorphism between groups was found. Analysis of variance showed that ADMA plasma levels was only dependent on DDAH2 1151 A/C polymorphism ($F=3.15$; $p=0.04$) and no interaction between groups and DDAH2 1151 A/C polymorphism was found ($F=0.35$; $p=0.70$).

Conclusion: The finding that DDAH2 1151 polymorphism regulates ADMA levels in type 2 diabetic patients with chronic renal failure allow to open a new insight on the pathway involving ADMA/DDAH/Nitric Oxide Synthase in the development and progression of chronic renal failure in type 2 diabetic patients. Determination of the DDAH2 1151 A/C polymorphism may help to identify those individuals at high risk to develop cardiovascular diseases at an early stage, suggesting a close monitoring of cardiovascular risk factors before the onset of cardiovascular disease.

1171

Paraoxonase genotypes and activity and oxidized LDL in type 2 diabetes mellitus: relationship with vascular complications

D. Lucchesi¹, L. Pucci¹, V. Longo², S. Triscornia¹, C. Fotino¹, G. Penno¹, S. Del Prato¹, R. Miccoli¹

¹Endocrinology and Metabolism, University of Pisa, ²Clinical Physiology Institute, National Research Council, Pisa, Italy

Background and aims: Atherogenic dyslipidemia and the unbalance between oxidative and anti-oxidative mechanisms in lipoprotein metabolism might be major determinants not only in the development of atherosclerosis, but also in the induction and progression of microvascular damage in diabetes mellitus.

Materials and methods: Serum enzymatic activity and Q192R and L55M gene polymorphisms of paraoxonase-1 (PON1), an esterase associated with apolipoprotein A-I (apoA-I) to which is largely attributed the antioxidant capacity of HDL, have been assessed in 306 type 2 diabetic subjects to investigate the relationship, eventually mediated through circulating oxidized LDL (oxLDL) concentrations, with vascular complications.

Results: PON1 activity, slightly lower in diabetic subjects than in 100 controls (66.1 \pm 41.3 vs 76.4 \pm 40.0 nmol/ml/min; $p=0.03$), was strongly affected by both gene variants, but also significantly modulated by apoA-I and HbA1c levels. Neither PON1 activity nor genotypes or their combination contributed to circulating oxLDL variability. OxLDL/apoB ratio (0.56 \pm 0.27 vs 0.51 \pm 0.18, $p=0.036$), an index of the proportion of oxidatively modified LDL, was higher in diabetics with cardiovascular disease (CVD) when compared with those with no CVD. No differences emerged in PON1 activity and genotypes distributions in subjects with CVD when compared with those without CVD. OxLDL and oxLDL/apoB ratio were also higher

in subjects with microalbuminuria or overt nephropathy and oxLDL/apoB ratio was increased in subjects with retinopathy when compared with those without microvascular complications. PON1 genotypes were equally distributed in subjects with and without retinopathy, while the LL genotype (L55M) resulted more frequent in those with raised albuminuria ($p=0.007$). Systolic blood pressure (sBP, $p=0.002$), HbA1c ($p=0.01$), apoB ($p=0.02$), LL genotype ($p=0.002$), and mainly oxLDL ($p<0.0001$) independently affected nephropathy. Duration of diabetes ($p<0.0001$), HbA1c ($p=0.006$), sBP ($p=0.003$), but also oxLDL ($p=0.01$) contributed independently to retinopathy.

Conclusion: In subjects with type 2 diabetes mellitus, gene polymorphisms in the coding and regulatory regions of PON1 largely affect serum activity of the enzyme but show no relationship with CVD or retinopathy, while the weak direct association of L55M variant with diabetic renal damage is of uncertain relevance. Our study does not support a causal relationship between PON1 activity and oxidative modification of circulating LDL. However, high oxLDL levels are strongly associated with albuminuria and with retinal lesions suggesting that oxLDL might play an independent role in initiation and progression of microvascular damage, mainly of nephropathy.

PS 112 Diabetic retinopathy screening: clinical aspects

1172

English national screening programme for diabetic retinopathy

F.K.M. O'Leary, I.M. Stratton, D.M. Prentis, P.H. Scanlon
National Screening Programme for Diabetic Retinopathy, Cheltenham, United Kingdom

Background and aims: The aim of the National Programme is to set up a screening system for two million people with diabetes in England. The purpose is to reduce the risk of vision loss by the prompt identification (and effective treatment if necessary) of sight threatening diabetic retinopathy at the appropriate stage during the disease process.

Materials and methods: The delivery of systematic care is done by 101 local programmes which identify patients and call them in for 2 field retinal photography with mydriasis. Grading is carried out and all image sets with pathology and 10% of normal image sets are at least double graded, with arbitration if needed. The National Programme organises quality assurance on these programmes and sets national standards by which performance is assessed. All programmes should submit an annual report using a standard pro forma to improve consistency of data collection. A national grading standard has been approved and it is now mandatory for software to support this.

Results: Initial data from 74 programmes have been received. Size of each programme is 17595 (12262 to 23589) median (25th to 75th centile). The proportion of eligible people invited (target 80%) is 70.5% (43.8% to 86.7%). The proportion of people with no discernable retinopathy was 69.3% (62.6% to 76.3%). Background retinopathy was seen in 25.1% (18.3 to 30.9%) of people and preproliferative and proliferative retinopathy in 4.6% (3.2% to 7.4%)

Conclusion: Despite careful drafting of grading criteria there is considerable variation in interpretation and application. Some of the variation may be due to differences in the populations screened, however it is likely that some of the variability is due to variation in the implementation of the grading criteria.

Initial data from 74 local programmes, grading data available from 66

	Median	25th centile	75th centile
People with diabetes	17595	12263	23590
Proportion invited to screening	70.5%	43.8%	86.7%
Inappropriate referrals	0.6%	0.0%	2.0%
% initial screens	56.5%	25.8%	99.0%
No retinopathy	69.3%	62.6%	76.3%
Background retinopathy	25.1%	18.3%	30.9%
Preproliferative and proliferative retinopathy	4.6%	3.2%	7.4%
Assessable image sets	96.3%	90.2%	97.5%
Results notified within 6 weeks	77.5%	38.0%	90.0%
Cataract referrals	8.2%	0.0%	14.4%

A multi-disciplinary team meeting as part of a diabetes eye screening programme: effects on referral to hospital eye clinics

C. Frickey¹, B. Jennings², L. Lacey³, W. Gatling^{1,3}, D.V. Coppini¹, M.G. Masding^{1,3}

¹Diabetes Centre, Poole Hospital NHS Foundation Trust, ²Medical Photography, Poole Hospital NHS Foundation Trust, ³Dorset Diabetic Eye Screening Programme, Dorset Primary Care Trust, Ferndown, United Kingdom

Background: Our county has a well-established optometrist-based screening programme for diabetic eye disease, previously using slit-lamp biomicroscopy. We have recently implemented an optometrist-based programme using mydriatic dual-view digital fundal photography. After initial capture and grading by optometrists and trained retinal screeners, the images of patients graded as having significant diabetic eye disease are discussed at hour-long weekly multi-disciplinary team (MDT) meetings in each of the secondary care centres involved in the programme, involving ophthalmologists, diabetologists and retinal screeners. The MDT options are for onward referral to the hospital ophthalmology department, recall to a specialist hospital diabe-

tes eye clinic involving ophthalmology and diabetology review, or return to the screening programme. We have reviewed the outcomes of our local MDT to assess referral rates for hospital care.

Material and methods: Records were kept of patients reviewed in the MDT between 1 February 2007 and 31 January 2008, and the outcome of that review.

Results: Of 11,600 patients screened in the Poole area, 516 patient images (4.4%) were reviewed in the MDT, with 276 (2.4%) of these eventually requiring hospital care. Of the patients reviewed in the MDT, 114 (22.1%) were referred for direct ophthalmology care (including laser treatment), 162 (31.4%) were recalled to specialist diabetes eye clinics, and 240 (46.5%) were referred back to the screening programme for digital photography by either optometrists or retinal screeners.

Conclusion: An image based optometric screening programme helps prevent unnecessary clinic referrals in nearly half of patients graded as having significant diabetic eye disease in a digital photography-based screening system. This helps ophthalmologists to use their time more productively to treat patients and reduces the stress and anxiety for patients who may previously have been referred for hospital care.

1174

Functional brain connectivity changes and neurocognitive functioning in T1DM patients with proliferative retinopathy: preliminary findings using magnetoencephalography

E. van Duinkerken¹, N.S.M. Schoonenboom², M. Klein¹, M. Diamant³, C.J. Stam², F.J. Snoek¹

¹Medical Psychology, ²Clinical Neurophysiology, ³Endocrinology, VU University Medical Centre, Amsterdam, Netherlands

Background and aims: Type 1 diabetes mellitus (T1DM) is associated with mild, specific cognitive deficits. Earlier research from our group in patients with and without proliferative retinopathy suggests that cognitive impairment is due to microvascular damage in the brain. Magnetoencephalography (MEG) is a well-established method to detect subtle changes in brain activation and is widely used in brain research. Using the synchronization likelihood (SL), correlations in brain activation over time between different brain regions can be computed, indicating functional connectivity. The aim of the present study was to use MEG to detect differences in functional connectivity comparing T1DM patients with and without proliferative retinopathy and healthy controls. Furthermore, neuropsychological assessment was used to compare cognitive functioning between groups in relation to MEG outcomes.

Materials and methods: Eight T1DM patients with proliferative retinopathy or previous lasercoagulation (DPR), 14 T1DM patients without complications (NDPR) and 14 healthy controls underwent an MEG and neuropsychological assessment. With MEG brain magnetic field was recorded for various frequency bands during eyes-closed condition, measuring default brain activity. SL was computed and intra-, inter- and local hemispheric locations were created. Neuropsychological assessment covered memory, executive functions, attention, motor speed and information processing speed. Repeated measures ANOVA was used to test for hemispheric differences in SL. MANOVA was used to test for differences in cognitive performance. Post-hoc testing was used to differentiate between groups.

Results: There were no differences between DPR patients (mean age (SD): 43 (8) yrs; median disease duration (range): 31 (18) yrs; mean age of disease onset (SD): 10 (3.12) yrs; mean HbA_{1c} (SD): 7.5 (0.88) %; education level: 5), NDPR patients (mean age (SD): 40 (10) yrs; median disease duration (range): 18 (30) yrs; mean disease onset (SD): 21 (9) yrs; mean HbA_{1c} (SD): 8.1 (1) %; education level: 5.5) and healthy controls (mean age (SD): 41 (10) yrs; education level: 5.6) with respect to age, sex and education level. DPR patients had significantly longer disease duration ($p=0.001$) and earlier disease onset ($p=0.001$) than NDPR patients. Lower SL was found for DPR compared to healthy controls for $\alpha 2$ frequency band inter hemispheric parietal region ($p=0.008$; $\eta^2 = 0.251$), local hemispheric left parietal region ($p=0.046$; $\eta^2 = 0.170$) and right frontal region ($p=0.017$; $\eta^2 = 0.220$). Neuropsychological performance did not differ between groups ($p=0.551$).

Conclusion: The lowered SL found in DPR compared to NDPR and healthy controls suggests significant changes in functional brain connectivity. It is unclear whether these abnormalities are related to earlier disease onset, as suggested from previous studies, using structural brain imaging, disease duration or the presence of microangiopathy in the brain. The unaffected neuropsychological performance found in the DPR group, despite MEG ab-

normalities, confirms earlier findings indicating that functional changes are diffuse and subtle, warranting longitudinal follow-up in larger samples.

Effects of blood pressure lowering on incidence and progression of retinopathy in patients with type 2 diabetes mellitus: a randomised controlled trial

J.W. Beulens¹, J.R. Vingerling², J.K. Cruickshank³, A.D. Hughes⁴, A. Stanton⁵, J. Lu⁶, A. Patel⁷, S.A.M. Thom⁴, D.E. Grobbee¹, R.P. Stolk^{8,1} on behalf of the AdRem Project Team and ADVANCE Management Committee

¹Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Utrecht, Netherlands, ²Departments of Ophthalmology & Epidemiology, Erasmus Medical Center Rotterdam, Rotterdam, Netherlands, ³Cardiovascular Sciences Research Group, University of Manchester & Royal Infirmary, Manchester, United Kingdom, ⁴International Centre for Circulatory Health, National Heart & Lung Institute, Imperial College London, United Kingdom, ⁵Molecular and Cellular Therapeutics and RCSI Research Institute, Royal College of Surgeons in Ireland, Dublin, Ireland, ⁶Department of Endocrinology, Chinese PLA General Hospital, Beijing, China, ⁷The George Institute for International Health, University of Sydney, Australia, ⁸Department of Epidemiology, University Medical Center Groningen, Netherlands

Background and aims: The risk of vascular retinal disorders is closely and continuously related to systolic blood pressure level, but data from long-term randomised controlled trials of blood pressure lowering on incidence or progression of retinal disorders in type 2 diabetes are scarce.

Materials and methods: The ADVANCE Retinal Measurements (AdRem) Study is a sub-study of ADVANCE, a randomised controlled double-blind trial of routine blood pressure lowering with a fixed combination of perindopril (4mg) and indapamide (1.25mg) in patients with type 2 diabetes. There were no blood pressure criteria for study entry. After a 6-week active run-in period, 1602 patients were randomised to active treatment or matching placebo, in addition to current therapy. At baseline and the final visit, seven-field stereoscopic retinal photographs of both eyes were taken and graded in a central reading center. New or worsening retinopathy defined as progression of ≥ 2 steps in ETDRS classification was the primary outcome. Gradable retinal images of both baseline and final photograph were received from 1241 patients.

Results: At baseline, retinopathy was present among 40.8% of patients. Mean \pm sd systolic and diastolic blood pressure were 141.8 ± 21.0 and 79.1 ± 10.7 mm Hg. Compared with patients on placebo, those on active therapy had a mean reduction in systolic and diastolic blood pressure of 6.1 ± 1.2 and 2.3 ± 0.6 mm Hg ($p < 0.001$). We documented progression of retinopathy in 59 (4.8 %) patients and incident retinopathy in 128 (10.3 %) patients during a median follow-up of 4.1 (3.7–4.3) years. Fewer patients on active therapy experienced new or worsening retinopathy compared with those on placebo (OR 0.78 (95%-CI: 0.57–1.06), but this difference was not significant ($p = 0.12$). Occurrence of any vascular lesion was similar in both groups ($p = 0.34$), but active therapy significantly reduced the occurrence of arteriovenous nicking compared to placebo (OR 0.60; 95%-CI: 0.38–0.94; $p = 0.025$).

Conclusion: Routine blood pressure lowering with a fixed perindopril/indapamide combination may reduce incidence or progression of retinal disorders among patients with established type 2 diabetes. The reduction in AdRem is similar to the 4.5-year results of UKPDS.

Diabetic retinopathy is associated with increased IMT and endothelial dysfunction in type 2 diabetes

J. Sieradzki¹, M.T. Malecki¹, G. Osmenda², M. Walus-Miarka¹, J. Skupien¹, T.J. Guzik¹, K. Cyganek¹, T. Adamek-Guzik², B. Mirkiewicz-Sieradzka¹

¹Department of Metabolic Diseases, ²Department of Internal Medicine and Agricultural Medicine, Jagiellonian University, Medical College, Krakow, Poland

Background and aims: Microangiopathy and macroangiopathy in type 2 diabetes (T2DM) frequently coexist. Both types of vascular diabetic complica-

tions share traditional risk factors, for example hyperglycemia and arterial hypertension. It is not clear whether the presence of microangiopathy, such as diabetic retinopathy (DR), constitutes a predictor of atherosclerosis in T2DM and what could be a putative mechanism of this association. The aims were: 1) To search in cross-sectional analysis for the association between DR and intima-media thickness (IMT) of carotid artery in T2M patients; 2) To compare endothelial function in T2DM patients with and without DR.

Materials and methods: We examined 182 consecutive patients with T2DM for at least 5 years, mean age at examination 56.3 ± 6.52 yrs. We assessed in these individuals: 1) IMT of carotid artery by ultrasound; 2) endothelial function by flow-mediated dilatation (FMD) method and measurement of concentrations of two biochemical markers: von Willebrand factor (vWF) and s-ICAM-1. All patients had ophthalmological examination with fundus photography. Statistical analysis included Student, Mann-Whitney, chi-square and Fisher tests and multiple regression analysis.

Results: DR was found in 71 (39.0%) diabetic patients. IMT was higher in patients with DR than in patients without DR (0.87 mm vs. 0.79 mm, $p=0.0001$, respectively). Additionally, FMD was lower in the complication group than in non-DR subjects (8.38% vs. 10.45% , $p=0.0023$, respectively). However, concentrations of circulating endothelial function markers s-ICAM-1 and vWF were not different between the groups. In multiple regression analysis DR was among the predictors of increased IMT ($p=0.016$) and decreased FMD ($p=0.002$). In addition, this analysis showed borderline significance for the association of DR with vWF and s-ICAM-1 levels ($p=0.07$ and $p=0.09$, respectively).

Conclusion: DR is associated with increased IMT thickness and endothelial dysfunction in T2DM. Therefore, diabetic patients with DR need particularly intensive cardiovascular screening. Impaired endothelial function may be a common denominator of pathogenesis of microvascular complications and atherosclerosis in T2DM.

Thickness changes of the retinal layers in diffuse diabetic macular oedema assessed by optical coherence tomography

G. Somfai¹, E. Tátrai¹, M. Ferencz¹, D. Cabrera²

¹Department of Ophthalmology, Mária street, Semmelweis University, Faculty of Medicine, Budapest, Hungary, ²Bascom Palmer Eye Institute, University of Miami, United States

Background and aims: Diabetic macular edema (DME) is the leading cause of visual impairment among patients with diabetes. There are several patterns of DME. In our study we aimed to assess which retinal layers show thickness changes in diffuse diabetic macular edema (dDME).

Materials and methods: 11 eyes with background retinopathy and dDME on optical coherence tomography (OCT) examination and 8 control healthy eyes were enrolled in our study with 1.0 best corrected visual acuity (mean age 56 [42–64] years and 54 [47–59] years, respectively). We performed standard macular mapping in all eyes using a Stratus OCT™ device. All OCT images were segmented using an algorithm of our own design, average thickness data were obtained for the following cellular layers: retinal nerve fiber layer (RNFL), ganglion cell layer and internal plexiform layer complex (GCL+IPL), inner nuclear layer (INL), outer plexiform layer (OPL) and outer nuclear layer (ONL). Mann-Whitney U test was performed for the pairwise comparison of the two groups.

Results: Average layer thickness significantly increased in all layers in the dDME group except for the RNFL. (RNFL: 43.83 ± 2.00 vs. 44.06 ± 2.64 [$p=0.934$], GCL+IPL: 73.10 ± 2.47 vs. 78.96 ± 3.01 [$p=0.003$], INL: 35.34 ± 1.69 vs. 38.06 ± 1.60 [$p=0.005$], OPL: 35.45 ± 2.01 vs. 37.55 ± 2.00 [$p=0.048$], ONL: 83.33 ± 3.61 vs. 95.02 ± 11.87 [0.016], results are mean $\mu\text{m} \pm \text{SD}$)

Conclusion: Our results show that all cellular layers of the retina but the RNFL become thicker in eyes with diffuse diabetic macular edema. It is still unknown how various cellular layers of the retina are involved in dDME formation, however OCT image segmentation may yield a closer look at the pathophysiology of the retina.

Low 5-year incidence of retinopathy in subjects with impaired fasting glucose (IFG), the NANSY-Eye Study

M. Tyrberg¹, A. Melander², U. Lindblad²

¹Department of Ophthalmology, Lund University, Helsingborg, ²Clinical Sciences, Lund University, Malmö, Sweden

Background and aims: Retinopathy is present early in type 2 diabetes. At baseline in the NANSY-Eye Study the prevalence of retinopathy was 10% in subjects with IFG. NANSY-Eye is a randomized placebo-controlled Swedish study investigating if treatment with sulfonylurea, in addition to dietary regulation and increased exercise, prevents the development of retinopathy in subjects with IFG.

Materials and methods: Subjects were surveyed in primary care with repeated fasting blood glucose measurements. Those with a mean of two consecutive values ≥ 5.6 and < 6.9 mmol/l were invited to participate. At baseline 154 had retinal photographs taken. After 5 years retinal photos from 75 subjects have been graded. Fundusphoto (dia) was taken in two fields after dilation of the pupil. The photos were graded according to the alternative classification of the Wisconsin Epidemiologic Study of Diabetic Retinopathy.

Results: 41 men and 34 women have been photographed. At baseline ten had retinopathy, and out of these three had retinopathy after 5 years. Five of these ten had been treated with sulfonylurea. At study term after 5 years four of the 75 had developed retinopathy, and out of these one had been treated with sulfonylurea. Those with retinopathy at study term had higher systolic (154 vs. 142 mmHg, $p=0.083$) and diastolic (87 vs. 77 mmHg, $p=0.005$) blood pressure compared with those without retinopathy.

Conclusion: The main finding in this study was the very low incidence of retinopathy in subjects with IFG who had received dietary and exercise advices. Larger studies are warranted to measure the incidence more accurately. Retinopathy in this narrow glucose interval is associated with high blood pressure.

HbA_{1c} as predictor of diabetic retinopathy in non-diabetic subjects: the Hoorn Study

H. Zavrelova^{1,2}, E. van 't Riet¹, B.C.P. Polak^{1,2}, R.J. Heine¹, C.D.A. Stehouwer³, G. Nijpels¹, J.M. Dekker¹

¹EMGO Institute, VU University Medical Center, Amsterdam, ²Department of Ophthalmology, VU University Medical Center, Amsterdam,

³Department of Internal Medicine, Academic Hospital Maastricht, Netherlands.

Background: HbA_{1c} is used to estimate mean blood glucose levels in known type 2 diabetes mellitus patients (KDM). For subjects with non-diabetic glucose levels HbA_{1c} is not in use as indicator of mean blood glucose, because of limited agreement on the correlation of fasting and postload glucose with HbA_{1c} in non-diabetic subjects. The aim of the present study was to address the question whether elevated HbA_{1c} predicts future diabetes complications in subjects with normal glucose metabolism (NGM) and impaired hyperglycaemia (IH).

Methods: In the Hoorn Study, a sex and glucose status stratified sample ($n = 631$, age 50–75) of a population-based cohort study underwent duplicate OGTT at baseline. At baseline and after 10 years a physical examination was performed. The 10 year incidence of diabetic retinopathy (DR) could be determined in 233 subjects. DR was assessed by fundus photography. WHO '06 criteria based on the mean of duplicate measurements were used to define glucose status. High HbA_{1c} was defined by the clinically used cut-off point of $\geq 6.0\%$. Logistic regression analysis with adjustment for age and gender was used. Odds ratios were computed in categories of glucose status with either low or high HbA_{1c}, all relative to NGM subjects with low HbA_{1c}.

Results: The study population of 233 subjects consisted of 110 NGM, 66 IH, 41 NDM and 16 KDM subjects. A total of 27 out of 233 subjects developed DR. Only 2.7% of NGM and 16.7% of IH subjects had high HbA_{1c} as opposed to 68.3% of NDM and 81.3% of KDM subjects. Subjects with HbA_{1c} $\geq 6.0\%$ had a strongly elevated risk of developing DR compared to subjects with low HbA_{1c}. This was observed, not only in diabetic patients, but also in

NGM and IH subjects (see table 1). IH and NDM subjects with $HbA_{1c} < 6\%$ had moderately elevated risk of developing DR.

Conclusion: Elevated HbA_{1c} predicts diabetic retinopathy, also in subjects without diabetes mellitus.

Table 1. Age and sex adjusted 10-year risk of developing diabetic retinopathy relative to NGM subjects with $HbA_{1c} < 6\%$. (Odds Ratio (95% CI interval)).

	NGM	IH	NDM	KDM
$HbA_{1c} < 6.0\%$	1; reference	1.31 (.39-4.38)	1.19 (.13-10.70)	–
$HbA_{1c} \geq 6.0\%$	10.14 (.75-136.24)	7.19 (1.63-31.77)	1.71 (.44-6.62)	8.71 (2.20-34.55)

1180

The impact of different type and severity of hypertension on retinopathy, nephropathy and the ECG abnormalities in diabetic patients

Z. Xu¹, Z. Wang¹, Y. Wang¹, Z. Mo², X. Li¹

¹306th Hospital of PLA, Diabetes Center, Beijing, ²The Third Xiangya Hospital, Endocrinology Department, Changsha, China

Background: There are 180 million people with hypertension and 40 million people with diabetes in China. About 50% of Chinese diabetic patients with hypertension. The awareness, treatment and control of hypertension were 30.2%, 24.7% and 6.1% respectively, based on the nationwide survey in 2002. Hypertension aggravates diabetic complications development.

Objective. To investigate the impact of different type of hypertension on diabetic retinopathy nephropathy and abnormal ECG.

Methods: 5841 patients from the diabetic complication assessment database from 1994 to 2006 were divided into the different groups based on their blood pressure level and the type of hypertension, group A (n=3580, BP <140/<90 mmHg), group B (n=456, BP <140/<90 mmHg, with hypotensive agents), group C (n=1271, BP=140-159 / 90 -99 mmHg), group D (n=396, BP=160-179 /100 -109 mmHg), group E (n=138, BP≥180 /110 mmHg), group 3 (n=1262, systolic hypertension only), group 4 (n=103, diastolic hypertension only) and group 5 (n=440, both systolic and diastolic hypertension), and analyzed for their retinopathy, nephropathy and abnormal ECG results.

Results: Of these patients, 1006 patients with retinopathy, including 898 (15.37%) with background and 108 (1.85 %) with proliferative retinopathy; 1145 with abnormal urine albumin excretion, 1077 with abnormal ECG. The prevalence of retinopathy, nephropathy and the abnormal ECG was increased from 15.0%, 17.2%, 29.9% in Group A to 34.8 %, 54.5 %, 66.7% in Group E. No differences in the prevalence of retinopathy and nephropathy between Group A and Group B (15.0 % vs.17.8 %; 17.2 % vs.16.3 %). There were significant differences of the ECG abnormalities between different groups (29.9 % for Group A, 37.4% for Group B, 40.5% for Group C, 49.4 % for Group D and 66.7 % for Group E). There were significant differences of the prevalence of retinopathy, nephropathy and abnormalities among Group 3 (21.6 %, 46.7 %, 42.3 %), Group 4 (11.0%, 35.6%, 45.0%), and Group 5 (22.8%, 47.3%, 49.5%).

Conclusion: Hypertension aggravates the retinopathy, nephropathy and abnormalities in the diabetic patients. No significant difference of the prevalence of retinopathy and nephropathy, except ECG abnormalities between the diabetic patients with normal blood pressure and those diabetic patients with taking the hypotensive agents and with satisfactorily controlled blood pressure.

Low prevalence of retinopathy and ocular lesions in patients with diabetes mellitus - , “Diabetes TÜV”, a continuous, biennial, cross-sectional analysis of diabetes metabolic control and diabetic complications - data of the years 2004 to 2006

C.S. Kloos¹, N. Müller¹, J. Dawczynski², R. Berner³, G. Wolf¹, U.A. Müller¹

¹University Hospital, Klinikum für Innere Medizin III, Jena, ²University Hospital, Jena, ³Controlling, Deutsche BKK, Deutsche BKK, Stuttgart, Germany

Background and aims: Since 1997, first as a pilot project, then on a nationwide scale, a health insurance company in Germany (“Deutsche BKK”) initiated an evaluation of treatment quality and prevalence of diabetic complications (“Diabetes TÜV”) for all insured patients with diabetes mellitus. Results of the ophthalmologic examinations are presented here.

Materials and methods: A total of 7166 patients from 2004 to 2006 participated in the “Diabetes TÜV”. 5777 patients (81%) were screened by 110 ophthalmologists (9076 examinations documented, multiple examinations 36.3%). A standardised documentation protocol was used (initiative group for early diagnosis of diabetic eye diseases, Prof. Kroll, Marburg, Germany). Years since diabetes diagnosis was documented in 100%, the type of diabetes in 88%, HbA_{1c} , blood pressure (RR) and age in 32%. Patients’ characteristics were as follows: diabetes mellitus type 1 (DM1): 7.4%, age $47.0 \pm 20.34y.$, years since diabetes diagnosis $13.7 \pm 12.0y.$, HbA_{1c} $7.21 \pm 1.23\%$, prevalence of arterial hypertension 31%, diabetes mellitus type 2 (DM2): age $66.3 \pm 10.2y.$, years since diabetes diagnosis $8.6 \pm 8.0y.$; HbA_{1c} $6.91 \pm 1.16\%$, prevalence of arterial hypertension 65%.

Results: 87.1% had no sign of diabetic retinopathy (DR) (years since diabetes diagnosis 7.4y, HbA_{1c} 7%). In 15.2% DR was detected, mostly early stages (grading of RD/diabetes diagnosis/ HbA_{1c} : mild DR 12.9%/12.6y/ HbA_{1c} 7.03%; severe non-proliferative RD 2.2%/12.6y/ HbA_{1c} 8.2%; proliferative RD 0.5%/15.5y/ HbA_{1c} 7.6%). Prevalence of RD did not differ significantly between DM1 and 2 (no RD in DM1 82% vs. DM2 87%, mild RD 95.7/97.5%, non proliferative RD 2.8/1.6%, proliferative RD 1.3/0.4%). Regression analysis revealed association of RD to duration of diabetes, HbA_{1c} and blood pressure (decreasing ranking, $p < 0.05$), but not for diabetes type and age. Macular edema was present in 0.7%, vitreous hemorrhage in 0.3%, retinal detachment with or without macular involvement in less than 0.1% (n=8), cataract or secondary cataract in 31.6%, an artificial lens in 14.7%, iris neovascularisation in less than 0.1% (n=4). As diagnostic or therapeutic measures were recommended: fluorescent angiography in 0.2%, focal laser coagulation in 0.4%, cryocoagulation in 0.1% and vitrectomy in less than 0.1% (n=4) of the patients. The frequency of ophthalmologic visits was once per year for 56.6% of the patients, twice for 31.1%, thrice for 11.3% and more in 1% (4 to 9 visits).

Conclusion: The quality of documentation in the check-up programme “Diabetes TÜV” of Deutsche BKK was satisfying. No lateralisation of the findings occurred. The prevalence of RD in the primary care level in diabetic patients is low, and mostly mild and comparable to the last evaluation in 2002 to 2004 (2002-04 11.6%, 2004-06 12.6%). Longer duration of diabetes, elevated HbA_{1c} and blood pressure are associated with the prevalence of RD, well in accordance with randomised studies (e.g. UKPDS). Attempts to further prevent diabetic eye complications should focus on improving insufficiently controlled blood pressure or glycemic control. The “Diabetes TÜV” is a successful tool to monitor the quality of care in diabetes on the primary care level.

Rosiglitazone inhibit the upregulation of monocyte chemoattractant protein-1 induced by advanced glycosylation end products in human renal mesangial cells

Y. Yuan, Z. Sun

Department of Endocrinology, ZhongDa Hospital, South East University, Nanjing, China

Background and aims: Previous work shown advanced glycosylation end products (AGEs) increased the expression of monocyte chemoattractant protein-1 (MCP-1) in human renal mesangial cells (HRMCs). The aim of this study was to further investigate the effect of rosiglitazone on the upregulation of MCP-1 induced by AGEs

Materials and methods: HRMC were incubated with AGE-bovine serum albumin (AGE-BSA) in the presence or absence of rosiglitazone. MCP-1 mRNA and protein expression in HRMC were analyzed by reverse transcription-polymerase chain reaction (RT-PCR) and Western blotting. The MCP-1 protein in supernatant was also quantified by ELISA.

Results: About a 50% increase in the MCP-1 mRNA (0.635 ± 0.030 vs 0.326 ± 0.025 , $P < 0.01$), protein (0.347 ± 0.041 vs 0.110 ± 0.015 , $P < 0.01$) and production was observed in HRMCs incubated with AGE-BSA ($80 \mu\text{g} \cdot \text{ml}^{-1}$) as compared to BSA ($80 \mu\text{g} \cdot \text{ml}^{-1}$) for 24h. Furthermore, the MCP-1 protein levels in lysates increased with the elevated AGE-BSA of 80, 160, 320 and $640 \mu\text{g} \cdot \text{ml}^{-1}$ ($361.80134.96$ vs 723.34 ± 21.61 ; 368.16 ± 32.49 vs 862.95 ± 21.28 ; 356.94 ± 28.14 vs 1016.63 ± 35.67 ; 367.61 ± 24.32 vs 1022.96 ± 37.15 $\text{pg} \cdot \text{ml}^{-1}$ respectively, $P < 0.01$ $n=3$). MCP-1 protein were increased significantly with prolongation of experimental time (1h, 4h, 8h, 24h, 48h) as well (0.212 ± 0.011 , 0.389 ± 0.032 , 0.356 ± 0.032 , 0.254 ± 0.033 , 0.213 ± 0.021) when HRMCs exposed to AGE-BSA ($160 \mu\text{g} \cdot \text{ml}^{-1}$). MCP-1 mRNA expression increased significantly at first hour (0.647 ± 0.045 vs 0.327 ± 0.0141 , $P < 0.01$), but the peak at 4h (1.071 ± 0.067). Rosiglitazone ($1 \mu\text{mol} \cdot \text{L}^{-1}$) show the significant role of inhibition for MCP-1 in HRMCs incubated with AGE-BSA ($160 \mu\text{g} \cdot \text{ml}^{-1}$) overexpression (mRNA: 0.348 ± 0.031 vs 0.635 ± 0.053 , $P < 0.001$ $n=3$; protein: 0.271 ± 0.028 vs 0.342 ± 0.031 , $P < 0.001$, $n=3$; protein in lysates: 463.85 ± 34.48 vs 962.95 ± 51.28 $\text{pg} \cdot \text{ml}^{-1}$, $P < 0.01$, $n=3$).

Conclusion: The present study suggest that AGEs have the potency of concentration- and time-dependently upregulation the expression of MCP-1 in cultured human mesangial cells. Rosiglitazone can markedly reduce the up-regulation of MCP-1 induced by AGE.

1183

Antioxidant SOD-mimetic prevents NADPH oxidase-induced oxidative stress and renal damage in the early stage of experimental diabetes and hypertension

E.B.M. Peixoto, B.S. Pessôa, S.K. Biswas, J.B. Lopes de Faria

Internal Medicine, University of Campinas, Brazil

Background and aims: Hypertension is common in patients with diabetes mellitus (DM), and their combination increases the frequency and severity of nephropathy in an additive manner. It has been demonstrated that the presence of hypertension increases renal oxidative stress by increasing NADPH oxidase dependent superoxide production and by decreasing antioxidant defense in the early stage of experimental DM. In the present study, we investigated whether the administration of tempol, an antioxidant that is a mimetic of the superoxide dismutase (SOD), corrects the oxidative imbalance and oxidative stress-induced renal injuries in the presence of DM and hypertension.

Methods: DM was induced in spontaneously hypertensive rats (SHR) by streptozotocin (60 mg/kg) at 4 weeks of age. Blood glucose levels of $\geq 270 \text{ mg/L}$ were considered diabetic. The diabetic rats were randomly assigned to receive intraperitoneally no treatment or treatment with tempol at a dose of 250 mg/kg , mean of 5 rats per group. After 20 days, rats were sacrificed and kidneys were collected. Renal extracellular antioxidant EC-SOD expression was assessed by Western Blot. Oxidative stress-induced DNA base modification was evaluated by immunohistochemistry for 8-hydroxy-2'-deoxyguanosine (8-OHdG). NADPH-induced superoxide generation was assessed by

lucigenin-enhanced chemiluminescence. Urinary albumin was assessed by single radial immunodiffusion. Renal collagen IV protein expression was evaluated by immunohistochemistry and Western Blot analysis.

Results: Plasma glucose levels were higher in untreated and treated diabetic than in control SHR (482 ± 52 vs 444 ± 276 vs $169 \pm 24 \text{ mg/dl}$, respectively, $p < 0.0001$). Systolic blood pressure was unaltered by diabetes or by treatment with tempol, control = 159 ± 11 , untreated diabetic = 156 ± 7 , tempol diabetic = $152 \pm 9 \text{ mmHg}$. Tempol treatment reestablished the imbalance in redox status induced by DM. Renal antioxidant SOD, in arbitrary units, that was 1.274 ± 0.823 in control rats diminished to 0.41 ± 0.60 in diabetic and raised to 2.45 ± 1.01 with treatment with tempol, $p < 0.0001$. Diabetes increases the renal NADPH-dependent superoxide production (RLU/20s/mg) from 11.84 ± 0.73 to 15.01 ± 2.01 , and it was markedly reduces ($p = 0.0495$) by tempol treatment to 4.58 ± 1.89 . 8-OHdG, a marker of oxidative stress-induced DNA damage in the kidney was elevated in diabetic rats (695 (642 - 754) vs 159 (130 - 206) positive cells/50 high field) and it diminished ($p = 0.016$) to 595 (555 - 659) with tempol treatment. Reduction of oxidative stress markers was associated with reduction in renal injuries parameters associated with diabetic nephropathy. Tempol reduced ($p = 0.052$) DM-induced albuminuria from 680 (180 - 1815) to 366 (109 - 1342) $\mu\text{g}/24 \text{ hour}$; and DM-induced elevation in glomerulus and tubulointerstitial expression of collagen IV was reduced by tempol ($p = 0.042$) to the level observed in control rats (4.24 ± 2.22 vs 1.55 ± 1.51 , arbitrary units).

Conclusion: In the context of these and previous findings by our group, we conclude that an imbalance in renal redox status is associated with markers of renal injury in the early stage of DM and hypertension. Antioxidant treatment not only reestablished the redox status but also prevented oxidative stress-induced renal damage.

Effectiveness of resveratrol treatment in the improvement of oxidative stress and protection against diabetic nephropathy via normalisation of Mn-SOD dysfunction

D. Koya, M. Kitada

Endocrinology & Metabolism, Kanazawa Medical University, Kahokugun, Ishikawa, Japan

Background and aims: Resveratrol (RSV), a one of the polyphenols found in red wines, is known as an antioxidants as well as an enhancer of mitochondrial biogenesis, and has the beneficial effects for several diseases including cardiovascular disease, insulin resistance, and extension of lifespan. However it remains unclear whether RSV has the protected effect against diabetic nephropathy.

Materials and methods: Male diabetic db/db mice and age-matched non-diabetic db/m mice, at 9 weeks of age, were divided into four groups; 1) non-diabetic db/m mice, 2) diabetic db/db mice, 3) db/m mice treated with RSV, 4) db/db mice treated with RSV. RSV was given orally mixed (0.3%) in chow. After 8 weeks, we performed following experiments. Mn-SOD (manganese-superoxide anion dismutase) activity in the kidney was measured by inhibiting extra cellular and Cu/Zn SOD activity with KCN (1 mM) by using SOD assay kit. Urinary albumin and 8-OHdG (8-hydroxydeoxyguanosine) excretion were measured using ELISA kit. The mRNA expression of Mn-SOD, PGC-1 α (peroxisome proliferative activated receptor γ coactivator-1 α), and NRF-1 (nuclear respiratory factors-1), cytochrome c oxidoreductase were estimated by real time PCR. Mitochondrial DNA contents were calculated as the ratio of cytochrome c oxidase subunit 2 DNA to uncoupling protein 2 DNA as mitochondrial DNA per nuclear genome. The tyrosine nitration of immunoprecipitated Mn-SOD was estimated by western blotting. The staining for nitrotyrosine was estimated by immunohistochemistry. Mesangial expansion was quantified as a PAS-stained positive area. The blood glucose levels were measured every two weeks, and HbA1c was measured by HPLC at the end of experiments.

Results: Urinary 8-OHdG excretion and the staining for nitrotyrosine in the kidney of db/db mice were increased compared with db/m mice. The alterations were improved on treatment with RSV. Reduced Mn-SOD activity and increased Mn-SOD nitrosation was observed in db/db mice compared with db/m mice. On the other hand, mitochondrial biogenesis indicated by overexpression of PGC-1 α , NRF-1, cytochrome c oxidoreductase and mitochondrial DNA contents, was significantly enhanced in db/db mice compared with db/m mice, accompanied by the Mn-SOD overexpression. Urinary albumin excretion and mesangial expansion increased in db/db mice significantly compared with db/m mice, and these abnormalities in db/db mice

improved on treatment with RSV. The blood glucose level was significantly elevated in db/db mice compared with db/m mice throughout the period of experiments. RSV significantly ameliorated the elevated blood glucose levels in db/db mice at the end of experiments; however, there was no difference in HbA1c between db/db mice and db/db mice treated with RSV.

Conclusion: These findings suggest that altered mitochondrial biogenesis with Mn-SOD dysfunction caused by oxidative stress occurs in the kidney of db/db mice. Therefore, reduction of oxidative stress by RSV, especially via normalization of Mn-SOD dysfunction, but not via enhancement of mitochondrial biogenesis, might be effective in protecting against diabetic nephropathy.

1185

TGF- β 1 upregulates insulin-like growth factor binding protein (IGFBP)-7 expression in human renal proximal tubular epithelial cell (HRPTEC)

J. Watanabe, Y. Takiyama, J. Honjyo, T. Isoe, H. Sakagami, Y. Makino, Y. Fujita, M. Haneda

Department of Medicine, Asahikawa Medical College, Japan

Background and aims: Tubulointerstitial fibrosis is presently considered to be a common pathway of various progressive kidney diseases including diabetic nephropathy (DN) leading to end-stage renal disease, and TGF- β 1 plays an important roles in these pathological mechanisms. In order to identify novel molecules derived from human renal tubular cell regulated by TGF- β 1, we used LC-MS/MS-based proteomic technique. Several proteins in cultured media of HRPTEC were identified to be upregulated by TGF- β 1, one of which was 33 kDa IGFBP-7. IGFBP-7, also named as IGFBP-related protein 1, MAC 25 or prostacyclin-stimulating factor is a recently described member of the low-affinity IGFBP family, which binds IGF-I, IGF-II and insulin by inhibiting insulin signaling. Recently, the serum concentrations of IGFBP-7 have been reported to be associated with insulin resistance. To clarify the potential effects of IGFBP-7 in DN, we assessed the regulation of IGFBP-7 expression in HRPTEC.

Materials and methods: First, we studied the time- (1–24 hrs) or dose- (0.625–10 ng/ml) dependent effect of TGF- β 1 on the expressions of IGFBP-7 protein and mRNA, using Western blotting analysis and quantitative real-time RT-PCR. We also examined the expression of IGFBP-7 in human kidney tissue with type 2 diabetes and overt nephropathy. Renal biopsy specimens were obtained with the informed consent of the patients with diabetic nephropathy, according to the regulations of the local ethics committee.

Results: HRPTEC barely expressed and secreted IGFBP-7 into cultured media. The secretion and intracellular expression of IGFBP-7 were also increased by the treatment of high glucose (30 mM D-glucose) overnight. Interestingly the biguanide metformin, known as an insulin sensitizer, decreased the secretion and intracellular expression of IGFBP-7, and furthermore inhibited TGF- β 1-enhanced the secretion and intracellular expression of IGFBP-7. The stimulatory effects of TGF- β 1 on the secretion and intracellular expression of IGFBP-7 protein were in a dose- and time-dependent fashion. We next examined the effect of TGF- β 1 on IGFBP-7 gene expression by quantitative real-time RT-PCR. The treatment with TGF- β 1 at the concentration of 2.5 ng/ml overnight significantly ($p < 0.01$) increased approximately two fold IGFBP-7 mRNA expression compared to control. Finally, in the immunohistochemical analysis, the positive staining for IGFBP-7 was observed in tubular cells but not in glomerular cells.

Conclusion: In conclusion, TGF- β 1 or high glucose enhances IGFBP-7 expression in HRPTEC, suggesting that IGFBP-7 may play a role in the renal tubular cell damage, leading to the progression of DN. Furthermore, we found that IGFBP-7 is expressed by human renal tubular cells in vitro and in human kidney tissue with overt DN accompanied with type 2 diabetes. Taken together, these data suggest that IGFBP-7 might be one of candidate biomarker for the diagnosis of DN, especially tubular injury.

The effect of α -lipoic acid on proteinuria and renal TGF β expression in OLETF rat

S. Lee¹, S. Kang², J. Kang¹, O. Ryu¹, C. Kim¹, B. Lee¹, E. Hong¹, H. Kim¹, D.-M. Kim¹, J. Yoo¹, S.-H. Ihm¹, M. Choi¹, H. Yoo¹, D.-S. Kim³, T. Kim³

¹Division of Endocrinology and Metabolism, Hallym University Sacred Heart Hospital, Anyang-Si, Gyenggi-Do, ²Division of Endocrinology and Metabolism, Seoul Red Cross Hospital, Seoul, ³Division of Endocrinology and Metabolism, College of Medicine, Hanyang University, Seoul, Republic of Korea

Background and aims: This study was undertaken to investigate whether α -lipoic acid (ALA) could reduce urinary protein excretion and renal TGF β protein expression in obese type 2 diabetes mellitus animal model, Otsuka Long Evans Tokushima Fatty (OLETF) rat.

Materials and methods: Obese 30 male OLETF rats were randomly divided to 3 groups at the age of 30 weeks. The rats in the Control group fed normal rat chow while the rats in the ALA group were fed with rat chow containing ALA (0.5% of food weight). Ten rats in the Pair-fed group were fed with normal rat chow, but were given the same amount of food as consumed by the ALA group. During 5 weeks of ALA feeding, food intake and body weight were checked in metabolic chamber. Blood glucose levels, HbA1c and urinary protein excretion were measured at 30 weeks and 35 weeks of age, and renal TGF β protein expression at 35 weeks of age was measured by Western blot and represented by relative unit (RU). Immunohistochemical staining for TGF β protein in renal tissue was also examined at 35 weeks of age.

Results: Food intake, body weight, blood glucose levels, HbA1c and urinary protein excretion among the Control, ALA and Pair-fed groups at 30 weeks of age were not different. At 35 weeks of age, food intake was significantly decreased in the ALA group than the Control group (Control group vs. ALA group, 27.7 ± 1.1 g/day vs. 22.4 ± 1.4 g/day, $P < 0.001$), and body weight was significantly decreased in the ALA group than the Control and Pair-fed groups (Control group: 694.4 ± 10.3 g, ALA group: 600.4 ± 7.4 g, Pair-fed group: 685.4 ± 11.6 g, $P < 0.001$). Blood glucose levels were significantly decreased in the ALA group than the Control and Pair-fed groups (Control group: 157.7 ± 4.6 mg/dL, ALA group: 130.7 ± 4.8 mg/dL, Pair-fed group: 153.7 ± 3.3 mg/dL, $P < 0.001$) although blood glucose levels from 30 weeks to 34 weeks of age and HbA1c at 35 weeks of age were not different among the groups. Urinary protein excretion and renal TGF β protein expression were significantly decreased in the ALA group than the Control and Pair-fed groups (urinary protein excretion, Control group: 5.033 ± 0.254 mg/mg-Cr, ALA group: 3.633 ± 0.303 mg/mg-Cr, Pair-fed group: 4.977 ± 0.339 mg/mg-Cr, $P < 0.001$; renal TGF β protein expression, Control group: 7.09 ± 0.17 RU, ALA group: 4.14 ± 0.26 RU, Pair-fed group: 7.00 ± 0.29 RU, $P < 0.001$). In the ALA group at 35 weeks of age, urinary protein excretion and renal TGF β protein expression were positively related in the Control, ALA and Pair-fed groups (Control group, $r = 0.847$, $P = 0.002$; ALA group, $r = 0.954$, $P < 0.001$; Pair-fed group, $r = 0.858$, $P = 0.002$). TGF β staining in glomeruli was observed in all groups but was decreased in the ALA group at 35 weeks of age.

Conclusion: These results suggest that ALA may prevent the increase of food intake, body weight, blood glucose, urinary protein excretion and renal TGF β protein expression in obese type 2 diabetic rat model. The effect of ALA on diabetic nephropathy presented as proteinuria and renal TGF β expression in diabetic patients needs to be further clarified.

1187

Involvement of matrix metalloproteinase-2 in down-regulation of pigment epithelium-derived factor in experimental diabetic nephropathy

K. Fukami¹, S.-I. Yamagishi², Y. Takamiya¹, S. Ueda¹, Y. Kaida¹, A. Hayashida¹, T. Kusumoto¹, K. Koike¹, S. Okuda¹

¹Department of Medicine, Division of Nephrology, ²Department of Medicine, Division of Cardiovascular Medicine, Kurume University School of Medicine, Kurume city, Fukuoka, Japan

Background and aims: Pigment epithelium-derived factor (PEDF), a glycoprotein that belongs to the superfamily of serine protease inhibitors, was first purified from the conditioned media of human retinal pigment epithelial cells as a factor which possesses potent neuronal differentiating activity. Recently, we, along with others, have found that PEDF has anti-oxidative and anti-inflammatory properties in vivo, both of which could potentially be exploited as a therapeutic option for the treatment of vascular complications in diabetes. Indeed, overexpression of PEDF was reported to allevi-

ate microalbuminuria, prevent the expression of fibrogenic factors, and to significantly reduce the production of an extracellular matrix protein in the diabetic kidney. However, the kinetics and regulation of PEDF in the diabetic kidney are not fully understood. Since PEDF is known to be a substrate for matrix metalloproteinase-2 (MMP-2), we investigated its implications for down-regulation of PEDF in the diabetic kidney.

Materials and methods: Nine wk-old Sprague-Dawley rats received single 50 mg/kg intravenous injection of streptozotocin. Control non-diabetic rats received citrate buffer alone. Animals with blood glucose levels greater than 250 mg/dl 48 h later were considered diabetic. After 16 weeks, MMP-2 expressions in the glomeruli and urine were evaluated by zymography. Urinary albumin excretion (UAE) was measured by an enzyme-linked immunosorbent assay. PEDF expression in the kidney was evaluated by western blot analysis and immunohistochemistry.

Results: Plasma level of glucose, HbA1c and kidney to total body weight ratio were increased by about 2–3-folds in diabetic rats, compared with non-diabetic control rats (plasma glucose; 589 \pm 38 mg/dl, HbA1c; 8.8 \pm 0.3 % in diabetic rats). Zymography revealed that both pro- and active-MMP-2 expressions in the glomeruli and urine were increased to about 4–5-folds in diabetic rats, which were associated with the increase in UAE. PEDF expression in the glomeruli was down-regulated in experimental diabetes. Further, when proteins extracted from glomeruli of control rats were exposed to MMP-2, PEDF levels were found to be decreased in an MMP-2-dose-dependent manner.

Conclusion: The present study demonstrated for the first time that MMP-2 overexpression at early phase of diabetic nephropathy was involved in PEDF down-regulation in the diabetic kidney. Our observations suggest that restoration of PEDF via MMP-2 suppression may offer a promising strategy for halting the development and progression of diabetic nephropathy.

Effects of 1,25 dihydroxyvitamin D3 on the early diabetic glomerulopathy

L. Wogensen¹, J. Nyengaard², S. Krag¹

¹Research Laboratory for Biochemical Pathology, ²Dept of Stereology, Aarhus University, Denmark

Background and aims: Diabetes is a common cause of renal disease. TGF- β 1 is known to be a key mediator in the pathogenesis of diabetic nephropathy. Recent evidence suggests that vitamin D can interact with the TGF-beta signaling pathway, and vitamin D has positive effects on different models of renal disease

Materials and methods: As a model of type 2 diabetes, diabetic db/db mice and non-diabetic db/+ control animals were divided into two groups each. One group was injected with 1,25 dihydroxyvitamin D3 (VitD3) 3 times weekly for 8 weeks, while the other half only received vehicle (Veh). After 8 weeks the animals were euthanized and renal morphology and collagen content evaluated.

Results: The diabetic mice treated with VitD3 had lower mean blood glucose compared with Veh controls (15.8 \pm 6.1 mM vs. 22.0 \pm 4.5 mM) ($p=0.016$). At the same time the plasma insulin level was higher in the db/db vitD3 than the Veh group (29.7 \pm 16.6 μ g/l vs 14.1 \pm 8.1 μ g/l) ($p<0.05$). To eliminate the effect of different blood glucose levels, subpopulations with comparable glucose levels were used in the morphological analysis. The basement membrane thickness (BMT) was increased in db/db VEH animals (151 \pm 11 nm, $n=10$). This increase was eliminated by VitD3 (136 \pm 13 nm $n=9$; $p=0.012$). Diabetes increased the volume fraction of the mesangium from 0.197 \pm 0.045 in the db/+ Veh control group to 0.273 \pm 0.035 in the db/db Veh group. However, VitD3 had no effect on the accumulation of mesangial matrix (db/db VitD3 0.258 \pm 0.030). Finally measurement of hydroxyproline revealed no differences among the four groups in total collagen content, and thus no sign of interstitial fibrosis. We have conducted mesangial cell culture experiments that support these findings since vitD3 further stimulates TGF- β 1-induced fibronectin synthesis ($p<0.05$).

Conclusion: VitD eliminates the basement membrane thickening in db/db diabetic mice without effect on diabetes-induced mesangial expansion.

Screening for kidney disease in diabetic patients - how useful are renal ultrasonography and serum immunology?

S.J.C. Sammut, T.S. Purewal

Diabetes and Endocrinology, Royal Liverpool University Hospital, United Kingdom

Background and aims: Kidney disease in diabetes is common. However, the incidence of non-diabetic kidney disease in diabetic patients is also as high as 30%. Identifying these potentially treatable conditions is important. The primary aim of this study was to evaluate the usefulness of performing immunological blood tests and renal ultrasound to screen for alternative renal pathology in patients with presumed diabetic nephropathy.

Materials and methods: Retrospective review and correlation of results of immunological blood testing and renal ultrasonography in diabetic clinics at the Royal Liverpool University Hospital over a three-year period.

Results: A total of 1186 immunology screens were performed over the time period (from a total of 24000 patient visits). 754 of these patients also had renal ultrasonography performed. There were a total of 232 positive immunology screens (20%). 454 patients had normal renal appearances on ultrasonography (60%); in 300 some abnormality was detected (40%), of which 154 were deemed of significance (20%). Of these 154 patients, 39 had a positive immunology screen (25%). Of the 232 patients with positive immunology: 88 had normal renal appearances on ultrasonography (38%); 78 did not have a renal ultrasound performed (34%); and 66 had some abnormality visualised (28%), of which 37 were deemed significant abnormalities (16%). The cost per case for picking up abnormal results at UK NHS costings was £190 per abnormal ultrasound scan (at £40 per scan) and £475 per positive immunology screen (at £121 each).

Conclusions: There was a striking similarity between the group of patients as a whole and the subgroup of patients with positive immunology, in terms of whether a renal ultrasound had been performed and if it showed a significant abnormality. This suggests that there is a poor correlation between abnormalities seen on ultrasound and abnormalities picked up on serum immunological screening. However, 20% of both immunological and renal ultrasound tests found significantly abnormal results. The abnormality pickup rate is high enough to justify continuation of both tests in screening of diabetic patients for non-diabetes related nephropathy. It should be noted, however, that these cases will often require further diagnostic workup. Ultrasound scanning should generally be performed first. Further work is needed to evaluate if these costs are truly justified, by showing that the tests lead to a final diagnosis (i.e. of non-diabetic nephropathy) and interventions that result in improved outcomes for patients.

Cystatin C formulas for prediction of GFR in patients with DM type 2 and renal dysfunction

M. Zavrsnik¹, S. Bevc², R. Hojs², E. Robert², M. Gorenjak³, L. Puklavac⁴

¹Department of Diabetology and Endocrinology, ²Department of Nephrology, ³Department of Clinical Chemistry, ⁴Department of Nuclear Medicine, University Medical Centre Maribor, Slovenia

Background and aims: Estimation of the glomerular filtration rate (GFR) is essential for the evaluation of patients with chronic kidney disease (CKD). Recently, serum cystatin C-based equations were proposed as markers for estimation of GFR. Present study compared serum cystatin C-based equations in patients with diabetes mellitus type 2 and CKD.

Materials and methods: GFR was estimated using six equations (Larsson, LeBricon, Hoek, Grubb, simple cystatin C formula (GFR = 100/cystatin C) and our own cystatin C formula (GFR = 90.63 x cystatin C^{-1.192}) that are based on serum cystatin C in 133 adult patients with diabetes mellitus type 2 and CKD. The serum cystatin C was determined by an immunonephelometric method. GFR was measured using ⁵¹CrEDTA clearance (gold standard), and the correlation, accuracy, bias and precision were determined. Ability to correctly estimate patient's GFR with different equations compare to gold standard below and above 60 ml/min/1.73m² was analyzed.

Results: The mean ⁵¹CrEDTA clearance was 42 ml/min/1.73m², the mean serum cystatin C was 2.58 mg/l. Statistically significant correlation between ⁵¹CrEDTA clearance with all six serum cystatin C-based equations ($r = 0.872$ - 0.901) was found. The Receiver Operating Characteristic (ROC) curve analysis

(cut-off for GFR 60 ml/min/1.73m²) showed no difference of diagnostic accuracy between serum cystatin C-based equations. The serum cystatin C-based equation showed different bias. All equations underestimated measured GFR (Larsson -50.9; Hoek -22.8; LeBricon -16.6; Grubb -17.8; our cystatin C formula -10.6; simple cystatin C formula -1.1 ml/min/1.73m²). According to bias the simple cystatin C formula turned out as most precise method for calculating GFR compare to measured GFR by gold standard. Analysis of the SD of the mean difference between estimated and measured GFR showed that all equations lacked precision (minimal Larsson 16.3; maximal our cystatin C formula 19.6 ml/min/1.73m²). Ability to correctly estimate patient's GFR was high for all equations (LeBricon 92.5%, Hoek 88.0%, Grubb 88.0%, simple cystatin C formula 88.7%, our cystatin C formula 91.7%), except for Larsson formula where 21.1% of subjects were misclassified. Percentage of correct estimation of patient's GFR was significantly higher for simple cystatin C formula, our cystatin C formula and LeBricon formula compared to Larsson formula (88.7% versus 78.9%, $P < 0.046$; 91.7% versus 78.9%, $P < 0.0057$; 92.5% versus 78.9%, $P = 0.035$). No difference in ability to correctly estimate patient's GFR between simple cystatin C, our cystatin C, LeBricon, Hoek and Grubb formulas was found.

Conclusion: Our results indicate that all serum cystatin C-based equations, excluding Larsson formula, are reliable markers of GFR in patients with diabetes mellitus type 2 and CKD and for daily clinical practice most simple formula (100/cystatin C) could be appropriate enough for estimation of GFR.

Efficacy of serum cystatin C and parathyroid hormone as renal function markers in Japanese patients with type 2 diabetes mellitus, and the correlation between elevated serum cystatin C level and diabetic complications

T. Kimura¹, H. Ikeda¹, J. Fujikawa², K. Nomura¹, T. Aoyama¹, Y. Wada¹, K. Nabe¹, Y. Hamamoto³, S. Honjo¹, H. Koshiyama¹

¹Center for Diabetes & Endocrinology, Tazuke Kofukai Foundation Medical Research Institute Kitano Hospital, Osaka, ²Department of Laboratory Medicine, Tazuke Kofukai Foundation Medical Research Institute Kitano Hospital, Osaka, ³Division of Diabetes & Clinical Nutrition, Kyoto University, Japan

Background and aims: There have been few reports about usefulness of serum cystatin C in Japanese diabetic patients. We examined the efficacy of serum cystatin C and serum intact parathyroid hormone (iPTH) as diagnostic markers for early diabetic nephropathy in Japanese patients with type 2 diabetes. We also investigated the prevalence of diabetic complications in the patients with elevated serum cystatin C level.

Subjects and methods: A total of 231 consecutive Japanese with type 2 diabetes (mean age 66 years; 147 male and 84 female) were included. Estimated GFR (eGFR) was calculated by the formula of Modification of Diet in Renal Disease. Correlation analysis and receiver operator characteristics analysis were used for examining the accuracy of serum cystatin C and that of iPTH to detect chronic kidney stage (CKD) stage 2 and 3. The subjects were divided into two groups: those with serum cystatin C equal or more than 0.85 mg/l (H-CysC group) and those with serum cystatin C less than 0.85 mg/l (L-CysC group). The differences of the prevalence of each diabetic complication between the two groups were analyzed by chi-square test.

Results: There was a significant positive correlation between the reciprocal of serum cystatin C and eGFR ($r = 0.86$, $p < 0.01$), although not between serum iPTH and eGFR ($r = 0.0059$, not significant). To detect CKD stage 3, the area under the curve (AUC) of cystatin C was high (0.965), whereas that of iPTH was low (0.567). Targeting CKD stage 2, the AUC of cystatin C was 0.873; that of iPTH was 0.452. To screen CKD stage 3, serum cystatin C had the best test characteristics at the cut-off level of 0.85 mg/L (sensitivity of 86% and specificity of 94%); and that of intact PTH was 37.5 pg/ml (sensitivity of 54% and specificity of 38%). To screen CKD stage 2, the best cut-off of cystatin C was 0.60 mg/L (sensitivity of 88% and specificity of 80%), and that of iPTH was 40 pg/ml (sensitivity of 61% and specificity of 59%). H-CysC group showed significantly higher prevalence of diabetic retinopathy, positive treadmill test, compared to L-CysC group. There was no significant difference in the prevalence of diabetic polyneuropathy, thickened intima-media of carotid arteries, and stroke between H-CysC and L-CysC groups. Urinary protein excretion per 24-hour was significantly better correlated with serum cystatin C than with eGFR, serum creatinine, and creatinine clearance.

Conclusion: These results suggest that serum cystatin C, not serum iPTH, is a useful marker for detecting mild decrease in GFR in Japanese patients with type 2 diabetes. Elevated serum cystatin C level was correlated with higher prevalence of diabetic retinopathy and positive treadmill test. Cystatin C showed

better correlation with urinary protein excretion than creatinine-based renal function markers. The present study suggests that diabetic patient with elevated serum cystatin C level should be carefully examined for systemic complications such as diabetic retinopathy, CKD, and asymptomatic ischemic heart disease.

Estimating renal function in (obese) diabetic patients; gaining renal function by gaining weight?

H. Joosten¹, L. Santing², L.A.G. Lievever³, S.J.J. Logtenberg², N. Kleefstra^{2,4}, H.J.G. Bilo^{2,5}

¹Internal Medicine, Isala Clinics, Zwolle, ²Diabetes Centre, Isala Clinics, Zwolle, ³Internal Medicine, Maxima Medisch Centrum, Eindhoven, ⁴Medical Research Group, Langerhans, Zwolle, ⁵Internal Medicine, UMCG, Groningen, Netherlands

Background and aims: Guidelines recommend the use of equations like the Cockcroft-Gault (CG) and the Modification of Diet in Renal Disease (MDRD-4) formula to estimate renal function in patients with diabetes mellitus (DM). The use of elaborate 24-hours urines sampling is receded to the background. Patients with diabetes are at risk for renal impairment. Early detection of renal function loss will help to alleviate risk on endstage renal and cardiovascular disease. Accurate assessment of renal function in DM is therefore of great importance. However, both the performance and generalizability of equation formulas in DM patients are debatable, as is the influence of body mass index (BMI) on the accuracy of these formulas. Our aim was to analyze the accuracy of renal function estimations and the influence of BMI on estimating renal function in DM patients.

Materials and methods: In this retrospective cohort study data from 849 consecutive subjects with DM, collected between 2005 and 2006 at the outpatient diabetes clinic of Maxima Medical centre in Eindhoven, were evaluated. Creatinine clearance was calculated from 24-hours urine samples (ml/min). Serum creatinine was measured using the enzymatic method. We compared creatinine clearance of 24-hours urine sampling (CrCl) with the individual estimations of renal function (eGFR) calculated with CG (ml/min) and MDRD-4 (ml/min/1.73 m²). Patients were subdivided into 2 groups; BMI in <30.0 kg/m² and BMI ≥ 30.0 kg/m². Accuracy was determined by mean difference and precision by standard deviation (SD).

Results: The cohort consisted of 380 females and 469 males. Patient characteristics (median (interquartile range)): age 63 (20-91) years, HbA1c 6.7 (6.0-7.5)% and BMI 27.7 (24.7-32.0) kg/m². Median plasma creatinine level was 79.0 (67.0-97.0) μ mol/l, with a mean (SD) CrCl of 112.6 (± 44.7) ml/min, mean CG of 97.5 ml/min (± 41.3) and mean MDRD-4 76.4 (± 24.6) ml/min/1.73m². Of all patients, 33.3% had a CrCl <90 ml/min, which doubled using the MDRD-4. In all subjects compared to CrCl, the CG had the smallest differences in both BMI groups.

In the BMI group <30 the CrCl was 114.6 and 96.8 ml/min, for man and woman respectively, compared to 133.9 and 110.7 ml/min in BMI ≥ 30 . In both BMI groups, the MDRD-4 estimates were significantly lower ($p < 0.01$) than the creatinine clearance, with increasing inaccuracy at increasing BMI.

Conclusion: Formulas to estimate renal function are very useful in clinical practice. Nowadays the MDRD-4 seems to dominate the CG and CrCl. In our study however, eGFR markedly differs when formulas are used compared to CrCl. In our DM patients, the CG is a more accurate formula to estimate renal function compared to the MDRD-4. MDRD-4 did not show accuracy until CrCl decreased below 30 ml/min. Precision of all renal function prediction equations increased with decreasing renal function. Despite the direct influence of weight (as a variable) in the CG formula, the CG does not overestimate CrCl in obese patients (BMI ≥ 30 kg/m²). In contrast to earlier reports, we conclude that CG is especially more accurate to estimate renal function in the higher BMI-group (≥ 30 kg/m²).

Risk factors and prognostic value of a renal artery stenosis in type 2 diabetic patients

I.I. Klefortova¹, M. Shamkhalova¹, O. Remizov², A. Bukhman², M. Shestakova¹, M. Shariya³, D. Ustyuzhanin³, E. Tugeeva⁴, U. Buziashvili⁴

¹Diabetic Nephropathy, Endocrinology Research Center, ²Tomography, Endocrinology Research Center, ³Tomography, Cardiology Research Center, ⁴Diagnostics, Bakoulev Scientific Center of Cardiovascular Surgery, Moscow, Russian Federation

Background and aims: To determine independent predictors and determine in prognostic value of RAS in subjects with type 2 diabetes and coexistent hypertension.

Materials and methods: We studied 157 patients (63 males, 94 female). All patients underwent duplex sonography (DS). Patients with RAS detected by DS underwent magnetic resonance angiography (MRA) or multislice computed tomography (MSCT) of the renal arteries. We used 1.5 T MR scanner and 16 slices MSCT.

Results: We found that DS, MRA and MSCT detected RAS in 58 type 2 diabetics (36.9%; 29.9% unilateral, 7.0% bilateral). RAS was associated with smoking (RR=1.84, CI 95% (1.23;2.75), $P < 0.05$), incidence of previous myocardial infarction (RR=1.63, CI 95% (1.09;2.45), $P < 0.05$), coronary arteries atherosclerosis (RR=2.06, CI 95% (1.41;3), $P < 0.05$), femoral artery atherosclerosis (RR=2.87, CI 95% (2.31;3.57), $P < 0.05$), carotid artery atherosclerosis (RR=1.89, CI 95% (1.25;2.87), $P < 0.05$) and isolated systolic hypertension (RR=1.89, CI 95% (1.25;2.87), $P < 0.05$). RAS was determined as a significant predictor of death, new heart failure episodes, myocardial infarction, doubling of serum creatinine, ESRD within 24 months of follow up according to the Kaplan-Meier survival method by log rank test ($p=0.00089$).

Conclusion: RAS was associated with smoking, coronary, carotid, femoral artery atherosclerosis, incidence of previous myocardial infarction and isolated systolic hypertension. The patients with RAS had poor prognosis.

Clinical performance of the CLINITEK[®] Microalbumin 9 reagent strip: a new urinalysis dry reagent strip

A.H.B. Wu¹, E.P. Jortani², E.P. Womack³, M. Vallen-Thompson³, J. Fan³, S.P. Volkir³, K. Schultz¹

¹Laboratory Medicine, University of California, San Francisco, ²Laboratory Medicine, University of Louisville School of Medicine, ³Siemens Healthcare Diagnostics Inc., Deerfield, United States

Background and aims: The CLINITEK Microalbumin 9 strip is a new urinalysis dry reagent strip developed for the CLINITEK family of instruments. When read on the CLINITEK 50, Status[®] or Advantus[™] analyzers, the Microalbumin 9 strip reports semiquantitative results for nine urine tests: albumin, blood (occult), creatinine, glucose, ketone, leukocyte, nitrite, pH, and total protein, as well as calculated results for albumin-to-creatinine (A:C) and protein-to-creatinine (P:C) ratios. Results are automatically displayed in approximately 1 minute. The use of analyzers reduces inter- and intrareader variability caused by such factors as timing variation, visual acuity, and variable lighting conditions. The objective of this study was to evaluate the clinical performance of the new urinalysis dry reagent strip.

Materials and methods: Evaluations of this strip were conducted at two clinical laboratory sites using 689 urine specimens over an 8-week period. One site tested four CLINITEK Advantus and the other tested four CLINITEK Status analyzers. Both sites also tested four CLINITEK 50 analyzers. Each site analyzed ≥ 338 urine specimens in singlicate, testing a minimum of 105 positive and negative specimens for each analyte. Three reagent strip types, two lots each, were used during the study.

Results: Positive, negative, exact, and \pm one-level agreement rates were determined as compared to existing MULTISTIX or Microalbumin 2 reagent strips. The all-site combined results ($n \geq 426$, range 426–2727) covering all tests and comparative strips across the complete set of analyzers are shown herein. The mean positive agreement rate for all reagents was 94.1% (range 79.9%–99.8%). The mean negative agreement rate was 94.9% (85%–99.4%). Mean exact agreement was 89.3% (80.5%–99.5%) and the mean " \pm one-level" agreement rate was 99.7% (98.2%–100.0%).

Conclusion: There was excellent agreement for all analytes between the CLINITEK Microalbumin 9 strip and existing MULTISTIX and Microalbumin 2 strips. Therefore, the CLINITEK Microalbumin 9 strip is clinically suitable for providing physicians with a single strip to monitor microalbuminuria, glucose, and traditional urinalysis tests to assist in the diagnosis and assessment of kidney function, urinary tract infections, and renal complications of metabolic disorders (e.g., diabetic nephropathy).

Normoalbuminuric CKD: its prevalence, clinical features, and impact on cardiovascular disease independent of microalbuminuria

H. Yokoyama¹, M. Oishi², K. Kawai³, Y. Fukumoto⁴, H. Sone⁵, M. Kobayashi⁶, G. JDDM-study¹

¹Internal Medicine, Jiyugaoka Clinic, Obihiro, ²Internal Medicine, Oishi Clinic, Kyoto, ³Internal Medicine, Kawai Clinic, Tsukuba, ⁴Internal Medicine, Fukumoto Clinic, Ibusuki, ⁵Dept. of Lifestyle Medicine & Applied Nutrition, Ochanomizu University, Tokyo, ⁶Internal Medicine, Toyama University, Japan

Background and aims: Existence of type 2 diabetic patients with normoalbuminuria and with chronic kidney disease (CKD), as defined by estimated glomerular filtration rate (eGFR, ml/min/1.73m²) < 60 , has been reported but the prevalence and associated clinical factors remain elucidated. Recent studies indicated that reduced eGFR is an independent risk factor for cardiovascular disease (CVD). However, it is uncertain whether reduced eGFR is associated with prevalent CVD independent of the effect of microalbuminuria (MA).

Materials and methods: We investigated what proportions of patients are distributed when stratified by nephropathy stages and CKD stages in a large-scale population of Japanese type 2 diabetes (N=3297), and the common and independent factors associated for increase in albuminuria and decrease in eGFR. We further investigated whether reduced eGFR is associated with CVD independent of MA.

Results: 1) The proportion of subjects with an eGFR < 60 was 16.6% among those with normoalbuminuria (N=2298), 20.6% among those with microalbuminuria (N=705), and 52.7% among those with macroalbuminuria (N=294). There were 381 patients with normoalbuminuria and with an eGFR < 60 , and 63.3% of them had neither diabetic retinopathy nor neuropathy. They were older, had more proportion of women, hypertension, hyperlipidemia, and CVD, and less smokers as compared with those with normoalbuminuria and with an eGFR ≥ 60 . Clinical factors that increased commonly to nephropathy stages and CKD stages were duration of diabetes, pulse pressure, hypertension, cardiovascular disease, retinopathy, and neuropathy. Age and female were only associated with decrease in eGFR. Male, BMI, A1c, systemic blood pressure, triglyceride, and smoking were only associated with increase in albuminuria. 2) Among patients without macroalbuminuria, those with reduced eGFR had a twofold, and those with MA also had a twofold higher prevalence of CVD. Compared with patients without reduced eGFR and without MA (OR 1.0), OR was significantly higher in those with reduced eGFR and without MA (OR 2.03, 95% CI 1.41–2.92) and was similarly higher in those with MA and without reduced eGFR (OR 1.92 95% CI 1.39–2.65). It was highest in those with reduced eGFR and MA (OR 4.09, 95% CI 2.64–6.35). The OR remained significant after adjustment for age, sex, hypertension, hyperlipidemia, smoking, BMI, and urinary albumin excretion rate.

Conclusion: Our finding indicates that a significant proportion of type 2 diabetic patients have non-albuminuric renal insufficiency. Renal disease in type 2 diabetes could be heterogeneous, implying a possibility of involvement of renal atherosclerosis and lipid toxicity. Reduced eGFR and MA were independently associated with increasing the prevalence of CVD, independent of the effect of traditional cardiovascular risk factors and urinary albumin excretion rate in Japanese patients with type 2 diabetes.

1196

Increased cardiovascular risk in normoalbuminuric type 2 diabetic patients with reduced renal function

A. Cignarelli, L. Laviola, S. Di Leo, S. Perrini, A. Leonardini, J. Rinaldi, G. Garruti, A. Bellomo Damato, G. Stefanelli, R. Giorgino, F. Giorgino D.E.T.O., Internal Medicine, Endocrinology and Metabolic Diseases, University of Bari, Italy

Background and aims: Reduced kidney function, estimated by the eGFR, predicts all-cause mortality and cardiovascular (CV) disease in the general population. In type 2 diabetic patients, albuminuria represents the most important marker of kidney damage, and is considered an independent indi-

cator of endothelial dysfunction and atherogenic risk. However, limited information is available on the association of reduced eGFR, albuminuria and CV risk in type 2 diabetes. The objective of this cross-sectional study was to evaluate the distribution of eGFR and of albuminuria in a cohort of type 2 diabetic patients, and the pattern of conventional CV risk factors and the estimated CV risk in type 2 diabetic patients with normal (eGFR >60 ml/min) or reduced (eGFR <60 ml/min) kidney function.

Materials and methods: 406 type 2 diabetic patients (227M, 179F) were consecutively enrolled in this cross-sectional study. eGFR was calculated by the Cockcroft-Gault equation; albuminuria was measured by a RIA assay and expressed as AER; the 10-y CV risk was estimated with the UKPDS risk engine.

Results: 42% of the patients showed eGFR >90 ml/min, 46% eGFR 60–90 ml/min, and 12% eGFR <60 ml/min; 77% were normo-, 21% micro-, and 2% macroalbuminuric. However, AER and eGFR appeared to be independently distributed in the study group, since 77% of the 64 patients with reduced kidney function (eGFR <60 ml/min) had AER in the normal range. Patients were then sub-grouped according to an eGFR value >60 (n=352) or <60 (n=55), respectively, and paired by glycemic control (HbA_{1c} = 7.8% in both groups). Patients with reduced eGFR were older and more often female, and showed lower body weight (67.0 vs 80.2 kg, $p<0.01$), longer diabetes duration (13.7 vs 9.7 y, $p<0.01$), but no difference in lipid profile, statin use, or anti-diabetic therapy. Diastolic blood pressure was lower in patients with reduced kidney function as compared with patients with normal eGFR (75.1 vs 79.3 mmHg, $p<0.01$), and this was associated with higher use of hypotensive medications (69% vs 57%). Interestingly, waist circumference showed a bi-modal distribution: it appeared to be positively correlated with eGFR in the type 2 diabetic population with normal kidney function, and not associated with eGFR in patients with eGFR <60 ml/min. The 10-year CHD risk, estimated by the UKPDS risk engine, was higher in diabetic patients with low eGFR (27.7% vs 19.5%, $p<0.01$). The OR for a high CHD risk was 6.62 (2.56–17.15, $p<0.001$) when adjusted for HbA_{1c} , diabetes duration, gender, smoking, systolic blood pressure, HDL, albuminuria, and waist. Finally, in the subgroup of normoalbuminuric patients, subjects with low eGFR (n = 42) showed a higher CV risk as compared with subjects with normal eGFR (n = 269) (23.9% vs 18.0%, $p=0.046$).

Conclusion: A significant fraction of type 2 diabetic patients shows a reduced kidney function in the presence of normoalbuminuria. The evaluation of eGFR may contribute to identify type 2 diabetic patients with higher CV risk.

1197

Carotid atherosclerosis and progression of diabetic nephropathy in patients with type 2 diabetes

D.-J. Chung, D.-H. Cho, J.-O. Chung, J.-Y. Yoon, M.-Y. Chung
Department of Endocrinology and Metabolism, Chonnam National University Medical School, Gwangju, Republic of Korea

Background and aims: Cardiovascular risk is higher among people with chronic kidney disease (CKD) than among those with normal renal function. This association is probably due to systemic atherosclerosis and reduced renal function. Carotid intima-media thickness (IMT) is an independent predictor of cardiovascular mortality in the type 2 diabetic patients. It was reported that carotid IMT was significantly higher in subjects with chronic kidney disease (CKD) in general population, but the relationship between carotid IMT and diabetic CKD was not well known. The aim of our study was to elucidate whether carotid IMT is associated with progression of diabetic nephropathy in type 2 diabetic patients.

Materials and methods: We recruited a total of 177 type 2 diabetic patients (89 men and 88 women) with CKD (\geq stage 2) by diabetic nephropathy and followed for 3.2 ± 2.4 years. Renal function was evaluated by serum creatinine levels, estimated glomerular filtration rate (eGFR) (calculated by the Cockcroft-Gault equation) and urinary albumin/creatinine ratio (ACR). The carotid IMT was assessed using B-mode ultrasound by measuring generally used parameters. Baseline-to-study end changes in eGFR were calculated, and yearly change of eGFR (mL/min/year) was computed.

Results: Overall, the mean age was 60.5 ± 11.2 years, duration of diabetes 15.6 ± 8.2 years, HbA_{1c} $7.8 \pm 2.2\%$, ACR $1,327.4 \pm 623.1$ mg/gCr, serum creatinine 2.1 ± 1.1 mg/dL, and systemic blood pressure (BP) $133.2 \pm 13.6/86.3 \pm 10.9$ mmHg. Mean calculated GFR was 62.4 ± 18.4 mL/min/ $1.73m^2$. Of the study population, 68 patients (38.4%) were smokers or exsmokers, 165 patients (93.2%) were having hypertension, and 159 patients (89.8%) were taking angiotensin converting enzyme inhibitor or angiotensin receptor blocker. Age,

waist circumference, duration of diabetes, serum creatinine, ACR and eGFR were significantly correlated with mean or maximum carotid IMT (Table 1). But lipid profiles, HbA_{1c} , and systolic and diastolic BP were not correlated with carotid IMT. Mean yearly change of eGFR was 5.3 ± 4.3 mL/min/year. Yearly change of eGFR was positively correlated with mean and maximum carotid IMT (Figure 1). Changes of ACR or serum creatinine were not significantly correlated with carotid IMT.

Conclusion: Our data suggests that chronic kidney disease is associated with an increased prevalence of carotid atherosclerosis and carotid atherosclerosis may be predictor of progression of diabetic nephropathy in patients with type 2 diabetes.

Table 1. Correlations between carotid IMT and clinical characteristics

Variables	Rt. mean IMT	Lt. mean IMT	Mean IMT	Maximum IMT
Age	0.350**	0.361**	0.394**	0.369**
Waist circumference	0.162*	0.121	0.159*	0.153
Duration of diabetes	0.382**	0.359**	0.360**	0.401**

Plasma hs-troponin T predicts cardiovascular and all cause mortality as well as deterioration in kidney function in type 1 diabetic patients with nephropathy

P. Rossing¹, A. Jorsal¹, L. Tarnow¹, H.-H. Parving^{2,3}

¹Steno Diabetes Center, Gentofte, ²Medical Endocrinology, Rigshospitalet, University of Copenhagen, ³Faculty of Health Science, University of Aarhus, Denmark

Background and aims: Patients with type 1 diabetes have an elevated risk for early death due to cardiovascular disease and development of end stage renal disease. Plasma high sensitive Troponin T (TnT) is a marker of myocardial injury and microvascular disease. The aim of this study was to investigate the predictive value of plasma levels of plasma hs-TnT in relation to mortality, cardiovascular (CVD) events and progression of diabetic nephropathy in patients with type 1 diabetes.

Materials and methods: A prospective observational follow-up study; including 442 type 1 diabetic patients with overt diabetic nephropathy (234 men; age 42.1 ± 10.5 years mean \pm SD, duration of diabetes 28.2 ± 8.8 years, GFR 76 ± 34 mL/min/ $1.73 m^2$) and a group of 458 patients with longstanding type 1 diabetes and persistent normoalbuminuria (278 men; age 45.4 ± 11.5 years, duration of diabetes 27.8 ± 10.1 years). Plasma hs TroponinT was measured at baseline.

Results: Follow-up: 8.2 (0.0–12.9) years (median (range)). During follow up 178 patients died (109 deaths due to CVD), and 89 patients developed end stage renal disease (ESRD). Individuals with high TnT levels (4th quartile) had significantly higher all-cause mortality than patients with low levels (1st quartile) (hazard ratio (HR) 8.00 (3.38 to 18.9) adjusted for sex, age, smoking, systolic blood pressure, HbA1c, eGFR, cholesterol, and history of CVD). For patients with diabetic nephropathy the HR_{adj} for high vs low TnT level was 12.2 (2.80 to 53.5). High TnT levels also predicted CVD mortality (covariate-adjusted HR 17.4 (3.83 to 79.5). Further adjustment for baseline levels of hsCRP and NTproBNP did not change the significant impact of TnT. For CVD fatal and non fatal events the HR_{adj} was 3.52 (1.80 to 6.87). Furthermore, patients with high TnT levels had significantly higher risk for progression to ESRD than patients with low levels (covariate-adjusted HR 1.48 (1.01 to 2.16)). In addition, we found that patients with high levels of plasma hsTnT had an elevated rate of decline in glomerular filtration rate.

Conclusion: High levels of plasma hsTropoin T predict all-cause and CVD mortality in patients with diabetic nephropathy. Furthermore, high levels of hsTnT predicted deterioration of kidney function towards end-stage renal disease.

Diabetes mellitus and anaemia in patients with chronic kidney disease

A. Lejnicks¹, V. Kuzema², A. Petersons²

¹Riga Stradins University, Department of Internal Medicine, Riga Eastern Hospital, Hospital "Linezers", ²Riga Stradins University, Department of Internal Medicine, Paul Stradins Clinical University Hospital, Centre of Nephrology, Latvia

Background and aims: Diabetic kidney disease is the leading cause of end-stage renal disease (ESRD) in USA and Europe. In Latvia, 23% of the ESRD patients suffered from diabetes mellitus. Anaemia is a most common complication of chronic kidney disease (CKD). In diabetic nephropathy (DN) anaemia develops at an earlier stage of CKD and tends to be more severe than in non-diabetic kidney disease. The aim of this study was to analyze the prevalence and severity of anaemia in diabetic and non-diabetic subjects with glomerular filtration rate (GFR) below 60 ml/min.

Materials and methods: This is a retrospective analysis of 2147 consultations in CKD patients with GFR < 60 ml/min during five years (2002–2006). The data was collected from the archive of Latvian Nephrology Centre. According to the guidelines by the Dialysis Outcomes Quality Initiative in 2006, the evidence of anaemia in subjects with CKD was considered in men with level of Hb < 13.5 g/dl and < 12 g/dl for woman. We used *T*-tests, ANOVA for comparisons between parameters in independent groups with the appropriation. The Pearson Chi-square or Mann Whitney U tests were used to compare qualitative variables. Survival times for decrease of haemoglobin (Hb) level below 11 g/dl were estimated using Kaplan-Meier method and log-rank test for comparison. The criterion for statistical significance was taken as a two-tailed *P* value < 0.05.

Results: A total of 641 patients with CKD III–V were analyzed. We found that 69.6% of diabetic patients and 52.1% of non-diabetic patients with CKD III–V had an anaemia (Chi-Square value 10.6; *P* = 0.001). Mean age in diabetics and non-diabetics were 63.9 ± 14.2 years and 60.4 ± 15.0 years (*P* < 0.001). Mean haemoglobin levels for diabetic versus non-diabetic patients were 12.5 ± 1.8 g/dl vs 13.0 ± 1.7 g/dl (*P* = 0.027); 10.3 ± 1.5 g/dl vs 11.1 ± 1.8 g/dl (*P* = 0.016); 9.3 ± 1.5 g/dl vs 9.5 ± 1.9 g/dl (*P* = 0.780) in CKD stage III, IV, V, respectively. We noted that the patients with diabetic kidney disease and GFR < 60 ml/min had lower median serum ferritin level than non-diabetics (98.2 ng/ml vs 105.5 ng/ml, *P* = 0.044). In addition, patients with diabetes and CKD III–V had a shorter median survival time to decrease of haemoglobin level below 11 g/dl compared to non-diabetic patients (12 months vs 21 months; log-rank 43.7, *P* < 0.001). The subjects with DN had higher mean systolic blood pressure (153.4 ± 23.7 mmHg vs 147.7 ± 23.8 mmHg, *P* < 0.001). The diastolic blood pressure records were similar in the both groups. Patients with diabetes and GFR < 60 ml/min had significantly lower albumin level (38.9 ± 6.5 g/l vs 40.8 ± 7.1 g/l, *P* = 0.021). Diabetic patients with CKD III–V had significantly lower mean Ca/P product than in non-diabetic patients (43.4 ± 14.1 mg²/dl² vs 39.6 ± 11.5 mg²/dl², *P* = 0.010). Median serum PTH levels were similar in analysed patients groups. The mean HbA1c in patients with diabetes was 7.6 ± 1.4 %.

Conclusion: Anaemia in patients with diabetic kidney disease and GFR < 60 ml/min is more prevalent and severe than in non-diabetic kidney disease. Anaemia constitutes an additional burden in diabetic kidney disease with

advancing age and comorbidities (hypoalbuminemia, arterial hypertension, metabolic disorders).

Insulin analogues mitigate the decline of haemoglobin in diabetic patients with nephropathy

C. Hasslacher¹, E. Collenberg¹, D. Raupp¹, J. Dreyhaupt²

¹Internal Medicine, St. Josephkrankenhaus, ²Medical Biometry, Institute of Biometry and Informatics, University of Heidelberg, Germany

Background and aims: Decrease of hemoglobin occurs in diabetic patients with nephropathy earlier than in nondiabetic patients, probably due to impaired synthesis of erythropoietin (EPO). Apart from EPO, insulin also stimulates erythropoiesis. We investigate whether there are differences between human insulin and insulin analogs in respect of their erythropoiesis-stimulating effect.

Materials and methods: Hemoglobin concentration and other factors which may influence hemoglobin levels (metabolic control (HbA1c), inflammation (hsCRP), antihypertensive medication (RAAS-blocking drugs, beta blocker) were analyzed in 142 type 1 diabetic patients with various degrees of kidney function. Sixty-eight patients were treated with human insulin and 74 patients received an insulin analog.

Results: Hemoglobin concentration did not differ in patients with normal renal function (creatinine clearance (CCL) >90 ml/min) treated with human insulin or insulin analogs. In patients with impaired renal function (CCL < 90 ml/min) there was a significant decrease of hemoglobin with declining kidney function in patients treated with human insulin (*r* = 0.469; *p* < 0.01) but not in patients treated with insulin analog (*r* = -0.012; *p* = 0.94). The difference between the respective correlations was significant (*p* = 0.03). Patients with moderately reduced kidney function (CCL 30–60 ml/min) who were treated with insulin analogs showed a significantly higher hemoglobin concentration than those treated with human insulin (142 ± 12.4 vs 125 ± 13.1 g/l; *p* = 0.006). There was no difference between the human and analog insulin treated groups with respect to gender (ratio male/female 0.9 vs 1.0), age (56 vs 57 years), diabetes duration (24 vs 25 years), metabolic control (HbA1c 7.8 vs 7.9%), kind of antihypertensive therapy (RAAS blocking drugs 74% vs 80%) and inflammation status (hs CRP 3.42 vs 3.12 mg/l).

Conclusion: Insulin analogs mitigate the decline of hemoglobin in diabetic patients with impaired renal function. This may be because these insulins stimulate erythropoiesis via IGF receptor or a sustained activation of the insulin receptor.

Efficacy of the biosimilar erythropoiesis-stimulating agent epoetin zeta to correct and/or maintain haemoglobin concentration in patients with diabetic nephropathy

P. Scigalla¹, R. Koytchev²

¹Clinical Research, CRC-International Clinical Research Consulting, Berlin,

²Clinical Research, CCDRD AG, Neuenhagen, Germany

Background and aims: Reports in the literature suggest more pronounced anaemia and reduced erythropoietin responsiveness in diabetic patients with chronic renal failure. We report efficacy data from 2 clinical trials of epoetin zeta versus epoetin alfa to correct and/or maintain haemoglobin (Hb) concentrations in a subgroup of end-stage renal failure patients with diabetic nephropathy.

Materials and methods: Two randomized, double-blind, multicentre, Phase III trials were conducted. In the correction phase study (Trial 1), patients had anaemia at baseline (Hb <9.0 g/dL), individually corrected up to a target Hb of 11.0–12.0 g/dL; the equivalence acceptance range for mean Hb concentration for the whole study population was ±1.0 g/dL during the last 4 weeks of the trial. In the maintenance study (Trial 2), patients had stable Hb of 10.5–12.5 g/dL at entry, with no change in Hb >0.6 g/dL in the previous 4 weeks; the equivalence acceptance range for mean Hb concentration was ±0.6 g/dL for the whole study population. In both trials, patients were randomly assigned to receive either epoetin zeta or epoetin alfa intravenously, 1–3 times weekly, for 24 weeks.

Results: Trial 1 (*n* = 609): in the last 4 weeks of treatment, 27 patients with diabetic nephropathy were receiving epoetin zeta. The Hb 95% CI for the complete haemodialysis population was -0.25 to 0.20 g/dL versus -0.81 to

0.67 g/dL for the diabetic nephropathy population. Trial 2 (n=313): in this crossover trial, 37 patients had diabetic nephropathy. The 95% CI for the complete haemodialysis population was 0.09 to 0.28 g/dL versus -0.03 to 0.36 g/dL for the diabetic nephropathy population. The dosage of epoetin zeta and epoetin alfa was equivalent for the entire population of both studies and no significant difference in dose requirements was observed in the subgroup of patients with diabetic nephropathy.

Conclusion: For the diabetic nephropathy population in Trial 1, the 95% CI was within the ± 1 g/dL acceptance range, despite this being wider than in the general haemodialysis population. The 95% CIs for the Trial 2 diabetic population was also wider than in the general population, but again remained well within the ± 0.6 g/dL acceptance range. These data suggest that epoetin zeta can effectively maintain Hb levels in this hard-to-treat subgroup when compared to the overall haemodialysis patient population.

Increased risk of chronic kidney disease among type 2 diabetic patients with nonalcoholic liver disease

G. Zoppini¹, L. Bertolini², S. Rodella³, M. Chonchol⁴, E. Bonora¹, M. Muggeo¹, G. Targher^{1,2}

¹Endocrinology, Ospedale Civile Maggiore, University of Verona, Italy,

²Diabetology, Ospedale Sacro Cuore, Negrar, Italy, ³Radiology, Ospedale Sacro Cuore, Negrar, Italy, ⁴Renal Diseases and Hypertension, University of Colorado Health Sciences Center, Denver, United States

Background and aims: It is unknown whether chronic kidney disease (CKD) is associated with the presence of non-alcoholic fatty liver disease (NAFLD) among patients with type 2 diabetes. We assessed whether NAFLD predicts the development of CKD in type 2 diabetic patients participating in the Valpolicella Heart Diabetes Study.

Materials and methods: We followed 1,760 outpatients with type 2 diabetes and normal or near-normal kidney function and without overt proteinuria for 6.5 years for the occurrence of CKD (defined as overt proteinuria and/or estimated glomerular filtration rate [GFR] < 60 ml/min/1.73 m²). NAFLD was diagnosed by liver ultrasound and exclusion of other common causes of chronic liver disease.

Results: During follow-up, 547 participants developed incident CKD (i.e., $\sim 4.5\%$ of participants progressed every year to estimated GFR < 60 ml/min/1.73 m² and/or overt proteinuria). The presence of NAFLD was associated with a moderately increased risk for CKD (hazard ratio 1.69; 95% confidence interval 1.3 to 2.6; $p < 0.001$). Adjustments for gender, age, BMI, waist circumference, blood pressure, smoking, diabetes duration, HbA1c, lipids, baseline estimated GFR, microalbuminuria, and medications (hypoglycemic, lipid-lowering, antihypertensive or anti-platelet drugs) did not appreciably attenuate this association (hazard ratio 1.49; 95% confidence interval 1.1 to 2.2; $p < 0.01$).

Conclusion: Our findings suggest that NAFLD is associated with an increased incidence of CKD in patients with type 2 diabetes independent of numerous confounding factors. Further prospective studies are required to confirm the reproducibility of these results.

PS 116 Human diabetic nephropathy: markers and associated factors

1203

Endothelial progenitor cells are decreased in type 2 diabetic patients depending on the urinary albumin excretion

G. Schernthaner¹, J. Brix¹, F. Hoeller², R. Koppensteiner², G.-H. Schernthaner²

¹Medicine I, Rudolfstiftung Hospital, ²Medicine II, Medical University of Vienna, Vienna, Austria

Background and aims: Patients with Type 2 Diabetes Mellitus (T2DM) and microalbuminuria (MIA) or macroalbuminuria (MAA) have an increased risk for cardiovascular disease (CVD) morbidity and mortality. The mechanisms responsible for this increased risk are not completely understood. Endothelial progenitor cells (EPC) are (supposedly) bone marrow derived cells circulating in the peripheral blood. They have been demonstrated to be involved in animal adult neovascularisation and (animal and human) endothelial homeostasis and may predict macrovascular disease and mortality (in humans). Thus, it was of interest to investigate the number of EPC in T2DM patients presenting with MIA or MAA in comparison with normoalbuminuric (NOA) patients.

Materials and methods: In total, 138 patients with T2DM were included: 72 NOA, 42 MIA and 24 MAA. The patients in the three groups were carefully matched and did not differ (by ANOVA) for age (65 ± 11 years), diabetes duration (13 ± 10 years), HbA1c ($7.8 \pm 1.6\%$), BMI (30 ± 5 kg/m²), systolic and diastolic blood pressure, total cholesterol, LDL-cholesterol, triglyceride and serum creatinine (1.2 ± 0.4 mg/dl) (given are mean of all patients). Circulating progenitor cells (CPC; CD34+/CD133+) and EPC (CD34+/CD133+/CD309+) were enumerated by fluorescence activated cell sorting out of peripheral blood specimen.

Results: EPC were significantly reduced in T2DM patients with MIA compared with patients with NOA (102 ± 54 vs 144 ± 84 , $p = 0.01$). In patients with MAA the number of EPC was even more decreased (53 ± 29 vs 144 ± 84 ; $p < 0.001$). Patients with MIA or MAA were also significantly different for the number of EPC (102 ± 54 vs 53 ± 29 , $p < 0.001$). By contrast, total circulating progenitor cells, were not significantly different among the 3 groups of patients with T2DM with NOA, MIA or MAA ($p = 0.16$). Multivariate linear regression showed that EPC were independently associated with diabetes duration (Beta = -0.165, $p = 0.036$) and history of cardiovascular disease (Beta = -0.203, $p = 0.01$) but strongest with status of albuminuria (Beta = -0.380, $p < 0.001$).

Conclusion: In conclusion, this is the first study demonstrating decreased numbers of endothelial progenitor cells in diabetic patients with microalbuminuria or macroalbuminuria. Since low endothelial progenitor cells are important predictors of future cardiovascular morbidity and mortality in nondiabetic high risk patients, these new findings could be relevant for the understanding of the high cardiovascular risk of type 2 diabetic patients with microalbuminuria or macroalbuminuria.

Urine matrix metalloproteinase-2, -8 and -9 activities in type 2 diabetic nephropathy

N.J. van der Zijl¹, R. Hanemaaijer², M.E. Tushuizen¹, R.K. Schindhelm³, J. Boerop¹, C. Rustemeijer⁴, H.J. Bilo⁵, J.H. Verheijen², M. Diamant¹

¹Endocrinology / Diabetes Centre, VU University Medical Centre,

Amsterdam, ²BioSciences, TNO Quality of Life, Leiden, ³Clinical Chemistry, Isala Clinics, Zwolle, ⁴Internal Medicine, Amstelland Hospital, Amstelveen,

⁵Internal Medicine, Isala Clinics, Zwolle, Netherlands

Background and aims: Matrix metalloproteinases (MMPs), including the gelatinases MMP-2 and -9 and the collagenase MMP-8, are involved in extracellular proteolysis. Since the development of diabetic nephropathy (DN) involves an increased synthesis and decreased degradation of the extracellular matrix (ECM) in the glomerulus, MMPs may play a pathophysiological role. Recently, we found increased urinary MMP-2 and -9 activities, but not plasma MMP antigen levels, in type 1 diabetic patients with nephropathy. However, no data are available on urinary MMPs in relation to DN in patients

with type 2 diabetes mellitus (T2DM). The objective of this study was to determine whether urinary MMPs might be early markers of DN.

Materials and methods: Active and total levels (active and pro-active forms) of MMP-2, -8 and -9 were measured in 24h urine collections from 75 T2DM patients and 28 age-matched healthy controls. T2DM patients were stratified according to albuminuria, defined as albumin-to-creatinine ratio (ACR) >2.5 mg/mmol for males and >3.5 mg/mmol for females (albuminuria (UA), n=28; without albuminuria (NA), n=47). Additionally, serum creatinine, fasting plasma glucose (FPG) and HbA_{1c} were measured. Urinary MMPs were adjusted for urinary creatinine. Only levels of active MMPs are presented, given their biological significance. The relation between clinical and biochemical variables and MMPs and the determinants of renal function, calculated according to the MDRD equation (eGFR_{MDRD}), were assessed by univariate and multivariable regression analyses.

Results: In the T2DM group (63% males; (median (IQR)) age 62 (54–70) yrs; diabetes duration 10 (4–17) yrs), 28 subjects had UA (ACR: 10.6 vs. 0.6 mg/mmol in NA). Urinary MMP-2, -8 and -9 levels were significantly elevated in T2DM subjects, irrespective of the presence of albuminuria, as compared to controls (MMP-2: 0.5 vs. 0.0 µg/mmol; MMP-8: 4.1 vs. 2.4 µg/mmol; MMP-9: 11.1 vs. 1.7 µg/mmol, all $P<0.001$). Similarly, T2DM UA subjects had higher urinary MMPs than T2DM NA subjects (MMP-2: 0.5 vs. 0.0 µg/mmol; MMP-8: 4.8 vs. 3.4 µg/mmol; MMP-9: 13.0 vs. 3.0 µg/mmol, all $P<0.05$). T2DM NA subjects with elevated MMPs scored worse on known risk factors for DN (systolic BP, diabetes duration, BMI, HbA_{1c} and FPG, all $P<0.01$). Univariate linear regression analyses identified age, sex, systolic BP, diabetes duration, BMI, HbA_{1c} and FPG as determinants of MMP-2, -8 and -9, all $P<0.03$). In multivariable regression analyses age, sex, diabetes duration and MMP-9 were independent determinants of eGFR_{MDRD} ($R^2=0.457$, all $P<0.05$). Of UA patients, 93% had at least one urinary MMP activity increased, as compared to 71% of NA and 25% of Controls ($P<0.05$).

Conclusion: Although urinary MMP-2, -8 and -9 activities are highest in T2DM UA patients, their elevated levels are already present in some T2DM patients without albuminuria who scored worse on the known risk factors for DN. We hypothesize that urinary MMP activity may reflect incipient diabetes-related renal disease and may be used as an early marker of DN. However, the predictive value of urinary MMP activities in DN should be addressed in large-scaled longitudinal studies.

1205

Serum lipopolysaccharide (LPS) activities are associated with early progression of nephropathy in patients with type 1 diabetes (The FinnDiane Study)

M.J. Lehto¹, P.J. Pussinen², A.M. Tuomainen², C. Forsblom^{1,3}, P.-H. Groop^{1,3} on behalf of the FinnDiane Study Group;

¹Folkhälsan Research Centre, Folkhälsan Institute of Genetics, Helsinki,

²Institute of Dentistry, University of Helsinki, ³Department of Medicine, Helsinki University Central Hospital, Finland

Background and aims: Based on prospective studies about one third of patients with type 1 diabetes develop diabetic nephropathy during their lifetime. Many of these patients suffer from low grade chronic inflammation, which might be caused by viral or bacterial pathogens. Lipopolysaccharide (LPS), which is an important component of the outer membrane of gram-negative bacteria, has been shown to induce systemic inflammation. High serum LPS concentrations, commonly found in e.g. patients with periodontitis, increase the risk of atherosclerosis and cardiovascular diseases. The aim of the current study is to investigate whether serum LPS activities are associated with progression of kidney disease in patients with type 1 diabetes.

Materials and methods: Type 1 diabetic patients were examined as a part of the nationwide Finnish Diabetic Nephropathy Study (FinnDiane). Totally 477 patients were selected for this study. The average follow-up time was 5.9 (SD 2.1) years. At the basal visit, 239 patients were normoalbuminuric [NA] (albumin excretion rate - AER < 20 µg/min) and 238 patients had macroalbuminuria [MA] (AER > 200 µg/min). Subjects were further divided into non-progressors and progressors based on the AER and kidney function at the time of re-examination. Eighty out of 239 normoalbuminuric patients had progressed to microalbuminuria [MI] (20 µg/min < AER < 200 µg/min), while 79 out of 238 macroalbuminuric patients had developed end-stage renal disease [ESRD]. All groups were matched for sex and smoking. Serum LPS activities were determined with Limulus Amoebocyte Lysate (LAL) chromogenic endpoint assay (Hycult Biotechnology).

Results: The relationship between serum LPS activities and various clinical parameters was assessed. The strongest correlation was found with serum

triglyceride concentrations ($r=0.61$, $p<0.001$). MA-patients had significantly higher serum LPS activity than NA-patients at baseline [53 (IQR 38–74) vs. 42 (IQR 31–60) EU/ml; $p<0.001$]. Patients who progressed from NA to MI had higher LPS activity [49 (IQR 34–87) vs. 39 (IQR 29–54) EU/ml; $p=0.001$], HbA_{1c}, cholesterol, triglycerides, as well as lower estimated glucose disposal rate than non-progressors. When these variables were analyzed with Cox-regression, only HbA_{1c} (HR 1.30 95%CI 1.13–1.50) was an independent predictor of progression. When non-smokers were analyzed separately with the same model, both HbA_{1c} (HR 1.28 95%CI 1.10–1.49) and lnLPS (HR 1.92 95%CI 1.04–3.55) predicted progression. Serum LPS was not associated with progression from MA to ESRD [58 (IQR 44–73) vs. 50 (IQR 35–75) EU/ml; $p=ns$].

Conclusion: Serum LPS is an independent predictor of early progression of diabetic kidney disease from normal AER to microalbuminuria in non-smoking patients with Type 1 diabetes.

Studies, University of Massachusetts Medical School, Worcester, United

States, ³Department of Veterinary Pathobiology, Faculty of Life Sciences,

Frederiksberg, Denmark, ⁴Department of Endocrinology, Rigshospitalet,

Copenhagen, Denmark, ⁵Faculty of Health Sciences, Aarhus University,

Denmark, ⁶Department of Small Animal Clinical Sciences, Faculty of Life Sciences, Frederiksberg, Denmark

Background and aims: Patients with diabetes (DM) have increased platelet activation and platelet reactivity compared to non-diabetic controls. High platelet reactivity has been associated with cardiovascular outcomes in type 2 DM. Patients with diabetic nephropathy are at increased risk of cardiovascular disease. We investigated the relationship between platelet activation/reactivity and the presence of nephropathy in patients with type 1 DM.

Materials and methods: Type 1 diabetic patients with persistent normoalbuminuria (n=53) or overt diabetic nephropathy (n=34), and healthy age- and sex-matched controls (n=30) were studied. Platelet surface P-selectin expression, activation of platelet surface GPIIb-IIIa (PAC1 binding), monocyte-platelet (MPAs) and neutrophil-platelet aggregates (NPAs) were measured by whole blood flow cytometry as markers of platelet activation. Platelet reactivity was assessed in response to exogenously added adenosine diphosphate (ADP) and thrombin receptor activating peptide (TRAP). Associations were explored using a 2-way analysis of variance for repeated measurements.

Results: Platelet P-selectin expression (mean fluorescent intensity; basal and in response to 0.5 or 20 µM ADP) was higher in nephropathy patients compared with patients with normoalbuminuria ($p = 0.019$), and non-diabetic controls ($p = 0.0059$). NPAs were higher in nephropathy patients (n=20) compared to patients with normoalbuminuria (n=26) ($p = 0.0088$). MPAs were significantly higher in nephropathy patients compared to non-diabetic controls only ($p = 0.0075$). There were no differences between groups in PAC1 binding or in response to activation with TRAP in any end-point. A significantly higher proportion of patients with nephropathy received aspirin (23 out of 34) compared to patients with normoalbuminuria (13 out of 53) ($p<0.0001$).

Conclusions: Type 1 diabetic nephropathy is associated with circulating activated platelets and platelet hyperreactivity to ADP, despite a higher number of these patients receiving anti-platelet treatment with aspirin. This platelet hyperreactivity may be pathogenically related to the known increased risk of cardiovascular events in patients with nephropathy.

Insulin resistance and C-reactive protein are associated with high-normal urinary albumin excretion in normoalbuminuric type 1 diabetic patients

L. Duvnjak, T. Bulum, N. Car, Z. Metelko

Clinical Department, VUK Vrhovac University Clinic, Zagreb, Croatia

Background and aims: Higher insulin resistance and low-grade inflammatory markers were found to be associated with increased risk of diabetic nephropathy in type 1 diabetic patients. As it is well known that the degree of albuminuria is closely related to the progression of nephropathy, we aimed to determine whether estimated glucose disposal rate (eGDR) and C-reactive protein significantly differ between type 1 diabetic patients with high normal and low normal urinary albumin excretion (UAE).

Materials and methods: Two hundred and 65 normoalbuminuric (UAE < 30mg/24h at three occasions) patients were included and divided upon the UAE median (13,2mg/24h) into low-normoalbuminuric (n=132) and high-normoalbuminuric group (n=133). None showed signs of renal or cardiovascular disease and received antihypertensive or other drugs that could attenuate low-grade inflammation. Estimated glucose disposal rate was calculated using the equation: $eGDR = 24.31 - (12.22 \times WHR) - (3.29 \times HT) - (0.57 \times HbA1c)$. The units were $mg \times kg^{-1} \times min^{-1}$, WHR=waist-to-hip ratio, HT=hypertension. This equation was derived from a substudy of 24 participants in the EDC Study who underwent euglycemic-hyperinsulinemic clamp studies. UAE and C-reactive protein were determined by an immunoturbidimetric assay.

Results: The low-normoalbuminuric (UAE= 7.15 ± 3.29) and high-normoalbuminuric group (UAE= 21.27 ± 5.94 , $p=0.0001$) did not differ regarding age, gender, BMI, HbA1c, HDL cholesterol, triglycerides, systolic and diastolic blood pressure, smoking status. High-normoalbuminuric in comparison to low-normoalbuminuric group showed significantly higher diabetes duration (22 ± 10.42 ; 18 ± 9.31 ; $p=0.003$), C-reactive protein (2.39 ± 4.09 ; 1.12 ± 2.03 mg/l; $p=0.04$), and lower eGDR (5.75 ± 1.74 ; 8.96 ± 1.9 ; $p=0.02$). UAE was positively correlated with diabetes duration, BMI, triglycerides, C-reactive protein, HbA1c, and inversely with eGDR and HDL. In a multiple regression analysis with diabetes duration, eGDR, C-reactive protein, BMI, HDL, triglycerides, UAE and HbA1c in a model, eGDR was independently associated with diabetes duration ($\beta = -0.20$, $p=0.01$), C-reactive protein ($\beta = -0.106$; $p=0.04$) and UAE ($\beta = -0.49$, $p=0.04$); C-reactive protein was independently associated with eGDR ($\beta = -0.20$, $p=0.04$) and diabetes duration ($\beta = 0.77$; $p=0.04$);

Conclusion: Insulin resistance and C reactive protein are associated with high-normal UAE in type 1 diabetic patients. The independent relation of diabetes duration with eGDR and C-reactive protein suggest that chronic exposure to glucose may stimulate an increase in insulin resistance and induce inflammatory activity already at the normoalbuminuric stage. Whether the detection of increased eGDR and C-reactive protein value in normoalbuminuric type 1 diabetics have predictive value for development of microalbuminuria needs to be assessed.

Changes in O-linked N-acetylglucosamine is associated with diabetic nephropathy in the human kidney

N. Fülöp¹, J. Cseh¹, P. Degrell¹, L. Pajor², J.C. Chatham³, I. Wittmann¹

¹2nd Department of Internal Medicine, University of Pécs, Pécs, Hungary,

²Department of Pathology, University of Pécs, Hungary, ³Department of

Medicine/Cardiovascular Disease, University of Alabama at Birmingham, United States

Background and aims: There is increasing evidence that the attachment of a single N-acetylglucosamine to the serine and threonine residues of nuclear and cytoplasmic proteins (O-GlcNAc) plays an important role in cell signaling pathways. It has also been reported that increases in O-GlcNAc contributes to the development of diabetes and diabetic complications; however, little is known about O-GlcNAc levels in diabetic nephropathy. Therefore the goal of this study was to determine whether O-GlcNAc could be detected in human kidney biopsy specimens, and if so to examine whether O-GlcNAc levels were increased in the kidneys of patients with diabetic nephropathy compared to the non-diabetic individuals.

Materials and methods: Using immunohistochemistry biopsy specimens of type-2 diabetic patients (n=6) and patients with previously diagnosed thin basement membrane nephropathy (n=7) serving as controls, O-GlcNAc was assessed by using CTD110.6 antibody.

Results: Protein O-GlcNAc was detected for the first time in the human kidney. In diabetic patients, we found significantly increased number of CTD110.6 positive podocytes in the glomeruli and significantly elevated staining in the tubuli (both in the nucleus and in the cytosol). Furthermore we detected an intense, granular staining in diabetic tubuli.

Conclusion: Therefore in conclusion we propose that increased O-GlcNAc levels may play a role in the development of diabetic nephropathy.

CTD110.6 positive tubuli and glomeruli in the control and diabetic groups (*: $p < 0.05$ vs control)

	Tubuli		Glomeruli	
	Cytoplasm	Nucleus		
	Diffuse	Granular		
Control	31.72%	1.00%	39.17%	38.24%
Diabetic	51.49%*	13.62%*	64.54%*	63.15%*

Reduced levels of 1,25 (OH)₂ D₃ and osteoprotegerin occur before the onset of microalbuminuria in diabetics

D.K. Singh¹, K. Farrington², B. Summerhayes³, A. Viljoen⁴, G. Sivakumar⁴, P. Winocour⁵

¹Diabetes and Renal, Lister Hospital, Stevenage, ²Renal Unit, Lister Hospital, Stevenage, ³Diabetes and Endocrinology, QEII Hospital, Welwyn Garden City, ⁴Chemical Pathology, Lister Hospital, Stevenage, ⁵Diabetes and Endocrinology, QEII Hospital, Welwyn Garden City, United Kingdom

Background: Derangements of mineral metabolism and associated bone disturbances along with accelerated vascular calcification may occur early in the progression of chronic kidney disease (CKD) in diabetes mellitus (DM). Abnormalities of vitamin D metabolism, and disturbances of the osteoprotegerin (OPG)/RANKL (Receptor activator of nuclear factor kappa B ligand) axis may be implicated. PTH and 1, 25 (OH)₂ D₃ influence bone metabolism by their action on the OPG/RANKL axis. In the vessel wall, RANKL promotes, whilst OPG tends to protect against calcification.

Aims: To study the relationship between 1,25 (OH)₂ D₃ and the OPG/RANKL axis in diabetic patients with normal estimated glomerular filtration rate (eGFR) and without microalbuminuria and in controls.

Materials and methods: We studied 41 non-diabetics, 40 type 1 diabetics and 41 type 2 diabetics with normal eGFR (>90 ml/min). We measured serum levels of 1,25 (OH) D₃ and other determinants of bone metabolism in addition to routine haematology and biochemistry.

Results: Median 1,25 (OH)₂ D₃ levels were lower in type 1 DM (41.0 pmol/l; $p < 0.001$) and type 2 (41.0 pmol/l; $p = 0.024$) than in non-diabetics (56.1 pmol/l), though the groups did not differ with respect to calcium, phosphate, iPTH, and Ntx (cross-linked N-telopeptides of type 1 collagen) levels. However, the levels of total alkaline phosphatase were higher in patients with Type 1 DM (median = 88.0 IU/L) than in controls (median = 69.0 IU/L; $p < 0.001$) and those with Type 2 DM (median = 81.0 IU/L; $p = 0.008$).

OPG levels were lower (median = 1.97 pmol/L) in patients with Type 1 DM than in controls (median = 2.57 pmol/L; $p = 0.002$) and in those with Type 2 DM (median level = 2.91 pmol/L; $p < 0.001$). RANKL levels and OPG/RANKL ratio did not differ significantly between the groups. There were no correlations between levels of 1,25 (OH)₂ D₃ and OPG and RANKL, however 1,25 (OH)₂ D₃ did correlate with alkaline phosphatase levels ($r = -0.208$, $p = 0.021$) across the whole study population.

Conclusion: Disturbances of 1,25 (OH)₂ D₃ and OPG levels occur in patients with diabetes before the onset of microalbuminuria. These abnormalities may play a vital role in the pathogenesis and progression of bone and vascular pathology.

Microvascular complications and risk factors in type 2 diabetic patients

F.J. Cañizo-Gómez¹, C. Fernandez-Perez², F.J. Pajuelo-Fernandez³

¹Endocrinology, Hospital Infanta Leonor, ²Preventative Medicine, Hospital Clinico Universitario, ³Clinical Research, MSD, Madrid, Spain

Background and aims: Various risk factors such as poor glycaemic control, dyslipidaemia, hypertension, obesity and cigarette smoking, act synergistically for the development of micro and macrovascular complications in type

2 diabetes mellitus (T2DM) subjects. Our aim was to perform a prospective study of T2DM patients without microvascular complications (nephropathy and retinopathy), analysing the association between various risk factors at baseline and the development of microvascular complications at follow-up, with data obtained from patients records.

Materials and methods: The prospective observational study consisted of 376 T2DM patients enrolled in 2004. The inclusion criteria at baseline in 2004 were normoalbuminuria (urine albumin < 30 mg/24 h.) and absence of retinopathy (assessed by fundoscopy). The clinical end-point was microalbuminuria (urine albumin > 30 mg/24 h.) and/or presence of retinopathy at follow-up in 2007. The mean study period was 3.5 years. The following variables were extracted from over diet dose at baseline in 2004: age, gender, diabetes duration, fasting plasma glucose, HbA1C, systolic (SBP) and diastolic blood pressure (DBP), weight, height, body mass index (BMI), waist circumference (WC), total cholesterol, triglycerides (TG), HDL-cholesterol, LDL-cholesterol, C-reactive protein (CRP), fibrinogen, microalbuminuria, creatinine, smoking status, exercise, alcohol consumption, use of hypoglycaemic and lipid-reducing drugs, antihypertensive medications, and other data such family history of diabetes and risk factors. Comparisons of mean levels were performed with the Student's *t*-test for unpaired samples, and comparison of proportions with the chi-square test. Logistic regression analyses were performed with development of microvascular complications at follow up as dependent variable, and age, gender, diabetes duration, and other risk factors included at baseline in 2004 as independent variables. Odds ratios (O.R.) were estimated, with an O.R. of > 1.0 signifying a positive association. $P < 0.05$ was considered statistically significant (SPSS, 13.0).

Results: Ninety five patients (25%) developed a microvascular complication at follow-up (46 nephropathy, 49 retinopathy). Compared to those who did not develop microvascular complications at follow-up, the ones who developed microvascular complications were predominantly males ($P < 0.05$), tended to be older than 60 years ($P = 0.011$), to have higher percentage of hypertension ($P = 0.008$), CRP > 3 mg/l ($P = 0.007$), to be taking more insulin ($P = 0.000$) and less oral hypoglycaemic agents ($P = 0.003$); and more likely to have a higher mean diabetes duration, WC, SBP, DBP, creatinine, microalbuminuria, and CRP ($P < 0.05$ for all). In the logistic regression analyses of baseline risk factors for the development of microvascular complications at follow-up, the principal independent risk factors were microalbuminuria > 12 mg/24 h. (O.R.: 6.12; $P = 0.000$), CRP > 3 mg/l (O.R.: 3.00; $P = 0.004$) and hypertension (O.R.: 2.43; $P = 0.023$).

Conclusion: In the T2DM patients studied, levels of microalbuminuria higher than 12 mg/24h., more than 3 mg/l of CRP and the presence of hypertension were all independent risk factors for the development of microvascular complications.

1211

Renal impairment among type 2 diabetic subjects

C.E. Koro^{1,2}, B. Lee¹

¹GlaxoSmithKline, Collegeville, ²Pharmaceutical Health Services Research, University of Maryland, Baltimore, United States

Background and aims: Type 2 diabetes is a major risk factor for chronic kidney disease (CKD). However, there are limited data on the epidemiology of renal impairment among type 2 diabetic subjects. This study aims to estimate the proportion of type 2 diabetic patients who have different degrees of renal impairment severity, quantified using CKD stages. The CKD stages were categorized based on the classification system established by the National Kidney Foundation Kidney Disease Outcomes Quality Initiative. Further, this study describes the patterns of antidiabetic drug use among subjects with various stages of CKD.

Materials and methods: Using data from the Fourth National Health and Nutrition Examination Survey (1999–2004 NHANES IV), which is representative of non-institutionalized adults in the United States, we performed a cross-sectional analysis on diabetic subjects who were 20 years old or older at the time of interview. To limit the analysis to adults with diagnosed type 2 diabetes, we excluded subjects who met both of the following criteria: age at the time of diagnosis was less than 30 years old and started insulin within one year of their diagnosis.

Results: Descriptive statistical analysis was performed for the study. About forty percent of diabetic subjects captured in this study had CKD. The majority of CKD patients (71.6%) were at stages 2 and 3. The proportion of CKD patients using one antidiabetic medication increased from 36.3% to 78.2% as CKD progressed from stage 1 to stage 5. On the other hand, the proportion of patients using two or more medications decreased from 36.2% at stage 1 to

1.3% at stage 5. The proportion of drug naive patients decreased from 18.0% at stage 1 to 6.6% at stage 4. The proportion of CKD patients using sulfonylurea decreased steadily from 45.1% at stage 1 to 11.7% at stage 5. Similarly, the proportion of CKD patients using metformin decreased from 45.6% at stage 1 to 23.8% at stage 3. Metformin was not used in subjects with CKD stages 4 and 5. The proportion of CKD patients on insulin only steadily increased from 6.7% at stage 1 to 58.3% at stage 5. On the other hand, the proportion of patients on OAD only steadily decreased from 69.0% to 27.8%.

Conclusion: The number of antidiabetic agents used trended towards a decrease with the increase in CKD stage. As the stage of CKD increased, subjects were more likely to be on insulin and less likely to be on OADs. Metformin was not used in stages 4 and 5, consistent with its labelled contraindication.

The distribution of renal impairment among type 2 diabetics by CKD stage

CKD Stage	n	N	%
No CKD	618	6,783,138	50.8
Stage 1	121	1,153,761	8.6
Stage 2	173	1,488,358	11.1
Stage 3	254	2,365,299	17.7
Stage 4	32	236,397	1.8
Stage 5	16	70,621	0.5

PS 117 Treating diabetic nephropathy

1212

The decrease in urinary albumin excretion induced by lifestyle intervention is mediated by the abdominal fat reduction in obese non-diabetic women

C. Invitti, L. Gilardini, M. Croci, G. Redaelli, C. Antonio
Unit of Metabolic Diseases and Diabetes, Istituto Auxologico Italiano, Milan, Italy

Background and aims: Microalbuminuria is a modifiable early marker of generalized endothelial dysfunction and atherosclerosis. Weight loss may reduce urinary albumin excretion (UAE); however it is unclear what weight loss-induced changes are responsible for UAE decrease. We therefore investigated the effect of 3-month lifestyle modifications on UAE in 123 non diabetic obese women (49.4±13.5 yrs, BMI 36.8 ±4.9 kg/m², waist circumference 111.5±10.7 cm).

Materials and methods: Before and after lifestyle modifications, all women underwent an oral glucose tolerance test and a bioimpedance analysis. A blood sample was taken for lipids and C-reactive protein (CRP) measurement. Microalbuminuria was defined by albumin/creatinine ratio (A/C) of 3.5–25 mg/mmol and metabolic syndrome (MS) defined by ATPIII criteria. Glomerular filtration rate (GFR) was estimated with Cockcroft–Gault formula.

Results: Seven percent of women had microalbuminuria. Women in the III tertile of A/C ratio had significantly higher BMI (38.2±5.6 vs 36.7±3.8 vs 35.9±5.1 kg/m², p<0.05 in the III, II and I tertile of A/C ratio), insulin (12.6±6.0 vs 10.9±5.9 vs 9.3±4.6 µU/ml, p<0.01), HOMA-IR (2.9±1.5 vs 2.5±1.6 vs 2.0±1.1, p<0.01) levels, had a higher prevalence of MS (43% vs 38% vs 29%) and have higher levels of all the other MS components compared to those in the II and I tertile of A/C ratio. GFR, fat mass and C-reactive protein levels did not influence A/C ratio. The lifestyle intervention induced a mean weight decrease of 5.2 ± 4.0%. Microalbuminuria reverted to normoalbuminuria in 80% of cases. Despite women in the I, II and III tertile of A/C ratio showed similar weight loss, A/C ratio decreased only in women in the III tertile (from 3.2±4.7 to 2.4±3.8 mg/mmol, p<0.01) who showed the greatest decrease in waist circumference (-4.4±2.5% vs 3.7±3.9% vs 2.3±3.0%, p<0.01 in the III vs II vs I tertile of A/C ratio) and a reduction in post-load insulin excursion (+20% ±11.0% vs +15±10.7% vs -7.0±4.8%). Changes in GFR, lipids, blood pressure and glucose did not influence changes in A/C ratio.

Conclusion: In non-diabetic obese women, lifestyle modifications induce a decrease in UAE which is mediated by the reduction in abdominal fat but not by changes in the others MS components.

1213

Obesity predicts changes in urine albumin/creatinine ratio in patients with type 2 diabetes: the DEMAND study

M. Comaschi¹, M.C. Rossi², A. Nicolucci², A. Ceriello³, D. Cucinotta⁴, C. Giorda⁵, I. Otranto³, F. Pellegrini², B. Pomili², U. Valentini⁶, G. Vespasiani⁷, S. De Cosmo⁸

¹Internal Medicine Unit, Emergency Department, University Hospital S. Martino, Genova, Italy, ²Department of Clinical Pharmacology and Epidemiology, Consorzio Mario Negri Sud, S. Maria Imbaro, Italy, ³University of Warwick, Coventry, United Kingdom, ⁴Department of Internal Medicine, Policlinico Universitario, Messina, Italy, ⁵Metabolism and Diabetes Unit, Chieri, Italy, ⁶Diabetes Unit, Spedali Civili, Brescia, Italy, ⁷Diabetes and Metabolism Unit, Madonna del Soccorso Hospital, S. Benedetto del Tronto, Italy, ⁸Unit of Endocrinology, Casa Sollievo della Sofferenza, S. Giovanni Rotondo, Italy

Background and aims: While central obesity has recently received attention as a potential risk factor for renal disease in nondiabetic subjects, its role in individuals with T2DM has been seldom investigated. Aim of this study was to evaluate whether waist circumference and BMI predicted the progression or regression of albumin/creatinine ratio (ACR) in a cohort of individuals with T2DM.

Materials and methods: A random sample of 1289 patients aged 18–80 years was recruited by 50 Italian diabetes clinics affiliated to the Associazione Medici Diabetologi. A morning spot urine sample was collected to centrally

measure ACR and to detect urinary infections. Patients were re-evaluated after one year. Progression of ACR was defined as a 50% increase in levels from baseline to follow-up, while regression was defined as a 50% reduction. A multivariate logistic regression was performed to evaluate factors associated with progression and regression of ACR.

Results: Overall, 1019 were included in the analyses, while 211 were excluded for urinary infections and 59 because of incomplete information. After one year, 170 (16.7%) patients had a progression of ACR levels, while 241 (23.7%) showed a regression. The likelihood of ACR progression increased by 14% for every five-years increase in diabetes duration (OR=1.14; 95%CI 1.03–1.27) and by 8% for each five-cm increase in waist circumference measured at baseline (OR=1.08; 95%CI 1.00–1.16). Furthermore, the risk of progression increased by 28% for every one-unit increase in BMI during the follow-up (OR=1.28; 95%CI 1.12–1.46). The likelihood of ACR regression increased by 3% (OR=1.03; IC95% 1.01–1.05) for every one-cm reduction of waist circumference during the study. No other variables were independently associated with regression of ACR.

Conclusion: In individuals with T2DM obesity is a factor for progression of ACR, independent of blood glucose, blood pressure, and baseline ACR levels. This independent effect could be mediated primarily by adipogenic inflammation and endothelial dysfunction which accompany central obesity. Reducing waist circumference can favor the regression of albuminuria, probably by improving the mechanism of insulin resistance.

1214

The SURE Study: effects of structured versus usual care on renal endpoint in type 2 diabetes: a randomized multi-centre study

W.Y. So¹, C.-Y. Yeung¹, G.T.C. Ko², K.W. Chan³, C.H. Chung³, G. Kum⁴, L.M. Fung⁵, T.P. Ip⁶, I.T. Lau⁷, J.K.Y. Li⁸, S.C. Siu⁹, M.W. Tsang⁴, V.T.F. Yeung⁹, W.Y.S. Leung¹⁰, J.C.N. Chan¹

¹Department of Medicine and Therapeutics, The Chinese University of Hong Kong, ²Department of Medicine, Alice Ho Miu Ling Nethersole Hospital, ³Department of Medicine, The Princess Margaret Hospital, ⁴Department of Medicine, The United Christian Hospital, ⁵Department of Medicine, Caritas Medical Centre, ⁶Department of Medicine, Tung Wah Eastern Diabetes Center, ⁷Department of Medicine, The Tseung Kwan O Hospital, ⁸Department of Medicine, Yan Chai Hospital, ⁹Department of Medicine, Our Lady of Maryknoll Hospital, ¹⁰Department of Pharmacy, The Queen Elizabeth Hospital, Hong Kong SAR, Hong Kong

Background and aims: Multifaceted care reduced mortality, micro and macrovascular complications in type 2 diabetes. We hypothesize that structured care (SC) reduces end stage renal disease (ESRD) in type 2 diabetes.

Materials and methods: Chinese Type 2 diabetic patients with plasma creatinine between 150 and 350 µmol/L were recruited from 9 public hospitals in Hong Kong. The SC group was managed by a diabetes team using a protocol with predefined clinic and assessment schedules and treatment goals: a) blood pressure <130/80 mmHg b) HbA_{1c} <7% c) LDL-C <2.6mmol/L d) triglyceride <2 mmol/L and e) persistence with blockers of renin angiotensin system. Main outcome measures were composite primary endpoints of death, ESRD defined as serum creatinine > 500 µmol/L or need for dialysis.

Results: 205 patients [mean (SD) age: 65±7.2 years; disease duration: 14±7.9 years; plasma creatinine: 197±39.9 µmol/L] were randomized to receive either SC (n=104) or UC (n=101). Of these, 167 patients (SC: 84 and UC: 83) completed the 2-year study. The SC group had better metabolic control than the UC group (HbA_{1c}: 7.3 ±1.3% vs 8.0 ±1.6%, p<0.01; LDL-C: 2.49 ±0.81 vs 2.84 ±1.05 mmol/L, p=0.01) with 61% (n= 63) in the SC group and 28% (n=28) in the UC group (p<0.001) attaining ≥ 3 treatment goals. Primary composite endpoint occurred in 24 patients in the SC group and 24 patients in the UC group. Patients who attained ≥3 treatment targets (n=91) had reduced risk of reaching composite endpoint [14 vs 34; RR: 0.43 (95% CI: 0.21 - 0.86)] and death [4 vs 15 deaths; RR 0.30 (95% CI 0.10 - 0.95)] than those who attained 2 or fewer targets (n=114).

Conclusion: Attainment of multiple treatment targets reduced ESRD and death rates in type 2 diabetes. In addition to protocol and specialist care, clinical audits and feedback are needed to improve clinical outcomes.

Effect of dietary salt supplementation on albumin excretion rate (AER) response to angiotensin receptor blockade +/- thiazide therapy in hypertensive patients with type 2 diabetes and increased AER

E.I. Ekinci, G. Thomas, B. Chappell, R. MacIsaac, C. Johnson, C. Houlihan, H. Hao, S. Finch, S. Panagiotopoulos, C. O'Callaghan, G. Jerums
Department of Endocrinology, Austin Health and The University of Melbourne, Australia

Background and aims: This was a double blind, crossover, randomised placebo controlled study to assess the effect of sodium chloride (NaCl) supplementation on the actions of angiotensin receptor blockade (ARB) alone +/- thiazide on AER in hypertensive patients with type 2 diabetes mellitus (T2DM) and elevated AER (10–200 mcg/min). Participants had either habitual low dietary sodium (LDS), 2/3 24 hour urine sodium (Na) excretion of < 100 mmol/day or high dietary sodium (HDS) intake, 2/3 24 hour urine Na excretion of > 200 mmol/day.

Materials and methods: During a washout period (week -6 to 0), usual antihypertensives were replaced by verapamil, prazosin, methylodopa or hydralazine in LDS (mean age 60, median AER 48mcg/min, mean BMI 32.9) and HDS (mean age 65, median AER 23 mcg/min, mean BMI 32.0) to target blood pressure ≤140/90. There was no statistically significant difference in baseline AER in HDS and LDS groups. Patients then received telmisartan 40 mg/day (T) for 4 weeks. In the next 4 weeks hydrochlorothiazide 12.5 mg/day (Hct) was added to T. For the second 2 weeks of each treatment period, patients randomly received capsules containing either 100 mmol/day NaCl or placebo (P). After a second 6 week washout period, median AER was unchanged from baseline in the LDS (53 mcg/min) and HDS (28 mcg/min) groups. The regimen was repeated but NaCl supplementation and P were reversed. 24 hr urinary AER and Na excretion were measured at weeks 0, 4, 8, 14, 18 and 22.

Results: Mean Na excretion (mmol/24 hr) in the LDS group with T + P was 124 ± 7 and 126 ± 13 with T + Hct + P. Mean Na excretion in the HDS group with T + P was 264 ± 24 and 249 ± 15 with T + Hct + P. An increase in mean urine Na excretion of 56 mmol/day was seen in both groups during NaCl supplementation. The statistical comparison of the various interventions on AER are shown in the table and the figure shows the AER response as treatment / baseline ratio.

Conclusion: This study shows that in diabetic subjects with habitually low salt intake, salt supplementation markedly reduces AER response to ARB with or without the addition of diuretic. By contrast, in subjects with habitually high salt intake, the response to ARB with or without diuretic, is already reduced and is not influenced any further by salt supplementation. In this analysis, the effects of the various interventions on AER were independent of changes in blood pressure.

Analysis of variance results from a 3 way analysis of covariance

Explanatory variable	F	P value
Salt supplement (Salt vs placebo)	5.18	0.026
Treatment (T vs T+Hct)	4.99	0.028
Habitual sodium intake group (High vs Low)	0.01	0.9
Salt supplement by Habitual sodium intake group	4.68	0.034
Change in Mean Arterial Pressure (covariate)	0.86	0.4

Irbesartan delays progression of nephropathy as measured by estimated glomerular filtration rate: post-hoc analysis of the Irbesartan Diabetic Nephropathy Trial

R.W. Bilous¹, S.C. Bain², C. Beckham³, S. Hogan⁴, M. Evans⁵

¹Academic Centre, James Cook University Hospital, Middlesbrough, ²Diabetes and Endocrine Unit, Swansea University, ³Bristol-Myers Squibb, Uxbridge, ⁴sanofi-aventis, Guildford, ⁵Department of Metabolic Medicine, Diabetes and Endocrinology, University of Wales College of Medicine, Cardiff, United Kingdom

Background and aims: Results from the Irbesartan Diabetic Nephropathy Trial (IDNT) showed that irbesartan slowed progression of type 2 diabetic nephropathy compared with amlodipine and placebo; this effect was independent of blood pressure (BP) reduction. IDNT had a primary composite endpoint of doubling serum creatinine, end-stage renal disease (characterized by need for dialysis or transplantation) or death. Based upon updated guidelines from the US Kidney Disease Outcomes Quality Initiative group, which are being implemented throughout Europe, estimated glomerular filtration rate (eGFR) is a more accurate and convenient measure for estimating kidney function than the previous standard measure, serum creatinine. eGFR is calculated using an equation that corrects serum creatinine measurements for patient variability in age, sex, and race. A post-hoc analysis to assess nephropathy as measured by eGFR in IDNT was performed.

Materials and methods: IDNT was a phase 3, randomized controlled trial in 1715 type 2 diabetic patients with nephropathy who received irbesartan (300 mg/day), amlodipine (10 mg/day), or placebo (non-angiotensin II receptor blocker, -angiotensin-converting enzyme inhibitor, or -calcium channel blocker antihypertensives). Median follow up was 2.6 years (31 months). The Modification of Diet in Renal Disease equation was used to calculate eGFR using baseline data for age, sex and race, and baseline and quarterly-measured serum creatinine levels.

Results: Similar reductions in BP (mean arterial pressure; MAP) were achieved in the irbesartan and amlodipine arms; MAP was reduced more effectively in both these arms vs placebo (p=0.001). There was a smaller mean change in eGFR from baseline (Δ eGFR) in the irbesartan arm compared with the placebo and amlodipine arms towards the end of the study (irbesartan vs placebo, -10.99 vs -14.81 ml/min/1.73m², p=0.011 at month 39; irbesartan vs amlodipine, -11.67 vs -16.11 ml/min/1.73m², p=0.004 at month 42, and -12.72 vs -16.46 ml/min/1.73m², p=0.043 at month 45). Rate of Δ eGFR from months 21–48 was significantly lower for irbesartan vs placebo and amlodipine (-1.66, -3.07, and -3.45 ml/min/1.73m² per year, respectively; p=0.0002 and p=0.00006 for irbesartan vs placebo and irbesartan vs amlodipine; p=0.75 for amlodipine vs placebo).

Conclusion: In patients with type 2 diabetes and nephropathy, irbesartan, compared to amlodipine or placebo, significantly reduced the rate of eGFR decline after 20 months of treatment.

East Hanover, United States, ⁵Novartis, Cambridge, United States,

⁶Department of Medical Endocrinology, University Hospital, Copenhagen,

Denmark, ⁷Faculty of Health Science, Aarhus University, Denmark

Background and aims: Blockade of the AT₁ receptor by irbesartan reduces albuminuria, but increases plasma renin activity (PRA) and angiotensin (Ang) I and II levels. Direct renin inhibition with aliskiren further reduces albuminuria when added to irbesartan; this may be due to reduction of PRA and more effective renin system blockade. We report the effect of aliskiren alone and in combination with irbesartan on renin system biomarkers in patients with type 2 diabetes, hypertension and albuminuria.

Materials and methods: In a double-blind, randomized, cross-over study, 24 patients were treated in 2-month periods with placebo, aliskiren 300 mg, irbesartan 300 mg or the combination. High-sensitivity PRA (using sheep angiotensinogen as substrate, hsPRA), plasma concentrations of renin (PRC), prorenin (Pro), Ang I, Ang II, angiotensinogen, aldosterone and ACE activity

were measured at the end of each treatment period. Treatment effects were assessed in a mixed model analysis. Results are geometric mean change vs placebo.

Results: Aliskiren significantly reduced hsPRA, Ang I and Ang II by 87%, 75% and 52% respectively; irbesartan had the opposite effect (Table). In combination, the stimulatory effect of irbesartan was inhibited by aliskiren to a similar degree (88%, 78% and 56% for hsPRA, Ang I and Ang II respectively). Renin specific activity (renin bioactivity/total renin) was 3% and 4% (i.e. 97% and 96% renin inactivation) after aliskiren and combination therapy respectively. Combination treatment caused a synergistic effect on the degree of RAAS blockade. Overall, active treatment-induced increases in PRC correlated significantly with reductions in UAER ($r=-0.339$, $p=0.005$). Similar correlations were observed for each treatment (aliskiren, $r=-0.420$, $p=0.052$; irbesartan, $r=-0.486$, $p=0.022$; combination, $r=-0.319$, $p=0.148$). Irbesartan reduced angiotensinogen by 26% ($p<0.001$); changes after aliskiren or the combination were not significant. There were no significant changes in ACE activity or aldosterone levels.

Conclusion: Each monotherapy reduced albuminuria and affected renin system biomarkers in the expected fashion. Combining aliskiren with an AT₁ receptor blocker provided a larger reduction in albuminuria that correlated with more complete intra-renal renin system blockade (reflected by increases in PRC), and thus improves renoprotection.

	hsPRA %	Pro %	PRC %	Ang I %	Ang II %

Renoprotective effects of direct renin inhibition compared to and in combination with maximum recommended dose of irbesartan in patients with type 2 diabetes and albuminuria

F. Persson¹, P. Rossing¹, H. Reinhard¹, T. Juhl¹, C.D.A. Stehouwer², C. Schalkwijk³, A.H.J. Danser³, F. Boomsma³, E. Frandsen⁴, H.-A. Dieterich⁵, M. Prescott⁶, W.P. Dole⁷, H.-H. Parving^{8,9}

¹Steno Diabetes Center, Gentofte, Denmark, ²Dept of Medicine, University Hospital, Maastricht, Netherlands, ³Dept of Medicine, Erasmus MC, Rotterdam, Netherlands, ⁴Dept of Clinical Physiology and Nuclear Medicine, University Hospital, Glostrup, Denmark, ⁵Novartis, Basel, Switzerland, ⁶Novartis, East Hanover, United States, ⁷Novartis, Cambridge, United States, ⁸Department of Medical Endocrinology, University Hospital, Copenhagen, Denmark, ⁹Faculty of Health Science, Aarhus University, Denmark

Background and aims: Like other pharmacological agents that block the renin-angiotensin-aldosterone system (RAAS), the direct renin inhibitor aliskiren has antiproteinuric and antihypertensive effects in patients with type 2 diabetes. We investigated if aliskiren (300 mg OD) has an antiproteinuric effect comparable to the maximum recommended dose of irbesartan (300 mg OD), and also if there is any additional benefit from the combination. In addition, treatment effects on cardiovascular biomarkers were investigated.

Materials and methods: Double-blind, randomised, cross-over trial. After 1 month washout 24 patients with type 2 diabetes, hypertension and albuminuria ($>30\text{mg/day}$) were randomised to four 2-month treatment periods, receiving treatment with placebo (baseline), aliskiren 300 mg once daily, irbesartan 300 mg once daily or the combination of the two active treatments, in random order. During washout and all treatment periods, patients also received long-acting furosemide in a stable dose to control sodium retention. The primary endpoint was change in urinary albumin excretion rate (UAER). Secondary measures included change in arterial blood pressure (BP).

Results: Placebo (baseline) geometric mean UAER was 258 mg/day (range 84–1265), seated office BP was 135/78 mmHg, GFR was 90 (SD 27) ml/min/1.73 m². Aliskiren treatment showed a significant reduction in UAER by 48% (95% CI 27–62) compared to placebo ($p<0.001$), not significantly different from irbesartan treatment, which reduced UAER by 58% (42–70) ($p<0.001$ vs. placebo). Dual RAAS blockade reduced UAER by 71% (59–79) which was significantly more than with either monotherapy ($p<0.001$ and $p=0.028$). Seated office BP was reduced 7/4 mmHg by aliskiren, 6/4 mmHg by irbesartan and 12/8 mmHg by the combination, all statistically significant compared to placebo, except for irbesartan on diastolic BP. GFR was significantly reduced 4.6 (8.8–0.3) ml/min by aliskiren, 8.0 (12.3–3.6) ml/min by irbesartan and 11.7 (15.9–7.4) ml/min by the combination. Combination treatment showed a slight increase in plasma potassium by 0.2 mmol/l ($p=0.036$). Both monotherapies achieved a reduction in hsCRP levels compared to placebo (from 2.5 mg/l to 1.6 mg/l for both, aliskiren $p=0.047$, irbesartan $p=0.043$), sICAM-1 was reduced compared to placebo by combination therapy (636 µg/l to 596 µg/l, $p=0.017$) while sVCAM-1, vWf, fibrinogen and NT-proBNP levels were unchanged through all treatments.

Conclusion: Direct renin inhibition with aliskiren showed similar beneficial effects on UAER and hsCRP as the maximum recommended dose of irbesartan. The combination showed significantly improved renoprotective (UAER) effects, compared to either monotherapy in type 2 diabetic patients with albuminuria.

A high saturated fat diet increased and low fat diets decreased pulse pressure and systolic blood pressure in men with metabolic syndrome in the LIPGENE dietary intervention studyI.M.F. Gjelstad^{1,2}, H.L. Gulseth^{1,2}, J. Lovegrove³, C. Defoort⁴, E. Blaak⁵, J. López Miranda⁶, L. Partyka⁷, B. Karlström⁸, H.M. Roche⁹, K.I. Birkeland², C.A. Drevon¹¹Dept Nutrition, University of Oslo, Norway, ²Dept Endocrinology, Aker University Hospital / University of Oslo, Norway, ³Hugh Sinclair Unit of Human Nutrition, University of Reading, United Kingdom, ⁴Nutrition Humaine et Lipids, INSERM, Marseilles, France, ⁵Dept Human Biology, Maastricht University, Netherlands, ⁶Lipid and Atherosclerosis Unit, Reina Sofia University Hospital, University of Cordoba, Spain, ⁷Dept Clinical Biochemistry, Jagiellonian University Medical College, Krakow, Poland, ⁸Dept Public Health and Caring Sciences / Clinical Nutrition and Metabolism, Uppsala University, Sweden, ⁹Conway Institute, University College Dublin, Ireland

Background and aims: Subjects with metabolic syndrome (MS) have increased risk for type 2 diabetes (T2D) and cardiovascular disease (CVD). Elevated blood pressure (BP) is a key feature of MS and contributes to the increased CVD risk in T2D. High pulse pressure (PP) is an independent risk factor of CVD and often coexists with MS and T2D. Dietary fatty acids affect plasma lipids and lipoproteins, but the impact of dietary fat on BP is controversial. We have evaluated the effects of amount and type of dietary fatty acids on BP in subjects with MS.

Materials and methods: Free-living subjects with MS from 8 European centres were randomized to follow one of four isoenergetic diets for 3 months: High fat (38 energy percent, E%) diet rich in saturated fatty acids (16 E%) (HF-SFA), high fat (38 E%) diet rich in monounsaturated fatty acids (20 E%) (HF-MUFA), and two low fat diets (28 E%) with or without supplement of 1.2 g/d marine omega-3 fatty acids (LF-n3 and LF-P). A food exchange model was used to achieve the dietary aims. 349 subjects (159 males, 190 females) aged 35–70 completed the study per protocol (HF-SFA: n=84, HF-MUFA: n=91, LF-n3: n= 89 and LF-P: n=85).

Results: There were no significant effects of the dietary intervention on BP in the total LIPGENE cohort. However, in males the change in PP was significantly different between the four diets in an one-way ANOVA (Δ PP: HF-SFA 3.8 mmHg, HF-MUFA -1.7 mmHg, LF-n3 -2.0 mmHg and LF-P -3.1 mmHg, $p=0.005$). After Bonferroni correction the change in PP remained statistically significant between the HF-SFA group and the LF-n3 and the LF-P groups; $p=0.032$ and 0.006 , respectively. In drug naïve males ($n=124$) systolic blood pressure (SBP) was significantly changed (Δ SBP: HF-SFA 4.6 mmHg, HF-MUFA -0.5 mmHg, LF-n3 -2.7 mmHg and LF-P -2.6 mmHg, $p=0.009$). In females there were no effects of the dietary intervention on BP.

Conclusion: Altered quantity and quality of dietary fatty acids significantly affected PP and SBP in males with MS, but not in females.

Control of blood pressure and low-density lipoprotein cholesterol with**single-pill amlodipine/atorvastatin: a pooled analysis of patients with and without diabetes**T.G. Jenssen¹, C.A. Aguilar-Salinas², F.D.R. Hobbs³, R.D. Feldman⁴, R.C. Blank⁵, R.A. Moller⁶, I.M. Schou⁷, H. Shi⁷¹Department of Medicine, Rikshospitalet, Oslo, Norway, ²Department of Endocrinology and Metabolism, Instituto Nacional de Ciencias Medicas y Nutricion, Mexico City, Mexico, ³General Practice Primary Care Clinical Sciences Building, University of Birmingham, United Kingdom, ⁴Roberts Research Institute, University of Western Ontario, London, Canada, ⁵Department of Cardiology, Presbyterian Hospital, Charlotte, United States, ⁶Pfizer Inc, New York, United States, ⁷Pfizer Australia, Sydney, Australia

Background and aims: Patients with type 2 diabetes (DM) are at increased risk of cardiovascular (CV) events and have difficulty reaching their blood pressure (BP) goal. This pooled analysis of the GEMINI-US, GEMINI-AALA, and JEWEL 1/2 studies compared the utility of single-pill amlodipine besylate/atorvastatin calcium (amlo/atorva) for BP and low-density lipoprotein cholesterol (LDL-C) control in patients with hypertension (uncontrolled) and dyslipidemia (controlled/uncontrolled), with or without DM.

Materials and methods: In these 14–16-week, open-label studies, amlo/atorva (5/10–10/80 mg) was electively titrated to achieve therapeutic goals. Changes in BP and LDL-C from baseline, and goal attainment, were evaluated, using study-specific targets (DM patients: BP goals = 130/80–140/80 mmHg, LDL-C goals = 2.5–3.0 mmol/L; non-DM patients: BP goals = 130/80–150/90 mmHg, LDL-C goals = 2.5–4.5 mmol/L).

Results: Of 5114 patients in the pooled population, 1637 had DM (mean baseline HbA1c was 7.0% for DM vs. 5.7% for non-DM). Mean age of DM and non-DM patients was 61.1 and 60.0 years, respectively, and 47.8% and 44.5% were female. Mean dose of amlo/atorva at study end was 7.4/23.4 mg for DM patients, and 6.9/24.0 mg for non-DM patients. BP reductions from baseline to study end were comparable for DM and non-DM patients, but the percentage reaching BP/both goals was lower for DM patients (47%/39% compared with 72%/60% for non-DM patients), contributed to by stricter BP goals for DM patients (Table). Among DM patients taking no add-on antihypertensive therapy ($n=815$), 50.8% reached their BP goal. Mean LDL-C reduction from baseline was slightly higher in non-DM patients. Adverse events-related discontinuations were similar for patients with and without DM (3.7% and 4.4%).

Conclusion: Single-pill amlo/atorva helps to control 2 major risk factors for CV disease by simultaneously producing large decreases in BP and LDL-C, and is well tolerated, in patients with and without DM. The differences in BP and LDL-C goal attainment between DM and non-DM patients, are mainly due to DM patients having lower targets.

regardless of metabolic status: a post-hoc analysis of an 8-week double-blind study

S.A. Yarows¹, S. Oparil², S. Patel³, V. Arora³, J. Zhang³

¹Chelsea Internal Medicine/IHA, Chelsea, ²UAB Vascular Biology and Hypertension Program, Birmingham, ³Novartis Pharmaceuticals Corporation, East Hanover, United States

Background and aims: More than one-third of patients with hypertension also have metabolic syndrome and are thus at increased cardiovascular risk. This *post-hoc* analysis in a double-blind study in patients with hypertension assessed the antihypertensive efficacy of the direct renin inhibitor (DRI) aliskiren in combination with valsartan compared with either agent alone in the subgroup of patients with metabolic syndrome.

Materials and methods: In all, 1797 patients with hypertension (mean sitting diastolic BP [msDBP] 95–110 mmHg) were randomized to aliskiren/valsartan 150/160 mg, aliskiren 150 mg, valsartan 160 mg or placebo once daily for 4 weeks, followed by forced titration to double the initial doses for 4 weeks. Metabolic syndrome was defined according to NCEP ATP III criteria. Changes from baseline in mean sitting systolic BP (msSBP), msDBP, and responder rates (msDBP <90 mmHg and/or ≥10 mmHg reduction) were assessed at week 8 endpoint for the intent-to-treat population.

Results: Baseline msSBP/msDBP was similar in the subgroups of patients with metabolic syndrome (154.0/100.3 mmHg; $n=827$) and without metabolic syndrome (153.6/100.3 mmHg; $n=944$). At week 8 endpoint, aliskiren/valsartan 300/320 mg provided highly effective BP lowering, regardless of metabolic status (Table). BP reductions and responder rates in the aliskiren/valsartan treatment group were significantly greater than for either monotherapy or placebo in both patient subgroups. There were no significant differences in the BP-lowering effects of study treatments between patients with or without metabolic syndrome ($p > 0.2$). Overall rates of AEs were similar across treatment groups and were not notably affected by the presence of metabolic syndrome (with, 31.7–36.4%; without, 33.0–38.6%). The most common AEs were headache (overall, 5.5%) and nasopharyngitis (3.2%).

Conclusion: Combination therapy with aliskiren and valsartan provided significant additional BP-lowering effects compared with either monotherapy in patients with metabolic syndrome, similar to those in patients without metabolic syndrome. Aliskiren/valsartan is thus a highly effective and generally well-tolerated treatment option for patients with hypertension, regardless of metabolic status.

Aliskiren-based therapy lowers blood pressure more effectively than hydrochlorothiazide-based therapy in obese hypertensive patients: subgroup analysis of a 52-week, randomized, double-blind trial

R.E. Schmieder¹, T. Philipp², J. Guerediaga³, M. Gorostidi³, V. Arora⁴, M.F. Prescott⁴, D.L. Keefe⁴

¹University of Erlangen-Nürnberg, Erlangen, Germany, ²University Hospital, Essen, Germany, ³Hospital San Agustín, Aviles, Spain, ⁴Novartis Pharmaceuticals Corporation, East Hanover, United States

Background and aims: To compare long-term blood pressure (BP) reduction and safety of the direct renin inhibitor aliskiren (ALI) and hydrochlorothiazide (HCT) in obese patients (body mass index [BMI] ≥30 kg/m²) with hypertension.

Materials and methods: *Post-hoc* analysis of the obese subgroup ($n=396$) in a double-blind, multicenter study in which, after a 6-wk placebo-controlled

phase, 1124 patients with sitting diastolic BP (DBP) 95–109 mmHg received ALI 300 mg ($n=567$) or HCT 25 mg ($n=557$) once daily for 46 wks. Amlodipine (AMLO) 5 mg was added from wk 12 and titrated to 10 mg from wk 18 if BP was ≥140/90 mmHg.

Results: Patients in the obese subgroup ($n=396$) had a mean body weight of 96.0 kg and BMI of 34.0 kg/m² (vs 75.4 kg and 26.3 kg/m² respectively in non-obese patients [$n=721$]). Compared with non-obese patients, the obese subgroup showed a higher incidence of metabolic syndrome (66.7% vs 29.5%) and diabetes (17.4% vs 7.4%) but similar mean baseline BP (154.5/99.2 vs 154.2/98.8 mmHg). Within the obese subgroup, ALI and HCT arms were well matched for demographics and baseline BP (155.0/99.4 vs 154.0/99.0 mmHg). At wk 12 endpoint (Table), ALI 300 mg monotherapy provided significantly larger reductions in mean sitting systolic BP (SBP) and DBP, and BP response (DBP <90 or ≥10 mmHg reduction) and control (<140/90 mmHg [pre-specified for the overall population]) rates than HCT 25 mg monotherapy. At wk 52 endpoint, ALI-based therapy (87/183 patients [47.5%] with add-on AMLO) provided significantly larger DBP reduction and response rates than HCT-based therapy (78/150 [52.0%] with add-on AMLO) and a trend towards larger SBP reductions and control rates. ALI lowered BP effectively in obese (Table) and non-obese patients (non-obese: wk 12, 17.1/12.3 mmHg; wk 52, 21.1/15.6 mmHg; all comparisons $p=NS$ vs obese patients). By contrast, HCT was significantly less effective in obese (Table) than non-obese patients (non-obese: wk 12, 15.7/11.3 mmHg; wk 52, 20.8/15.4 mmHg; all comparisons $p < 0.05$ vs obese patients). Larger BP reductions with ALI relative to HCT were also observed at wk 52 endpoint in obese patients who received only monotherapy throughout the study (19.9/16.4 mmHg with ALI monotherapy [$n=96$] vs 16.7/12.6 mmHg with HCT monotherapy [$n=72$]; $p=0.007$ for DBP). AE rates in obese patients were similar with ALI- and HCT-based regimens (72.1% vs 68.1%).

Conclusion: In this *post-hoc* analysis of obese patients with hypertension, ALI lowered BP more effectively than HCT as monotherapy (300 mg and 25 mg respectively) or with add-on AMLO (5–10 mg).

Efficacy in the obese subgroup

Parameter	Week 12 endpoint (monotherapy)		Week 52 endpoint (with add-on AMLO)	
	ALI 300 mg ($n=208$)	HCT 25 mg ($n=185$)	ALI-based regimen ($n=183$)	HCT-based regimen ($n=150$)

Does salt sensitivity influence the magnitude of microalbuminuria in hypertensive type 2 diabetic patients?

S.D. Jelic¹, M. Sumarac-Dumanovic², Z. Caparevic¹

¹University Clinic for Internal Medicine, CHC "Dr Dragisa Misovic",

²Institute for Endocrinology, Diabetes and Metabolic Diseases, School of Medicine, University of Belgrade, Serbia.

Background and aims: Objective of this investigation was to assess the influence of the salt sensitivity of blood pressure on the magnitude of microalbuminuria in hypertensive type 2 diabetic patients.

Materials and methods: The study included 66 (35 female/31 male) hypertensive non-proteinuric type 2 diabetic patients (mean age: 49.51±6.29 years; duration of diabetes: 11.29±5.02 years and duration of hypertension: 11.86±6.02 years). After obtaining an informed consent and three-week wash-out period (without any anti-hypertensive drug), normal (150 mmol of sodium daily), low- (40 mmol of sodium daily) and high-salt (300 mmol of sodium daily) diet was sequentially applied in every patient for 3, 9 and 9 days respectively. The increment of mean arterial pressure (Δ MAP) on high- vs. low-salt diet exceeding 10 mmHg was used as the criterion for salt sensitivity. Sodium sensitivity index (SSI) as given by Imanishi M et al. (Diabetes Care 2001; 24: 111–116) is also calculated for every subject. During the last 5 days of low- as well as high-salt diet, inhibitor of the angiotensin-converting enzyme, captopril, was given in a daily dose of 50 mg in order to assess the influence of the dietary salt intake on the renoprotective effects of this group of anti-hypertensive drugs. Urinary albumin excretion (UAE) during salt restriction and salt-load was compared with values during normal salt intake in both salt-sensitive and salt-resistant subjects. The effects of acute administration of captopril on UAE, during different levels of dietary salt intake, in these two groups of patients were also compared. Statistical analysis was performed using the STATISTICA 4.5 program (StatSoft, Tulsa, OK, USA).

Results: According to the given criterion 34 (51.51%) of studied hypertensive type 2 diabetic patients were salt-sensitive. Mean UAE during the normal salt intake, were higher in salt-sensitive (SS) than in salt-resistant (SR) subjects (117.44±81.33 vs 83.31±60.23 mg/day, $P=0.0564$), but this difference was of borderline significance. Salt restriction significantly reduced UAE only in SS (113.35±77.55 mg/day, $P0.1$). During low-salt intake, captopril significantly reduced UAE in both groups (SS: 109.73±76.64 mg/day, $P=0.00001$; SR: 80.75±50.24 mg/day, $P=0.000018$). Salt load significantly raised UAE in SS (121.68±81.57 mg/day, $P=0.000001$), but not in SR subjects (84.28±60.31 mg/day, $P=0.067$). Again, captopril significantly reduced UAE in both groups (SS: 117.15±80.69 mg/day, $P<0.00001$; SR: 81.58±60.51 mg/day, $P<0.00001$) during high-salt intake.

Conclusion: This study demonstrated that dietary salt intake influenced UAE only in salt-sensitive subjects with hypertension and type 2 diabetes. However, angiotensin-converting enzyme inhibitor, captopril, has reduced UAE in salt-sensitive as well as in salt-resistant subjects, independently of dietary salt intake.

1224

Diurnal changes in urinary excretions of immunoglobulin G, transferrin, and ceruloplasmin depend on diurnal changes in blood pressure in normoalbuminuric type 2 diabetic patient

M. Hosoba, T. Narita, H. Fujita, T. Morii, T. Shimotomai, J. Koshimura, Y. Yamada

Department of Endocrinology, Diabetes and Geriatric Medicine, Akita University School of Medicine, Japan

Background and aims: We reported that urinary excretions of immunoglobulin G (IgG), transferrin and ceruloplasmin (molecular radii<55 Å) selectively increased in parallel with enhanced glomerular filtration rate after acute protein loading (APL), which cause increased glomerular capillary pressure (GCP) due to afferent arterioles dilatation, mimicking diabetic intra-renal hemodynamic changes. However, increased urinary excretions of albumin and α_2 -macroglobulin were not detected. Furthermore, we found that increased urinary excretions of IgG and ceruloplasmin were present in normoalbuminuric type 2 diabetic patients were stabilized after strict glycemic control without change in albuminuria. Taken together, we hypothesized that changes in urinary excretions of IgG, transferrin and ceruloplasmin may be more sensitive clinical markers of changes in GCP, especially in normoalbuminuric state than urinary excretion of albumin. Aim of this study is to clarify whether changes in blood pressure influence urinary excretions of

these plasma proteins (molecular radii < 55 Å), which may reflect impaired renal hemodynamics in diabetic state.

Materials and methods: Ambulatory blood pressure monitoring was used to examine diurnal changes in blood pressure. Urinary excretions of IgG, transferrin, ceruloplasmin, α_2 -macroglobulin (88 Å) and albumin (36 Å) were measured in urine samples collected separately during day and night times in 20 healthy subjects and 26 normotensive- normoalbuminuric diabetic patients. Diurnal index (DI) as % of (nighttime mean - daytime mean) / daytime mean was used for the evaluations of blood pressure levels and urinary excretions of above mentioned plasma proteins. U-IgG/Cr, U-CRL/Cr, U-Tf/Cr, U-Alb/Cr, and U-A₂/Cr represent ratios of urinary immunoglobulin G, ceruloplasmin, transferrin, albumin, and α_2 macroglobulin to urinary creatinine in daytime and nighttime urine samples, respectively.

Results: Statistically significant strong correlations between DI of SBP and those of U-IgG/Cr, U-Tf/Cr and U-CRL/Cr ($r = 0.613$, $p = 0.0009$; $r = 0.415$, $p = 0.0352$, and $r = 0.506$, $p = 0.0083$, respectively) were found in diabetic patients, whereas these close relationships were not found in control subjects. In contrast with these results, the correlation between DI of U-Alb/Cr and that of SBP was not found ($r = 0.306$, $p = 0.1285$) even in diabetic patients. Furthermore, DI of U-A₂/Cr did not reveal significant correlations with DI of SBP in both control subjects and diabetic patients ($r = 0.049$, $p = 0.836$ and $r = 0.227$, $p = 0.2655$, respectively).

Conclusion: Labile tendency of GCP following systemic blood pressure changes in normotensive- normoalbuminuric diabetic patients was clinically detected by measurement of urinary excretions of IgG, transferrin and ceruloplasmin. Considering the relation between increased GCP and progression of diabetic nephropathy, the present finding supports an importance of early introduction of blood pressure control even in normotensive- normoalbuminuric diabetic patients.

The effect of achieving the goal for antihypertensive treatment in type 2 diabetic patients. Comparing office and 24 h blood pressure levels

O. Torffvit

Nephrology, Clinical Sciences, Lund, Sweden

Background and aims: Antihypertensive treatments in studies are effective in arresting diabetic complications. How is it in daily practice? Do 24 hour measurements offer an advantage beyond office pressure?

Materials and methods: 109 type 2 diabetic patients (22 females), 65 (35–89) years old, with micro- ($n=46$) and macroalbuminuria ($n=63$) were followed for median 5 years (1–9 years) with yearly measurements of renal function (GFR), night urine collections and 24 hours ambulatory blood pressure (ABP) measurements. The aim for antihypertensive treatment was 140/80 mmHg.

Results: 51% ($n=55$) developed one or more of the following cardiovascular complications: 16% ($n=17$) died, 6% ($n=7$) had stroke, 11% ($n=12$) myocardial infarction, 13% ($n=14$) heart failure, 34% ($n=37$) uraemia ($GFR \leq 30$ ml/min/1.73m²), 16% ($n=17$) needed dialysis, and 20% ($n=22$) angina pectoris. Dependent on the type of measurements different number of patients achieved the aim of BP below 140/80: Office blood pressure (BP) ($n=11/28$) was compared with daytime (26/44) and night-time (49/85) and 24 hour ABP (36/57) measurements, in parenthesis (number of patients who achieved aim for systolic/diastolic BP). Achieving the goal for treatment of night BP levels resulted in reduction of the frequency of stroke (0% vs. 12%, $p=0.013$) and uraemia (20% vs. 44%, $p=0.009$). Mean of 24 h ABP below 140/80 mmHg resulted in reduction of dialysis treatment (6% vs. 21%, $p=0.042$). In contrast, the development of angina pectoris (24 h diastolic ABP, 28% vs. 12%, $p=0.032$; night diastolic ABP, 25% vs. 4%, $p=0.032$) and heart failure increased (office BP, 36% vs. 10%, $p=0.014$; 24 h diastolic ABP, 21% vs. 4%, $p=0.007$) when the aim of 140/80 mmHg was achieved.

Conclusion: Achieving the goal of 140/80 mmHg for 24h ABP significant reductions in renal complications beyond the effect of treating office BP. The increase in cardiac complications was probably not the results of good antihypertensive treatment but of poor function of the ischemic heart.

Insulin inhibits secretion of N-terminal-proANP₅₃₋₉₀: novel mechanism in obesity associated hypertension

N.N. Rudovich^{1,2}, O. Pivovarov^{1,2}, W. Doehner³, S.D. Anker³, A. Ernst⁴, N.G. Morgenthaler⁵, A. Bergmann⁵, A.F.H. Pfeiffer^{1,2}

¹Clinical Nutrition, DIFE Potsdam-Rehbrücke, Nuthetal, ²Endocrinology, Diabetes and Clinical Nutrition, Campus B. Franklin, Berlin, ³Cardiology, Campus Virchow-Klinikum, Berlin, ⁴SphingoTec GmbH, Borgsdorf, ⁵B.R.A.H.M.S AG, Berlin, Germany

Background and aims: Central obesity is highly associated with hypertension. Previous studies have shown that obesity and obesity associated hypertension is favoured by low levels of atrial natriuretic peptide. We aimed to assess the ANP levels and their relationship with insulin and other factors of the metabolic syndrome in normotensive obese and non obese subjects and in patients with hypertension.

Materials and methods: One hundred and twenty-one non diabetic, non hypertensive subjects (63 non obese and 58 with central obesity) and 58 patients with essential hypertension (ET) were examined with an oral glucose tolerance test (75g glucose, 180 min); a subgroup of these patients (17 non hypertensive and 14 subjects with ET, all subjects without type 2 diabetes) underwent 2-h euglycemic hyperinsulinemic glucose clamps (100 mU of human insulin \times m² body surface /min). Clinical, biochemical parameters, and levels of N-terminal (NT)-proANP₅₃₋₉₀ were assessed.

Results: Normotensive subjects with central obesity had lower NT-proANP₅₃₋₉₀ levels compared with non obese subjects and patients with hypertension ($p < 0.05$; $p < 0.01$, respectively). In non hypertensive subjects, fasting NT-proANP₅₃₋₉₀ levels were significantly inversely correlated with BMI, diastolic blood pressure, fasting insulin and HOMA-IR and positively with age and HDL-cholesterol. In all study groups, NT-proANP₅₃₋₉₀ levels decreased rapidly at 30 min after oral glucose loading and remained suppressed during the tests ($p < 0.0001$; for basal levels vs. levels at 30, 60, 90, 120 and 180 min of the oGTT). Post-loading concentrations of NT-proANP₅₃₋₉₀ were significantly lower in obese subjects. Fasting and post-loading NT-proANP₅₃₋₉₀ levels correlated inversely with insulin levels during oGTT. In the euglycemic hyperinsulinemic clamps, NT-proANP₅₃₋₉₀ levels decreased at 120 min of the test under continuous insulin infusion in hypertensive and non hypertensive subjects (mean \pm sem; 61.0 ± 8.4 vs. 54.2 ± 8.8 , $p = 0.026$; 59.5 ± 4.5 vs. 49.3 ± 3.6 , $p = 0.001$; respectively).

Conclusion: The present study demonstrates that endogenous and exogenous insulin unexpectedly suppressed secretion of NT-proANP₅₃₋₉₀ in humans. Subjects with central obesity had significantly reduced basal and postprandial NT-proANP₅₃₋₉₀ levels which were significantly inversely related to the BMI, diastolic blood pressure, fasting insulin and HOMA-IR. Our findings provide a novel and causal link between hyperinsulinemia and nutrition with elevated blood pressure in central obesity and the Metabolic Syndrome.

1227

Obesity and blood pressure: explaining the relationship

A. Casolaro, A. Natali, E. Muscelli, E. Ferrannini

Department of Internal Medicine, University of Pisa, Italy

Background and aims: Obesity and hypertension are strongly associated in the population both cross-sectionally and longitudinally. The mechanisms that link blood pressure to fat depots, however, are still not entirely clear, particularly within the physiologic domain of fat mass and blood pressure levels (BP). The aims of this study were: a) to evaluate which index of obesity is more strongly associated with blood pressure and whether there are gender differences; b) to verify whether aging, sedentary life style, insulin resistance/hyperinsulinaemia or plasma adiponectin concentrations play any role in mediating the effect of obesity on BP; c) to verify whether this effect of obesity is amplified by the genetic predisposition to develop hypertension.

Materials and methods: In 19 European recruiting centres, waist, hip and thigh circumference, body fat (by electrical bioimpedance), insulin sensitivity (euglycaemic clamp) and BP (multiple automatic measurements) were measured by standardised procedures in 1,476 (808 women) non-diabetic, non-hypertensive subjects aged 30-60 yrs and covering a wide BMI range (18-44 kg \cdot m⁻²). Insulin exposure (as the plasma insulin area under the OGTT

curve), plasma total adiponectin, and the ACE *D/I* genotype were measured in centralised laboratories. Information on family history of hypertension and alcohol consumption was collected through validated questionnaires. Physical activity was estimated by a portable accelerometer (Actigraph) carried for 4–7 days.

Results: a) Of the anthropometric indices, waist, percent body fat and BMI, in that order, were the strongest correlated of BP, with *r* values ranging from 0.37–0.33 in women and from 0.28–0.23 in men. Systolic, diastolic and mean BP all showed a similar pattern of associations. b) Age, physical activity, alcohol consumption, insulin resistance (as the *M/I* value), insulin exposure and adiponectin levels did not account for these associations as their strength was reduced by less than 20% when they were all introduced as confounders. c) Unexpectedly, the sensitivity of BP to the effect of obesity was lower in subjects with family history of hypertension (*n*=, age-adjusted *r*= 0.33 vs 0.54 and 0.26 vs 0.37, in women and men, respectively) and was significantly (*p*) attenuated by the presence of the ACE *D* allele (age-adjusted *r*'s in *II*, *ID* and *DD* = 0.54, 0.47, 0.33 and 0.40, 0.30, 0.26, in women and men, respectively).

Conclusion: In non-hypertensive subjects, waist circumference and percent body fat, are strong determinants of blood pressure, particularly in women. This association is not explained by age, lifestyle or metabolic traits and is weaker in the individuals predisposed to develop hypertension or carrying the ACE *D* allele.

1228

Alterations of vasorelaxation after oral glucose intake in obese patients with hypertension

Y. Jaber, Z. Nehar, M. Nguyen, M. Brahimi, S. Chiheb, E. Cosson, P. Valensi
Department of Endocrinology, Diabetology, Nutrition, Paris Nord University - CRNH IdF, Paris, France

Background and aims: Artery stiffness is increased in diabetic, hypertensive and obese patients. The vasorelaxing effect induced by plasma insulin increase after a carbohydrate-rich meal has been shown to be reduced in insulin resistant subjects. The aim of this study was to examine the influence of hypertension on the changes in artery stiffness after an oral glucose load (OGTT) in nondiabetic obese patients.

Materials and methods: We included 35 obese patients, aged 41.9 ± 13.0 yrs, free of known dysglycaemia and with no diabetes according to OGTT, 19 of them with mild or moderate hypertension. Peripheral (radial artery) and central (aorta) blood pressure (BP) and artery stiffness (amplification index, AIx) were measured repeatedly at 30-min intervals during 180 min after glucose intake by aplanation tonometry (SphygmoCor®).

Results: During OGTT, there was a trend to higher blood glucose and plasma insulin responses in hypertensive patients. Peripheral and central BP decreased significantly only in hypertensive patients while remaining higher than in normotensive patients. Peripheral and central AIx decreased significantly after glucose in both hypertensive and normotensive patients. However the decrease in central AIx was significantly delayed in hypertensives as compared to normotensives. The decrease in peripheral and central AIx at 30 minutes was significantly lower in the hypertensive patients with central pulse pressure ≥ 40 mmHg (*n* = 9) than in those with pulse pressure < 40 mmHg (*n* = 7 patients) (*p* < 0.05 for both).

Conclusion: In obese patients, 1- oral glucose intake induces a vasorelaxation both at peripheral and central levels, but this effect occurs later in hypertensives, in particular in those with a more severe artery stiffness, than in normotensives; 2- vasorelaxation is likely to result from insulin response; 3- the abnormal vascular response occurs despite BP decrease and is likely to result from a more severe vascular insulin resistance.

1229

The metabolic correlates of nondiabetic hyperglycaemia in subjects with essential hypertension

G. Penno¹, G. Dell'Omo², L. Pucci¹, D. Lucchesi¹, E. Russo¹, G. Daniele¹, R. Miccoli¹, S. Del Prato¹, R. Pedrinelli²

¹Endocrinology and Metabolism, ²Cardio-Thorax Disease, University of Pisa, Italy

Background and aims: Non-diabetic hyperglycemia (impaired fasting glucose, IFG), a slightly increased fasting plasma glucose (FPG) below the diabetic threshold, constitutes a relatively new nosologic category aimed at the

early identification of people at risk for diabetes. IFG is a clinically and pathophysiologically relevant parameter in non-diabetic hypertensive patients but the knowledge about its metabolic and clinical correlates is limited. IFG also concurs to diagnose Metabolic Syndrome (MetS), a frequent and prognostically negative phenotype in essential hypertension, but the impact of its not univocal definition (either 110–125 or 100–125 mg/dL by the NCEP-ATPIII and AHA-NHLBI definitions, respectively) on the identification of patients with MetS is unclear.

Materials and methods: A group of 983 non-diabetic, referred essential hypertensive patients without history of cardiovascular disease have been recruited. They were stratified by normal fasting plasma glucose (FPG, <100 mg/dL; *n* = 652), milder (100–109 mg/dL; *n* = 196) and more advanced (110–125 mg/dL; *n* = 135) non-diabetic hyperglycemia. MetS was screened by using either 110 or 100 mg/dL as a FPG cutoff for IFG. Furthermore, the 10-year predicted coronary heart disease (CHD) risk was calculated by Framingham Risk Score, a conventional risk factor stratification system.

Results: Fasting plasma glucose ≥ 100 mg/dL was associated with older age, male gender, atherogenic dyslipidemia, obesity, higher white blood cell (WBC) count and worse CHD risk profile without differences between the 100–109 and 110–125 mg/dL categories except for older age and higher WBC count in the latter. IFG increased markedly (from 13% to 33%) by the 110 and 100 mg/dL thresholds (*p* < 0.001). Abdominal obesity, triglycerides at or above 150 mg/dL, and HDL below the gender-adjusted cut-offs were present in 38%, 33% and 29% of the overall sample. MetS prevalence augmented only marginally (from 34% to 42%) and mainly by inclusion of less metabolically compromised patients. Indeed, the 8% increase in MetS was due to the inclusion of 76 additional subjects with lower triglycerides, BMI, WBC count, higher HDL-C, less frequent atherogenic dyslipidemia and obesity.

Conclusion: The metabolic abnormalities and negative CHD risk profile are largely prevalent and homogeneously distributed in referred hypertensive patients with either mild or more advanced nondiabetic hyperglycemia. Use of a lower FPG threshold increased markedly the prevalence of IFG but had a largely less than proportional impact on MetS and mainly because of the inclusion of patients with slightly metabolically compromised profile. Thus, lowering the FPG threshold seems to have a relatively limited impact on Metabolic Syndrome diagnosis.

1230

Independent impact of blood pressure on definition of metabolic syndrome in African American women

T. Gaillard, K. Osei;

Division of Endocrinology, Diabetes and Metabolism, The Ohio State University, Columbus, United States

Background: African American women (AAW) suffer disproportionately from hypertension and its consequences. Metabolic Syndrome (MetS), defined by The Adult Treatment Panel (ATP) III criteria include systolic (SBP) (≥ 130 mmHg) and diastolic (DBP) (≥ 85 mmHg) blood pressure. However, whether BP is associated with the other 4 components of ATP III parameters as well as other cardiovascular disease (CVD) risk factors in AAW is unknown. Therefore, we investigated CVD risk clusters, prevalence of various components of MetS as well as MetS associated with both SBP and DBP in non-diabetic adult, overweight and obese AAW.

Methods: We studied the clinical and metabolic CVD risk factors of 258 AAW (mean age 42.0 ± 7.7 yrs and mean BMI of 33.3 ± 8 (kg/m²). Fasting serum insulin, glucose and c-peptide levels were obtained in each subject. Waist circumference (WC), SBP and DBP were measured. Insulin sensitivity (Si), (Bergman's minimal model method) and insulin resistance (IR) (homeostasis model assessment (HOMA) were calculated. We measured 1) metabolic CVD risk factors associated with each tertile of the BP (i.e. serum glucose, insulin resistance, LDL-C, HDL-C, triglyceride and 2) examined the prevalence of various components of MetS and prevalence of MetS as defined by ATP III according to the tertiles of BP.

Results: Mean age and BMI did not differ with the worsening of SBP and DBP tertiles. MetS was found in 35.5% of our AAW. Percent of MetS did not differ per SBP and DBP tertiles. Worsening of SBP and DBP was associated with worsening of WC, but had only minimal effects on serum glucose, HOMA-IR, SI and serum triglyceride (albeit within normal limits). Comparing SBP and DBP tertiles, we found similar percent of the components and prevalence of MetS. The prevalence of MetS was not significantly associated with the tertiles BP.

Conclusion: Both SBP and DBP are associated with MetS independent of glucose, IR and lipids and lipoproteins. The 3rd tertile of BP was not associated

with greater prevalence of various components of MetS nor the prevalence of MetS. Our study suggests that both SBP and DBP are equally associated with MetS in AAW. We conclude that obese/overweight AAW with family history of type 2 diabetes, BP appears to have an independent impact on the definition of MetS as defined by ATP III. Thus, nondiabetic, obese/overweight AAW meeting ATP III criteria for systolic or diastolic BP should be targeted for screening for MetS.

Morning blood pressure surge in diabetic patients - relationship with metabolic syndrome

I. Pietrzak, A. Szadkowska, B. Mianowska, E. Czerniawska, J. Bodalski, W. Młynarski

Department of Pediatrics, Medical University, Lodz, Poland

Background and aims: The elevated morning blood pressure surge is regarded as one of risk factors of diabetic micro- and macroangiopathy. The pathogenetic background of this relationship is still unknown.

To estimate the relationship between morning blood pressure surge and components of the metabolic syndrome in children and adolescents with type 1 diabetes mellitus.

Materials and methods: 146 patients (F-54, M-92) aged 9.8-19.5 years, with duration of diabetes 0.1-15.6 years, without evidence of arterial hypertension were recruited. In all patients 24-hour automatic blood pressure monitoring was performed with an oscillometric device. We defined morning blood pressure surge (MBPS) as the average of systolic/diastolic BP during the first 2 hours upon waking minus the average of systolic/diastolic BP during the first hour that included the lowest sleep BP (MBPS-SBP/MBPS-DBP). The height, weight, waist circumference, adipose tissue mass were measured. HbA1c and plasma lipids concentrations were examined. Euglycemic-hyperinsulinemic clamp was performed to establish insulin resistance. Glucose disposal rate was calculated as M-index in mg/kg/min. Body mass index and daily dose of insulin were calculated.

Results: We diagnosed 16 hypertensive and 32 prehypertensive patients according to ABPM results. In hypertensive and prehypertensive patients the MBPS-SBP was higher than in normotensive individuals (respectively MBPS-SBP - 27.3 ± 2.1 vs 23.2 ± 1.4 vs 18.4 ± 1 , $p < 0.001$, MBPS-DBP - 21.1 ± 2.4 vs 18.6 ± 1.6 vs 15.0 ± 1.2 , $p = 0.054$). We found the positive correlation between MBPS-SBP and adipose tissue mass ($r = 0.42$, $p = 0.01$). There were no significant relationships between MBPS and BMI-SDS, waist circumference, daily dose of insulin, HbA1c, lipids and M-index.

Conclusion: 1) Diabetic children and adolescents with elevated blood pressure have higher morning blood pressure surge than normotensive patients. 2) There is the positive correlation between systolic MBPS and adipose tissue mass.

1232

Relation of pulse pressure and ambulatory arterial stiffness index with clinical characteristics and cardiovascular risk factors in type 2 diabetic patients

A. Januszewicz¹, S. Ito², J.L. Izzo Jr.³, S. Katayama⁴, A. Mimran⁵, A.J. Rabelink⁶, E. Ritz⁷, L.M. Ruilope⁸, L.C. Rump⁹, G. Viberti¹⁰, H. Haller¹¹

¹Department of Hypertension, Institute of Cardiology, Warsaw, Poland,

²Department of Clinical Medicine, Division of Nephrology, Endocrinology, and Vascular Medicine, Tohoku University Graduate School of Medicine, Sendai, Japan, ³Department of Medicine, Erie County Medical Center, Buffalo, United States, ⁴The Fourth Department of Medicine, Saitama Medical School, Iruma, Japan, ⁵Department of Internal Medicine, Hospital Lapeyronie, Montpellier, France, ⁶Department of Nephrology and Hypertension, Leiden University Medical Center, Netherlands, ⁷Department of Nephrology, University of Heidelberg, Germany, ⁸Division of Hypertension, Hospital 12 de Octubre, Madrid, Spain, ⁹Medical Clinic, Marienhospital Herne, University Clinic Ruhr-University-Bochum, Herne, Germany, ¹⁰Unit for Metabolic Medicine, KCL Guy's Hospital, London, United Kingdom, ¹¹Nephrology Section, Hannover Medical School, Germany

Background and aims: Whether ambulatory arterial stiffness index (AASI) outperforms pulse pressure (PP) in cardiovascular risk prediction in Type 2 diabetic patients (T2DM) is controversial.

Materials and methods: We evaluated relationship between office PP and cardiovascular risk factor in 4449 (46%M) T2DM patients with normoalbuminuria and one or more additional cardiovascular risk factors enrolled in the ROADMAP study at baseline. We also evaluated relationship between ABPM - mean 24hr systolic BP (SBP), diastolic BP (DBP), PP and AASI - in a subgroup of 1137 patients at baseline.

Results: In the whole group mean (SD) age was 57.7 (8.7) yrs, duration of diabetes 6.1 (6.0) yrs. Office PP level correlated significantly (with $p < 0.001$, if not stated otherwise) with age ($r = 0.389$), known duration of DM ($r = 0.173$), 10yr risk of CHD ($r = 0.377$), metabolic syndrome (MS) ($r = 0.158$), history of cardiovascular disease (CVD) ($r = 0.209$), GFR ($r = -0.094$), fasting plasma glucose (FPG) level ($r = 0.063$), albumin to creatinine ratio (ACR) ($r = 0.080$), and HDL cholesterol level ($r = 0.038$; $p < 0.05$). When adjusted for age and systolic BP only correlations with known duration of DM ($r = 0.092$), 10yr risk of CHD ($r = 0.058$) and MS ($r = -0.084$) were significant (with $p < 0.001$). In the subgroup of 1137 patients with ABPM performed, after adjusting for 24h SBP there were significant correlation between PP and AASI and: age ($r = 0.349$; $p < 0.0001$ and $r = 0.074$; $p < 0.05$), female gender (only for PP: $r = 0.129$; $p < 0.0001$), 10yr risk of CHD ($r = 0.218$; $p < 0.0001$ and $r = 0.081$; $p < 0.01$), known duration of diabetes ($r = 0.164$; $p < 0.0001$ and $r = 0.061$; $p < 0.05$), BMI (only for AASI: $r = -0.059$; $p < 0.05$), creatinine clearance ($r = -0.232$; $p < 0.0001$ and $r = -0.064$; $p < 0.05$) and GFR (only for PP: $r = -0.164$; $p < 0.0001$). Adjusted for AASI, PP correlated significantly (with $p < 0.0001$, if not stated otherwise) with: age ($r = 0.184$), female gender ($r = 0.070$; $p < 0.05$), BMI ($r = 0.173$), 10yr risk of CHD ($r = 0.217$), history of CVD ($r = 0.181$), known duration of diabetes ($r = 0.126$), MS ($r = 0.179$), FPG level ($r = 0.120$), ACR ($r = 0.146$) and HbA1C level ($r = 0.076$; $p < 0.05$). Adjusted for PP, AASI correlated significantly only with BMI ($r = -0.069$; $p < 0.05$).

Conclusion: In this group of T2DM with normoalbuminuria office PP, adjusted for age and SBP levels, correlated significantly with duration of diabetes and 10yr risk of CHD. The relation between ambulatory 24h PP and cardiovascular risk factors as compared with AASI was more pronounced.

PS 120 Autonomic neuropathy: clinical features

1233

Autonomic neuropathy is related to hypertension in type 1 and even in newly diagnosed type 1 diabetes mellitus

K. Keresztes, I. Istenes, Z. Putz, N. Tóth, N. Németh, P. Vargha, P. Kempler
Semmelweis University Budapest, I. St. Dept. of Medicine, Hungary

Background and aims: Autonomic neuropathy is a serious complication of diabetes mellitus associated with poor prognosis. However, factors leading to increased mortality have not been clarified up to now. The aim of our study was to evaluate a possible connection between autonomic neuropathy and hypertension in type 1 and in newly diagnosed type 1 diabetic patients.

Materials and methods: We examined 32 patients with Type 1 diabetes (mean age: 37.8 ± 12.7 years), 40 patients with newly diagnosed Type 1 diabetes (mean age: 34.7 ± 11.3 years) and 25 healthy control subjects (mean age: 38.3 ± 12.8 years). The five standard cardiovascular reflex tests of cardiovascular autonomic function were applied; the severity of autonomic neuropathy was characterized by the autonomic score. Ambulatory 24-hour blood pressure monitoring (ABPM) was performed by MEDITECH ABPM 04 device.

Results: Autonomic dysfunction was found in 29/32 Type 1, and in 12/40 newly diagnosed Type 1 diabetic patients. There was a significant correlation between the severity of autonomic neuropathy and the blood pressure load (systolic: $p < 0.001$; diastolic: $p < 0.01$), the hyperbaric impact values (systolic: $p < 0.01$; diastolic: $p < 0.05$) and microalbuminuria ($p < 0.001$) in Type 1 diabetic patients. Autonomic neuropathy as well as microalbuminuria, were independently associated with hypertension among Type 1 diabetic patients. Decrease of systolic blood pressure after standing correlated positively with systolic ($p < 0.01$) and diastolic ($p < 0.05$) diurnal blood pressure indices. Analysing the relationship between ABPM parameters and the five cardiovascular reflex tests separately, the blood pressure load and the hyperbaric impact values correlated negatively with the 30/15 ratio and Valsalva ratio - both tests reflect mainly parasympathetic function. The autonomic score was higher in newly diagnosed diabetic patients than in controls ($p = 0.005$). Among patients with newly diagnosed Type 1 diabetes autonomic dysfunction was independently associated with smoking ($p < 0.01$), serum cholesterol and hypertension (both: $p < 0.05$). In the newly diagnosed diabetic group also a predominantly parasympathetic test - the heart rate variation after standing - was inversely related to the diastolic blood pressure values ($p < 0.05$). These associations remained significant even after adjustment for other cardiovascular risk factors.

Conclusion: Autonomic dysfunction is quite frequent complication and seems to be related to hypertension in both Type 1 and newly diagnosed Type 1 diabetes mellitus. Our data suggest that a relative sympathetic overactivity due to predominantly parasympathetic neuropathy might be responsible for the higher blood pressure values observed. ABPM is suggested being performed for the early assessment of hypertension in both type 1 and newly diagnosed type 1 diabetic patients with autonomic neuropathy, while non-dippers should be screened for postural hypotension. Our data suggest that traditional cardiovascular risk factors should be considered as potential risk factors for the development of nerve dysfunction even in newly diagnosed Type 1 diabetic patients. Hypertension itself as well as orthostatic hypotension and diminished diurnal indices may contribute to poor prognosis of autonomic neuropathy.

1234

Cardiac autonomic neuropathy in type 1 diabetes - association with metabolic syndrome and diabetic nephropathy

L. Duarte, J. Costa, P. Matos, A. Pereira, I. Almeida, A. Gralho, R. Duarte, J.F. Raposo, J.M. Boavida
Portuguese Diabetes Association, Lisbon, Portugal

Background and aims: Cardiac autonomic neuropathy has been associated with increased morbidity and mortality in patients with diabetes. The prevalence and importance of metabolic syndrome in type 1 diabetes has been gaining growing evidence in the last years. The aim of this study was to estimate the prevalence of cardiac autonomic neuropathy in a cohort of patients with type 1 diabetes and evaluate whether it is associated with metabolic syndrome, with individual cardiovascular risk factors and with diabetic nephropathy.

Materials and methods: A cohort of 209 type 1 diabetic patients with more than 10 years of duration of diabetes, randomly selected from our clinical files, was studied. Cardiac autonomic neuropathy was assessed by three tests of heart rate variation (maximum-minimum heart rate during deep breathing, Valsalva and lying-standing change) and one of blood pressure variation (lying-standing change). Metabolic syndrome was defined according to the International Diabetes Federation criteria and diabetic nephropathy was assessed by determination of albumin excretion rate. Statistical analysis was performed using SPSS - version 11.0. Descriptive statistics are presented and comparison between groups was performed using Student's *t* test, Mann-Whitney test and χ^2 test.

Results: The cohort was constituted by 209 type 1 diabetic patients (58.9% men), mean age 37 ± 11 years and duration of diabetes 23.8 ± 7.6 years. There was no significant difference according to gender in any of the analysed parameters. The overall prevalence of cardiac autonomic neuropathy was 42.1% and of metabolic syndrome was 32.1%. Analyzing the subgroups of patients with and without cardiac autonomic neuropathy we found statistically significant differences in duration of diabetes (26 ± 7 vs 22 ± 8 years, $p < 0.001$), HbA1c (9.1 ± 1.4 vs 8.6 ± 1.4 , $p = 0.007$), systolic blood pressure (138 ± 19 vs 129 ± 14 mmHg, $p < 0.001$), diastolic blood pressure (82 ± 13 vs 79 ± 10 mmHg, $p = 0.024$), triglycerides [95.3 (24.8 - 608.1) vs 74.5 (28 - 290) mg/dl, $p = 0.001$], serum creatinine [1.08 (0.74 - 3.9) vs 0.97 (0.6 - 2.9) mg/dl, $p = 0.001$], and creatinine clearance (70.7 ± 21.7 vs 83.8 ± 16.7 ml/min/ 1.73 m², $p < 0.001$). The prevalence of metabolic syndrome in patients with cardiac autonomic neuropathy (43.2%) was significantly higher than in patients without cardiac autonomic neuropathy (24%), $p = 0.004$. Although the difference in microalbuminuria and proteinuria individually was not statistically significant, the prevalence of diabetic nephropathy (microalbuminuria and/or proteinuria) in patients with cardiac autonomic neuropathy (50%) was significantly higher than in patients without cardiac autonomic neuropathy (15.1%), $p < 0.001$.

Conclusion: Our study suggests that cardiac autonomic neuropathy is associated with cardiovascular risk, with increased prevalence of metabolic syndrome and with increased prevalence of diabetic nephropathy. These findings may have implications in more aggressive medical intervention to improve prognosis and survival in this population.

Cardiac autonomic neuropathy, arterial hypertension and microcirculation in type 2 diabetic patients

D. Roula¹, A. Belhadj-Mostefa¹, M.K. Bourahli², A. Bouguerba¹, F. Touati¹, J.R. Attali³, P. Valensi³

¹Medicine, Department of Internal Medicine, Constantine, Algeria,

²Department of Physiology, Constantine, Algeria, ³Department of Endocrinology Diabetology Nutrition Jean Verdier Hospital, Bondy, France

Background and aims: Several data suggest the role of hypertension and cardiac autonomic neuropathy (CAN) in diabetic microangiopathic complications. The aim of this study was to evaluate the influence of hypertension and CAN on peripheral microcirculation, endothelial dysfunction and artery stiffness in patients with type 2 diabetes (T2D).

Materials and methods: 98 patients (48 men), mean age 54.7 ± 8.4 years, with T2D known since 7.8 ± 6.5 years and poor glycemic control (HbA1c 8.1 ± 1.9 %), with hypertension for 60 of them, were included. CAN was assessed by 3 heart rate variability tests. A post-ischemia reactive hyperaemic test was performed, and changes in blood flow (F2/F1) and diameter (D2/D1) of the brachial artery which account mostly for the reactivity of downstream microvasculature and for endothelium function, respectively, were evaluated by pulsed Doppler velocimetry. Artery stiffness was assessed by measuring pulse wave velocity (PWV) between the carotid and femoral arteries using the Complior device.

Results: F2/F1 was not correlated with HbA1c and did not differ significantly in patients with or without hypertension, microangiopathic complications or both. F2/F1 was significantly lower in CAN+ patients ($n: 73$, 4.4 ± 1.6 vs 5.7 ± 1.7 in CAN-; $p < 0.005$). In hypertensive patients and in those with microangiopathic complications, F2/F1 was lower in those with CAN (respectively, 4.5 ± 1.9 vs 6.1 ± 1.7 ; $p < 0.002$ and 4.3 ± 1.6 vs 5.7 ± 1.5 ; $p < 0.005$) while there was no influence of CAN in normotensive patients and in patients without microangiopathic complications. D2/D1 did not differ significantly in patients with or without CAN, hypertension or microangiopathic complications. In CAN+ patients, PWV was higher in hypertensive than in normotensive patients (12.6 ± 3.0 m/s vs 10.6 ± 2.2 m/s; $p < 0.005$) while hypertension had no significant influence on PWV in CAN- patients (12.2 ± 1.7 m/s and 11.3 ± 2.1 m/s, respectively).

Conclusion: Our results suggest, in T2D, the role of nerve control impairment in microcirculation dysfunction, particularly in patients with hypertension or microangiopathic complications, and the role of hypertension on artery stiffness only when CAN is present.

The spatial QRS-T angle is increased in patients with type 2 diabetes mellitus and cardiac autonomic neuropathy

C. Voulgari¹, N. Tentolouris¹, I. Moysakakis², D. Perrea³, D. Kyriaki¹, N. Katsilambros¹

¹1st Department of Propaedeutic Medicine, Athens University Medical School, Laiko General Hospital, ²Department of Cardiology, Laiko General Hospital, ³Department of Experimental Surgery and Surgical Research, Athens University Medical School, Greece

Background and aims: Cardiac autonomic neuropathy (CAN) is a common complication of diabetes and it has been associated with dispersion of ventricular repolarization and arrhythmia provocation. QT prolongation has long been used as an indicator of ventricular repolarization heterogeneity in patients with diabetes but it has been criticized as being a poor indicator of ventricular arrhythmogenicity. The spatial QRS-T angle (sQRS-Ta) is a novel vectorcardiographic marker akin to the concept of the ventricular gradient and a robust index of ventricular repolarization heterogeneity. Recent data suggest that it is a dominant predictor of cardiovascular morbidity and mortality in the general population. We have previously shown that the sQRS-Ta is increased in uncomplicated subjects with type 2 diabetes (T2DM). However, no data exists on the effect of CAN on the sQRS-Ta. In this cross-sectional study we examined differences in the sQRS-Ta between diabetic patients with and without CAN. Additionally, potential relationships between the sQRS-Ta and demographic, clinical and metabolic variables were studied.

Materials and methods: A total of 138 patients (mean age 57.3 ± 9.3 years) with T2DM and free of macrovascular complications and 138 healthy control subjects, strictly matched with the diabetic subjects in terms of gender and age were studied. Diagnosis of CAN was based on the battery of the classical autonomic function tests. All subjects underwent a digital 15 min ECG and 30 min heart rate recordings. ECG parameters were measured and analyzed using the MEANS program. Indices of the spectral analysis of the heart rate variability (HRV) were obtained using the *VariaCardio* system. Ankle-brachial-pressure index (ABI), LV mass index (LVMI) and myocardial performance index (Tei index) were assessed by ultrasonography.

Results: Among participants with T2DM there were 66 subjects with CAN, and 72 without CAN. The sQRS-Ta values were higher in the diabetic in comparison with the control subjects ($24.5 \pm 10.7^\circ$ versus $9.7 \pm 4.5^\circ$, respectively, $P < 0.001$). Additionally, the sQRS-Ta values were higher in the patients with CAN than in those without CAN ($30.1 \pm 11.3^\circ$ versus $19.5 \pm 7.1^\circ$, respectively, $P < 0.001$). On the contrary, no significant differences were found in the values of the QT interval between diabetic and control subjects or between those with and without CAN. Multivariate linear regression analysis in the patients with T2DM, after adjustment for age, sex, BMI, waist circumference, fasting glucose and lipids, ABI, LVMI, glomerular filtration rate and presence of microalbuminuria, demonstrated independent associations between the sQRS-Ta and the presence as well as the severity of CAN ($P < 0.001$), HbA1c ($P < 0.001$), duration of diabetes ($P = 0.011$), ($P = 0.027$), Tei index ($P = 0.02$) and all indices of HRV ($P < 0.001$).

Conclusion: The sQRS-Ta is increased in patients with T2DM with CAN, suggesting ventricular repolarization heterogeneity. Additionally, it is strongly associated with duration and degree of hyperglycaemia as well as myocardial performance. Increased sQRS-Ta values warrants consideration for risk stratification and prevention strategies in patients with T2DM.

Can spectral analysis of heart rate variability detect subclinical autonomic dysfunction as reliably as spontaneous baroreceptor sensitivity?

E.J. Robinson, J.L.B. Marques, S.R. Heller

Academic Unit of Diabetes, Endocrinology & Metabolism, University of Sheffield, United Kingdom

Background and aims: Cardiovascular autonomic neuropathy is one of the most serious complications of diabetes. However it is often detected late,

when treatment options are limited. Of the tools that have been used to detect early autonomic neuropathy, spontaneous baroreceptor sensitivity (BRS) has emerged as the gold standard. However, this is expensive to perform and relatively operator dependent. Spectral analysis of heart rate variability (HRV) is cheaper, easier to perform and therefore is more suitable as a screening test. We aimed to identify whether HRV was able to identify subclinical autonomic neuropathy with the same accuracy as BRS.

Materials and methods: Fifty young patients with Type 1 diabetes (age 18–40 years) underwent BRS analysed in the sequence method and spectral analysis of heart rate variability (Total Power-TP, Low frequency power-LF and high frequency power-HF). Patients were divided into two groups, normal (BRS+) and abnormal (BRS-) baroreceptor sensitivity. 14 age matched controls underwent HRV.

Results: Total BRS (mean \pm SD) was 19 ± 8 and 8 ± 3 in the BRS+ and BRS- groups respectively. All logarithmically transformed HRV measures were significantly lower ($p < 0.0001$) in the BRS- group when compared to both BRS+ group and healthy volunteers. TP- 5.4 ± 0.72 , 6.7 ± 0.97 and 7 ± 1.12 , LF- 4.2 ± 0.83 , 5.6 ± 1.02 , 5.8 ± 1.32 and HF 3.7 ± 1.08 , 5.4 ± 1.23 , 5.7 ± 1.5 for each group respectively. There was no significant difference between BRS+ group and healthy volunteers in any of the spectral parameters analysed. Pearson's correlation coefficient was > 0.74 for Total BRS and each of the spectral parameters ($p < 0.001$).

Conclusion: Spontaneous baroreceptor sensitivity testing and spectral analysis of heart rate variability are equally able to differentiate degrees of autonomic dysfunction in young people with Type 1 diabetes. HRV is a robust tool which should now be used in a prospective study to determine the natural history of subclinical autonomic neuropathy.

Reproducibility of power spectral analysis of heart rate variability in acute and chronic phase of Charcot's neuroarthropathy

R. Bem, A. Jirkovská, M. Dubský, V. Fejfarova, J. Lupinkova, J. Skibova
Diabetes Centre, Institute for Clinical and Experimental Medicine, Prague, Czech Republic

Background and aims: Autonomic neuropathy increases blood flow of the foot and may play a crucial role in the pathogenesis of Charcot's neuroarthropathy (CNO), but its diagnosis is applied very rarely in daily practice. According to our previous studies, the power spectral analysis of heart rate variability (PSA of HRV) may be preferable to the traditional Ewing's test for detecting autonomic neuropathy because of its minimal requirements for patient collaboration and time expenditure. The aim of our study was to evaluate the differences of autonomic neuropathy assessed by PSA of HRV in acute and chronic phase of CNO and their potential association with parameters of CNO activity and bone turnover.

Materials and methods: Thirty-four patients with acute CNO treated consecutively in our foot clinic during a 16-month period were enrolled in this study. Inclusion criteria consisted of the clinical diagnosis of acute CNO and the ability to tolerate at least two Ewing's tests. The clinical diagnosis of CNO was reinforced by positive bone scans. Bone turnover was monitored by ICTP (COOH-terminal telopeptide region of type 1 collagen) and by scintigraphic parameters. Autonomic neuropathy was indicated by abnormal results on at least three of the four Ewing's tests. The PSA compower LFHF 1+2+3 is the cumulative parameter of low-frequency (LF) and high-frequency (HF) bands in all three supine-standing-supine positions, for diagnosis of severe autonomic neuropathy, we selected the fifth percentile of the results obtained from the 123 healthy controls with normal Ewing's tests. PSA of HRV and Ewing's test were assessed in the acute phase immediately after diagnosis of CNO and in chronic phase which was defined by clinical signs and as decrease of temperature differences, laboratorial and scintigraphic parameters one year from the inclusion.

Results: No significant correlations between PSA compower LFHF 1+2+3 and markers of CNO activity and bone remodeling (ICTP and scintigraphic parameters) were seen. Severe autonomic neuropathy was seen in 31/34 (91.2%) of the patients by Ewing's tests and in 34/34 (100%) of the patients by PSA of HRV. There was no significant difference in the assessment of autonomic neuropathy by PSA of HRV in acute and chronic phase of CNO in the same patient (mean compower LFHF 1+2+3: 156.8 ± 151.1 vs. 175.5 ± 178.7 ; NS); a strong correlation of this parameter in acute and chronic phase of CNO was seen ($r = 0.828$, $p < 0.0001$). In addition, there were no significant differences in Ewing's tests between acute and chronic phase of CNO.

Conclusion: This study suggests that PSA of HRV may be used for diagnosis of autonomic neuropathy both in acute and chronic phase of CNO; the parameters of PSA of HRV were not influenced by the activity of CNO.

Cardiac autonomic dysfunction and score of risk of diabetes

I. Banu, M. Nguyen, I. Pinal, S. Chiheb, E. Cosson, P. Valensi
Department of Endocrinology, Diabetology, Nutrition, Paris Nord University, France

Background and aims: The Finnish risk score (Findrisk) has been developed to evaluate the risk of incident diabetes. An association has also been reported between this score and glycemic disorders and metabolic syndrome. Cardiac autonomic dysfunction (CAD) is often found in nondiabetic obese patients. The aim of this study was to look for a relationship between the Findrisk score and CAD in overweight or obese patients.

Materials and methods: We included 267 patients, free of known dysglycaemia and referred consecutively to our department (Jan 1998–Oct 2005) for overweight or obesity (BMI 38 ± 7 kg/m²). Findrisk score was calculated, an oral glucose tolerance test was performed with prediabetes and diabetes defined according to WHO 1999, metabolic syndrome was defined according to IDF criteria, and CAD was assessed on heart rate variability during three standard tests (deep-breathing, lying-to-standing and Valsalva) which were interpreted according to age.

Results: Findrisk score was found to be ≥ 15 in 88 patients. The score correlated significantly with BMI, prediabetes and diabetes, metabolic syndrome, HOMA insulin resistance index, systolic and pulse blood pressure ($p < 0.04$ to < 0.001). In 230 patients the 3 CAD tests were normal or only one of them was abnormal (mild CAD) while 2 or 3 tests were abnormal (confirmed or severe CAD) in the remainder. In the patients with a score ≥ 15 , the rate of confirmed or severe CAD was significantly higher than in those with a score < 15 (22.7% vs 9.5%; $p = 0.003$). This difference was still significant after age adjustment (OR 2.424 [95% CI: 1.08–5.44]; $p = 0.03$). In multivariate analyses the association between the score and confirmed and severe CAD was independent of age, BMI, glycemic disorders and metabolic syndrome.

Conclusion: In overweight or obese patients, 1- a higher Findrisk score is associated significantly with current glycemic and metabolic disorders, and with confirmed or severe CAD; 2- CAD might contribute to insulin resistance and increased blood pressure.

1240

Small fiber neuropathy and impaired autonomic function characterise neuropathy in subjects with impaired glucose tolerance

Z. Putz¹, Á. Tabák¹, N. Tóth¹, I. Isteneš¹, R. Gandhi², Z. Hermányi³, N. Németh¹, K. Keresztes¹, G. Jermendy³, S. Tesfaye², P. Kempler¹;

¹1st Department of Medicine, Semmelweis University, Budapest, Hungary,

²Diabetic Research Unit, Royal Hallamshire Hospital, Sheffield, United

Kingdom, ³3rd Department of Internal Medicine, Bajcsy Zsilinszky Hospital, Budapest, Hungary

Background and aims: Impaired glucose tolerance (IGT) is currently identified in about 40% of subjects with neuropathy of unknown origin. The clinical characteristics of IGT associated neuropathy are not well understood.

Materials and methods: We examined 46 patients with IGT (age: 53.04 ± 11.10 years, fasting blood glucose 5.40 ± 0.57 mmol/l; 120 min blood glucose: 8.61 ± 1.01 mmol/l; HbA_{1c}: 5.97 ± 0.38 %; $x \pm SD$) and 45 healthy controls subjects (age: 55.84 ± 11.41 years). Cardiovascular autonomic neuropathy was assessed by the five standard cardiovascular reflex tests and heart rate variability (HRV) characterized by the triangle index (HRV_{ti}). Sensory nerve function (current perception threshold [CPT]) was assessed by the Neurometer R device, Medoc equipment and the Rydel-Seiffer calibrated tuning fork. Peak plantar pressure was measured by dynamic pedobarograph. The frequency and intensity of symptoms were graded using Neuropathy Total Symptom Score (NTSS).

Results: Significant differences were found between IGT and control subjects regarding the following parameters: beat-to-beat variation: 11.9 ± 5.7 vs. 19.5 ± 4.1 beats/min; $p = 0.0001$; Valsalva ratio: 1.23 ± 0.25 vs. 1.46 ± 0.22 ; $p = 0.0001$; postural systolic blood pressure changes: -4.37 ± 5.7 vs. -0.6 ± 2.0 mmHg; $p = 0.0001$; sustained handgrip: 19.9 ± 7.9 vs. 23.7 ± 6.1 mmHg; $p = 0.012$; and HRV_{ti}: 26.7 ± 7.8 vs. 39.3 ± 9.0 ; $p = 0.0001$. Both hyperaesthesia representing

the early neuropathy (median nerve $p < 0.001$, peroneal nerve $p < 0.01$) just as hypaesthesia (both median and peroneal nerves $p < 0.005$) were detected more frequently at 5 Hz Neurometer CPT testing among IGT subject compared to controls. Heating detection thresholds were increased among IGT subjects compared to controls at both upper and lower limbs while a significant increase was found only at lower limb for cooling detection threshold. There were no significant differences between the two groups at Rydel-Seiffer tuning fork assessment. It is of particular importance that peak plantar pressure measured by the dynamic pedobarograph was significantly higher in the IGT group versus controls ($p < 0.005$). Mild to moderate symptoms of neuropathy (NTSS) were present in 5 subject with IGT while none of them was detected in healthy controls.

Conclusion: Small fiber neuropathy including widespread impairment of autonomic function represents the key clinical characteristics of IGT associated nerve dysfunction. Our data indicate that neural impairment could be non-invasively detected in these subjects and non-invasive methods may serve as an alternative to skin punch biopsy. Cardiovascular autonomic neuropathy may contribute to the increased cardiovascular risk among subjects with IGT.

Diabetes induces hyperactivity in the spinal dorsal horn neurons: a time-course study in streptozotocin-induced diabetic rats

C. Morgado, I. Tavares

Institute of Histology and Embryology, Faculty of Medicine of Porto and IBMC, University of Porto, Portugal

Spontaneous pain is a common sign of neuropathy in diabetic patients. Several studies showed an increase in the background activity of dorsal horn spinal neurons during diabetes, which may explain that abnormal pain condition. The spinal hyperactivity is probably related to the constant barrage of peripheral input, since peripheral fibres of diabetic rats show ectopic activity. It may also reflect plastic changes at the spinal cord and, more interestingly, of brainstem centres devoted to descending pain modulation.

In the present study, we performed a time-course evaluation of spinal dorsal horn neurons activity in streptozotocin diabetic rats, using Fos expression as a marker of neuronal activity. Furthermore we evaluated the contribution of peripheral input to the spinal neuronal activity by blocking the primary afferent input. Diabetes was induced in adult male Wistar rats by i.p. injection of streptozotocin (STZ; 50 mg/kg). One group of rats was sacrificed prior to the injection (time-point 0) and the others at 1, 2, 4, 6 and 10 weeks post-injection (n= 6 rats per time-point). Spinal segments T13-L5 were removed and immunoreacted against Fos protein (Ab5; Oncogene). At 4 weeks post-injection an additional group was submitted to peripheral nerve block by applying a 5% lidocaine patch to the internal surface of the left thigh. The patch was daily replaced during 3 days. At this time the animals were sacrificed, the spinal segments L2-L3 were removed and immunohistochemically processed for Fos as in the others experimental groups. Fos-immunoreactive (Fos-IR) neurons in the superficial (laminae I-II) or deep (laminae III-V) dorsal horn were counted bilaterally in the time-course study and ipsilateral in the lidocaine treated rats. Data were compared by ANOVA, followed by the Tukey *post-hoc* test. The numbers of Fos-IR neurons increased moderately at 1 and 2 weeks after STZ injection. A significant increase of Fos level was observed at 4 weeks, followed by a slight decrease at 6 weeks and an even higher increase at 10 weeks post-injection. Peripheral nerve block did not change spinal dorsal horn Fos expression when compared with baseline level at 4 weeks. These findings show that diabetes induces a gradual increase in spontaneous activity of spinal dorsal horn neurons, which is more pronounced at 4 and 10 weeks after STZ injection, and may underlie the spontaneous pain associated to diabetic neuropathy. Since peripheral nerve block did not affect spinal Fos expression it seems that spinal hyperactivity is not exclusively due to the constant input from the periphery but seems to involve plastic changes at spinal and, probably, supraspinal levels.

Effects of rimonabant on painful diabetic neuropathy in male STZ rats. Comparison with duloxetine and gabapentine

P. Chamiot-Clerc, M.-A. Chabanaud, F. Gillot, L. Noah, M.-P. Pruniaux, A.-M. Galzin

Pharmacology Metabolism, sanofi-aventis, Rueil-Malmaison, France

Background and aims: Recent clinical studies evidenced beneficial effects of Rimonabant (RIMO) in type 2 diabetic patients. Furthermore, RIMO has been shown to display anti-nociceptive effects in both inflammatory and neuropathic pain models (1-2). We aimed at assessing the effects of RIMO on streptozotocin (STZ)-induced painful diabetic neuropathy (PDN) in rats, in comparison with Duloxetine (DULOX) and Gabapentine (GABA) that are the two reference treatments used against PDN in humans.

Materials and methods: Male Sprague Dawley rats (200-225g) were administered i.p. with STZ 65 mg/kg (STZ-rats) or solvent (Sham-rats) on day 0 (D0). Body weights (BW) were recorded daily. From D14, STZ-rats were treated orally with RIMO (10 mg/kg/d, n=10), DULOX (30 mg/kg, n=10), GABA (100 mg/kg, n=10) or vehicle (VHC) (Tween 0.1%, n=10), whereas Sham-rats received VHC only. Mechanical allodynia was assessed at D14 and D28, using the electronic Von Frey system and spontaneous horizontal locomotor activity was monitored from D24 to D27 using an infra-red lighted open field

and videorecording system (Videotrack[®], Viewpoint). At the end of the study, blood was collected for the determination of plasma metabolites.

Results: Before any treatment (D14), a significant increase in blood glucose levels was observed in STZ-rats in comparison to Sham-rats (586.4 ± 10.2 mg/dl vs. 109.9 ± 4.9 mg/dl respectively; $p < 0.005$) associated with a decrease in BW (-27% vs Sham-rats, $p < 0.005$). Furthermore, STZ-rats showed a significant decrease in the nociceptive threshold, as compared to Sham-rats (49.6 ± 1.5 g vs 75.8 ± 1.6 g respectively; $p < 0.005$). At D28, this threshold was further decreased in VHC-treated STZ rats vs Sham-rats (46.2 ± 1.5 g vs. 77.7 ± 1.2 g respectively; $p < 0.005$) whereas it was increased by RIMO treatment (+27% vs VHC-treated STZ rats; $p < 0.05$). DULOX and GABA treatment also increased the nociceptive threshold in a similar manner (+28% and +27% vs VHC respectively, $p < 0.05$). Nocturnal locomotor activity (total distance) of VHC-treated STZ rats was significantly decreased compared to Sham-rats (-57%; $p < 0.01$). Locomotor activity in STZ animals was not affected by treatment except by DULOX during the first three hours of observation (-52% vs. VHC-treated STZ rats; $p < 0.05$). Blood glucose levels at D28 were still significantly higher in VHC-treated STZ-rats than in Sham-rats (520.4 ± 17.2 mg/dl vs. 135.7 ± 2.7 mg/dl respectively, $p < 0.005$). No significant difference was observed between the different treated groups at D28 (481.8 ± 15.6 mg/dl; 484.2 ± 12.7 mg/dl and 482.9 ± 20.9 mg/dl in RIMO-, DULOX- and GABA-treated STZ-animals respectively) and vs. VHC-treated STZ-rats. Whereas VHC-, DULOX- GABA-treated STZ rats lost BW by 47%, 18 % and 9% respectively between D14 and D28, RIMO-treated rats lost 8% only during the same period ($p < 0.01$ vs. VHC-treated STZ rats). Although non significantly, RIMO and GABA improved insulinemia by +41% and +121% respectively vs VHC-treated STZ rats, whereas DULOX did not (-2% vs. VHC).

Conclusion: These results show that Rimonabant prevents the development of allodynia in STZ-induced diabetic rats, similarly to the reference compounds Duloxetine and Gabapentine but without significantly altering spontaneous locomotor activity. Furthermore, Rimonabant prevents BW loss and increases insulinemia indicating a reduced severity of diabetes symptoms in this model.

The effect of transplantation of adipose tissue-derived mesenchymal stem cells on the established stage of experimental diabetic neuropathy

H. Mizukami¹, S.-I. Yamagishi¹, A. Sugawara¹, S. Ogasawara¹, K. Sugimoto², S. Yagihashi¹

¹Pathology and Molecular Medicine, ²Laboratory Medicine, Hirosaki University, Hirosaki, Japan

Background and aims: Diabetic neuropathy is the most common complication of diabetic patients. There is no curative therapy for the advanced stage of this disorder and stem cell transplantation has now been experimentally applied. We investigated the effects of adipose tissue-derived mesenchymal stem cells (ADMSC) on the established stage of experimental diabetic neuropathy in rats since ADMSC are easily accessible and have a greater potential of the production of growth factors with high proliferative activity compared to other stem cells derived from bone marrow or peripheral blood.

Materials and methods: ADMSC were isolated from subcutaneous fatty tissue of male Wistar rats and confirmed to have diverse differentiation. As recipients of ADMSC, female rats were made diabetic at 8 weeks of age by streptozotocin and followed for 16 weeks until they developed a constant delay of motor nerve conduction velocity (MNCV) and altered pain sensation. Then, ADMSC (2.0×10^6) were transplanted to the right soleus muscle in these diabetic rats. The medium was injected to the contralateral side. The mRNA expression of various growth factors in ADMSC as well as in transplanted tissues was evaluated by RT-PCR. The survival of ADMSC in transplanted sites was examined by SRY gene detection of Y-chromosome and capillary density of the muscles was morphometrically evaluated.

Results: ADMSC were CD90+, CD117-, CD34-, CD45- by FACS and Sca1+, CD90+ by RT-PCR, and differentiated into adipocytes, osteocytes and neuronal cells in a specific medium. Two weeks after transplantation, MNCV in the transplanted side was nearly normalized whereas that in contralateral side was still significantly slow. At 4 weeks, MNCV in the treated side was declined but still faster than the contralateral side. Pain sensation threshold was reduced in diabetic rats and there was a trend to improve in the treated side. The quantitation of capillary density did not find significant difference by the treatment at 4 weeks. Expression of mRNA of growth factors in ADSC was high and augmented expression of TGF-beta in diabetic muscle was normalized in the treated side.

Conclusion: These results suggest that ADSC transplantation was promising for the treatment of advanced stage of diabetic neuropathy, but still needs to be well designed for the longer survival of transplanted cells.

Glucocorticoid receptor antagonist metyrapone reduces neuronal loss in hippocampus and protects beta cells during streptozotocin diabetes development

M.A. Orlovsky, Y.V. Lebed, G.G. Skibo

Cytology, Bogomoletz Institute of Physiology, Kyiv, Ukraine

Recent studies had shown that the first signs of diabetic encephalopathy (hippocampal neuronal loss, astrogliosis etc) are already observed at the early terms of diabetes development. Several lines of evidences suggests that glucocorticoids (GC), whose levels are elevated in diabetes, can cause neuronal damage and death in hippocampus, giving possible explanation for the mechanisms of diabetic encephalopathy. In the present study we had tried to elucidate whether or not blockade of GC synthesis can protect hippocampal neurons during the development of streptozotocin diabetes mellitus. Experiments were accomplished on Wistar-line male adult rats kept under the standard conditions. Single i.p. streptozotocin injection (45 mg/kg in citrate buffer) were used to model diabetes type I. Metyrapone was given s.c. in dose of 100 mg/kg each 12 hr starting from the streptozotocin injection. Control rats received vehicle s.c. in the same manner. The total duration of diabetes was 7 and 14 days: according to our previous findings a significant neuronal loss is observed in the pyramidal layer of the hippocampus at these terms. Immunofluorescent confocal microscopy with antibodies to specific neuronal marker NeuN was used to measure the amount of neurons in different regions of the hippocampus. Islet's beta-cells were studied in pancreatic sections using immunofluorescent microscopy with insulin antibodies. It was established, that at the day 7 metyrapone led to a significant reduction in fasted glucemia level down to 7.97 ± 1.40 mM as compared 16.43 ± 2.29 mM in vehicle-treated animals; the similar difference in glucemia level was preserved till the end of the experiments. Metyrapone administrations also inhibited neuronal loss in CA1, CA2 and CA3 areas of hippocampus with the most prominent changes observed in CA2 area (see table). Additionally, metyrapone protected pancreatic beta-cells: there were 22 ± 4 beta-cells/islet in metyrapone-treated group (day 14) in respect to 8 ± 2 beta-cells/islet in vehicle-treated group and 36 ± 8 in non-diabetic control. Thus, it can be concluded, that metyrapone can protect pancreatic beta-cells and hippocampal neurons during diabetes development, however further studies needed to find out the primary mechanism of metyrapone-induced neuroprotection (inhibition of GC synthesis, glucemia reduction or normalization of insulin production).

Effects of metyrapone on the neuronal count in CA2 area during the diabetes development

neurons per mm of pyramidal layer length	Vehicle	Metyrapone
Control	220.19 ± 13.98	–
Diabetes, day 7	168.13 ± 10.12	215.36 ± 16.12 *
Diabetes, day 14	160.80 ± 9.97	183.54 ± 7.70 *

Effects of all-trans retinoic acid on treatment of type 2 diabetic neuropathy

J. Park, M. Cho, J. Nam, J. Han, J. Yoo, C. Ahn, B. Cha, E. Lee, S. Lim, K. Kim, K. Kim, H. Lee

Internal medicine, Yonsei University College of Medicine, Seoul, Republic of Korea

Background and aims: Peripheral neuropathy is one of the most common complications in diabetes mellitus. Nerve growth factors (NGF) are believed to regulate peripheral and central nervous system, neuronal differentiation, and regeneration of damaged nerves, and their role in diabetic neuropathy is being emphasized these days. Retinoic acid increases the endogenous expression of NGF. The aim of the present study was to investigate the effects of All Trans Retinoic Acid on diabetic neuropathy in OLETF rats, an animal model of type 2 diabetes

Materials and methods: In order to evaluate the effect of ATRA (All-Trans Retinoic Acid, Promega, Madison, WI, USA), we orally administered of 10 mg/kg body weight ATRA dissolved in cellulose to 20 OLETF (Otsuka Long-Evans Tokushima Fatty) rats for 16 weeks, and we administered cellulose as a vehicle to 20 OLETF rats and 10 LETO (Long-Evans Tokushima Otsuka) rats. At the end of the treatment period, we measured blood glucose levels and contents of NGF (nerve growth factor) in serum and sciatic nerve. Neurometer CPT tests were conducted to examine improvements of the current stimulus thresholds in rats.

Results: Fasting glucose levels were significantly lower in the LETO rats (105.4 ± 14.4 mg/dL) than in the non treated OLETF rats (178.5 ± 38.3 mg/dL, $P < 0.01$) or in the ATRA treated OLETF rats (151.0 ± 25.1 mg/dL, $P < 0.01$). A decrease in serum glucose was observed in the ATRA treated OLETF rats when compared with the non treated OLETF rats. Contents of NGF in LETO rats were 1423.50 ± 503.21 pg/mL in serum and 150.0 ± 28.8 pg/g in nerve; in non treated OLETF rats the values were 683.71 ± 169.89 pg/mL in serum and 243.2 ± 41.9 pg/g in nerve; and in ATRA treated OLETF rats the values were 1855.17 ± 667.34 pg/mL in serum and 377.9 ± 61.5 pg/g in nerve ($P < 0.05$). The non treated OLETF rats significant increase ($P < 0.01$) in the thresholds for current stimulus. No differences were found between LETO rats and ATRA treated OLETF rats

Conclusion: Our results have shown that ATRA treatment increases serum and nerve contents of NGF in OLETF rats and suggest that ATRA has a potential therapeutic role for diabetic neuropathy.

Long-term safety and efficacy of pregabalin as treatment of painful diabetic neuropathy: findings from 7 open-label extension studies

K. Murphy, B. Emir

Pfizer Inc, New York, United States

Background and aims: Pregabalin has consistently demonstrated robust efficacy for treating painful DPN in randomized clinical trials (RCTs) of 5-13 weeks' duration. We report safety and efficacy findings from pooling 7 long-term, open-label (OL) extensions of pregabalin RCTs in painful DPN.

Materials and methods: Pregabalin dosage was adjusted between 150 and 600 mg/d based on response and tolerability. Mean daily dosage was monitored and pain evaluated quarterly (100-mm visual analog scale [VAS]).

Results: The pooled OL population included 1426 patients. At baseline, mean age was 58.8 years (SD=10.7); mean weight, 92.5 kg (SD=19.2); mean duration of diabetes, 11.02 years (SD= 9.0); mean HbA_{1c} level, 8.01% (SD=7.33); and mean pain VAS (n=1321), 60.5 (SD=23.59). The most common dosage range throughout the OL studies was 300-449 mg/d pregabalin (40.7% of patients), followed by 600 mg/d (32.0%). 349 pregabalin patients completed 2 years of treatment. 12 weeks into the OL extensions, mean pain VAS (n=770) had decreased to 30.6 (SD=23.81). Throughout the remainder of the studies, mean pain VAS remained stable at this level through endpoint, 32.9 (SD=26.52; n=1246). Most AEs were of mild-to-moderate intensity and generally transient. No clinically meaningful changes in HbA_{1c} levels were noted (mean change 0.14%), and mean weight change for all patients was +3.4 kg at endpoint.

Conclusion: Data from these 7, long-term, OL extension studies suggest that, in patients with painful DPN, the pain-relieving effect of pregabalin is durable over at least a 2-year period. Long-term use of pregabalin is generally well-tolerated and is not associated with clinically meaningful changes in HbA_{1c} levels.

Effect of duloxetine 60 mg once daily in patients with diabetic peripheral neuropathic pain in long-term open-label study

V. Skljarevski¹, D. Desai¹, Q. Zhang¹, A.S. Chappell¹, M.J. Detke¹, J.L. Gross²

¹Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, United States, ²Centre De Pesquisas Em Diabetes, Centre De Pesquisas Em Diabetes, Porto Alegre, Brazil

Background and aims: This open-label study was designed to evaluate the maintenance of effect of duloxetine 60 mg once daily over 26 weeks of therapy in patients with diabetic peripheral neuropathic pain (DPNP) following 8 weeks of acute therapy.

Materials and methods: Patients (≥ 18 years of age) who had daily pain for ≥ 6 months due to symmetric sensorimotor diabetic peripheral neuropathy (confirmed by a score of ≥ 3 on Michigan Neuropathy Screening Instrument), and had Brief Pain Inventory (BPI) 24-hour average pain score ≥ 4 , were first treated with duloxetine 60 mg once daily for 8 weeks. Responders (i.e., those who had $\geq 30\%$ reduction in BPI 24-hr average pain score) at the end of acute therapy continued on duloxetine 60 mg once daily (maintenance treatment arm), and nonresponders were escalated to duloxetine 120 mg once daily (rescue treatment arm) for 26 weeks. The primary efficacy measure was change from baseline (Week 8) to endpoint in the patient-rated BPI 24-hr average pain score for patients entering maintenance phase only. Secondary efficacy measures included BPI Severity (BPI-S) and Interference (BPI-I), Sensory Portion of the Short-Form McGill Pain Questionnaire (SF-MPQ), Patient's Global Impression of Improvement (PGI-I), and Clinical Global Impression of Severity (CGI-S). These variables were assessed for the change from baseline using a within-group t-test with 95% confidence interval (CI). Vital signs and treatment-emergent adverse events (TEAEs) were assessed.

Results: Of the 216 patients enrolled, 53% were responders, 32% were nonresponders, and 15% discontinued at the end of acute therapy. The BPI 24-hr average pain score (mean change, -2.49) and scores on all the secondary efficacy measures significantly ($P < .001$) improved at the end of acute therapy. During the maintenance therapy, the change of BPI 24-hr average pain score from baseline to endpoint is 0.35 with 0.79 as the upper bound of the 97.5% CI which is less than the prespecified noninferiority margin of 1.5 ($P < .001$). At the same time, most BPI-S and BPI-I scores slightly increased, with no significant difference from zero except for the pain right now (mean change, 0.48, $P = .026$) and normal work (0.63, $P = .016$) scores. In the rescue treatment arm, BPI-S scores achieved statistically significant pain reduction (average pain, $P < .001$; worst pain, $P < .001$; least pain, $P = .016$; and pain right now, $P = .011$); BPI-I scores were improved significantly for general activity, walking ability, and normal work. The PGI-I score at endpoint was 2.32 in the maintenance and 3.04 in the rescue therapy. Also in the rescue therapy, CGI-S and SF-MPQ scores did not change significantly except for CGI-S (-0.46, $P = .003$). TEAEs and vital signs in this study were similar to those reported in randomized DPNP studies of duloxetine.

Conclusion: Following 8 weeks of acute treatment, duloxetine maintained its efficacy in the management of DPNP for 26 weeks and was well tolerated.

Safety and efficacy of duloxetine in the treatment of diabetic peripheral pain in elderly patients

J.F. Wernicke¹, A.D. Wasan², M.J. Ossanna¹, J. Raskin³, M.J. Robinson¹, J.A. Hall¹, S.E. Edwards¹, S. Lipsius⁴, A.L. Meyers¹, B.H. McCarberg⁵

¹Eli Lilly, Indianapolis, United States, ²Dept of Anesthesiology, Brigham and Women's Pain Management Center, Chestnut Hill, United States, ³Eli Lilly Canada, Toronto, Canada, ⁴Statprobe, Ann Arbor, United States, ⁵Department of Family Medicine, Kaiser Permanente, Escondido, United States

Background and aims: Treatment of diabetic peripheral neuropathic pain (DPNP) in elderly patients (≥ 65 years of age) can be challenging due to frequent use of concomitant medications and presence of coexisting illnesses in this population. Tricyclic antidepressants are often used to treat DPNP, but in elderly patients, tolerability and safety issues often result in insufficient treatment. Duloxetine (DLX) is a selective serotonin and norepinephrine reuptake inhibitor approved for management of DPNP. We present a post-hoc analysis of the safety and efficacy of duloxetine in the elderly.

Material and methods: Data from 3 double-blind, placebo-controlled trials in adult patients with DPNP were pooled and stratified by age (< 65 and ≥ 65 years). Patients were randomized to DLX 60 mg once daily (QD; $n = 105$ elderly, 239 nonelderly [< 65]), 60 mg twice daily (BID; $n = 109$ elderly, 232 nonelderly), or placebo (PBO; $n = 109$ elderly, 230 nonelderly) for 12 weeks of acute treatment. Each acute study was followed by an extension phase, with acute phase completers re-randomized to routine care or DLX 60 BID for 52 weeks. The primary efficacy measure was the weekly mean 24-hour average pain score measured by a patient-rated 11-point Likert scale. Safety and efficacy of DLX in elderly patients were assessed using both acute and extension phase data. Safety assessments included spontaneously reported treatment-emergent adverse events (TEAEs) and discontinuation rates due to TEAEs. All analyses were done on an intent-to-treat basis. Fisher's exact test was used for pairwise comparisons within each age group and logistic regression was used for age and therapy-by-age subgroup analyses.

Results: In the acute phase, the age subgroups did not significantly differ in overall rates of TEAEs. A significant relationship between therapy and age was observed for nasopharyngitis ($p = .047$; higher incidence in nonelderly [9.5%] vs elderly [1.8%] for DLX 60 BID) as well as for abdominal pain ($p = .037$; higher incidence in elderly [5.7%] vs nonelderly [0.8%] for DLX 60 QD). A greater percentage of elderly patients discontinued due to TEAEs ($p < .001$). The greater discontinuation rate for the elderly was seen in all treatment groups (therapy-by-age interaction $p = .926$). In the extension phase of the trials, a therapy-by-age interaction was observed in overall rate of TEAEs due to age subgroup differences in the routine care group (≥ 1 TEAE: elderly [86.6%], nonelderly [74.6%]); in the DLX group, TEAE rate was 77.3% in elderly and 77.9% in nonelderly. DLX showed improvement in weekly mean 24-hour average pain vs PBO in both age groups ($p < .01$).

Conclusion: Duloxetine was well tolerated and efficacious in the treatment of DPNP regardless of age strata. There were few significant differences between age groups that were dependent on therapy received, and there was no consistent signal indicating that safety and efficacy of duloxetine might differ significantly in elderly vs nonelderly patients. This suggests that in patients 65 years of age and older, duloxetine may be a valuable option for treatment of DPNP, in particular for those who have difficulty tolerating other DPNP medications.

Evidence of neuroregeneration using vascular endothelial growth factor zinc finger protein activator (SB-509) in diabetic neuropathy: a chronic degenerative polyneuropathy

D.G. Ando¹, M. Merren², W. Douglas³, S. Hamilton⁴, Y.-L. Lee⁴, K. Spratt⁴, E. Benaim⁴, M. Kipnes³

¹Therapeutic Development, Sangamo BioSciences, Richmond, ²Neurology, Diabetes and Glandular Disease Research Associates, San Antonio,

³Clinical, Diabetes and Glandular Disease Research Associates, San Antonio,

⁴Development, Sangamo BioSciences, Richmond, United States

Background and aims: Diabetic Neuropathy (DN) is a progressive neurodegenerative disease with an incidence up to 50% in long-term patients. Although the pathogenesis is related to hyperglycemia, the specific mechanisms are not clear. The pathophysiology includes severe nerve damage with demyelination and alteration in axonal transport. Vascular Endothelial Growth Factor (VEGF) has protective and regenerative effects on neuronal cells in culture.

Materials and methods: Using VEGF zinc finger protein activator (SB-509) we have treated twenty-four patients with a single treatment of sixty mgs of SB-509, intramuscularly in the lower extremities, in a placebo-control clinical trial. Patients were treated in both legs with either SB-509 or placebo and evaluated by quantitative sensory testing (QST) using the Vibratron 2 instrument, and motor/sensory nerve conduction velocities (NCV) in the lower extremities.

Results: In 24 evaluated patients, improvements in motor NCVs and sensory NCVs were seen at the six-month time-point in the SB-509 group when the average of all motor NCV (2 peroneal and 2 tibial NCV per patient) and the average of two sural NCV from baseline was compared to placebo. The mean value of motor NCV improvement in the SB-509 group (twelve patients) was 0.78 M/sec compared to -0.93 M/sec in the placebo group (twelve patients) ($p = 0.21$). The mean value of sural NCV improvement in the SB-509 group was 1.18 M/sec compared to -0.43 M/sec in the placebo group ($p = 0.29$). QST testing at six months showed a 25% improvement in vibration units from baseline in the SB-509 group compared to 5% worsening in the placebo group ($p < 0.02$). Improvements in NCV included three patients with unmeasurable NCVs who, after treatment with SB-509, showed improved NCV over the six-month follow-up.

Conclusion: These improvements in neurologic endpoints suggest that SB-509 has novel regenerative potential for the reversal of nerve damage in diabetic neuropathy. This single treatment data showing improvement in sensory and motor neuropathic deficits are the basis on which two multi-dosing clinical trials in mild to moderate and severe diabetic neuropathy are currently in progress.

LDI flare demonstrates early functional changes in painful diabetic neuropathy

S.T.M. Krishnan¹, C. Quattrini², M. Jeziorska³, R. Malik², G. Rayman¹
¹Diabetes Centre, Ipswich Hospital NHS Trust, ²Division of Cardiovascular Medicine, The University of Manchester, ³Division of Regenerative Medicine, The University of Manchester, United Kingdom

Background and aims: Structural and functional changes in small unmyelinated C fibres appear to precede large fibre pathology and have been implicated in foot ulceration in people diabetes. Furthermore, C fibre dysfunction is considered to be involved in the genesis of neuropathic pain. The present study has 2 aims a) to compare 3 methods of assessing small fibre function, 2 non-invasive and functional, the LDI flare and Quantitative Sensory Testing (QST) and one invasive and structural, the measurement of dermal nerve fibre density (NFD) and b) to examine the hypothesis that painful neuropathy is associated with functional defects in C-fibre function whereas painless neuropathy with more advanced structural pathology reflected by reduction in NFD.

Methods: Fifteen healthy controls (HC), 10 painful (PFN) and 12 painless (PLN) neuropaths were studied. The LDI flare was assessed by heating dorsal foot skin to 44 degree C to induce axon reflex vasodilatation and measuring the flare size by laser Doppler imaging. NFD per mm² was assessed in 3mm skin biopsies taken from the same site, immunostained with PGP 9.5. QST was measured using Computer Aided Sensory Evaluator (CASE IV).

Results: Compared with controls, mean NFD and all the QST measures were significantly abnormal in the PLN group but not in the PFN group (Table 1). In contrast, the LDI flare in cm² was reduced in both neuropathic groups (PFN 1.59+/-0.41; PLN 1.51+/-0.56) compared to HC 4.38+/-1.4 ($p < 0.001$). Across the groups NFD correlated well with LDI flare ($r = 0.57$, $p < 0.0001$).

Table 1

	HC	PFN	PLN
LDI flare (cm ²)	4.38+/-1.4	1.59+/-0.4†	1.51+/-0.56†
NFD (mm ²)	424+/-176.3	307.6+/-164.5	205.8+/-165.3*
VPT (Volts)	7.0+/-2.8	8.7+/-2.2	37.0+/-12.9†
VDT (JND)	18.4+/-3.2	19.5+/-3.2	23.0+/-3.7‡
CDT (JND)	10.4+/-5.0	13.8+/-5.1	19.5+/-4.6†
WDT (JND)	17.5+/-2.0	18.3+/-6.1	25.2+/-1.8†
HPO (JND)	21.6+/-1.8	21.3+/-3.0	25.3+/-1.6†

(† - $p < 0.0001$); (* - $p = 0.006$); (‡ - $p = 0.004$) Mean+/-SD
 Symbols indicate p value when compared to HC

Conclusion: Thus, the LDI flare demonstrates early functional abnormalities in painful neuropathy whereas skin nerve fibre density and QST were only abnormal in those with more advanced painless neuropathy. As the LDI flare correlates with NFD, is non invasive and has excellent reproducibility, it may be valuable in detecting early small fibre dysfunction. Further, bigger studies are warranted to confirm the findings.

1251

Current perception threshold determined with a novel method, the Neurometer is clinically useful in detecting functional abnormalities of large and medium-size myelinated nerve fibres in patients with type 2 diabetes mellitus

T. Inukai, R. Matsutomo, K. Hara, T. Nakano, M. Suetsugu, S. Matsumoto, T. Nakamachi, K. Takebayashi, Y. Aso
 Department of Internal Medicine, Dokkyo Medical University Koshigaya Hospital, Koshigaya, Japan

Background and aims: Diabetic neuropathy is a common and important complication of diabetes mellitus, however there are few methods to evaluate objectively and quantitatively diabetic peripheral neuropathy. The measurement of the current perception threshold (CPT) using the Neurometer (Neurotron Inc. Baltimore, USA), a novel method, could elucidate the functional

status of three distinct nerve fibre types - large myelinated (A β) fibres, medium-size myelinated (A δ) fibres and unmyelinated (C) fibres, at setting of 2000Hz, 250Hz and 5Hz, respectively. We compared the Neurometer method and several conventional methods in type 2 diabetic patients.

Materials and methods: The current studies were conducted in 116 patients with type 2 diabetes mellitus and age-matched healthy controls. At each frequency, a CPT below the normal range measured by the Neurometer is considered as hyperaesthesia, while a CPT above the normal range is considered as hypoaesthesia. As the conventional methods, the measurement of the motor and sensory nerve conduction velocities (MNCV, SNCV), of the coefficient of variation of the R-R interval on ECG (CVr-r), of vibration perception threshold (VPT) by SMV5 vibrometer, of Δ sBP in Schellong test and the status of Achilles tendon reflexes were applied.

Results: The CPT at 2000Hz was significantly higher in diabetic patients than in controls ($p < 0.05$) and showed significantly negative correlation with MNCV and SNCV ($r = -0.279$, $p < 0.01$, $r = -0.350$, $p < 0.01$, respectively). At 2000Hz and 250Hz, the CPTs exhibited positive correlations with VPT ($r = 0.288$, $p < 0.01$, $r = 0.207$, $p < 0.05$, respectively). At 5Hz, Δ sBP in patients with hypoaesthesia (higher CPT) tended to be less than in those with normoaesthesia (normal CPT) and hyperaesthesia (lower CPT). There were no significant differences in CVr-r among normoaesthesia, hyperaesthesia and hypoaesthesia groups classified by CPTs at 5Hz. Significantly higher CPT values at 2000Hz were obtained in patients with proliferative diabetic retinopathy and with macroalbuminuria, compared with those without complications ($p < 0.01$, $p < 0.05$, respectively).

Conclusion: The present investigations suggest that the CPT measurement by the Neurometer is clinically useful in detecting functional abnormalities of large and medium-size myelinated nerve fibres, rather than unmyelinated nerve fibres in patients with type 2 diabetes.

1252

Investigation into the role of human bias in 10g monofilament force delivery

M.C. Spruce¹, C.H. Lewis², M. Griffin²

¹School of Health Professions, ²Institute of Sound and Vibration Research, University of Southampton, Southampton, United Kingdom.

Background and aims: To verify the dynamic effects of multiple testers on 10g monofilament reliability

Previous studies advocate that the 10g monofilament is capable of providing repeatable force for ≤ 100 compressions, after which, a 24 hour rest period is required. However, these studies are based upon automated force delivery equipment. Whilst this approach tests fibre integrity, it fails to account for the potential non-linearity in human application. Consequently, the rate of mechanical degradation under real-time dynamic conditions, as would be the case in a busy clinical environment, remains unknown. Similarly, there have been no investigations into the inter-reliability and repeatability of the 10g monofilament between multiple users.

Materials and methods: Twenty new CE approved 10g monofilaments (same brand) were tested by 20 trained male subjects for peak force. Devices were applied in five runs of ten cycles against a research grade strain gauge at a controlled rate. All data was captured using an oscilloscope recording device permitting statistical handling.

Results: Significant differences in both mean and median peak force were found between all subjects ($p = 0.021$). Further post hoc analysis revealed highly significant differences in the above modalities on Run 3 and 5 ($p = 0.013$, $p = 0.03$) respectively, in comparison to Run 1. Finally, a highly significant difference was observed between subjects for the total range of peak force ($p = 0.001$).

Conclusion: This is the first study to demonstrate that when used by a human, rather than a machine, the 10g monofilament suffers premature mechanical decay at 50% of the recommended number of applications. Similarly, the total range of peak force varies significantly between subjects. Hence, the clinical reliability of the 10g monofilament appears unstable, once the human variable is factored in, requiring a fresh approach to both method and equipment.

Same day intra-subject reproducibility of vibration perception threshold in type 1 diabetes

C.L. Martin¹, B.H. Waberski², R. Pop-Busui³, J.W. Albers⁴, W.H. Herman⁵, P. Cleary²

¹Michigan Diabetes Research and Training Center, University of Michigan, Ann Arbor, ²The Biostatistics Center, The George Washington University, Rockville, ³Division of Metabolism Endocrinology and Diabetes, University of Michigan, Ann Arbor, ⁴University of Michigan Medical School, University of Michigan, Ann Arbor, ⁵University of Michigan Health Systems, University of Michigan, Ann Arbor, United States

Background and aims: All surviving Diabetes Control and Complications Trial (DCCT) participants were invited to enroll in the Epidemiology of Diabetes Interventions and Complications (EDIC) study in 1994. Of these 1,375 subjects (96%) agreed to participate; 687 and 688 from the former intensive (INT) and conventional (CONV) treatment groups, respectively. Beginning 13 years after DCCT completion quantitative sensory testing was added to the EDIC annual test battery, and vibration perception threshold (VPT) was assessed for the first time among former DCCT subjects. To evaluate VPT reproducibility, same-day, same examiner repeated tests were performed on a random subset of participants.

Materials and methods: Study coordinators from the 28 EDIC clinical sites were centrally trained and certified to perform VPT using the Vibratron II (Physitemp, Inc., Clifton NJ). Unilateral, dominant side VPTs for the index finger and great toe were determined using a forced choice algorithm. Vibration units (VU) were adjusted up or down in 10% increments following incorrect or correct responses, respectively. Testing continued until five errors were recorded over a minimum of 18 trials. VUs for the first five errors and five lowest correct responses were rank ordered, the highest and lowest values discarded, and the remaining 8 values averaged to determine the VPT. To evaluate test reproducibility 2 to 6 subjects per site were randomly assigned to repeat testing of the dominant side great toe. Examiners were instructed to allow at least 30 minutes between the primary and repeat test during which time the subject was to wear the same footwear worn prior to the primary test. The same examiner performed both tests and was not masked to primary test results. Tests were reviewed and scored centrally. Intraclass correlation was performed to determine the coefficient of reliability for primary versus repeated tests.

Results: The 94 subjects identified for repeat testing were representative of the EDIC cohort in age, (mean 46.1±7.5 years) gender (53% male), diabetes duration (mean years 24.2±4.5) and treatment assignment (50% INT). Repeat VPT of the dominant great toe has been completed in 81 (86%) subjects. Completion of repeat testing among sites ranged from 50% (3 sites) to 100% (19 sites). The mean primary VPT was 3.74±2.73 VU and the mean repeat VPT was 4.01±2.77 VU and the difference was not statistically significant (p=0.10). The calculated test-retest coefficient of reliability was 0.85.

Conclusion: VPT among this sample of EDIC subjects demonstrated good overall reproducibility. These results were not obtained with any masking of examiners, and, aside from instructions to wait at least 30 minutes between the initial and repeated test and to otherwise reproduce the EDIC VPT protocol, were not performed under rigidly controlled circumstances. We plan to relate VPT to other measures of peripheral neuropathy collected concurrently in EDIC subjects.

Transforming growth factor 1 (TGFβ 1) and aminoterminal pro-brain natriuretic peptide (NT-proBNP) levels could be associated to diabetic neuropathy

J.M. Pou¹, J. Jurado², M. Ferrandiz³, J. Merce⁴, L. Comerma², J. Freixa⁴, J. Ybarra⁵

¹Dpt. Endocrinology and Nutrition, Autonomous University of Barcelona. Hospital Sta. Creu i S. Pau, Barcelona, ²Primary Care Center, Institut Catala de la Salut, Olot, Girona, ³Dept. Neurophysiology, Institut Catala de la Salut, Hospital Josep Trueta, Girona, ⁴Dpt. Biochemistry, Autonomous University of Barcelona, Hospital Sta. Creu i S. Pau, Barcelona, ⁵Instituto de Cardiología Avanzada (ICAMED), Centro Medico Teknon, Barcelona, Spain

Background and aims: The plasma levels of the N-terminal fragment of brain natriuretic peptide (NT-proBNP) recently gained extreme importance

as marker of myocardial dysfunction in type 2 diabetes mellitus (T2DM). In a previous work, we observed that NT-proBNP levels also display a significant association with the Diabetic Neuropathy (DPN), even after correction for age and cardiovascular disease (CVD). Scarce data is available regarding the association between diabetic polyneuropathy (DPN) and other peptides as Transforming Growth Factor Beta 1 (TGFβ 1). TGFβ 1 manifested several important roles in diabetic nephropathy but its relationship to DPN and other microangiopathy is not quite understood.

Materials and methods: Hence, we set forth a cross-sectional pilot study, to assess the hypothetical relationships between NT-proBNP and TGFβ 1 levels, CVD and DPN in a group of T2DM patients (N=190; W:46 %) randomly selected from the North Catalonia Diabetes Study (NCDS). CVD and DPN (clinical and neurophysiology evaluation) prevalence were assessed. NT-proBNP was measured by immunoassay (Elecys®, Roche Diagnostics, Indianapolis, Inc.) and total TGFβ 1 by ELISA (ProOmega®)

Results: Patients' age: 65.6±7.2, T2DM duration: 11.2±4.5 years, HbA1c: 7.3±1.7; DPN: 48.6%. Log-transformed NT-proBNP levels (logNT-proBNP) were significantly higher in T2DM patients with CVD (P<0.004) and DPN (P<0.000) and also log-transformed TGFβ 1 (Log TGFβ 1) was higher in CVD (p< 0.001) and DPN (p< 0.04) patients. LogNT-proBNP manifested an important correlation with log TGFβ 1 (p<0.0001). Log NT-proBNP correlated with: age (P<0.001), microalbuminuria (p<0.03), CVD (P<0.000) and DPN (P<0.000) -even after correction for age and CVD (p<0.001)-Log TGFβ 1 correlated with creatinine (p<0.001), microalbuminuria (p<0.001), C-reactive protein plasma levels (CRP) (p<0.02), CVD (P<0.006) and DPN (P<0.000) -even after correction for microalbuminuria, creatinine and CVD (p<0.014)

Conclusion: Noteworthy, TGFβ 1 displays a new and significant association with DPN independent of microalbuminuria and renal function. TGFβ 1 and NT-proBNP plasma levels appear as important molecules for diabetic microangiopathic complications' development and screening. Further prospective trials are warranted.

Epidemiology of neuropathic pain in pre-diabetes and diabetes. The MONICA/KORA Augsburg Surveys and Myocardial Infarction Registry (KORA-A Study)

D. Ziegler¹, W. Rathmann², T. Dickhaus³, C. Meisinger^{3,4}, A. Mielck⁵

¹Institute for Clinical Diabetes Research, German Diabetes Center, Düsseldorf, ²Institute of Biometrics and Epidemiology, German Diabetes Center, Düsseldorf, ³Institute of Epidemiology, Helmholtz Zentrum München - German Research Center for Environmental Health, Neuherberg, ⁴MONICA/KORA Myocardial Infarction Registry, Central Hospital of Augsburg, ⁵Institute of Health Economics and Health Care Management, Helmholtz Zentrum München - German Research Center for Environmental Health, Neuherberg, Germany

Background and aims: The lowest glycaemic threshold and risk factors for the development of neuropathic pain have not been established. The aim of this study was to determine the prevalence and risk factors of neuropathic pain in two different populations in relation to the degree of hyperglycaemia.

Materials and methods: KORA-A is based on participants from the population-based MONICA/KORA Augsburg Surveys (S2+S3) and the Augsburg Myocardial Infarction Registry (MIR). Subjects aged 25-74 years with diabetes (S2+S3: n=195; MIR: n=214) and controls matched for age and sex (S2+S3: n=198; MIR: n=212) were assessed for neuropathic pain by the Michigan Neuropathy Screening Instrument using its pain-relevant questions in conjunction with an examination score cutpoint >2. An oral glucose tolerance test was performed in the controls.

Results: Among the control subjects from the S2+3 population, 46 (23.2%) had impaired glucose tolerance (IGT), 71 (35.9%) had impaired fasting glucose (IFG), and 81 had normal glucose tolerance (NGT). The corresponding numbers among the MIR control subjects were 61 (28.8%), 70 (33.0%), and 81. Among the S2+S3 participants the prevalence of neuropathic pain was 13.3% in the diabetic subjects, 8.7% in those with IGT, 4.2% in those with IFG, and 1.2% in those with NGT (p=0.003 for diabetic vs NGT, IFG, and IGT). In the MIR subjects the prevalence of neuropathic pain was higher in each group, reaching 21.0% in the diabetic subjects, 14.8% in those with IGT, 5.7% in those with IFG, and 3.7% in those with NGT (p<0.001 for diabetic vs NGT, IFG, and IGT). Multivariate analyses showed that in the entire

S2+S3 population studied (n=393), age, weight, peripheral arterial disease (PAD), and diabetes were independent factors significantly associated with neuropathic pain, while in the diabetic group it was age, weight, and PAD (all $p < 0.05$). In the entire MIR group studied (n=426), age, waist circumference, peripheral arterial disease (PAD), and diabetes were independent factors significantly associated with neuropathic pain, while in the diabetic group neuropathic pain was associated with waist circumference, physical activity, and PAD (all $p < 0.05$).

Conclusion: The prevalence of neuropathic pain is 2–3fold increased in subjects with IGT and diabetes compared to those with IFG, but even higher among survivors of myocardial infarction with diabetes and IGT. Neuropathic pain is predominantly associated with cardiovascular risk factors and disease including obesity, low physical activity, and peripheral arterial disease which may constitute important prevention targets.

KORA research platform and the MONICA Augsburg were financed by the Helmholtz Zentrum München - German Research Center for Environmental Health, funded by the German Federal Ministry of Education, Science, Research and Technology and by the State of Bavaria

Investigation of the impact of painful diabetic peripheral neuropathy on sleep quality and sleep architecture in type 1 and 2 diabetic patients using polysomnography

M.E.V. Eriksson¹, R. Gouni², L.C. Gribble¹, D.D. Coppini³, D. Kerr², J. Boyle¹

¹Faculty of Health & Medical Sciences, University of Surrey, Guildford, United Kingdom, ²Bournemouth Diabetes and Endocrine Centre, The royal Bournemouth and Christchurch Hospitals, Bournemouth, United Kingdom, ³Poole Diabetes Centre, Poole General Hospital, Poole, United Kingdom

Background and aims: Painful diabetic peripheral neuropathy (DPN) is a common complication of diabetes mellitus (DM). Diabetic neuropathic pain is known to be more severe at night and patients with painful DPN often report that their pain has a severe impact on their sleep. Loss of sleep and poor sleep quality may have a great impact on patients' psychological and physical well being and the aim of this study was to investigate how neuropathic pain may interfere with sleep in these patients.

Materials and methods: Sleep architecture and pain interference for 45 type 1 and type 2 diabetic patients (males = 29, females = 16, mean age of $65.0 \pm \text{SD } 9.7$ years) with painful DPN was studied. Inclusion criteria required neuropathic pain of diabetic origin and a score of above 12 on the Leeds Assessment of Neuropathic Symptoms and Signs (LANSS). Patients had a mean of $16.7 \pm \text{SD } 13.6$ years since diagnosis of diabetes, established neuropathy for a mean of $7.9 \pm \text{SD } 9.5$ years and had a mean HbA1c of $8.0 \pm \text{SD } 1.6$ %. Patients were randomised and have completed the baseline period of a 36 day double-blind parallel groups investigation into the effects of pregabalin, duloxetine and amitriptyline on aspects of pain and sleep. Overnight sleep was measured between 23.00h to 07.00h using polysomnography (PSG) and subjective sleep was assessed using sleep diaries. Daytime sleepiness and pain interference were measured using the Karolinska Sleepiness Scale (KSS) and the Short Form Brief Pain Inventory (BPI), respectively.

Results: Increased pain interference correlated with increased PSG number of awakenings (NAW) ($r = 0.40$, $p = 0.0133$) and increased duration of stage 1 ($r = 0.34$, $p < 0.05$). Mean PSG sleep efficiency (SE %) was $77.7 \pm \text{SD } 11.8$ %, indicating poor sleep. In addition, pain interference correlated significantly with subjective quality of sleep (sQOS) ($r = 0.43$, $p < 0.01$) and subjective daytime sleepiness ($r = 0.32$, $p < 0.05$). Both pain interference and sQOS correlated with years since neuropathy diagnosis ($r = 0.33$, $p < 0.05$ and $r = 0.34$, $p < 0.05$, respectively). Pearson correlations were used on all above baseline data.

Conclusion: These important findings provide objective evidence that diabetic patients with painful DPN have poor sleep. Pain is associated with increased number of PSG awakenings and increased amount of stage 1 sleep, resulting in more fragmented and lighter sleep. Observations of poor sleep and day time sleepiness adds further important information to the better understanding of painful PDN, enabling possible improvements in treatment strategies for affected patients.

Truncal pruritus of unknown origin may be a symptom of diabetic polyneuropathy

H. Sasaki¹, H. Yamaoka¹, K. Ogawa¹, M. Nakatani¹, J. Ibata¹, H. Yamasaki¹, H. Furuta¹, M. Nishi¹, K. Naka², Y. Yamamoto², K. Nanjo¹

¹First Department of Medicine, Wakayama University of Medical Science,

²Department of Internal Medicine, Wakayama Rosai Hospital, Wakayama, Japan

Background and aims: To know the clinical significance of the pruritus in diabetic (DM) patients, we investigated the prevalence of pruritus in DM and non-diabetic (NDM) subjects, and the relevance to the signs and symptoms of diabetic polyneuropathy (DPN) of pruritus. Furthermore, the relationships between pruritus and quantitatively assessed nerve functions were examined.

Materials and methods: I. Prevalence and relevance of pruritus to signs and symptoms of DPN A large scale survey questionnaire for 2,656 DM outpatients was performed by 48 medical practitioners and hospital physicians in Wakayama Prefecture, Japan. The relations between pruritus and following parameters were investigated: age, sex, duration of DM, hemoglobin A1c (HbA1c), Achilles tendon reflex (ATR), vibration perception time at the ankles measured by C128 tuning fork (VPT) and subjective symptoms including numbness in toes and soles, pain in toes and soles, painful leg cramp and pruritus. The similar questionnaire was also administered to 499 NDM subjects. II. Nerve functions associated with pruritus. The relationships between pruritus and several nerve functions: motor and sensory nerve conduction velocities (MCV, SCV), sensory nerve action potential, heart rate variability, quantitatively assessed VPT, a fall of systolic blood pressure at head-up tilt test (dBP) were investigated in 66 DM patients. Statistical analyses were performed by chi-squared test, unpaired t-test and multiple logistic regression analysis.

Results: I. Prevalence and relevance of pruritus to signs and symptoms of DPN Prevalence of numbness, pain, and pruritus in DM (27.5%, 9.6%, 26.3%) is significantly higher than those in NDM (8.0%, 4.4%, 14.6%). Although the truncal pruritus of unknown origin (TPUO) was more high-frequency in DM than NDM (11.3%, vs 2.9%, $p = 0.0001$), the prevalence of limb pruritus or pruritus of known origin was similar between the both groups. The prevalence of numbness, pain, leg cramp, bilateral areflexia of ATR and decreased VPT (VPT < 10 sec) in the patients with TPUO was significantly higher than those in the patients without TPUO. Duration of diabetes in the patients with TPUO was significantly longer than that in the patients without TPUO. Multiple logistic regression analysis revealed that numbness and ATR areflexia were independent risk factors of TPUO from age, sex, duration and HbA1c. II. Nerve functions associated with pruritus. MCV and dBP in the patients with TPUO were significantly impaired than those without TPUO. Slow MCV and large dBP were also extracted as significant risk factors of TPUO by multiple logistic regression analysis.

Conclusion: The prevalence of TPUO in DM was significantly higher than that in NDM. TPUO was significantly associated with symptoms and signs of DPN, orthostatic hypotension and decreased motor nerve conduction velocity. Therefore TPUO seems to be a newly recognized symptom of DPN.

1258

Gait alterations of diabetic patients while walking on different surfaces

L. Allet^{1,2}, S. Armand², R.A. de Bie¹, Z. Pataky³, A. Golay³, K. Aminian⁴, E.D. de Bruin⁵

¹Department of Epidemiology, Maastricht University, Netherlands,

²Neurosciences, Geneva University Hospital and University of Geneva,

Switzerland, ³Service of Education for Chronic Disease, Geneva University

Hospitals and University of Geneva, Switzerland, ⁴Laboratory of Movement Analysis and Measurement, EPFL, Lausanne, Switzerland, ⁵Institute of Human Movement Sciences and Sport, ETH, Zurich, Switzerland

Background and aims: Diabetic patients have been shown to suffer from increased risk of injurious falls. Since peripheral neuropathy (PN) affects both sensory and motor function, the neuromuscular damage it implies, may result in altered lower extremity biomechanics. This could lead to associating gait abnormalities with the aforementioned heightened fall risk. However, to date, the cause of increased fall risk in diabetic patients is still under debate. In most existing studies gait was assessed in specialized kinesiology laboratories. Activities in daily life however, require us to move about in challenging environments. We aimed to evaluate gait parameters in diabetic patients

under various real life conditions and compared them to those recorded for healthy controls.

Materials and methods: This clinical observation has been reviewed by the Local Ethics Committee. The gait of 45 subjects was assessed on three different surfaces (tar, grass, stones) with the Physilog[®] (BioAGM, CH), a system containing accelerometers and gyroscopes. Temporal and spatial gait parameters as well as stride-to-stride variability of 30 patients with type 2 diabetes, 15 with and 15 without clinical neuropathy were compared to 15 healthy controls.

Results: The effect of diabetic neuropathy and the effect of surfaces were calculated with an ANOVA for repeated measures and a Bonferroni post hoc analysis. Diabetic patients' gait parameters differed significantly ($p < 0.05$) from those of healthy controls. Post hoc analysis revealed a significant difference between healthy individuals and patients with PN for all evaluated gait parameters (e.g.: velocity $p = 0.000$, stride $p = 0.008$ and coefficient of variation of stride as a gait instability index $p = 0.006$) except for shank ($p = 0.09$) and knee ($p = 1$) range. It further showed a significant differences between diabetic patients without PN and healthy controls in all evaluated gait parameters (e.g.: for velocity $p = 0.001$ and for coefficient of variation of stride $p = 0.002$) except for stride ($p = 0.4$) and lower limb movements ($p > 0.06$). No difference was observed between diabetic patients with and without PN. Patients with and those without PN adjusted to the variety of different surfaces using identical strategies. These strategies were also similar to those used by healthy controls. Nevertheless, the surface effect was most important in patients with PN followed by patients without PN and healthy controls.

Conclusion: Walking in real life conditions revealed gait difficulties in patients with type 2 diabetes before neuropathy was clinically detectable. The strategies patients used while changing from a flat (tarred walkway) to a more complex surface (grass or stones) remain the same between patients with and those without sensory loss. Although the change in velocity is not important enough to really influence patients' quality of life, clinicians should be aware that diabetic individuals' gait capacity decreases and fall risk increases in an already early stage of the disease.

1259

Subclinical hearing impairment: an earliest complication of type 1 diabetes mellitus?

M. Dabrowski¹, G. Niedzielska², A. Nowakowski³

¹Diabetology, NZOZ Beta-Med, Rzeszow, ²Otolaryngology, Medical University, Lublin, ³Endocrinology, Medical University, Lublin, Poland

Background and aims: The data regarding hearing function in type 1 diabetes are inconsistent. The aim of this study was to evaluate hearing threshold, cochlear micromechanics and central auditory pathway in relatively young type 1 diabetic patients, with short duration of the disease.

Materials and methods: 31 patients with type 1 diabetes, aged below 45 years (mean 29.1 ± 7.1 years), with diabetes duration < 10 years (mean 4.6 ± 2.7 years) and no evident hearing impairment, were compared with age-matched (30.3 ± 7.8 years) control group of 26 healthy volunteers. In all subjects pure-tone audiometry, otoacoustic emissions and auditory brainstem responses were evaluated. Metabolic control of diabetes was determined by HbA_{1c} assessment.

Results: Pure-tone audiometry was performed in frequency range 125–12000 Hz. 25 diabetics had normal hearing, 5 had mild and 1 moderate hearing loss. In control group 23 subjects had normal hearing, and 3 had mild hearing loss. The hearing threshold in frequencies 3–12 kHz was significantly higher in diabetic group than in control group (fig. 1), and was correlated with age, but no association was found with metabolic control and duration of diabetes. Transient evoked otoacoustic emissions (TEOAEs) in diabetic group were absent bilaterally in 6 and unilaterally in 2 subjects. In control group there were 2 and 1 subject respectively. The TEOAE amplitude was significantly lower in diabetic group when compared with controls (table 1), and in diabetics showed negative linear correlation with age ($p < 0.001$), but not with HbA_{1c} or duration of diabetes. Auditory brainstem responses (ABR) in diabetic group revealed significantly longer latency time of wave V (5.78 ± 0.25 vs 5.69 ± 0.18 ms, $p = 0.04$) and interval I–V (4.03 ± 0.20 vs 3.95 ± 0.17 ms, $p = 0.03$) when compared with control group. The negative linear correlation between diabetes duration and latency time of wave V ($p = 0.015$), intervals I–III ($p < 0.05$), III–V ($p = 0.03$), and I–V ($p = 0.002$) was revealed. No association between ABR and age or metabolic control was found.

Conclusion: The results of this study confirmed existence of subtle but significant hearing impairment in type 1 diabetic subjects. Both cochlear micromechanics, and central auditory pathway function are altered in diabetes. The

abnormalities in audiological evaluations can occur before development of diabetic microvascular complications, but the prognostic value of this finding remains unclear, due to lack of long-term prospective observations.

Fig. 1. Hearing threshold in diabetic and control groups (mean \pm SD)

Table 1. TEOAE amplitude and ABR responses in diabetic and control group

TEOAE amplitude in diabetic and control groups (dB) (mean \pm SD)

PS 123 Diabetic foot: pathogenetic mechanisms

1260

The involvement of insulin in skin complications under pathological conditions

H. Lederman¹, G. Weingarten¹, M. Hochberg², D. Enk², E. Wertheimer¹
¹Pathology, Tel Aviv University, ²Dermatology, Hadassah University Hospital, Jerusalem, Israel.

Background and aims: Maintaining skin integrity is essential for life. This is achieved by continuous skin cell proliferation, differentiation and programmed cell death. These processes are impaired in diabetes, leading to delayed wound healing that might result in limb amputations and even death. In our previous studies we have demonstrated that insulin directly regulates skin turnover, regulating skin proliferation and differentiation. Furthermore we have found that impaired insulin signaling leads to abnormal skin turnover. In the current work we investigated the effects of insulin and its downstream signaling on the additional process participating in skin turnover, skin apoptosis.

Materials and methods: We studied genetically manipulated primary skin epidermal cells which were genetically manipulated to under- or over-express various proteins involved in mediating insulin signaling, including insulin receptor (IR), insulin receptor substrates 1 and 2 (IRS-1 and IRS-2 respectively), PI-3-Kinase (PI3K) or Ras. Apoptosis was induced in these cells by UVB assault, and the effect of the genetic manipulations on induction of apoptosis was measured.

Results: We found that lack of IR caused a dramatic increase of keratinocyte cell death following UVB assault. We next studied the IRS family which play a role as docking proteins and are the first to be phosphorylated by the IR. Surprisingly, while manipulating IRS-2 expression had no significant effects on skin cell death, over-expression of IRS-1 resulted in a marked increase in the number of apoptotic skin cells after UVB irradiation. Lack of IRS-1 expression had no significant effect, perhaps due to redundancy between the members of the IRS family.

Over or under-expression of the downstream insulin signaling protein PI3K had no effect on keratinocytes apoptosis induced by UVB. In contrast, it was found that Ras, which mediates the signal to the Raf-MEK-MAPK cascade is involved in cell death after UVB. Over expression of constitutively active Ras caused a significant increase in apoptosis in response to cellular assault.

Conclusion: This data provides evidence that insulin signaling participates in programmed cell death in skin cells under pathological conditions. This signal in keratinocytes is mediated by IRS-1 via the Ras pathway. IR inactivation tilts the balance towards increased apoptosis, perhaps by delaying cell differentiation thus exposing the cells to a greater assault.

Unveiling the mechanism of insulin involvement in skin turnover is of major importance for our understanding of normal skin physiology and the process of skin wound healing and hopefully will lead to new insights on the pathogenesis of skin diseases.

1261

One of the possible pathogenetic mechanisms of foot problems in diabetic patients on dialysis therapy is haemodynamic changes during dialysis procedure

E.V. Bublik¹, G. Galstyan², G. Melnichenko¹, V. Safonov³

¹Endocrinology, Moscow Sechenov Medical Academy, ²Diabetic foot, National Research Centre of Endocrinology, ³Nephrology, Moscow Sechenov Medical Academy, Russian Federation

Background and aims: The cause of high prevalence of neuroischemic ulcers in diabetic patients on dialysis therapy is still not well understood. The aim is to study prevalence of diabetic foot complications in diabetic patients on dialysis therapy and evaluate the role of the haemodynamic changes during dialysis procedure on arterial blood flow in lower extremities.

Materials and methods: We studied 109 dialysis patients. Follow-up period - 18 months. Mean age 49 years. 60 had diabetes mellitus (29 on haemodialysis, 31 on peritoneal dialysis) and 49 were non-diabetic patients (matched by sex, age and dialysis duration to diabetic group) (24 on haemodialysis, 25 on peritoneal dialysis). Mean duration of diabetes was 24 years; 60% of patients had type 2 diabetes. Distal polyneuropathy was diagnosed according

to Neurological Disability Score. Vascular status was assessed by Doppler and toe pressure measurements. Criteria of transient intradialysis hypotension is increasing of systolic BP more than 30 mmHg more than 10 cases during 10 months). We monitored systolic BP in brachial, ankle and toe arteries during dialysis procedure.

Results: Peripheral Vascular Disease - 26,6% (17/60) in diabetic group and 4% (2/49) in non-diabetic group. Ulcers were diagnosed in diabetic patients only - 13,3% (8/60) (5 of them were neuroischemic). The number of patients with neuroischemic ulcers had increased after starting dialysis therapy and it was statistically significant in haemodialysis group only ($p=0,023$, $\chi^2=4,17$). The possible explanation is changes in BP during dialysis procedure. Changes in BP were significant during haemodialysis procedure only. The lowest systolic BP in brachial, ankle and toe arteries was registered in the middle of haemodialysis procedure. In this point decreasing of BP (%) was the most strongly pronounced in toe than in brachial and ankle arteries (19% vs 8,4% vs 4,7%). The intradialysis hypotension is the most clinically significant decrease in systolic BP. Among patients with Peripheral Vascular Diseases the neuroischemic ulcers were frequently diagnosed in the group with intradialysis hypotension than without ($p=0,001$).

Conclusion: Prevalence of neuroischemic ulcers increases after starting of haemodialysis. It may be due to decrease in systolic BP in brachial, ankle and toe arteries during haemodialysis procedure. Evident decrease of BP might induce or make worse limb ischemia especially in diabetic patients with Peripheral Vascular Disease.

1262

Connexin mimetic peptide Gap27 accelerates wound healing in ex-vivo wound healing models, enhances the proliferation and migration of human fibroblasts and keratinocytes but has no effect on the migration of human keratinocytes from diabetic origin

R. Lobmann^{1,2}, S. Pollok³, A. Pfeiffer³, P. Houdek³, I. Moll³, J.M. Brandner³

¹Endocrinology and Metabolism, University Hospital of Magdeburg,

²Endocrinology, Diabetology and Geriatrics, General Hospital Stuttgart,

³Dermatology and Venerology, University Hospital Hamburg-Eppendorf, Germany

Background and aims: Connexins are transmembrane proteins that form Gap Junctions (GJ), communicating channels that allow the exchange of small molecules between adjacent cells. GJ are important for migration, differentiation and proliferation of cells. Connexin 43 (Cx43) has been shown to be ubiquitously expressed in human epidermis and to be downregulated during early wound healing at the wound margins and in regenerating epidermis. The fact that Cx43 is still present at the margins of chronic wounds implicates that the downregulation is important for an effective wound closure. Phosphorylation of Cx43 on serine368 (S368) has been shown to decrease gap junctional intercellular communication (GJIC).

Materials and methods: For the evaluation of Cx43 phosphorylation in the course of wound healing and of the influence of inhibition of Cx43 by a mimetic peptide (Gap 27) our well established porcine ex-vivo wound healing model was used. Cell migration was investigated by life cell imaging of cultured human keratinocytes and fibroblasts

Results: We could observe an even distribution of pS368 throughout the epidermal layers of native porcine skin. After wounding, pS368 was downregulated in parallel to Cx43. To further elucidate the role of Cx43 we investigated the influence of a Cx43 mimetic peptide (Gap27) which results in a disruption of GJIC. Treatment of porcine ex-vivo wound healing models with Gap27 resulted in a significantly accelerated wound healing compared to the controls. The treated models showed a higher number of proliferative keratinocytes in the regenerating epidermis and at the wound margins. No difference concerning Cx43 phosphorylation (pS368) was observed. Confluent keratinocyte and fibroblast cultures that were treated with Gap27 prior to a scratch wound assay showed an enhanced migration that resulted in a faster wound closure. Interestingly, Gap27 treatment had no effect on the migration of human keratinocytes from diabetic origin.

Conclusion: These data suggest a different influence of Gap27 on wound healing in diabetic and non-diabetic keratinocytes.

Stabilisation of HIF-1 alpha is sufficient to reverse the negative effect of hyperglycaemia on HIF function and to markedly improve wound healing in diabetic mice

S.-B. Catrina¹, I. Botusan¹, V.G. Sunkari¹, O. Savu^{1,2}, A. Catrina³, J. Grünler¹, S. Lindberg¹, T. Pereira⁴, L. Poellinger⁴, K. Brismar¹

¹Molecular Medicine and Surgery, Karolinska Institute, Stockholm, Sweden, ²National Institute for Diabetes "C. Paulescu", Bucharest, Romania, ³Rheumatology, Karolinska Institute, Stockholm, Sweden, ⁴Cellular and Molecular Biology, Karolinska Institute, Stockholm, Sweden

Background and aims: Hypoxia is essential in wound healing since it plays a pivotal role in regulation of all the critical processes involved in tissue repair, i.e. cell motility, recruitment of circulating angiogenic cells, and angiogenesis. Hypoxia inducible factor alpha (HIF-1alpha) is the critical transcription factor that regulates the adaptive responses to hypoxia. HIF-1alpha stability and function is regulated by oxygen-dependent soluble hydroxylase enzymes targeting critical proline and aspariginyl residues in two different transactivation domains. We and others showed that hyperglycemia complexly affects both HIF-1alpha stability and activation.

We proposed to further investigate the mechanisms which lie behind the repressive effect of hyperglycemia on HIF function and their consequence on diabetic wound healing.

Materials and methods: The effect of the different oxygen-dependent hydroxylase inhibitors on the HIF-1alpha stability and their effect on HIF critical target genes was studied in primary mouse fibroblasts by western blot, reporter gene, QRT-PCR. Transient transfections using Gal4-reporter system together with constitutively or siRNA induced VHL deficient cells were used for studying the molecular mechanisms of the HIF repression in hyperglycemia. Gain of function studies with different adenovirus carried HIF constructs were performed in a wound model in db/db mice.

Results: Hyperglycemia affects by a VHL dependent mechanism HIF stability and modulates both its transactivation domains. Consecutively it suppresses expression of HIF-1 target genes essential for wound healing both in vitro and in vivo. However, by blocking HIF-1alpha hydroxylation through chemical inhibition it is possible to reverse this negative regulatory effect of hyperglycemia and to improve the wound healing process (granulation, vascularisation, epidermal regeneration, and recruitment of endothelial precursors). Local adenovirus-mediated transfer of two stable HIF constructs demonstrated that stabilisation of HIF-1alpha is necessary and sufficient for promoting wound healing in a diabetic environment. Our findings outline the necessity to develop specific hydroxylase inhibitors as therapeutic agents for chronic diabetes wounds.

Conclusion: We demonstrate for the first time that negative regulation of HIF-1alpha is essential for development of diabetic wounds and we provide mechanistic rationale that stabilization of HIF-1alpha is sufficient to reverse the pathological process.

High glucose causes direct impairment of cellular activities associated with wound healing

E. Yefet, G. Weingarten, E. Wertheimer

Pathology, Sackler Faculty of Medicine Tel Aviv University, Israel

Background and aims: Diabetes mellitus is one of the most severe metabolic diseases affecting people worldwide. One major complication of diabetes mellitus is impaired wound healing leading to amputations and even death. Therefore, it is crucial to understand the mechanisms which are involved in the pathogenesis of this complication. In the present study we examined how the high glucose affects cellular activities that participate in the wound healing process.

Materials and methods: The studies were carried on primary skin epidermal keratinocytes, which are central players in the wound healing process. We chose to focus on keratinocytes adhesion due to its important role in the wound healing process. In addition, we explored some of the molecular pathways involved in adhesion. Finally, we examined whether glucose has any effect on skin organization in a three dimensional skin co-culture model. This model allowed us to examine skin organization and differentiation in conditions that are in close proximity to those of the whole animal.

Results: The results demonstrate that high glucose has a negative effect on keratinocytes adhesion when both cells were pre-incubated and extracellular matrix (ECM) was produced in high glucose. Adhesion is also decreased when cells were plated onto ECM produced by cells grown in high glucose. Moreover, adhesion is also decreased when cells were plated on ECM proteins-collagen, laminin and fibronectin that were directly exposed to high glucose environment. This last finding is suggestive of a possible direct reaction between glucose and those ECM proteins. On the other hand, cells that were pre-incubated in high glucose attached more rapidly to the various ECM proteins surfaces. Molecular analysis of cells-ECM interactions has demonstrated that in ECM produced under high glucose there was a lower expression of laminin 5, but a higher expression of integrin alpha 3 - the receptor for laminin, collagen and fibronectin. These changes could explain the results in keratinocytes adhesion. Our studies further showed that insulin increases keratinocytes attachment ability, but only in the control group and not in the high glucose environment, suggesting that under conditions of hyperglycemia, insulin effects on cell adhesion is impaired. Finally, we followed skin organization using the 3D skin organotypic coculture. Our results demonstrated that high glucose leads to abnormal skin organization that includes abnormal epidermal appearance, several dividing layers instead of only one and thinner suprabasal layers.

Conclusion: In summary, our results demonstrate that high glucose might cause direct impairment in wound healing process regardless of secondary impairment due to neuropathy and angiopathy that were previously described. Therefore, new therapeutic approaches for diabetes should focus on the pathophysiology of the skin.

1265

Serum proinflammatory cytokines TNF-alpha and IL-6 are raised in acute Charcot osteoarthropathy and correlate with a marker of bone resorption

M. Edmonds¹, T. Dew², R. Musto², S. Thomson², R. Sherwood², C. Moniz², N. Petrova¹

¹Diabetic Foot Clinic, King's College Hospital NHS Foundation Trust, London, ²Department of Clinical Biochemistry, King's College Hospital NHS Foundation Trust, London, United Kingdom

Background and aims: The Charcot foot is characterised by severe inflammation but its role in pathogenesis is poorly understood. The aim of this study was to investigate serum proinflammatory cytokines and bone turnover in acute Charcot osteoarthropathy.

Materials and methods: We studied 3 groups of patients: 27 presenting with acute Charcot osteoarthropathy, 14 with chronic Charcot osteoarthropathy and 24 diabetic control patients. We measured markers of inflammation, namely serum proinflammatory cytokines, tumour necrosis factor-alpha (TNF-alpha) and interleukin-6 (IL-6), as well as serum high sensitivity C-reactive protein (hsCRP) - an acute phase protein, in the three groups of patients. We also measured serum C-telopeptide of type I collagen (CTX), a marker of bone resorption, serum bone specific alkaline phosphatase (BAP), a marker of bone formation and serum osteoprotegerin (OPG), a cytokine that modulates bone resorption and osteoclastic activity.

Results: In acute Charcot patients, there was a significant increase in the serum levels of IL-6 (3.8 ± 3.6 pg/ml) compared with chronic Charcot patients (1.7 ± 1.2 pg/ml) and diabetic controls (1.9 ± 1.5 pg/ml), $p=0.025$. Furthermore, there was a significant rise in serum TNF-alpha in acute Charcot patients (1.7 ± 0.9 pg/ml) compared with chronic Charcot patients (1.3 ± 0.4 pg/ml) and diabetic control patients (1.1 ± 0.4 pg/ml), $p=0.008$. Similarly, serum hsCRP was significantly increased in acute Charcot patients (10.1 ± 13.4 mg/l) compared with chronic Charcot patients (2.6 ± 2.2 mg/l) and diabetic control patients (4.8 ± 4.3 mg/l), $p=0.013$. Serum CTX, a breakdown product of type I collagen, was significantly raised in patients with acute Charcot foot (0.41 ± 0.39 ng/ml), compared with patients with chronic Charcot foot (0.10 ± 0.04 ng/ml) and diabetic patients (0.11 ± 0.68 ng/ml), $p=0.001$. Serum BAP was also significantly raised in acute Charcot patients (18.5 ± 9.2 µg/L) compared with chronic Charcot patients (12.7 ± 4.4 µg/L) and diabetic controls (14.7 ± 5.1 µg/L), $p=0.041$. Serum OPG was significantly raised in acute Charcot patients (5.5 ± 1.7 pmol/l) compared with chronic Charcot patients (4.9 ± 1.4 pmol/l) and diabetic patients (4.4 ± 1.4 pmol/l), $p=0.048$. Serum CTX was significantly correlated with serum IL-6 ($r=0.472$, $p<0.001$) and with serum TNF-alpha ($r=0.556$, $p<0.001$). Similarly, serum CTX was significantly correlated with serum hsCRP ($r=0.561$, $p<0.001$).

Conclusion: This study has shown that the proinflammatory cytokines, TNF-alpha and IL-6, as well as hsCRP are raised in acute Charcot osteoarthropathy

and are significantly associated with CTx. These findings indicate that inflammation may play an important role in the pathological bone resorption of the acute Charcot foot.

1266

Increased percentage of CD14+ monocytes in acute Charcot osteoarthropathy

N.L. Petrova¹, M. Edmonds¹, A. Sabokbar², G. Mabilieu²

¹King's College Hospital NHS Foundation Trust, Diabetic Foot Clinic, London, ²University of Oxford, Botnar Research Centre, Oxford, United Kingdom

Background and aims: Recently, we have demonstrated that osteoclasts generated *in vitro* from patients with acute Charcot osteoarthropathy were functionally more aggressive and exhibited a considerable increase in the extent of their resorbing activity in response to the cytokine receptor activator of nuclear factor κ B ligand (RANKL). It is possible that this increased osteoclastic activity may be a result of a relative increase in the proportion of CD14+ monocytes (osteoclast precursors) in peripheral blood mononuclear cells (PBMCs). Thus the aim of this study was to measure the percentage of CD14+ monocytes in acute Charcot osteoarthropathy.

Materials and methods: We studied 11 diabetic patients with recent onset of acute Charcot osteoarthropathy and these were matched for age, gender and type of diabetes with 10 diabetic patients with no previous history of Charcot osteoarthropathy. We also studied 6 aged and sex-matched healthy controls. Peripheral blood mononuclear cells were isolated from EDTA treated whole blood and were labelled with an anti-CD14 monoclonal antibody labelled with phycoerythrin. Data was acquired using FACSCalibur-BD and analysed by CellQuest software.

Results: The mean percentage of CD14+ monocytes in PBMCs was significantly greater in the patients with acute Charcot osteoarthropathy (8.7 ± 3.4 %) compared with diabetic patients (5.2 ± 3.3 %) and healthy controls (4.0 ± 2.5 %), ($p=0.013$). Furthermore, the percentage of CD14+ monocytes in acute Charcot osteoarthropathy was 1.7 times and 2.1 times greater when compared with the percentage in diabetic patients ($p=0.028$) and healthy controls ($p=0.009$).

Conclusion: This study has shown that in acute Charcot osteoarthropathy there is a relative increase in the percentage of CD14+ monocytes, acting as osteoclast precursors, and these findings may explain the increased bone resorption of the acute Charcot foot.

PS 124 Diabetic foot: assessment

1267

Evaluation of a laser Doppler device O2C[®] for the measurement of microvascular skin blood flow and skin oxygenation in diabetic and non-diabetic subjects

C. Hohberg¹, E. Tarakci¹, S. Forst¹, A. Pfützner¹, T. Forst^{1,2}

¹Medical, Institute for Clinical Research and Development, ²Endocrinology, Johannes Gutenberg University, Mainz, Germany

Background and aims: Laserdopplerfluxmetry of skin capillary blood flow is an important feature for the evaluation of microvascular function in patients with diabetes mellitus. This study was done to evaluate a new device for the measurement of skin microvascular function and Hb oxygenation.

Materials and methods: Twenty non-diabetic subjects (age 46.6 ± 14.8 years; mean \pm SD) and twenty diabetic patients (age 59.4 ± 8.4 years) participated in two repeated microvascular measurements using micro-lightguide spectrophotometry (O2C; LEA Medizintechnik, Giessen, Germany). This technique allows simultaneous, non-invasive measurement of microvascular blood flow by laserdopplerfluxmetry (LDF) and the Hb oxygenation (SO₂) at the same anatomical area. A skin probe was placed on non-hairy skin at the hypotenar side of the left hand for the measurement of SO₂, and the postischaemic microvascular response was measured in two different laser penetration depths of 2 mm (LDF_{skin}) and 8 mm (LDF_{muscle}).

Results: As shown in the table a high correlation could be observed between the repeated measurements of LDF_{skin}, LDF_{muscle} and SO₂ in non-diabetic and in diabetic subjects. The coefficient of variation for repeated measurements were found at 15.0 ± 19.6 % for LDF_{skin}, 7.5 ± 5.6 % for LDF_{muscle}, and 43.4 ± 73.8 % for SO₂ in non-diabetic patients and at 18.2 ± 19.9 % for LDF_{skin}, 7.9 ± 9.1 % for LDF_{muscle}, and 34.2 ± 46.7 % for SO₂ in diabetic patients.

Conclusion: Lightguide spectrophotometry is an easy, non-invasive and reliable method for the measurement of superficial microvascular blood flow and Hb oxygenation in non-diabetic and in diabetic subjects. Further studies are required to clarify the pathology of these measures in diabetic populations with specific complications like diabetic microangiopathy or neuropathy.

Correlation of repeated measurements

		Coefficient of correlation (r)	Significance (p)
Control	LDF _{skin}	0.97	< 0.0001
Control	LDF _{muscle}	0.93	< 0.0001
Control	SO ₂	0.74	= 0.0002
Diabetic	LDF _{skin}	0.95	< 0.0001
Diabetic	LDF _{muscle}	0.89	< 0.0001
Diabetic	SO ₂	0.93	< 0.0001

Increased QT time is associated with mortality in patients with diabetes mellitus, foot ulcer and lower extremity arterial disease

M. Löndahl¹, C. Johansson², P. Katzman¹

¹Department of Endocrinology, Lund University Hospital, Lund,

²Department of Anesthesiology, Helsingborg Hospital, Helsingborg, Sweden

Background and aims: Long QT-time as well is known risk factors for mortality in patients with or without diabetes mellitus. The magnitude of long QT-time as a risk factor for mortality in a high risk population such as diabetic patients with lower extremity arterial disease and foot ulcer is however unknown. The aim of this study was to evaluate the significance of increased QT-time on long-term mortality in patients with diabetes and arterial disease in the lower limb.

Materials and methods: A retrospective chart study was performed including all patients with a foot ulcer and critical ischemia visiting the Diabetic Foot Clinic during one year. Peripheral ischemia was defined as previous performed vascular surgery including PTA, or present systolic arterial toe blood pressure below 50 mm Hg. Patients were divided into groups according to QTc-time < or \geq 440 ms.

Results: 102 patients (64 M / 38 F, 22 with type 1 diabetes / 80 with type 2 diabetes) were included. Hypertension was seen in 86 patients and a history of myocardial infarction was present in 36 patients. QTc was < 440 ms in 61 patients and \geq 440 ms in 41. The 6-year mortality rate was significantly higher in the group of patients with longer QTc ($p<0.0001$, figure 1).

Conclusion: Even in a high risk population as diabetic patients with foot ulcer and lower extremity arterial disease QTc-time seems to be a significant additional risk factor for long-term mortality.

An evaluation of the accuracy and usability of a novel optical wound measurement system

F.L. Bowling¹, L.D. King², J.A. Paterson³, H. Fadavi¹, R.W. Daniel⁴, D.R. Matthews⁵, A.J.M. Boulton¹

¹Dept of Diabetes and Endocrinology, University of Manchester,

²Diabetic Foot Clinic, Oxford Centre for Diabetes, Endocrinology and Metabolism, ³Wound Imaging Group, Eykona Technologies Ltd, Oxford,

⁴Dept of Engineering, University of Oxford, ⁵Oxford Centre for Diabetes, Endocrinology and Metabolism, University of Oxford, United Kingdom

Background and aims: We present initial results from a novel optical wound imaging system which may be beneficial to remote diagnosis and telemedicine.

Materials and methods: Accuracy and performance of a prototype imaging system was evaluated in a two-centre study. 36 foot ulcers from 31 patients (age 45–93) were inspected across 12 weeks. 25 ulcers were reviewed at consecutive visits, resulting in a total of 76 wound inspections. Mean ulcer size was $1097 \pm 1094 \text{ mm}^2$. Digital Elliptical Measurement (DEM) and hand-measured Elliptical Measurement (EM) were taken. Image processing produced calibrated-colour three-dimensional (3D) models of the ulcers and surrounding region. Off-line DEM was then performed on the 3D models using interactive tools. Absolute system accuracy was estimated by imaging a fabricated wound of known-size from five viewpoints and performing six independent sessions of Digital Area Measurement (DAM). Repeatability of DEM was estimated by repeating digital measurement five times on six representative wounds and observing variation.

Results: Pearson, Spearman and Kendall correlations between Length, Width and Elliptical Area measurement of DEM under clinician control against traditional hand-measured EM are presented in Table 1. In all cases $P < 0.001$ ($N = 76$).

Table 1 - Correlation of DEM to EM measurement

Measurement	Pearson	Spearman	Kendall	Min Error	Max Error
Length	0.958	0.922	0.801	0.01mm	14.95mm
Width	0.948	0.906	0.755	0.02mm	14.96mm
Elliptical Area	0.961	0.929	0.791	0.51mm ²	886.7mm ²

DAM consisted of marking the boundary in the 3D model allowing an area (mm²) to be calculated. Variation from the standard known-size wound area was <8% across 30 trials. Intra-observer variation of wound Length and Width using DEM gave a coefficient of variation of <3%. 3D wound images are ideal for electronic transmission and can provide reliable monitoring of wounds over time.

Conclusion: Correlation of DEM against traditional EM was excellent. Side tests into absolute accuracy (DAM) and measurement repeatability (DEM)

are promising. Early clinician feedback and empirical results suggest this has great potential due to simplicity and speed of use in clinical settings. The interactive 3D images are particularly appropriate for telemedicine and remote diagnosis.

1270

CRP as a marker for infection in diabetic foot ulcers

P.L.H. van Battum, L. Prompers, N.C. Schaper, M.S.P. Huijberts

Medicine, Division of Endocrinology, Maastricht University Medical Center, Netherlands

Introduction: Diabetic foot disease is a feared complication of diabetes and is often accompanied by infection. Infection in diabetic foot disease can be limb threatening and is the main reason for (major) amputation. However, classical clinical signs of infection often lack in this situation and markers of infection like c-reactive protein (CRP) may be of additional value. The aim of this study was to investigate whether CRP is a reliable marker of infection and/or its severity in patients with diabetic foot ulcers.

Methods and patients: In the Eurodiale study, a prospective cohort study of 1232 patients presenting with a new diabetic foot ulcer, patients were followed on a monthly basis until healing, death, major amputation or up to a maximum of 1 year. Ulcers were treated according to international guidelines. The presence of infection was defined according to the PEDIS classification and the clinical impression of the treating physician.

Results: In 669 subjects data were obtained on both PEDIS classification and CRP. In patients with infection ($n = 416$) CRP was normal in 33%, elevated < 3 x the upper limit of normal (ULN) in 23% and > 3 x ULN in 44%. In patients without infection these numbers were: 58%, 22% and 20% respectively. The positive predictive value (PPV) and negative predictive value (NPV) for CRP were 72.4% and 51.6% respectively.

In patients with limb threatening infection according to the clinician ($n = 106$) CRP was normal in 24%, < 3 x ULN in 20% and > 3 x ULN in 56%. The PPV and NPV of CRP for the diagnosis of limb threatening infection were 31.9% and 90.9% respectively. In case of osteomyelitis (diagnosed by X-ray) ($n = 144$) CRP was normal in 27%, < 3 x ULN in 26% and > 3 x ULN in 47%. The PPV and NPV of CRP were 39.6% and 85.2% respectively.

Conclusion: CRP is a poor diagnostic marker for the presence of infection, moreover CRP seems not to be of additional value in separating mild from severe infection. These data suggest that for the diagnosis of infection, and its severity, the clinician has to rely on clinical examination and, if necessary, imaging procedures.

1271

Health status and quality of life of patients affected by Charcot neuroarthropathy

L. Vileikyte¹, J.S. Gonzalez², M. Peyrot^{3,4}, J.S. Ulbrecht⁵, R.R. Rubin⁴, A.P. Garrow¹, P.R. Cavanagh⁵, A.J.M. Boulton¹

¹Medicine, University of Manchester, Manchester, United Kingdom,

²Psychiatry, Harvard Medical School, Boston, United States, ³Sociology,

Loyola College, Baltimore, United States, ⁴Medicine, Johns Hopkins

University, Baltimore, United States, ⁵Medicine, Pen State University,

State College, United States, ⁶Diabetic Foot Clinic, The Cleveland Clinic, Cleveland, United States

Background and aims: While it is recognized that Charcot Neuroarthropathy (CN) is associated with high ulceration and amputation rates, little is known about the impact of CN on an individual's health status and quality of life (QoL).

Materials and methods: This UK and USA study of 489 high-risk patients for neuropathic foot ulceration (71% male; mean age 62years; 71% type 2 DM, diabetes duration 17years; 16% active ulcers; 36% past ulceration) identified 67 patients who were diagnosed both clinically and radiologically with mid-foot deformity characteristic of CN. Patient-reported measures of health status and QoL included - both generic (SF-12 and Hospital Anxiety and Depression Scale, HADS) and foot problem-specific (NeuroQoL) instruments. Neuropathy severity was assessed by the Neuropathy Disability Score (NDS) and the Vibration Perception Threshold (VPT).

Results: Compared to high-risk patients with no CN, the CN patients were younger (59 vs 62 years, $p = .04$), reported more co-morbidities (1.3 vs 0.9, $p < .001$), had more severe neuropathy (NDS: 8.6 vs 7.2, $p < .001$; VPT: 47 vs 40 volts, $p < .001$) and more past (84% vs 36%, $p < .001$) and active foot ulceration

(40% vs 16%, $p<.001$). Further, CN patients reported more severe NeuroQoL symptoms of reduced feeling (3.8 vs 2.7, $p<.001$) and unsteadiness (2.8 vs 2.3; $p=.007$); more impaired activities of daily living, NeuroQoL-ADL (3.2 vs 2.4; $p<.001$); and more NeuroQoL-emotional burden (2.8 vs 2.0; $p<.001$). However, no differences in symptoms of pain, anxiety or depression were observed between those with and without CN. In multivariate regression analyses, controlling for disease, demographic characteristics, neuropathy severity and active foot ulceration, CN was a significant independent predictor of NeuroQoL-emotional burden ($\beta=.10$, $p<.05$), poorer foot problem-related QoL ($\beta=.17$, $p<.001$) and diminished SF12 physical functioning ($\beta=-.08$, $p<.05$), but not mental functioning. Furthermore, no significant association was found between CN and HADS-depression or anxiety.

Conclusion: These data illustrate the detrimental effect Charcot Neuroarthropathy has on individuals' functioning, as indicated by generic and condition-specific measures. However, only condition-specific measures were able to identify emotional effects. The latter finding emphasizes the importance of condition-specific measures when assessing the emotional state of patients with CN.

Successful conservative management of forefoot osteomyelitis in diabetes using magnetic resonance imaging to establish diagnosis and determine antibiotic duration

J. Valabhji¹, N. Oliver¹, D. Samarasinghe², L. Bloomfield³, T. Mali³, D. Hogg⁴, W.M.W. Gedroyc⁵, N.J.W. Cheshire⁶, R.G.J. Gibbs⁶

¹Department of Endocrinology, ²Department of Microbiology, ³Department of Podiatry, ⁴Department of Orthotics, ⁵Department of Radiology, ⁶Department of Vascular Surgery, Imperial College Healthcare NHS Trust, London, United Kingdom

Background and aims: To assess the effectiveness over 5 years of a clinical algorithm for the conservative management in diabetes of forefoot osteomyelitis diagnosed by magnetic resonance imaging (MRI), in which interval MRI was used to determine antibiotic duration.

Materials and methods: Subjects presenting with neuropathic forefoot ulcers and MRI suggesting associated osteomyelitis were treated for a minimum 3 months with augmentin (clindamycin and ciprofloxacin if penicillin allergic; rifampicin and doxycycline if known methicillin-resistant staphylococcus aureus carriage). Antibiotics were modified if isolates were resistant. MRI was repeated at 3 months: if the lesion had healed with resolution of, or significant improvement in, underlying bone signal change, then antibiotics were discontinued. If healing had not yet been achieved or if there was no significant improvement in underlying bone signal change on MRI, then antibiotics were continued for a further 3-month cycle with interval MRI. If there was clinical or radiological deterioration, endoluminal or open vascular surgical intervention was undertaken where appropriate, or the subject underwent digital or more proximal amputation.

Results: Thirty-one out of 42 episodes of forefoot osteomyelitis in 36 subjects were treated successfully without amputation (74%). A second episode in the same subject was at an anatomically distant site. Median (range) duration of antibiotics was 15 (3–48) months. Of the 11 episodes in which treatment failed, 8 deteriorated on treatment, and 3 relapsed at 2, 17 and 39 months post-cessation of antibiotics. Of the 36 subjects (mean (standard deviation) age 64 (13) years, duration of diabetes 16 (11) years and HbA1c 8.3 (1.8) %; 5 with Type 1 diabetes), all had clinical evidence of a peripheral neuropathy; 89% had retinopathy; 47% had chronic kidney disease at stages 3, 4 or 5 (equivalent to a glomerular filtration rate less than 30 ml/min). Staphylococcus aureus was identified in 27 episodes, 6 of which were methicillin resistant and beta-haemolytic streptococcus in 9; other isolates included coliforms, proteus and enterococcus. Age, HbA1c, renal function and presence of peripheral vascular disease were not significant predictors of successful outcome. Three subjects died at 12, 22 and 28 months post-cessation of antibiotics of cardiovascular disease without foot lesions at time of death.

Conclusion: The clinical algorithm for the conservative management of forefoot osteomyelitis in diabetes successfully avoided any form of amputation in 74% of subjects. Determination of antibiotic duration using interval MRI may have contributed to the low rate of relapse.

PS 125 Diabetic foot: treatment

1273

Safety and effectiveness of a novel super-oxidized solution (sos) in managing post-surgical lesions of the diabetic foot: a prospective, randomized clinical trial

C. Goretti, S. Mazzurco, A. Scatena, A. Tedeschi, L. Rizzo, A. Piaggese
Department of Endocrinology and Metabolism, University of Pisa, Italy

Background and aims: To evaluate the efficacy and safety of SOS (Dermacyn[®], Oculus Innovative Sciences, Petaluma, CA) in the management of infected lesions of the diabetic foot after surgical debridement.

Materials and methods: 40 patients with surgical outcomes > 5 cm² on account of an infected foot lesion, an ankle-brachial pressure index ≥ 0.9 and the presence of at least two arteries in the ankle documented by palpable pulses or Doppler CW have been randomized to receive local SOS treatment (Group A, n. 20) or standard local treatment with povidone iodine (Group B, n. 20) in addition to metabolic control, systemic antibiotics and off loading, as necessary. At baseline and at weekly control visits area of lesions, clinical signs of infection, microbiological sampling eventual new debridement procedures and adverse events were recorded blindly to the local treatment. Endpoints at week 24 included healing rate (HR), healing time (HT), time for sterilization of the lesions (ST), number of debridement procedures (ND) and number of adverse events (NA).

Results: 85% of Group A patients healed in 24 weeks compared to 53% of group B ones ($p<.01$); HT was 10.5 ± 1.3 wks in Group A vs 16.5 ± 1.7 wks in Group B ($p<.01$), ST was 5.5 ± 2.1 wks in Group A compared to 16.2 ± 6.6 wks in Group B ($p<.01$), ND were carried out in 3 patients of group A and in 9 of group B ($p<.05$), no differences were observed in NA (4 in group A vs 9 in Group B).

Conclusion: SOS local treatment proved to be as safe as and more effective than diluted povidone iodine in the management of wide post-surgical infected lesions of the diabetic foot left to heal for secondary intent.

1274

Physical and psychological determinants of adherence to foot care in patients at high risk for ulceration

J.S. Gonzalez^{1,2}, L. Vileikyte³, M. Peyrot^{4,5}, R.R. Rubin⁵, J. Ulbrecht⁶, P.R. Cavanagh⁷, A.J. Boulton³

¹Psychiatry, Harvard Medical School, Boston, United States, ²Psychiatry, Massachusetts General Hospital, Boston, United States, ³Manchester Diabetes Centre, University of Manchester, United Kingdom, ⁴Sociology, Loyola College, Baltimore, United States, ⁵Johns Hopkins University, Baltimore, United States, ⁶Pen State University, State College, United States, ⁷Diabetic Foot Clinic, The Cleveland Clinic, Cleveland, United States

Background and aims: Educational interventions to enhance preventive foot care (PFC) have met with limited success, and factors shaping PFC are seldom addressed.

Materials and methods: This cross-sectional study of 376 UK and US patients with diabetic neuropathy (DN) (67% male, 76% type 2 diabetes, 25% with past foot ulceration (PFU), mean Vibration Perception Threshold (VPT) 40 volts) employed hierarchical multivariate regression analyses to examine the relationships between objective DN severity (VPT, PFU), subjective DN severity (NeuroQoL-symptoms of pain and reduced feeling), psychological factors (personality: Big Five Inventory, BFI- conscientiousness; Hospital Anxiety and Depression, HADS-depression scale; Patient Interpretation of Neuropathy instrument (PIN) assessing DN-specific cognitions and emotions), and 9-item PFC scale, based on ADA guidelines (Cronbach's alpha =.58).

Results: After controlling for demographic and disease variables, independent predictors of better PFC in the total sample were: PFU ($\beta=.22$; $p<.001$); VPT ($\beta=-.10$; $p=.044$); NeuroQoL-pain ($\beta=.15$; $p=.008$); BFI-conscientiousness ($\beta=.17$; $p<.001$); and PIN measures - understanding of foot ulcer causes ($\beta=.10$; $p=.03$) and anticipated consequences ($\beta=.09$; $p=.037$). While PIN-anger at health care providers was associated with less PFC ($\beta=-.13$; $p=.004$), the relationship between HADS-depression and PFC was non-significant. The total model accounted for 36% of variance in PFC with psychological factors accounting for 9% of incremental variance. There were more predictors of PFC in patients without PFU than in those with PFU. Specifically, in

those without PFU, DN severity (VPT: $\beta=1.3$; $p=.021$), BFI-conscientiousness ($\beta=.19$; $p=.001$), PIN-anticipated consequences ($\beta=.13$; $p=.02$) and PIN-foot ulcer unpredictability beliefs ($\beta=.12$; $p=.03$) were predictive of better PFC. In contrast, in patients with PFU only PIN-anger at health care providers ($\beta=-.27$; $p=.013$) was predictive of less PFC.

Conclusion: These data suggest that although PFU is the strongest independent predictor of PFC, psychological factors such as personality, DN-specific cognitions and emotions are also important determinants of PFC and should be addressed when designing future interventions. In addition, addressing psychological factors prior to developing foot ulcers would seem to be more effective than addressing them after a foot ulcer has developed.

MRSA infection can be reduced in diabetic foot clinic

S. Neupane¹, S.T. Lo¹, A. Arosi¹, D. Orr², S.M. Rajbhandari¹

¹Diabetes Dept, ²Microbiology Dept, Lancashire Teaching Hospital, Chorley, United Kingdom

Background and aims: MRSA infection is common in diabetic foot ulcer and is associated with increased morbidity and mortality. In our previous audit in 2002 the prevalence of MRSA was 33.3% so we implemented changes such as active screening for MRSA from foot wound, restrict the use of antibiotics only in clinically infected cases and developed close liaison with microbiologist on choice of antibiotics. In addition we also used disposable gloves and apron and washed hand with alcohol gel after each patient contact in foot clinic. The aim of this audit was to study if these measures reduced the prevalence of MRSA. The secondary aim was to evaluate outcome of these patients and their foot ulcers.

Materials and methods: This was a retrospective re-audit conducted on patients attending foot clinic between January 2006 to December 2007. The list of subjects attending foot clinic in 2 local hospitals was obtained from clinical coding department. Their clinical, biochemical and microbiology record were studied and relevant information was collected.

Results: We found that the overall prevalence of MRSA has reduced from 33.3% in 2002 to 15% of subjects with ulcers and to 18.7% of total positive cultures by 2006/07. Of the 133 patients with foot ulcers seen in 2006/07, 19 did not have diabetes and were excluded from further analysis. Of the remaining 114 subjects (71 male & 16 type 1 DM), MRSA was isolated from 19 (14.3%) subjects. There were no difference in age, sex, type of diabetes, HbA1c, presence of cardiovascular disease, serum creatinine and total cholesterol between subjects with and without MRSA. Serum albumin was significantly lower in subjects with MRSA (39.6 ± 6.4 vs 32.9 ± 8.6 gm/L; $p < 0.001$). We found that only 42.9% of ulcers with MRSA infection healed by 6 months in comparison to 80.9% of ulcers without MRSA infection ($p < 0.05$). There was higher overall mortality (31.6% vs 11.6%; $p < 0.05$) and amputation (35.7% vs 11.3%; $p < 0.05$) in subjects with MRSA infection.

Conclusion: Our observation shows that incidence of MRSA can be reduced in foot clinic with strict hygiene but its presence is still associated with higher morbidity and mortality.

1276

A structured follow-up reduces the incidence of ulcerative recurrences in high risk diabetic foot patients: a prospective study

A. Piaggese, L. Rizzo, E. Fallani, A. Tedeschi, S. Del Prato

Department of Endocrinology and Metabolism, University of Pisa, Italy

Background and aims: A retrospective analysis showed an incidence of foot ulceration in high risk patients of our clinic of 39.7 % in one year, 60.6 % in three years and 70% in five years. We did this study to test if a structured follow-up program would be effective in reducing the incidence of ulceration in high risk patients.

Materials and methods: All patients presenting at our clinic for the prevention of lower limb complication were screened for ulcerative risk according to the score proposed by the International Consensus on Diabetic foot. All patients with a score ≥ 2 received, as a part of a structured prevention program, custom orthosis and shoes, in relation with the severity of their risk condition according to the protocol described by Dahmen et al. Patients were then followed for the incidence of ulceration for one year. A subset of patients was followed up for three and five years.

Results: 1423 patients were screened for ulceration risk in 2002 and among them 226 (15.9%) were at high risk for ulceration; 203 (age $63.9 \pm$ yrs, DD

18.3 ± 9.3 yrs, HbA1c $8.9 \pm 1.4\%$) accepted to participate and were enrolled in the study. Among them 44% had neuropathy and deformity, 22% had previous ulceration, 27% previous minor amputation and 7% had neuro-osteopathy.

During the first 12-month follow-up, 12.7% of patients which received orthosis and shoes developed an ulcer, thus showing a reduction of -27% compared to the expected figures. This group had a more severely impaired VPT at baseline compared to non-developers (37.1 ± 15.1 vs 26.5 ± 8.2 volt, $p < 0.01$) and reported to use the orthosis and shoes for a shorter time during the day (5.7 ± 3.4 vs 7.8 ± 1.6 hrs, $p < 0.05$). Among the subgroup of patients (N.55) with a longer follow-up, the observed cumulated incidence of ulceration was 17.3% (- 43.3%) and 21.2% (- 48.8%) in three and five years, respectively.

Conclusion: A structured follow-up prevention program, with the use of orthosis and shoes, is effective in reducing the incidence of re-ulceration in diabetic patients at high-risk for lower limb complications.

1277

Resource utilisation and costs for management of patients with diabetic foot ulcers. Experiences from 10 European countries in the EURODIALE trial

G. Ragnarson Tennvall on behalf of the EURODIALE Group

The Swedish Institute for Health Economics, IHE, Lund, Sweden

Background and aims: As part of the EURODIALE trial the aim of the study was to investigate the resource utilisation and cost for management of the diabetic foot in 10 European countries and to analyse the costs associated with diabetic foot disease.

Materials and methods: Information about resource utilisation was collected in the trial. For analysis of resource use 1088 patients were available and out of these 821 patients were included in the costing analysis based on country specific unit cost data. Costs were calculated individually for each patient by multiplying the unit cost for every type of resource by the number of resources used from inclusion into the trial and until a defined endpoint. The endpoints were when the foot was healed, the patient had deceased, a lower leg amputation was performed, or when 12 months follow-up had ended. The cost calculation covered direct costs for diagnostic procedures, off-loading techniques, interventional procedures, hospitalisations, antibiotic therapy, specialist consultations, topical treatment, and indirect costs. Indirect costs are related to loss of production for patients who had an employment and who had been on sickness leave because of the foot ulcer.

Results: Resource use as well as costs varied between outcome groups and between disease severity groups. The total direct and indirect costs were 7700 Euro for patients who healed and 25200 Euro for patients who underwent major amputation. The total costs per patient in the group with the most severe disease (both infection and peripheral arterial disease) were about four times higher (16800 Euro) than for patients in the least severe group (4500 Euro) without infection or peripheral arterial disease. For patients with infection only the total costs were 9300 Euro. The total costs for patients with peripheral arterial disease but without infection were 9850 Euro. The average number of procedures used was generally low with the exception of antibiotic therapy, topical treatment, hospitalisation, and consultations. The distribution of different types of costs within each outcome group differed in comparison with previously published studies.

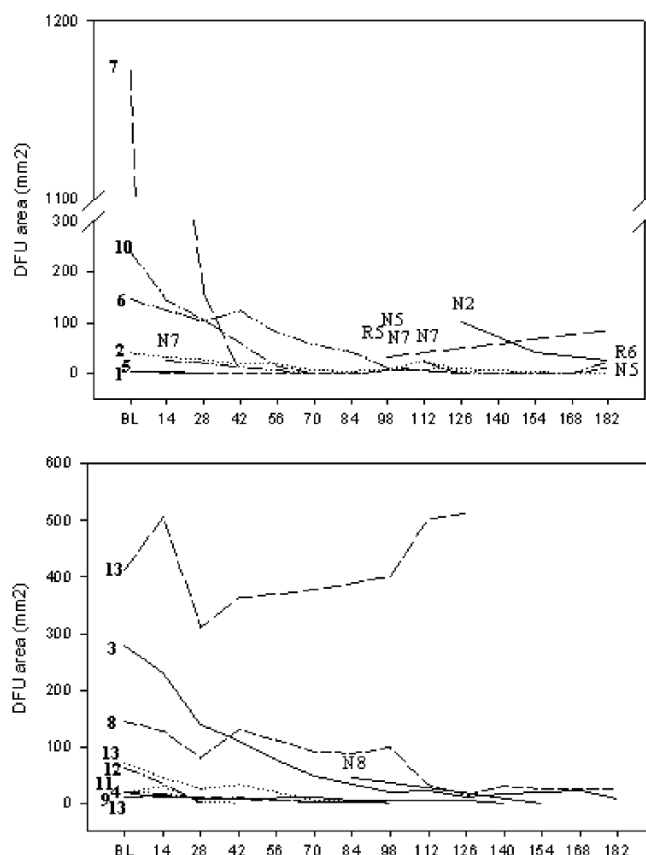

Conclusion: The costs of diabetic foot ulcers are highly related to the outcome and the severity of the disease and the cost increases sharply in patients with both peripheral arterial disease and infection. Given these high costs there is an urgent need for efforts to prevent these conditions and for new strategies to treat them more effectively, at an earlier stage. The results show substantial differences in resource use and cost between different patient groups treated in Europe. The information is important in illustrating the magnitude of the problem in economical terms for decision makers both within and outside the health care system.

Healing of diabetic foot ulcers may be modified by high dose atorvastatin - a 6 month randomised controlled pilot trialO.E. Johansen¹, K.I. Birkeland², A.P. Jørgensen¹, E. Orvik¹, B. Sørsgård¹, B.R. Torjussen³, T. Ueland⁴, P. Aukrust⁴, L. Gullestad⁵¹Medical department, Asker and Baerum Hospital, RUD, ²Dept of Endocrinology, Aker University Hospital, Oslo, ³Medical department, Østfold County Hospital, Sarpsborg, ⁴Research Institute for Internal Medicine, Rikshospitalet-Radiumhospitalet University Hospital, Oslo, ⁵Department of Cardiology, Rikshospitalet-Radiumhospitalet University Hospital, Oslo, Norway.**Background and aims:** Diabetic foot ulcers (DFUs) are common complications of diabetes mellitus, with a complex pathogenesis involving mechanical, vascular, inflammatory, oxidative, endothelial and nutritive factors. Given the beneficial “pleiotrophic” effects of statins on several aspects of cardiovascular disease, including modulation of inflammation and endothelial function in addition to their lipid-lowering effects, possibly even so in a dose dependent manner, we explored whether low (10 mg) or high (80 mg) dose atorvastatin could modulate the DFU burden.**Materials and methods:** Thirteen diabetic patients (10 men, 11 type 2 diabetes, mean age/diabetes duration 64/18 years) with neuropathic DFUs < 4 months from two centres were randomised to treatment with 10 or 80 mg atorvastatin for six months in addition to conventional DFU care (prompt debridement of contaminated and necrotic tissue, management of any underlying infection and provision of pressure relief measures).**Results:** Six patients with six ulcers received 10 mg, and seven patients with nine ulcers received 80 mg atorvastatin. Background (micro- and macrovascular complications, medications) and DFU characteristics (duration [median 33 days], University of Texas DFU grading [I-A (46%), I-B (46%) and II-B (8%)]) were similar. All ulcers in the 10 mg and six of nine in the 80 mg group healed. However, two previously healed DFUs recurred and six novel ulcers developed in the 10 mg group, as compared to none and one, respectively, in the 80 mg group ($p=0.048$) (Fig 1). There was a significant between-group change in CRP (-1.5 mg/l, $p=0.044$) and a trend towards greater between-group reductions in lipid parameters and a tendency towards an increase in ankle-brachial pressure index (0.15 , $p=0.201$), favouring the 80 mg group (Table 1). No significant impact was found on liver enzymes.**Conclusion:** The observed beneficial impact on reducing recurrent and novel DFUs of 6-months high-dose atorvastatin treatment could be related to its pleiotrophic effects. Larger studies are needed to explore this therapeutic option further.**Table 1. Impact of 10 or 80 mg atorvastatin added to conventional DFU treatment for six months.**

	10 mg Study start (n=6)	atorvastatin Study end (n=6)	80 mg Study start (n=7)	atorvastatin Study end (n=7)	Mean between-group changes (Z-value)

The improvement of diabetic foot care in Tuscany: results in amputation reductionR. Anichini¹, A. De Bellis¹, C. Seghieri², C. Baggione³, S. Nuti², A. Piaggese⁴¹Diabetology, Diabetes Foot Unit, Pistoia, ²Epidemiology University of Pisa, Lab MES, ³Internal Medicine, Diabetes UNIT, Florence, ⁴Malattie del Metabolismo e Diabetologia, Diabetes Foot Unit, Pisa, Italy**Background and aims:** In order to improve the organization of diabetic foot care in Tuscany and to standardize diagnostic and therapeutic protocols, in years 1999-2002 the implementation of international consensus of diabetic foot (ICDF) has been performed. In 2004 the Official Regional Health Authority established a new model of organization of diabetic foot care in Tuscany in three different levels, on the basis of the complexity of foot care service (from the simple surgical debridement to the revascularization and major

surgery procedures). All diabetic foot units were able to perform screening, education and preventive programme, according to the international guidelines. One of the most important objectives was defined as an epidemiological surveillance based on clinical outcomes as a high percentage of population screened, reduction in hospital admissions and reduction in lower extremity amputations.

Methods: We studied a relatively stable population 3536392 inhabitants in 2000 and 3638211 in 2007 (with increase in the years minor of 3%). The data base for this study was extracted from the DRG of Health Regional System database (Tuscany) for diagnosis of diabetes, for foot lesions, procedures, number and duration of hospitalization and type of amputation.

Results: Here we show the following preliminary data: in years 2000–2007 there were in Tuscany 4374 major lower extremity amputations (LEA) of which 1232 were diabetes related (about 28%). Among individuals with diabetes LEA rates went from 4,2/100,000 inhabitants in the first year (148) to 3,3/100,000 inhabitants in the eighth year (120). Over the same period non diabetic related LEA decreased from 11,8 to 10,5/100,000 inhabitants. Moreover, hospitalization rate for diabetic foot was significantly reduced from 4,3 to 3,1/1000 patients.

Conclusions: Our data demonstrate that the introduction of a better organized diabetes foot care is able to improve in outcomes one of the most feared diabetic complications.

PS 126 Oxidative stress and endothelial function

1280

Low-grade inflammatory markers and oxidative stress in patients with type 1 diabetes mellitus

M.B. Gomes¹, R.A. Cobas¹, E. Nunes², H.C. Castro-Faria-Neto², M.N. Silva¹, M.F. Bevilacqua¹, E. Tibiriçá²

¹Diabetes Unit, State University of Rio de Janeiro, ²Immunopharmacology laboratory, FIOCRUZ, Rio de Janeiro, Brazil

Background and aims: Patients with type 1 diabetes present a high mortality and morbidity rate from cardiovascular disease. The underlying mechanisms that cause accelerated atherosclerosis in these patients are poorly understood. An association with glucose control, oxidative stress, markers of insulin resistance and of low-grade inflammation have been suggested. Few studies have been conducted on patients with type 1 diabetes with and without chronic complications or on subjects without diabetes to assess whether these factors could exist independently of the presence of diabetes. The present study was designed to evaluate if type 1 diabetic patients matched to subjects without diabetes (controls) have altered levels of low-grade inflammatory markers (Platelet-activating factor acetylhydrolase activity (PAF-AH), hs-CRP, white blood cells count (WBC) and sedimentation rate, and markers of oxidative stress (Oxidized LDL) and whether their levels are related to clinical complications and metabolic variables.

Materials and methods: We studied cross-sectionally 118 type 1 diabetic outpatients (45.8% males) aged 27.1 ± 11.3 years with a duration of diabetes of 12.3 ± 8.5 years, with ($n=38$) and without ($n=80$) clinical chronic complications and 110 controls subjects (49% males) aged 26.1 ± 7.2 years. Clinical complications were evaluated by ECG, direct ophthalmoscopy, microalbuminuria. PAF-AH activity was measured with PAF-AH assay kit (Cayman Chemical, Ann Arbor, MI, USA). Analysis of the LDL oxidation coefficient (OxC) was performed using spectrophotometric readings at 205, 232 and 280 nm at different time points: 0, 1 hour, 3 hours, 6 hours and 24 hours after CuSO₄ addition of copper sulfate to purified LDL fractions. Laboratory analysis included lipid profile, WBC, sedimentation rate, uric acid, HbA1c (HPLC), FBG, 2h glucose, hs-CRP.

Results: Diabetic patients had higher PAF-AH activity [(0.015 ± 0.005) vs (0.013 ± 0.005) $\mu\text{mol}/\text{min}/\text{mL}$ $p=0.02$], hs-CRP [$0.12(0.01-1.02)$ vs $0.04(0.01-1.02)$ mg/dL $p=0.001$], WBC (7.2 ± 1.7 vs $6.1 \pm 1.4 \times 10^3/\mu\text{L}$ $p=0.004$) and sedimentation rate [$14(1-50)$ vs $7(1-40)$ mm/h $p=0.0001$] levels than controls. No difference was noted between patients with and without chronic complications. Patients had a lower level of uric acid than controls, respectively (3.5 ± 1.1 vs 4.8 ± 1.3 mg/dL $p=0.000$). Basal OxC values were similar in the two groups. Patients with type 1 diabetes had earlier LDL oxidation with lower coefficient (OxC) than controls, one (6.9 ± 2.6 vs 8.0 ± 2.6 , $p=0.008$) and three hours (6.2 ± 1.9 vs 7.1 ± 2.1 , $p=0.01$) after the addition of CuSO₄. In patients, a correlation was found between PAF-AH and OxC 1h ($r=0.26$ $p=0.01$) and OxC 3h ($r=-0.25$ $p=0.02$). Separated stepwise multiple regression with PAF-AH or hs-CRP or OxC 1h or OxC 3h as a dependent variables showed that diabetes was the most important significant independent variable.

Conclusion: According to our results, markers of low-grade inflammation and oxidative stress are increased in patients with type 1 diabetes probably independent of the presence of clinical microvascular disease. The natural anti-oxidant defense represented by uric acid is decreased in these patients. The influence of low-grade inflammatory and oxidative markers on the development of cardiovascular disease in patients with type 1 diabetes must be addressed in prospective studies.

FORT and FORD two novel assays for the assessment of oxidative stress in patients with newly diagnosed patients with diabetes mellitus type 2

I. Papassotiriou¹, M. Pavlatou^{1,2}, M. Papastamataki¹, F. Apostolaki¹, N. Katsilambros², N. Tentolouris²

¹Clinical Biochemistry, Aghia Sophia Children's Hospital, ²First Department of Propaedeutic Medicine, University of Athens Medical School, Athens, Greece

Background and aims: To evaluate the levels of free oxygen radicals (free oxygen radicals test, FORT) and free oxygen radicals defense (FORD) in pa-

tients with newly diagnosed patients with diabetes mellitus type 2 (DM2). The disease seems to be involved strongly in the production of reactive oxygen species (ROS).

Materials and methods: Forty-five patients with newly diagnosed DM2 and 20 apparently healthy individuals (control group) were included in the study. ROS were determined using the FORT test (Callegari, Parma, Italy), which is based on the Fenton reaction. When a 20 μ L blood sample was dissolved in an acidic buffer, the hydroperoxides reacted with the transition metal ions liberated from the proteins in the acidic medium and were converted to alkoxy- and peroxy-radicals. The radical species produced by the reaction, which are directly proportional to the quantity of lipid peroxides present in the sample, interact with an additive (phenylendiamine derivative) that forms a radical molecule evaluable by spectrophotometer at 505 nm (Form CR 2000; Callegari, Parma, Italy). Results are expressed as FORT U (Fort units) whereby 1 FORT U corresponds to 0.26 mg/L H_2O_2 . Similarly, the FORD test uses, preformed stable and colored radicals and determines the decrease in absorbance that is proportional to the blood antioxidant concentration of the sample according to the Lambert Beer's law. In the presence of an acidic buffer (pH=5.2) and a suitable oxidant ($FeCl_3$) the chromogen, which contains 4-Amino-N,N-diethylaniline sulfate forms a stable and colored radical cation photometrically detectable at 505nm. Antioxidant compounds in the sample reduce the radical cation of the chromogen quenching the color and producing a decoloration of the solution, which is proportional to their concentration. The absorbance values obtained for the samples are compared with a standard curve obtained using Trolox (6-Hydroxy-2,5,7,8-tetramethylchroman-2-carboxylic acid), a permeable cell derivative of vitamin E commonly employed as an antioxidant.

Results: The main results of the study showed that: a) free oxygen radical levels (FORT) were increased in diabetic patients (2.86 ± 0.56 mmol/L H_2O_2) compared to controls (1.87 ± 0.26 mmol/L H_2O_2), ($p < 0.0001$) and b) FORD levels were lower in diabetic patients (1.23 ± 0.18 mmol/L Trolox) compared to controls (1.34 ± 0.14 mmol/L Trolox), ($p < 0.01$). The intraassay and interassay coefficients of variation were 3.7% and 6.2%, respectively for FORT, while the intraassay and interassay coefficients of variation were 4.2% and 6.6%, respectively for FORD.

Conclusion: The determination of free oxygen radicals (FORT) and free oxygen radicals defense (FORD) seem to play an important role in the generation of oxidative stress, an imbalance between oxidants and antioxidants that can lead to oxidative damage and is involved in the pathogenesis of several diseases, such as DM2. The methodology described above is simple, reliable, rapid and reproducible.

1282

Hyperglycaemia, both chronic and in short-term peaks, results in rapid increase of expression of monocyte inducible cyclooxygenase (COX-2) in subjects with type 2 diabetes mellitus

P. Rossetti, P. Candeloro, T. Corazzi, C.G. Fanelli, F. Porcellati, P. Cioli, L. Cecchetti, P. Greselo, G.B. Bolli
Internal Medicine, University of Perugia, Italy

T2DM is associated with a two-to-four fold increase of vascular complications as result of both chronic hyperglycemia (elevated A1C) and isolated spikes of (post-prandial) hyperglycemia. Monocyte inducible COX-2 has been advocated as a player in the pathogenesis of ischemic events. Aim of our study was to establish if both chronic and acute, short-term hyperglycemia affect COX-2 expression in monocytes of subjects with T2DM. Peripheral blood monocyte COX-2 was measured (Western Blotting) in 120 subjects with T2DM (A1C $7.9 \pm 1.0\%$; fasting BG (FBG) 180 ± 9 mg/dl; age 67 ± 9 years) and 50 age and sex-matched healthy controls (A1C $5.9 \pm 0.3\%$; FBG 94 ± 9 mg/dl; age 62 ± 14 years). COX-2 was expressed in monocytes of 84% of T2DM subjects and 4% of normal volunteers ($p < 0.01$). Average monocyte COX-2 was 0.31 ± 0.05 ng/ μ g total proteins in T2DM and correlated with FBG ($r = 0.52$; $p = 0.05$) and A1C ($r = 0.52$; $p = 0.03$). In 5 T2DM subjects with poor control at baseline in whom BG was optimally improved for 3 months (A1C decreased from $8.1 \pm 0.4\%$ to $7 \pm 0.6\%$; $p < 0.01$), monocytes COX-2 decreased from 0.18 ± 0.06 to 0.12 ± 0.05 ng/ μ g total proteins, $p < 0.05$. Following these observations, monocytes were isolated from healthy volunteers and cultured in 22mM glucose-containing medium for 4 hours, showing increase of COX-2 (0 to 0.6 ± 0.15 ng/ μ g total protein, $p < 0.001$). After 4-h additional incubation at 5.5 mM glucose-containing medium, COX-2 reduced to 0.3 ± 0.11 ng/ μ g total protein, $p < 0.01$, and incubation for additional 20-h abolished it ($p < 0.01$). Five T2DM subjects with good baseline glycemic control (A1C $6.4 \pm 0.3\%$, FBG 110 ± 6 mg/d), underwent two subsequent differential steps (4h-each) of

hyperglycemia (clamp, BG 13.9 mM) and euglycaemia (clamp, BG 5.5 mM). After acute hyperglycemia monocyte COX-2 expression increased by 56%. However a prompt normalization of BG reached after 30 min and maintained thereafter (i.v. insulin bolus of 100 mU/kg, followed by a constant infusion of 0.5 mU/Kg/min) decreased COX-2 expression by 71% after 4-h.

Conclusion: Hyperglycemia is associated with COX-2 induction both in chronic as well as acute states. Short-term hyperglycemia mimicking postprandial spikes, induces a rapid upregulation of monocyte COX-2. This phenomenon is rapidly reversible after BG normalization. These observations may have practical implications for clinical management of T2DM.

1283

Role of p66^{Shc} in the modulation of oxidative stress responses in human liver cells

F. De Stefano, F. Losurdo, A. Quagliara, S. Perrini, A. Natalicchio, A. Peschechera, M. Melchiorre, A. Cignarelli, A. Leonardini, M. Barbaro, A. Conserva, L. Laviola, F. Giorgino
D.E.T.O., Internal Medicine, Endocrinology and Metabolic Diseases, University of Bari, Italy

Background and aims: Oxidative stress plays an important role in the pathogenesis of nonalcoholic fatty liver disease (NAFLD). However, the molecular determinants of oxidative stress-induced liver damage remain poorly understood. The protein p66^{Shc} has been proposed as a cellular sensor of the mitochondrial redox balance. Specifically, p66^{Shc}, through its phosphorylation on Ser³⁶, has been shown to modulate various cellular responses and apoptotic rates in cells exposed to oxidative stress. The objective of our study was to investigate the role of p66^{Shc} in the regulation of intracellular responses to oxidative stress in human liver cells.

Materials and methods: Human HepG2 hepatoma cells with adenovirus-mediated overexpression of p66^{Shc} (Adp66^{Shc}) were exposed to H_2O_2 , a commonly used oxidative stress inducer. Cellular responses to oxidative stress were assessed by gene expression and immunoblotting techniques.

Results: HepG2-Adp66^{Shc} cells were characterized, under basal conditions, by increased p66^{Shc} phosphorylation on Ser³⁶ (approximately 50-fold; $p < 0.005$) vs. control cells (wild type and Mock HepG2 cells). Moreover, increased p66^{Shc} protein levels were associated to increased mRNA expression levels of the antioxidant enzyme MnSOD as compared to controls, suggesting a potential biochemical compensation to the increased oxidative stress associated with the overexpression of p66^{Shc}. HepG2-Adp66^{Shc} exposed to 0.5 mM H_2O_2 showed a further increase in the level of Ser³⁶ phosphorylation of p66^{Shc} (2-fold vs. control cells; $p < 0.005$), associated with increased Erk-1 phosphorylation, peaking at 15 min (7-fold vs controls; $p < 0.005$). Additionally, H_2O_2 -treated HepG2-Adp66^{Shc} showed increased Akt phosphorylation on Ser⁴⁷³ (approximately 2-fold; $p < 0.005$) as well as increased Thr³²-phosphorylation of FOXO3a, a member of the Forkhead family of transcription factors. Following Thr³²-phosphorylation, the ability of FOXO3a to induce gene expression of anti-oxidants is diminished. Indeed, treatment of HepG2-Adp66^{Shc} with H_2O_2 resulted in reduced expression of MnSOD, a gene controlled by FOXO3a.

Conclusion: Overexpression of the p66^{Shc} protein isoform in human hepatoma cells induces an increase of the intracellular oxidative stress under basal conditions, and a reduced cellular ability to react against oxidative stress inducers via an Akt/Foxo3a signalling pathway. Thus, the p66^{Shc} protein activates a specific intracellular signaling pathway that modulates the response to oxidative stress in liver cells. This may be relevant to the pathogenesis of the hepatic dysfunction associated with the metabolic syndrome and type 2 diabetes.

Changes in serum corticosterone levels and adrenal cortex nitric oxide synthase activity in streptozotocin-diabetic rats: involvement of oxidative stress

E.M. Repetto^{1,2}, J.M. Cipelli¹, R. Sanchez¹, F. Astort^{1,2}, C. Martinez Calejman^{1,2}, J.M. Di Gruccio¹, G.G. Pirol¹, P. Arias³, C.B. Cymeryng^{1,2}
¹Human Biochemistry, University of Buenos Aires, ²Conicet, CEFYBO, ³Physiology, University of Buenos Aires, Argentina

Background and aims: Increased oxidative stress, arising as a consequence of excess fuel supply, has been associated with the pathogenesis of chronic diabetic complications. The aim of the present study was to evaluate different

parameters of oxidative stress and its role in the induction of nitric oxide synthase (NOS) activity in the adrenal cortex of streptozotocin (STZ)-diabetic rats. The impact of STZ-induced diabetes and of antioxidant treatment on corticosterone secretion was also evaluated.

Materials and methods: Male Wistar rats were treated with STZ (40 mg/kg i.p. for three consecutive days) or citrate buffer (controls). After instauration of hyperglycemia, different groups of STZ-treated and control animals received antioxidant treatment (melatonin 7.5 mg/kg p.o. or α -tocopherol 100 mg/kg, p.o.). Thiobarbituric acid-reactive substances (TBARS, an index of lipid peroxidation), HO-1 expression, superoxide dismutase (SOD), catalase and NOS activities, and reduced glutathione (GSH) levels were determined in adrenal cortex homogenates at different time points after the induction of the diabetic state. Serum corticosterone levels were measured by RIA. Statistical evaluation was performed using an ANOVA followed by Tukey's post hoc test.

Results: After 4 weeks of treatment STZ-diabetic animals showed a significant increase in basal corticosterone levels (101 ± 8.7 versus 49.7 ± 2.0 ng/ml; mean \pm SEM) and in tissue TBARS concentrations, as compared to controls. NOS activity was increased from the second to the eighth week of treatment. GSH and antioxidant enzyme activities (HO-1, SOD and catalase) were increased by 4–8 weeks. Antioxidant treatment reduced TBARS levels and prevented the increase in HO-1 and NOS activity. Corticosterone levels were clearly reduced in melatonin and α -tocopherol-treated diabetic animals (43.4 ± 6.1 and 45.6 ± 10.4 ng/ml, respectively).

Conclusion: Our results suggest that, in the adrenal cortex of STZ-treated rats, increased oxidative stress is associated with an increase in NOS activity. Upregulation of HO-1, SOD and catalase activities is probably involved in cytoprotective mechanisms triggered by the production of reactive oxygen or nitrogen species, or by other parameters of cell damage associated with the diabetic state. As described previously, STZ-induced diabetes resulted in elevated corticosterone levels; this increase was not present in diabetic animals receiving antioxidant treatment. Accordingly, the involvement of oxidative stress-induced mechanisms in the dysregulation of the hypothalamic-pituitary-adrenal axis observed in STZ-treated animals is postulated.

Induction of stearoyl-CoA desaturase (SCD-1) protects human arterial endothelial cells against lipotoxicity

A. Peter, C. Weigert, H. Staiger, K. Rittig, A. Cegan, P. Lutz, F. Machicao, H.-U. Häring, E. Schleicher
Department of Internal Medicine, Division of Endocrinology, Diabetes, Vascular Medicine, Nephrology, University of Tübingen, Germany

Endothelial lipotoxicity has been implicated in the pathogenesis of multiple stages of cardiovascular disease from early endothelial dysfunction to manifest atherosclerosis and its complications. Saturated free fatty acids are the major inducers of endothelial cell apoptosis and inflammatory cytokines. In humans, the enzyme stearoyl-CoA desaturase-1 (hSCD-1) is the limiting step of the desaturation of saturated to monounsaturated fatty acids. Since we could demonstrate the expression of SCD-1 in primary human arterial endothelial cells (HAECs) we aimed to prove a beneficial role of upregulated hSCD-1 expression. In contrast to other cells which are less susceptible to lipotoxicity, hSCD-1 was not upregulated in HAECs upon palmitate treatment. Following that, we could show that upregulation of hSCD-1 using the LXR activator TO901317 in HAECs protects the cells against palmitate-induced lipotoxicity, cell apoptosis and expression of inflammatory cytokines IL-6 and IL-8. Increased hSCD-1 activity was determined as C16:1/16:0-ratio and enhanced triglyceride storage in palmitate treated cells. The beneficial effect was clearly attributed to enhanced hSCD-1 activity. Overexpression of hSCD-1 blocked palmitate-induced cytotoxicity and knockdown of hSCD-1 using si-RNA abolished the protective effect of TO901317 in HEK293 cells. Additionally, inhibition of hSCD-1 with 10/12 CLA blocked the effect of TO901317 on palmitate-induced lipotoxicity, cell apoptosis and inflammatory cytokine induction in HAECs. We conclude that upregulation of hSCD-1 led to a desaturation of saturated fatty acids and facilitates their esterification and storage thereby preventing downstream effects of lipotoxicity in HAECs. These findings add a novel aspect to the atheroprotective actions of LXR activators in cardiovascular disease.

Protective effects of a prescribed traditional Chinese medicine preparation on oxidative stress induced by high glucose in bEnd.3 cells

X. Gao¹, Y. Kang¹, L. Zhou², M. Wang²

¹Endocrinology & Metabolism, Zhongshan Hospital, ²The National Center for Drug Screening, Shanghai Institute of Materia Medica, Chinese Academy of Science, Shanghai, China

Background and aims: Endothelial dysfunction is a critical and initiating factor in the pathogenesis of diabetic vascular complications. An underlying mechanism for such abnormality is the enhanced generation of endothelial mitochondrial reactive oxygen species (ROS). We previously observed that a prescribed traditional Chinese medicine preparation "Qing Huo Yi Hao" (QHYH) could decrease urinary microalbumin excretion in type 2 diabetic patients and improve endothelial cell growth in high glucose medium. This study was designed to gain some insights into the antioxidant effects of QHYH on oxidative stress induced by high glucose in endothelial cells. Since a recent report suggests that genetic ablation of uncoupling protein 2 (UCP2) produces more ROS in endothelial cells, we therefore investigated the effect of QHYH on UCP2 expression, and whether it is accounted for the antioxidant action of QHYH in endothelial cells.

Materials and methods: Mice brain microvascular cells (bEnd.3 cells) were cultured in normal glucose (NG, 5.6 mM), high glucose (HG) or HG in the presence of QHYH (1:100 dilution). High glucose concentration was 35 mM except for ROS detection experiments in which 25 mM glucose was applied. ROS and nitric oxide (NO) production were measured by the fluorescent probes H₂DCF-DA and DAF-FM DA, respectively. UCP2 mRNA was detected by real-time PCR. Phosphorylation of endothelial nitric oxide synthase (eNOS) and protein kinase B (Akt), and UCP2 protein expression were determined by Western blotting. UCP2 siRNA was used to evaluate the role of UCP2 in the antioxidant effect elicited by QHYH.

Results: High glucose (25 mM) increased ROS production ($142.27 \pm 11.44\%$ vs. $100.00 \pm 1.92\%$ in NG, $P < 0.01$) in bEnd.3 cells while UCP2 mRNA and protein expression were decreased at the same time. UCP2 mRNA was reduced by glucose in a concentration- and time-dependent manner, with the maximum effect observed at 35 mM ($69.90 \pm 4.84\%$, $P < 0.01$ vs. NG) occurring after 48 hours of incubation ($66.93 \pm 4.73\%$, $P < 0.001$ vs. 0 h). High glucose (35 mM) also down-regulated phosphorylation of eNOS at Ser1177 and Akt at Ser 473, and diminished NO generation in bEnd.3 cells compared to NG treatment. Addition of QHYH reversed the high glucose induced ROS production ($53.65 \pm 8.11\%$ vs. $142.27 \pm 11.44\%$ in HG group, $P < 0.001$), eNOS and Akt phosphorylation ($72.81 \pm 7.02\%$ vs. $45.49 \pm 2.51\%$ in HG group, $P < 0.05$ and $76.71 \pm 4.00\%$ vs. $120.98 \pm 1.20\%$ in HG group, $P < 0.001$, respectively), NO generation ($118.82 \pm 2.95\%$ vs. $53.83 \pm 3.98\%$ in HG, $P < 0.001$, and UCP2 protein expression ($94.09 \pm 6.30\%$ vs. $53.83 \pm 3.98\%$ in HG, $P < 0.001$). When UCP2 expression was blocked by UCP2 siRNA, the antioxidant action of QHYH against high glucose was attenuated, and had little effect on ROS production and NO generation in high glucose environment.

Conclusion: QHYH is capable of protecting endothelial cells from high glucose induced ROS production, down-regulation of eNOS and Akt phosphorylation and reduction of NO generation. The protective action of QHYH was partially related to UCP2 protein expression, since deletion of UCP2 by siRNA led to its abolishment. These results suggest a therapeutic potential of QHYH in the treatment of diabetic vascular complications.

Protective effects of berberine against vascular dysfunctions: molecular mechanisms and therapeutic implications

Y. Wang¹, Y. Huang², K.S.L. Lam¹, C.W. Lau², A. Xu¹

¹Department of Medicine and Research Centre of Heart, Brain Hormone and Healthy aging, Faculty of Medicine, The University of Hong Kong, ²Department of Physiology, The Chinese University of Hong Kong, Hong Kong, China

Background and aims: Vascular disease is one of the most common complications in type 2 diabetic patients. Endothelial dysfunction, characterized by impaired vasodilation, is a key early event of vascular disease as well as diabetes. Endothelium-derived nitric oxide (NO) has multiple beneficial effects such as enhancing vasodilation, suppressing platelet aggregation and leucocytes migration, decreasing cellular adhesion to endothelium and attenuating vascular smooth muscle cell proliferation and migration. Berberine, an isoquinoline alkaloid purified from traditional Chinese Medicine, has a

wide spectrum of clinical applications such as in bacterial diarrhea, intestinal parasitic infection, cardiovascular diseases, inflammation and hypercholesterolemia. This study evaluated the effect of berberine on endothelial functions, and investigated the cellular mechanisms involved.

Materials and methods: The effects of berberine on the production of nitric oxide (NO) and activation of eNOS and AMP-activated protein kinase (AMPK) were examined in human umbilical vein endothelial cells (HUVEC). Aortic rings isolated from Sprague-Dawley rats were used for evaluation of vascular reactivity.

Results: Berberine stimulated phosphorylation of eNOS at ser1177 and the NO production in HUVEC in a time- and concentration-dependent manner. In addition, berberine induced endothelium-dependent vasodilatation in rat aortic rings. These effects were largely inhibited by Compound C, a selective inhibitor of AMPK. Further analysis revealed that berberine activated AMPK through its upstream kinase LKB1. In HeLa cells (which lack LKB1), the ability of berberine to stimulate phosphorylation of AMPK was significantly attenuated. Berberine stimulated phosphorylation of LKB1 at Ser428, and enhanced the physical interaction between LKB1 and AMPK. On the other hand, STO609, a selective inhibitor of calmodulin-dependent kinase β , had no obvious effect on berberine-induced activation of AMPK and eNOS.

Conclusion: Berberine stimulates endothelium-dependent vasodilatation through the activation of the AMPK/eNOS/NO signaling cascade. Berberine and its derivatives might represent a new class of therapeutic agents for the treatment and/or prevention of endothelial dysfunctions associated with obesity and diabetes.

Glucose-potentiated aortic smooth muscle cell migration to oxidised low-density lipoprotein: statin and angiotensin-converting enzyme inhibitor sensitivity

M. Campbell¹, D.W. Harkin^{2,3}, E.R. Trimble^{1,4}, I.S. Young^{1,4}

¹Nutrition and Metabolism Group, Queen's University, ²Clinical Vascular Research, Queen's University, ³Regional Vascular Surgery, Belfast Hospitals Trust, ⁴Clinical Biochemistry, Belfast Hospitals Trust, Belfast, United Kingdom

Background and aims: In diabetes there is premature onset and increased severity of atherosclerosis. Glucose-potentiated signalling events, including extracellular signal-regulated kinase (ERK) activation, are implicated in cellular changes associated with atheroma formation. In atherosclerosis vascular smooth muscle cells (VSMC) migrate to factors, such as oxidised (ox)LDL, which are found at raised levels in plaques. Statins and ACE inhibitors, used to treat dyslipidaemia and hypertension, respectively, have additional (pleiotropic) benefits in atherosclerosis therapy. The aims of this work are to assess the interactions of high glucose (15 mmol/l: HG) and oxLDL on explant-derived aortic VSMC migration and to identify if clinically relevant statin or ACE inhibitor concentrations can inhibit migration.

Materials and methods: Migration was recorded over 18 h using the Dunn chamber and analysed by cyclical statistics (Rayleigh test; $n \geq 30$). Total and phosphorylated ERK cellular protein levels were assessed by western blot (data presented as mean \pm SEM, $n=4$) and analysed using ANOVA and Fisher's LSD ($p < 0.01$ considered significant). ERK activation was confirmed by activity assay.

Results: Migration, absent in a native LDL gradient (≤ 100 μ g/ml), was detected in a gradient of oxLDL (≥ 50 μ g/ml, $p < 0.01$) for VSMC exposed to 5 mmol/l D-glucose (normal glucose: NG). In HG the threshold for migration to oxLDL was lowered to 25 μ g/ml ($p < 0.01$, detected after 6 h). In NG supplemented with the non-metabolisable analogue L-glucose (10 mmol/l) the threshold did not differ from that for NG alone (osmotic control). Irrespective of glucose level pre-incubation of the cells (2 h) with CD36 antibody (0.5 μ g/ml) prevented migration to 50 μ g/ml oxLDL. Under similar conditions clinically relevant (circulating) levels of ACE inhibitor (enalapril, 1 μ mol/l) or statin (pravastatin, 10 nmol/l) also prevented migration. These antibody and inhibitor effects were specific since migration occurred to 50 μ g/ml oxLDL in NG and HG in the presence of non-specific antibody or solvent (dimethylsulphoxide) controls ($p < 0.01$ for all). A significant increase in phospho-ERK occurred (western blot), compared to basal (0.5% bovine serum albumin), for cells exposed for 18 h to 50 μ g/ml oxLDL in NG ($+170 \pm 20\%$, $p < 0.01$) or 25 μ g/ml oxLDL in HG ($+260 \pm 30\%$, $p < 0.01$). No changes in total ERK protein levels were detected and solvent did not significantly alter phospho-ERK levels. Pravastatin decreased phospho-ERK to basal levels for 50 μ g/ml

oxLDL in NG ($+20 \pm 25\%$, $p < 0.01$ vs solvent alone), and 25 μ g/ml oxLDL in HG ($+5 \pm 15\%$, $p < 0.01$ vs solvent alone). Enalapril also significantly decreased phospho-ERK but to a lesser degree for 50 μ g/ml oxLDL in NG ($+50 \pm 20\%$, $p < 0.01$ vs solvent alone) and 25 μ g/ml oxLDL in HG ($+40 \pm 15\%$, $p < 0.01$ vs solvent alone). Similar results to those for phospho-ERK were found when an ERK activity assay was employed under matched conditions ($n=3$).

Conclusion: Aortic VSMC migration, a key event in atheroma formation, occurs to lower levels of oxLDL in the presence of raised glucose. Migration to oxLDL depends on ERK signalling which can be blocked by clinically relevant levels of pravastatin or enalapril.

Resistin and high glucose induce ICAM-1, P-selectin and fractalkine in human endothelial cells

I.I. Manduteanu, E. Dragomir, M. Calin, A. Gan, D. Stan, M. Pirvulescu, M. Simionescu
Cell Adhesion and Thrombosis, ICBP "N.Simionescu", Bucharest, Romania

Background and aims: Atherosclerosis is accelerated in diabetic conditions. Clinical data, and *in vivo* and *in vitro* studies suggest that endothelial dysfunction play a key role in this process and that cell adhesion molecules, cytokines and chemokines are actively involved. Resistin, a recently described cytokine, has an established role in mice as a link between obesity and diabetes but an unclear function in humans where it is assumed to be primarily involved in inflammation. Recent clinical data indicate that plasma resistin levels are increased in patients with diabetes complicated with atherosclerosis, but the involved mechanisms are not very well known. To better understand resistin role in these conditions, we performed studies on resistin and high glucose (as inducers of accelerated atherosclerosis in diabetic conditions) direct action on human endothelial cells (HEC). The aims of our studies were: i) to investigate the effects of resistin and high glucose on ICAM-1, P-selectin and fractalkine expression in HEC; ii) to reveal the signaling pathways possible involved.

Materials and methods: Human endothelial cells (Eahy926 cells) in culture were exposed to resistin (50 or 100 ng/ml), high glucose (33 mM) or resistin and high glucose for 6, 18, 24 and 48 hours. The expression of cell adhesion molecules ICAM-1, P-selectin and fractalkine was detected by RT-PCR (gene expression) and by Elisa and Western blot (protein expression). To identify resistin and high glucose downstream signaling pathways the activation of p38, and JNK MAPK and of transcription factors NF- κ B and AP1 was determined (western blot). In addition, intracellular accumulation of reactive oxygen species (ROS) in HEC was monitored by fluorimetry using 2',7'-dichlorofluorescein diacetate (DCFH-DA).

Results: Our data show that resistin or high glucose induced: i) an increase in gene and protein expression of ICAM-1, P-selectin and fractalkine; ii) an enhancement of the nuclear level of p65 and pc-Jun proteins; iii) an increase in the intracellular level of ROS; iv) an increased activation of JNK and p38 MAPK. Co stimulation with resistin and high glucose: i) induced ICAM-1, P-selectin and fractalkine at levels that do not exceed the levels of every inducer alone; ii) activated p38 and JNK MAPK at similar levels as every inducer alone and iii) increased intracellular ROS levels at similar levels as every single inducer.

Conclusion: Our results suggest that resistin, high glucose or resistin and high glucose activate human endothelial cells by inducing the cell adhesion molecules ICAM-1, P-selectin and fractalkine and MAPK, ROS and the transcription factors NF- κ B and AP-1 may be involved in the activation process. *Supported by: Romanian Academy and Ministry of Research and Education-National Center of Grants Management*

Effect of consumption of conjugated linoleic acids on the LDL induced expression of adhesion molecules on endothelial cells

J. Schrezenmeier¹, K. Pfaffnerodt², P. Winkler³, C. Laue³, U. Helwig², M. Pfeuffer²

¹Physiology and Biochemistry of Nutrition, Max Rubner-Institut (MRI), Karlsruhe, ²Physiology and Biochemistry of Nutrition, Max Rubner-Institut (MRI), Kiel, ³Teucra GmbH Medizin & Biotechnik, Kiel, Germany

Background and aims: Increased expression of adhesion molecules, such as the intercellular adhesion molecule (ICAM-1), is associated with an activated endothelium. Adhesion molecules promote the migration of leucocytes into the intima, an early step in atherogenesis. Further, elevated levels of soluble adhesion molecules are frequently observed to be a risk marker for the development of type 2 diabetes. This study focused on conjugated linoleic acids (CLA) and their effect on the LDL-induced expression of ICAM-1 on endothelial cells.

Materials and methods: In a randomized, double blind, crossover study, 20 healthy males, age 50 to 75 years, with an increased body mass index

(BMI: 25–30 kg/m²) consumed 4.25 g/d of either linoleic acid (LA) or cis-9, trans-11 CLA isomer or the trans 10, cis-12 CLA isomer or a 50:50 mix of both isomers for 4 weeks. 4-week treatments were separated by 4–6 week washout periods. Blood samples were drawn in the fasting state and 5 h after ingestion of a liquid fat- and sucrose-rich test meal plus 3 capsules of the respective supplement (2.125 g). Fasting and postprandial LDL were isolated by ultracentrifugation and adjusted to a protein concentration of 0.3 mg/ml. Aliquots were oxidized with copper (2 or 5 μ M Cu, 18 h). Human umbilical vein endothelial cells (HUVECs) were incubated for 16 h with native LDL as well as oxidized LDL. The expression of ICAM-1 was determined by an enzyme-linked immunosorbent assay (ELISA). Cytotoxicity induced by the incubation of HUVECs with LDL was assessed from the release of lactate dehydrogenase (LDH) into the culture media. Statistical analysis of the results was carried out by a multi-factor analysis of variance (MANOVA) followed by post hoc Bonferroni. Data given are means \pm SEM.

Results: Oxidized LDL induced expression of ICAM-1 more than native LDL, and expression was higher with higher degree of oxidation (2 or 5 μ M Cu). LDL isolated from subjects after consumption of trans-10, cis-12 CLA stimulated ICAM-1 less than LDL after LA intervention (Bonferroni, $P < 0.05$). ICAM expression after consumption of the CLA mix and cis-9, trans-10 CLA intervention tended to be lower than after LA consumption. Interestingly, postprandial LDL did not increase the ICAM-1 expression beyond that of fasting LDL, but they were more cytotoxic (Bonferroni, $P < 0.05$). LDL obtained after CLA mix intervention were more cytotoxic than after all other interventions (Bonferroni, $P < 0.05$). But overall the cytotoxic effects were low.

Conclusion: LDL obtained after CLA-enriched diets, in particular after consumption of the trans-10, cis-12 CLA isomer, decreased expression of ICAM-1 in endothelial cells compared to LA. This indicates that CLA may attenuate inflammatory processes and thus act in a beneficial manner.

Centella Asiatica inhibits TNF α -induced adhesion molecule expression in endothelial cells of umbilical cords from gestational diabetic women

N. Di Pietro¹, P. Di Tomo¹, A. Giardinelli¹, P. Di Fulvio², S. Di Silvestre¹, G. Formoso², P. Lanuti³, M. Marchisio³, A. Arduini⁴, A. Consoli², A. Pandolfi¹

¹Dept. Biomedical Sciences, Ce.S.I. Institute, University G d'Annunzio, Chieti, ²DMSI, Ce.S.I. Institute, University G d'Annunzio, Chieti, ³Dept. Biomorphology, Ce.S.I. Institute, University G d'Annunzio, Chieti, ⁴Dept., Iperboreal Pharma, Chieti, Italy

Background and aims: Diabetes mellitus is associated with inflammatory endothelial activation and increased vascular leukocyte adhesion molecules expression, both playing a prominent role in the development of vascular complications. *Centella Asiatica* (CA) has shown anti-inflammatory properties in a variety of experimental models; however, its actions on vascular adhesion molecule synthesis and exposure have not yet been tested. Thus, we evaluated the effect of CA on TNF α -stimulated adhesion molecule expression in cultured endothelial cells obtained from umbilical cords of gestational diabetic and control women.

Materials and methods: Human Umbilical Vein Endothelial Cells (HUVEC) obtained at delivery from umbilical cords of 10 healthy women (C) and 10 women with gestational diabetes (GD) were stimulated with TNF α (1 ng/mL) after a 48 hours pre-incubation with CA (25 μ g/mL) or with buffer. After 12 and 16 hours, vascular cell adhesion molecules (VCAM-1), intercellular cell adhesion molecules (ICAM-1) and E-Selectin protein levels (Western Blot) and their surface expression (biparametric flow cytometry analysis) were assessed. The functional consequences of C- and GD-HUVEC treatment with CA on VCAM-1 membrane exposure were also evaluated by human monocyte cell (U937 line) adhesion assay.

Results: After a 12 hours TNF α stimulation, VCAM-1, ICAM-1 and E-Selectin protein levels were significantly higher in GD- as compared in C-HUVEC ($p < 0.05$, Western Blot analysis). Preincubation with CA significantly decreased the effects of 12 hours TNF α -stimulation on VCAM-1 protein levels in GD-HUVEC (25–30%), while no effect was observed on C-HUVEC. Flow cytometry analysis demonstrated that, following CA pre incubation, the percentage of cells positive for surface VCAM-1 and ICAM-1 expression was modestly but significantly lower both in C- and GD-HUVEC after 12 and 16 hours TNF α stimulation. In addition, as compared to cells not pre-exposed to CA, both VCAM-1 and ICAM-1 MFI ratio (Mean Fluorescence Intensity) was lower in both CA-preincubated C- and GD-HUVEC after 12 (MFI R

for VCAM-1: 0.85 and 0.65, respectively; MFI R for ICAM-1: 0.80 and 0.70, respectively) and 16 hours (MFI R for VCAM-1: 0.85 and 0.65, respectively; MFI R for ICAM-1: 0.88 and 0.90, respectively) TNF α -stimulation. We also examined the functional consequences of C- and GD-HUVEC treatment with CA in terms of U937 cell adhesion to cells. In agreement with data on TNF α -increased VCAM-1 expression, treatment of C- and GD-HUVEC with CA for 16 hours produced a significant decrease in U937 cell adhesion ($p < 0.001$).

Conclusion: In conclusion, our *in vitro* study demonstrates a role for *Centella Asiatica* in mitigating the potentially dangerous effects on endothelium of chronic exposure to hyperglycemia *in vivo*.

VEGF induces von Willebrand Factor (VWF) secretion from endothelial cells via activation of PKC- δ

O.M. Lorenzi, M. Frieden, P. Villemin, M. Fournier, M. Foti, U.M. Vischer PHYM, Centre Médical Universitaire, Geneva, Switzerland

Background and aims: VEGF plays a significant role in diabetic retinopathy and atherosclerosis, in part via the activation of protein kinase C (PKC). Von Willebrand Factor, secreted from endothelial cells, is a key mediator of primary haemostasis. It may play a role in retinal capillary occlusion and in the progression of atherosclerosis. In the present study we investigated the mechanisms of VEGF-induced VWF secretion from cultured endothelial cells. In particular, we sought to identify the PKC isoenzyme(s) involved in endothelial secretion.

Materials and methods: VWF secretion from human umbilical vein endothelial cells (HUVEC) in response to VEGF and histamine was measured by ELISA, and the effect of various inhibitors (including siRNA to inactivate PKC) was tested. We also measured the effect of the secretion agonists on cytosolic free calcium ($[Ca^{2+}]_i$) by single cell imaging using fura-2 fluorescence.

Results: VEGF and histamine rapidly induced VWF secretion, with a similar time course. Several PKC inhibitors (staurosporine, Ro31-8220, Myristoylated PKC peptide inhibitor and Go6983) blocked VEGF-but not histamine-induced VWF secretion in cultured HUVEC. PKC- α and novel PKCs (δ , ϵ , and η), but not PKC- β , were expressed in these cells. Both VEGF and histamine activated PKC- δ , as judged from Western Blots using antibodies against the activated/phosphorylated isoenzyme. However, gene inactivation experiments using siRNA indicated that PKC- δ (but not PKC- α) is involved in the regulation of VEGF- but not histamine-induced secretion. Both VEGF and histamine induce a rise in $[Ca^{2+}]_i$, but the response to VEGF is weaker and even absent in a significant subset of cells. Further, VEGF-induced secretion is largely preserved when the rise in $[Ca^{2+}]_i$ was blocked by BAPTA- AM.

Conclusion: Our data firmly establish the key role of PKC- δ in VEGF-induced endothelial VWF secretion. They also identify striking agonist specificities in signal-secretion coupling. Both VEGF and histamine activate phospholipase C, leading to a rise in $[Ca^{2+}]_i$ and PKC activation. However, histamine-induced VWF secretion is dependent on $[Ca^{2+}]_i$ but not PKC, whereas VEGF-induced secretion is largely dependent on PKC- δ and only to a smaller extent on $[Ca^{2+}]_i$. These discrepancies indicate that a third, VEGF-specific signalling intermediate - which remains to be identified - is required as a PKC- δ co-activator. Our data also argue against the notion of redundancy among PKC isoenzymes. PKC- δ is a possible target for agonist-specific inhibition of endothelial VWF secretion.

Ursodeoxycholic acid inhibits endothelial cell plasminogen activator inhibitor-1 expression induced by high glucose depend on transforming growth factor signalling

T. Yokoi¹, Y. Wada², H. Koshiyama², H. Masaki¹, H. Takahashi¹

¹Department of Clinical Sciences and Laboratory Medicine, Kansai Medical University, Moriguchi, Osaka, ²Center for Diabetes and Endocrinology, The Tazuke Kofukai Medical Research Institute Kitano Hospital, Osaka, Japan

Background and aims: Plasminogen activator inhibitor-1 (PAI-1) is an independent risk factor for ischemic cardiovascular events. PAI-1 levels are elevated in the plasma of diabetes mellitus (DM) patients and this elevation

correlates with vascular complications of DM. Although PAI-1 expression is upregulated depend on transforming growth factor (TGF) signaling, the molecular mechanism to prevent the PAI-1 elevation in DM remain unclear. Here, we show that Ursodeoxycholic acid (UDCA), known as a drug for chronic liver disease, inhibit endothelial cell PAI-1 expression induced by high glucose depend on TGF signaling.

Materials and methods: Cell culture and reagents: Human umbilical vein endothelial cells (HUVECs) were purchased from Sanko Junyaku (Tokyo, Japan) and cultured in endothelial basal medium-2 (Sanko Junyaku) supplemented with 2% FCS. Western blot analysis: Protein extract (10 μ g) was fractionated on SDS-PAGE gels and transferred to a polyvinylidene difluoride membrane (Immobilon-P; Millipore). The membrane was blocked with T-phosphate-buffered saline (1x PBS, 0.3% Tween 20) containing 3% dry milk and incubated with primary antibody (anti-PAI-1, anti- α -tubulin, and anti-TGF- β 1, anti-phosphorylated endothelial nitric oxide synthase at Ser1177) overnight at 4°C. The immune complexes were detected by chemiluminescence methods (ECL; Amersham International). Measurement of PAI-1 levels by enzyme-linked immunosorbent assay: Total secreted PAI-1 and urokinase type plasminogen activator antigen levels (free plus complex forms) were measured (in duplicate) in conditioned culture media and plasma by using a commercial PAI-1 activity assay kit (CHEMICON).

Result: Western blot analysis showed that high glucose (glucose at 5.5 to 33 mM) increased the levels of PAI-1 expression in endothelial cells (ECs) in a time- and dose-dependent manner. High glucose also increased PAI-1 concentration of its supernatant, whereas mannitol as an osmotic negative control had no effect. Interestingly, first cultured with UDCA (at 100 to 1000 μ M), high glucose did not increase PAI-1 expression in ECs and concentration of its supernatant. We next examine the mechanism that UDCA suppress the PAI-1 expression induced by high glucose in ECs. Although high glucose decreased the levels of eNOS expression in ECs, first cultured with UDCA high glucose did not decrease the levels of eNOS. N-nitro-L-arginine-methyl-ester (L-NAME), a nitric oxide synthase (NOS) inhibitor, suppressed the UDCA-induced eNOS expression, but it did not antagonize the inhibitory effects of ursodeoxycholic acid on PAI-1 reduction. It has only partially effect on PAI-1 reduction. The conjugates of UDCA have no effect of PAI-1 reduction. We next paid attention to TGF expression in ECs. Although UDCA suppressed TGF- β 1 expression induced by high glucose, L-NAME did not inhibit this suppressive effect. siRNA targeting of TGF- β 1 markedly suppressed PAI-1 upregulation induced by high glucose.

Conclusion: These data suggest that UDCA inhibits PAI-1 expression in ECs induced by high glucose under the pathway of TGF signaling.

1294

Elevated long pentraxin 3 relates with the endothelial apoptosis due to glucose fluctuation

K. Konno, G. Fukuda, M. Kumekawa, A. Kumakura, R. Ito, T. Takahashi, T. Miwa, M. Odawara

The 3rd Department of Internal Medicine, Tokyo Medical University, Japan

Background and aims: Progression of atherosclerosis is a critical disorder for the patient with diabetes mellitus, hypertension or obesity. Continuous high concentration of glucose leads to systematic atherogenic changes. Recent studies revealed that glucose fluctuation also contributes to develop the atherosclerosis in macro vasculature. The long pentraxin 3 (PTX3) originally produced by endothelial cells is increased in patients with the acute coronary syndrome and independent from liver function, but its involvement in diabetic atherogenic changes is unclear. In this study, we investigated the association between PTX3 and fluctuated glucose concentration concerning apoptosis in endothelial cells.

Materials and methods: Human umbilical vein endothelial cells (HUVEC) were seeded on 6 cm Petri dishes or glass slides set in Petri dishes for imaging. Culture medium was changed every 24 hours and continued for 14 days. Experiments were classified into 4 groups including (1) a control group with 5 mM glucose (L group), (2) an experimental group with 5 mM glucose and 20 mM mannitol (M group), (3) an experimental group with 25 mM glucose (H group), and (4) an experimental group with 5 mM or 25 mM glucose (fluctuated glucose concentration group; LH group). Total RNA was isolated and real-time PCR (Bio-Rad, USA) was carried out for 18S, PTX3, Bcl-2 mRNA quantification. Each mRNA level was compared by arbitrary ratio to 18S ribosomal RNA. The protein level of the PTX3 in culture medium was measured by ELISA-based assay (Perseus Proteomics Inc. Japan). Cell apoptosis was detected with transferase mediated dUTP biotin nick end labeling (TUNEL) method for the glass slides by TUNEL assay kit (Promega,

USA). Images were observed by confocal microscopy (Zeiss, Germany). Caspase 3/7 activity in treated HUVEC was measured by use of Caspase-Glo 3/7 Assay kit (Promega). One-way ANOVA and post hoc test were used for the statistical analysis.

Results: The level of PTX3 mRNA in HUVEC was significantly increased in the H (2.4 folds) and the LH group (2.7 folds), which glucose concentration was fluctuated every 24 hours, as compared to the L group. There was not significant difference of the PTX3 mRNA level between the H and the LH group. In contrast, the level of Bcl-2 mRNA showed a decreasing tendency in the H and the LH group as compared to the L group. The PTX3 protein in the conditioned medium was significantly increased in the H and the LH group as compared to the L group. There was no significant difference of PTX3 level between the H and the LH group. Observing the apoptosis, the H group cells show a 1.2 folds significant increase of caspase 3/7 activity as compared to the L or the M group cells. The LH group cells show a 1.6 folds significant increase of caspase 3/7 activity as compared to the L or the M group cells. TUNEL assay showed that glucose fluctuation in the LH group induced high apoptosis of HUVEC than continuous normal concentration of glucose in the L group. The apoptosis rate was increased in the LH group but there was no significant difference between the H group and the LH group.

Conclusion: These data suggest that glucose fluctuation may be related with PTX3 expression which contributes to early diagnosis of atherogenic disorder in diabetes mellitus. PTX3 would be a useful marker to help clarifying the endothelial damage.

Oxidised LDL decreases the expression of scavenger receptor class BI in vascular endothelial cells

H. Imachi, K. Murao, T. Muraoka, M. Fujiwara, R.A.M. Ahmed, J. Li, T. Ishida

Division of Endocrinology and Metabolism, Department of Internal Medicine, Kagawa University, Kita-gun, Kagawa, Japan

Background and aims: HDL mediates a normal physiological process called reverse cholesterol transport. In this process, a scavenger receptor of the class BI (SR-BI) facilitates the cellular uptake of cholesterol from HDL. Our previous report shows that human homologue of SR-BI/CD36 and LIMPII analogous-1 (hSR-BI/CLA-1), like mouse SR-BI functions as a receptor for HDL. In endothelial cells, HDL activates endothelial nitric-oxide synthase (eNOS) and produces nitric oxide via hSR-BI. On the other hand, oxidized LDL (OxLDL), a atherogenic lipoprotein, suppresses eNOS expression on endothelial cells and associates with development of atherosclerosis. In this present study, we have examined the role of OxLDL on hSR-BI expression in human endothelial cells.

Materials and methods: Total RNA and protein were extracted from human umbilical vein endothelial cells (HUVECs). HSR-BI expression was tested by real-time PCR and western blot analysis. HSR-BI promoter activity was detected using the reporter construct contained the hSR-BI gene sequences spanning the region from -1200 to +2, as determined from the published sequences.

Results: The results of our studies showed that hSR-BI protein expression in HUVECs was suppressed by exposure to OxLDL in a dose-dependent manner. OxLDL decreased endogenous mRNA expression of hSR-BI. Transcriptional activity of hSR-BI promoter in HUVECs paralleled endogenous mRNA expression, and this activity was dependent on OxLDL. Using several pharmacological inhibitors for the signal transduction pathways, the inhibitory effect of OxLDL on hSR-BI promoter activity was abrogated by a specific inhibitor of p38 mitogen-activated protein (MAP) kinase. A dominant negative p38 MAP kinase also abrogated the inhibitory effect of OxLDL on hSR-BI promoter. Co-transfection with the transcriptional factor, liver X receptor (LXR), increased hSR-BI promoter activity. However, OxLDL decreased LXR expression in HUVECs.

Conclusion: In conclusion, p38 MAP kinase pathways participate in OxLDL-suppression of SR-BI expression and LXR may affect this pathway. These results suggest one of the mechanisms of atherogenesis via OxLDL.

Inhibitory effect of adiponectin on palmitate-induced apoptosis: cross-talk between cAMP and AMPK pathway

S.-Y. Park^{1,2}, J.-E. Kim³, Y.-W. Kim³, J.-Y. Kim³, J.-M. Dan⁴, K.-C. Won⁵, Y.-B. Ahn⁶, K.-H. Song⁶

¹Physiology, College of Medicine, Yeungnam University, Daegu, ²Aging-associated vascular research center, College of Medicine, Yeungnam University, Daegu, ³Physiology, College of Medicine, Yeungnam University, Daegu, ⁴Orthopedics, College of Medicine, Pochon Cha University, Gumi, ⁵Internal Medicine, College of Medicine, Yeungnam University, Daegu, ⁶Internal Medicine, The Catholic University of Seoul, Seoul, Republic of Korea

Background and aims: Adiponectin has anti-inflammatory and anti-apoptotic effects in endothelial cells. However, it is unclear whether adiponectin prevents palmitate-induced apoptosis in endothelial cells. In the present study, we elucidated the effects of adiponectin on palmitate-induced apoptosis in human umbilical vein endothelial cells (HUVEC).

Materials and methods: HUVEC isolated from human umbilical cord vein were cultured in M199 and the passage of 3 to 5 were used in this experiment. Apoptosis was measured by annexin V staining and caspase-3 activity and reactive oxygen species (ROS) was measured by live microscopy and flow cytometry using H₂DCFDA. Western blotting was used for protein expression.

Results: Palmitate induced apoptosis and increased ROS generation. Antioxidant N-acetyl cysteine inhibited ROS generation and apoptosis in HUVEC. Treatment of 5 µg/ml globular adiponectin inhibited palmitate-induced apoptosis, which was followed by reduced ROS generation. Adiponectin increased phosphorylated AMP activated protein kinase (AMPK), pAKT, and intracellular cAMP level in HUVEC. Treatment of AMPK inhibitor compound C (40 µM) prevented inhibitory effects of adiponectin on palmitate-induced apoptosis, whereas AMPK activator AICAR (1 mM) inhibited palmitate-induced apoptosis. PI-3 kinase inhibitor LY294002 (50 µM) also prevented inhibitory effects of adiponectin on apoptosis. PKA inhibitor H-89 (10 µM) and cAMP inhibitor SQ22536 (50 µM) reversed inhibitory effects of adiponectin, whereas cAMP activator cholera toxin (100 ng/ml) and forskolin (20 µM) inhibited palmitate-induced apoptosis. Suppressed palmitate-induced ROS generation by adiponectin was also reversed by compound C, LY294002, and H-89. Co-treatment of forskolin with compound C or forskolin with LY294002 did not inhibit palmitate-induced apoptosis, whereas co-treatment of AICAR with SQ22536 or AICAR with H-89 inhibited palmitate-induced apoptosis. Forskolin increased pAMPK level in HUVEC.

Conclusion: These results suggest that inhibitory effect of adiponectin on palmitate-induced apoptosis is mediated by the activation of AMPK and cAMP and cross-talk between cAMP and AMPK pathway may involve.

Effects of pravastatin on akt-survival pathway in human pancreatic islet endothelial cells in hyperglycaemic condition

E. Favaro, I. Miceli, I. Ossola, I. Masi, E. Dellavalle, L. Semperboni, P. Cavallo Perin, M.M. Zanone

Department of Internal Medicine, University of Turin, Italy

Background and aims: The 3-hydroxy-3-methylglutaryl Coenzyme A (HMG-CoA) inhibitors, statins, are known to modulate the phosphatidylinositol 3-kinase (PI3K)/Akt pathways and improve vascular function, independently from their lipid-lowering effects. In endothelial cells, statins rapidly promote the activation of PI3K/Akt pathways, mediating cell survival, NO synthesis and migration. In the present study, we aimed to analyse whether the HMG-CoA inhibitor pravastatin may reverse the sensitivity to apoptosis of human islet microvascular endothelial cells (MECs) in high glucose conditions or after incubation with oxidatively modified LDL (oxLDL), and whether this may depend on activation of the PI3K/Akt pathway.

Materials and methods: Purified islet MECs were cultured in 28mM glucose, and, in time course experiments, apoptosis assessed by enzyme immunoassay measuring DNA fragmentation, phosphorylated Akt (p-Akt) and Akt detected by WB analysis and by ELISA assay. Cells were incubated with oxLDL or treated with increasing doses of pravastatin. Three different conditions were assayed: pravastatin was given daily, or started after four days of high glucose culture, or just overnight before cell collection.

Results: In high glucose culture, apoptosis progressively increased, from 7% after 2 days to 79% after 30 days ($p < 0.05$ compared to normal glucose), with early increase of caspase-3 activity. Apoptosis was accompanied by re-

duced p-Akt/Akt ratio (mean ratio 1.9 ± 0.6 for normal glucose, 0.8 ± 0.3 for high glucose cultures, $p < 0.05$). The p-Akt/Akt ratio exhibited a trend of progressive decrease with the duration of high glucose culture. Similarly, ox-LDL induced dephosphorylation of Akt. Exposure to pravastatin significantly inhibited apoptosis of islet MECs chronically exposed to high glucose, and apoptosis induced by oxLDL ($p < 0.05$). The effect of pravastatin was evident at the daily dose of 1 micromol/L, with lower concentration having not significant effect. The reduced apoptosis detected with pravastatin treatment was accompanied by prevention of the reduction of p-Akt/Akt ratio. This effect increased with treatment duration, with an increase of the p-Akt/Akt ratio of 12% for 1 day pravastatin treatment, 70% increase for 3 day treatment, and 130% increase for daily treatment when the cells were cultured for 8 days in high glucose (mean ratio 2.35 ± 0.12 for normal and 1.17 ± 0.2 for high glucose culture respectively, and 2.1 ± 0.7 for all statin treatment regimes, $p < 0.05$). These results were further confirmed by an Akt ELISA assay, detecting a similar trend. The protective effect of pravastatin on Akt phosphorylation was reduced by overnight treatment of islet MECs with pharmacological inhibitors of PI3K, wortmannin and LY294002, suggesting that this effect was at least in part dependent on the activation of PI3K.

Conclusion: Chronic hyperglycemia reduced islet MECs survival inhibiting the serine-threonine kinase Akt pathway, possibly contributing to the progressive reduction of beta cell function and mass characterising the natural history of the diabetic condition. Pravastatin by affecting this pathway represents a potential tool to improve islet vascularisation and, indirectly, islet function, being pancreatic islet microendothelium and beta cells linked in an interdependent physical and functional relationship.

Background: Advanced glycation end products (AGEs), glycation and glyco-oxidation modification products of proteins and lipids, have been linked to premature atherosclerosis in patients with diabetes, and in non-diabetic subjects. Biologically reactive dicarbonyl methylglyoxal (MG) is the major intracellular substrate in the formation of AGEs. The arginine-modification N δ -(5-hydro-5-methyl-4-imidazolone-2-yl)-ornithine (MG-H1) represents the most abundant protein modification by glycation in diabetes, and occurs both in extra- and intra-cellular proteins. We have previously reported that high levels of serum AGEs, measured with a polyclonal anti-AGE antibody, predict increased coronary heart disease mortality in diabetic and non-diabetic women.

Aims: To investigate the association of the levels of MG-H1 type of AGE-modified proteins (MG-H1-AGE) with cardiovascular disease (CVD) mortality in an 18 year follow-up study in Finnish diabetic and non-diabetic subjects.

Methods: The study design was a nested case-control study. Serum MG-H1-AGE levels in samples drawn at baseline were measured with a DELFIA type immunoassay in 220 diabetic subjects (108 men and 112 women) and 61 non-diabetic subjects (48 men and 13 women) who died from CVD during the follow-up, and age- and gender-matched 157 diabetic subjects (85 men and 72 women) and 159 non-diabetic subjects (122 men and 37 women) who did not die from CVD.

Results: In type 2 diabetic subjects serum MG-H1-AGE levels were similar in subjects who died from CVD and in subjects who did not, 32.6 (24.6 ; 42.1) (median and the interquartile range) vs. 31.3 (22.5 ; 40.7) U/ml ($p=0.281$). In non-diabetic subjects serum MG-H1 levels were significantly higher in subjects who died from CVD than in subjects who did not, 35.4 (28.1 ; 44.7) vs. 31.3 (24.2 ; 38.6) U/ml ($p=0.025$). Corresponding MG-H1 levels were 41.2 (35.6 ; 58.7) vs. 31.1 (26.7 ; 35.7) U/ml, $p=0.003$ in women, and 34.4 (26.3 ; 41.2) vs. 32.0 (22.8 ; 40.3) U/ml, $p=0.270$ in men. Multivariate logistic regression analysis after the adjustment for confounding factors showed a significant association of serum levels of MG-H1-AGE with CVD mortality in non-diabetic women ($p=0.018$), but not in non-diabetic men.

Conclusion: High baseline serum levels of MG-H1 type of AGE-modified proteins were associated with CVD mortality during an 18 year follow-up study in non-diabetic women, but not in non-diabetic men or in diabetic subjects.

Methylglyoxal modifies predominantly heat shock protein 27 in human diabetic hearts

T. Gawlowski¹, B. Stratmann¹, I. Stork¹, A. Brodehl², R. Körfer², H. Milting², D. Tschöepe¹

¹Diabeteszentrum, Ruhr-Universität Bochum, Herz- und Diabeteszentrum NRW, Bad Oeynhausen, Germany, ²E.&H. Klessmann-Institut für Kardiovaskuläre Forschung und Entwicklung, Ruhr-Universität Bochum, Herz- und Diabeteszentrum NRW, Bad Oeynhausen, Germany

Background and aims: The existence of “diabetic cardiomyopathy” is controversially discussed although it is well known that patients with diabetes mellitus (DM) have an increased risk of developing heart failure. However, the definition of diabetic cardiomyopathy suggests that structural and functional abnormalities of the myocardium are independent of other risk factors, such as hypertension and coronary artery disease. This clearly indicates the need for studies specifically in diabetic patients with cardiomyopathy to better understand the mechanisms which initiate and lead to the progression of diabetic cardiomyopathy. In patients with DM hyperglycemia plays an important role in the pathogenesis of diabetic complications including accumulation of methylglyoxal (MG), a highly reactive α -dicarbonyl metabolite of

glucose degradation pathways. MG reacts with arginine residues of proteins to form the posttranslational modification argpyrimidine. However, little is known on the contribution of MG and argpyrimidine in the development of a cardiomyopathy.

Materials and methods: Left ventricular myocardial samples from explanted hearts of patients with cardiomyopathy with (CM/DM; n=8) or without (CM; n=8) DM and from non-failing hearts (NF; n=6) were investigated for the MG-modification argpyrimidine by western blot and immunohistology. Moreover, rat cardiomyoblast cell line H9c2 was treated with glucose or MG for the investigation of the modification argpyrimidine.

Results: HSP27 reveals to be the most argpyrimidine containing protein in cardiac tissue. It is highly expressed and co-localized with plakophilin-2 in intercalated discs of human myocardium. In relation to the total amount of HSP27 argpyrimidine modifications in diabetic hearts were significantly increased 3-fold ($p<0.05$) compared to CM and 9-fold ($p<0.05$) compared to NF. Moreover, we observed a 3.4-fold increase of phosphorylation in CM/DM compared to NF and a 1.8-fold increase compared to CM. Experiments using the rat cardiomyoblast cell line H9c2 show that hyperglycemia (25 mM glucose) increases argpyrimidine content (8.8-fold vs 5 mM glucose; $p<0.01$) and phosphorylation (3.8-fold vs 5 mM glucose; $p<0.01$) of HSP27. Treatment of H9c2 cells with high amounts of MG [50–400 μ M] revealed that argpyrimidine modification was not restricted to HSP27 but were also detectable in additional high molecular weight proteins.

Conclusion: These observations show that altered cardiac metabolism associated with DM leads to covalent modifications of human myocardial HSP27. However, up to now the functional and pathophysiological consequences of HSP27 modification remain to be elucidated.

Elevated intracellular levels of methylglyoxal impair endothelium dependent vasodilatation in rat mesenteric arteries by an oxidative stress dependent pathway

O. Brouwers¹, P.M.G. Niessen¹, J.G.R. De Mey², G.R.M. Haenen², T. Miyata³, M. Brownlee⁴, C.D.A. Stehouwer¹, C.G. Schalkwijk¹

¹Internal Medicine, Maastricht University, Netherlands, ²Pharmacology and Toxicology, Maastricht University, Netherlands, ³Centre for Translational and Advanced Research, Tohoku University, Japan, ⁴Medicine and Pathology, Albert Einstein College of Medicine, New York, United States

Background and aims: Increased formation of the glycolysis-derived reactive dicarbonyl compound methylglyoxal (MGO) and MGO-derived advanced glycation endproducts (AGEs) is thought to be implicated in endothelial dysfunction and, subsequently, in the development of diabetic vascular complications. A common feature of endothelial dysfunction is an impaired nitric-oxide (NO)-dependent vasodilatation. We now investigated the effect of MGO on vasoreactivity, the effect of glyoxalase-I (GLO-I), i.e. the enzyme detoxifying MGO, and the direct effect of free MGO and MGO-modified human albumin on NO bioavailability.

Materials and methods: Isolated mesenteric arteries of healthy and diabetic wild type and transgenic GLO-I rats were mounted in a myograph. The effect of MGO on NO-dependent vasodilatation was tested with acetylcholine (ACh; 0.01–10 μ M) in the presence of indometacin (10 μ M) during contraction with potassium (65 mM). GLO-I transgenic animals are developed by overexpression of the full-length human GLO-I cDNA under control of a β -actin promoter system. Rats were made diabetes by a 65-mg/kg intra-venous streptozotocin injection. The reaction of MGO and MGO-modified human albumin with NO gas in deoxygenated water was measured with an Iso-NO electrode.

Results: Treatment of healthy mesenteric arteries with 0, 0.1, 0.33 and 1.0 mM MGO significantly ($p<0.05$) reduced the acetylcholine-induced vasodilatation, as indicated by decreased potency (log EC₅₀ was -6.33, -6.21, -6.17 and -5.94 M, respectively) and efficacy (E_{max} was 71; 58; 51 and 49 percentage dilatation, respectively). This effect was endothelium dependent as indicated by unaltered relaxing responses to the NO donor sodium nitroprusside. Impairment of dilatation by MGO was not observed in mesenteric arteries of GLO-I transgenic rats compared with their wild type littermates, indicating an intracellular MGO effect. In addition, the impaired dilatation of mesenteric arteries of diabetic rats was reduced by GLO-I overexpression. A pre-incubation of healthy mesenteric arteries with MGO increased staining of the major MGO-adduct 5-hydro-5-methylimidazolone (MG-H1) in endothelial cells and adventitia accompanied by an increase in the oxidative stress marker ni-

tro-tyrosine. The MGO-induced impaired vasoreactivity was normalized by a pre-incubation of the vessels with the antioxidant N-Acetyl Cysteine. Free MGO, but not MGO-modified albumin, reduced the half-life of NO, albeit with a very low potency (constant rate of 1.02 log M / sec).

Conclusion: We found that MGO inhibits endothelium-dependent NO mediated vasodilatation in rat mesenteric arteries. The MGO-induced impairment of NO-mediated dilatation depends on an intracellular effect and is probably due to an increase in oxidative stress and not to a direct quenching of NO. Diabetes induced impaired dilatation can be improved by overexpression of GLO-I. These data implicate that MGO leads to impaired endothelial function and that GLO-I may prevent this.

Prevention of dicarbonyl stress induced by hyperglycaemia in microvascular endothelial cells by sulforaphane

P.J. Thornalley^{1,2}, Q. Qian², N. Rabbani^{1,2}

¹Clinical Sciences Research Institute, University of Warwick, Coventry,

²Department of Biological Sciences, University of Essex, Colchester, United Kingdom

Background and aims: Increased formation of dicarbonyl metabolites, glyoxal, methylglyoxal and 3-deoxyglucosone (3-DG), by microvascular endothelial cells during hyperglycaemia leads to increased formation of advanced glycation endproduct (AGE) residues in cellular and extracellular matrix proteins. Dicarbonyl glycation of the extracellular matrix is linked to endothelial cell detachment, anoikis and other dysfunction - correlating with increased circulating endothelial cells and risk of vascular disease in diabetes. A strategy to prevent increased levels of dicarbonyl metabolites in hyperglycaemia is to induce the expression of transketolase (TK) and other antioxidant response element (ARE) linked gene expression by activation of transcription factor of NF-E2-related factor-2 (nrf2) with small molecular activators such as the dietary bioactive compound sulforaphane (SFN). The aim of this study is to assess the involvement of nrf2 and TK in the counteracting of hyperglycaemia-induced accumulation of dicarbonyl metabolites by endothelial cells with SFN.

Materials and methods: Human microvascular HMEC-1 endothelial cells were cultured in MCDB-131 medium with 10% serum, 10 mM L-glutamate, 10 ng/ml epidermal growth factor, and 1 μ g/ml hydrocortisone. Incubations also contained low glucose (5 mM) or high glucose (30 mM) in the absence and presence of 4 μ M SFN. Knockdown of nrf2 and TK was achieved with nrf2 siRNA and TK siRNA - confirmed by PCR and real time RT-PCR. The concentration of dicarbonyls, glyoxal, methylglyoxal and 3-DG, in the culture medium was determined by derivatisation with 1,2-diaminobenzene and quantitation of the adducts by stable isotopic dilution analysis with liquid chromatography and tandem mass spectrometric detection. Data are mean \pm SD (n = 3).

Results: Incubation of HMEC-1 endothelial cells with high glucose for 24 h increased the concentration of dicarbonyls in the culture medium: glyoxal concentration was increased 3-fold (123 ± 18 nM versus 46 ± 14 nM; $P<0.01$), methylglyoxal was increased 2-fold (96 ± 4 nM versus 53 ± 5 nM; $P<0.001$), and 3-DG was increased 4-fold (369 ± 38 nM versus 99 ± 7 nM; $P<0.001$). Incubation with SFN (4 μ M) reversed the increases induced by high glucose concentration completely for glyoxal and methylglyoxal ($P<0.01$ and $P<0.001$, with respect to high glucose control, respectively). The high glucose concentration-induced increase in 3-DG concentration was only partially reversed by SFN: 3-DG 223 ± 16 nM (-54%; $P<0.001$ and $P<0.01$ with respect to low and high glucose concentration controls). Knockdown of nrf2 and TK abolished the decrease of dicarbonyl concentrations by SFN in incubations with high glucose; it also increased methylglyoxal concentration in incubations with low glucose concentration.

Conclusion: This shows that high glucose concentrations increase the synthesis and secretion of dicarbonyl glyating agents by microvascular endothelial cells and these increases may be reversed totally for glyoxal and methylglyoxal and partially for 3-DG by activation of nrf2 with SFN. The effects of SFN were mediated by nrf2-linked increased expression of TK. Both nrf2 and TK are, therefore, influential regulators of dicarbonyl metabolism in hyperglycaemia. Small molecule activators of nrf2 and inducers of ARE-linked gene expression such as SFN may prevent endothelial cell dysfunction in hyperglycaemia.

Glyceraldehyde-derived advanced glycation end products (ages): a novel biomarker of postprandial hyperglycaemia in diabetic ratsY. Jinnouchi¹, S.-I. Yamagishi¹, T. Matsui¹, K. Nakamura¹, T. Imaizumi¹, M. Takeuchi², K. Miura³, T. Mine³, Y. Kitahara³¹Department of Internal Medicine, Kurume University School of Medicine, Kurume, ²Department of Pathophysiological Science, Hokuriku University, Kanazawa, ³Pharmaceutical Research Laboratories, Ajinomoto, Kawasaki, Japan

Background and aims: There is accumulating evidence that postprandial hyperglycemia is an independent risk factor for cardiovascular disease (CVD) in diabetic patients. Moreover, postprandial hyperglycemia is associated with endothelial dysfunction and increased intima-media thickness as well as a higher prevalence of atherosclerotic plaques of the common carotid arteries. These findings suggest that postprandial hyperglycemia is a therapeutic target for preventing CVD in diabetes. However, there is no convenient biomarker that could reflect cumulative postprandial hyperglycemia in diabetes. We have recently found that glyceraldehyde can rapidly react with amino groups of proteins to form glyceraldehyde-derived advanced glycation end products (AGEs), which evoke vascular inflammation and endothelial dysfunction, thereby being implicated in accelerated atherosclerosis in diabetes. In this study, we examined whether glyceraldehyde-derived AGEs were a biomarker that could reflect cumulative postprandial hyperglycemia in a type 2 diabetic animal model, Goto-Kakizaki (GK) rats fed twice a day.

Materials and methods: Male GK rats at 6 weeks of age were trained to consume their chow within 1 hour that was provided twice a day during the dark period. After 2 weeks, the GK rats were divided into 2 groups; either the vehicle (GK/VEH) or 50 mg/kg of nateglinide (GK/NAT) was administered twice daily just before each meal for 6 weeks. At the end of the treatments, daily blood glucose was monitored, and HbA_{1c}, glucose-derived AGEs and glyceraldehyde-derived AGEs were measured.

Results: There was no significant difference of body weight and food intake between the two groups. The daily blood glucose profile revealed that postprandial blood glucose levels were significantly higher in GK/VEH rats than those in GK/NAT rats (Fig.1). HbA_{1c}, glucose-derived AGEs or glyceraldehyde-derived AGEs levels in GK/VEH at the end of the experiments were not different from those at baseline. Further, although HbA_{1c} or glucose-derived AGEs levels were not different between GK/VEH and GK/NAT (HbA_{1c}; 3.93±0.07 % vs. 3.93±0.16 %, glucose-derived AGEs; 11.07±5.55 U/ml vs. 7.67±4.45 U/ml), glyceraldehyde-derived AGEs levels were significantly reduced in GK/NAT rats, compared with GK/VEH rats (1.93±0.60 U/ml vs. 5.70±1.47 U/ml, $p<0.05$).

Conclusion: The present study demonstrated for the first time that glyceraldehyde-derived AGEs, but not HbA_{1c} or glucose-derived AGEs, were a biomarker that could reflect cumulative postprandial hyperglycemia in diabetic rats. Glyceraldehyde-derived AGEs may a novel therapeutic target for preventing CVD in diabetes.

Increased protein damage by advanced glycation endproducts and oxidation adducts in low density lipoprotein of type 2 diabetic patients

N. Rabbani, P.J. Thornalley

Clinical Sciences Research Institute, University of Warwick, Coventry, United Kingdom.

Background and aims: Formation of advanced glycation endproducts (AGEs) and oxidation and nitration on apolipoprotein B100 - the major protein of low density lipoprotein (LDL) - have been implicated in increase of the atherogenic risk of LDL in type 2 diabetes. The gold standard method of quantifying markers of protein damage is stable isotope dilution analysis with liquid chromatography and tandem mass spectrometric analysis (LC-MS/MS). The aim of this study was to quantify the content of AGEs, oxidation and nitration markers in apolipoprotein B100 of type 2 diabetic patients and normal healthy control subjects by LC-MS/MS.

Materials and methods: Normal healthy human subjects (n = 7) and subjects with type 2 diabetes (n = 25) were recruited for this study. Glycated haemoglobin HbA_{1c} of the diabetic patients was 8.5 ± 1.6 %. LDL was isolated from venous plasma, stabilised with aprotinin and collected in the fasted state, by density gradient ultracentrifugation using Iodixanol. Purified LDL was washed with argon-purged water by ultrafiltration over a 100 kDa microspin filter. The content of AGE, oxidation and nitration adduct residues in apolipoprotein B100 was analysed after de-lipidation and exhaustive enzymatic hydrolysis by stable isotope dilution analysis with LC-MS/MS. The following markers of protein damage were quantified: AGEs - N_ε-carboxymethyl-lysine (CML), N_ε-carboxyethyl-lysine (CEL), N_ε-carboxymethyl-arginine (CMA), glyoxal-derived hydroimidazolone G-H1, methylglyoxal-derived hydroimidazolone MG-H1, 3-deoxyglucosone-derived hydroimidazolone 3DG-H, methylglyoxal lysine dimer (MOLD) and pentosidine; oxidation markers - methionine sulfoxide MetSO, dityrosine and N-formylkynurenine (NFK); and the nitration marker 3-nitrotyrosine (3-NT).

Results: Methylglyoxal-derived hydroimidazolone MG-H1 and glyoxal-derived AGEs G-H1 and CMA were AGEs of apolipoprotein B100 increased significantly in type 2 diabetes. AGE residue contents (pmol/mg protein): MG-H1 - controls 107 ± 73, diabetics 270 ± 117 ($P<0.01$); CMA - controls 16 ± 15, diabetics 51 ± 33 ($P<0.01$); and G-H1 - controls 0.6 ± 0.5, diabetics 5.5 ± 4.1 ($P<0.01$). Protein oxidation markers were also major markers of damage to apolipoprotein B100 and were increased in type 2 diabetes. Protein oxidation adduct residue contents (pmol/mg protein): MetSO (median; minimum - maximum) - controls 644 (426 - 2876), diabetics 6078 (753 - 24,706), $P<0.001$; dityrosine - controls 10 ± 9, diabetics 19 ± 10 ($P<0.05$). Other markers of protein damage were not increased significantly in apolipoprotein B100 of type 2 diabetic patients with respect to normal control values.

Conclusion: This study indicates that apolipoprotein B100 of LDL is highly susceptible to oxidation on methionine residues and this is markedly increased in type 2 diabetes. Major AGE residues of apolipoprotein B100 increased in type 2 diabetes are formed by glyoxal and methylglyoxal glycation, possibly from nascent dicarbonyls generated within the lipid particle.

Follow-up skin autofluorescence as a marker of altered tissue AGE accumulation and oxidative stress in type 2 diabetes mellitusE.G. Gerrits¹, H.L. Lutgers², A.J. Smit², H.J.G. Bilo^{1,2}¹Internal Medicine, Diabetes Centre, Isala Clinics, Zwolle, ²Internal Medicine, University Medical Center Groningen, Netherlands

Background and aims: Advanced Glycation Endproducts (AGEs) accumulate with age on long-lived proteins, but at a more rapid rate in conditions like diabetes mellitus, renal failure, and during high oxidative stress levels in general. Measuring AGEs by skin autofluorescence (AF) is a practically applicable and non-invasive method, which can be used for measuring skin AGE levels over time. The aim of this prospective study was to investigate the changes in skin autofluorescence, as a marker of AGE-accumulation and oxidative stress, in patients with type 2 diabetes mellitus.

Material and methods: Skin AF levels were measured in 452 well-controlled type 2 diabetic patients at baseline and after follow-up. Skin AF was assessed by an autofluorescence reader (AFR) at the ventral side of the lower arm.

Results: After a mean follow-up period of 3.3 ± 0.4 years 22% of the study population showed a decrease in skin AF levels compared to baseline, 43% had stable follow-up skin AF levels, and 35% had an increase in skin AF lev-

els. Minor associations were seen between the progression of AGE formation and a longer diabetes duration, less well controlled lipid levels, a lower estimated glomerular filtration rate, the use of ACE-inhibitors, and/or previous macrovascular events.

Conclusion: These data suggest that in a well-controlled type 2 diabetes mellitus population, progression of AGE accumulation is limited. A higher degree of continuous oxidative stress based on various factors may play a role in the progression of AGE accumulation, at least when monitored by skin autofluorescence.

Polymorphisms in glyoxalase 1 gene are not associated with markers of atherosclerosis and arterial stiffness: the Hoorn and CoDAM studies

L. Engelen¹, I. Ferreira², O. Brouwers¹, J.M. Dekker³, G. Nijpels³, R.J. Heine³, M.M.J. van Greevenbroek¹, C.J. van der Kallen¹, E.E. Blaak⁴, E.J.M. Feskens⁵, H. ten Cate², C.D.A. Stehouwer², C.G. Schalkwijk¹

¹Department of Internal Medicine, Maastricht University, Netherlands, ²Department of Internal Medicine, University Hospital Maastricht, Netherlands, ³Institute for Research in Extramural Medicine, VU Medical Center, Amsterdam, Netherlands, ⁴Department of Human Biology, Maastricht University, Netherlands, ⁵Division of Human Nutrition, Wageningen University, Netherlands

Background and aims: The formation and accumulation of advanced glycation endproducts (AGEs) has gained increasing acceptance as a significant mechanism contributing to cardiovascular complications. Methylglyoxal (MGO), a reactive glycolysis derived dicarbonyl metabolite, is the most reactive precursor in the formation of AGEs. MGO can be detoxified by glyoxalase (GLO)-1 to D-lactate and therefore, the activity of GLO-1 may play an essential role in the formation of AGEs. Because genetic variation in the GLO-1 gene may alter the expression and/or the activity of GLO-1, we investigated whether single nucleotide polymorphisms (SNPs) in the GLO-1 gene are associated with vascular complications in a Dutch cohort.

Materials and methods: The study entailed cross-sectional analyses of data from two joint observational studies, the CoDAM Study and the Hoorn Study, comprising a total of 1278 subjects, aged 64.5 ± 8.58 years; 43.5% had normal glucose tolerance status, 23.2% had impaired glucose tolerance status and 33.3% had type 2 diabetes. Using HapMap and Haploview database, all potential SNPs of the GLO-1 gene that have a minor allele frequency > 5% were identified. Nine tag SNPs that cover the common variation of the GLO-1 gene were selected and genotyped using TaqMan 7900HT. Plasma levels of the AGEs N^ε-(carboxymethyl) lysine (CML) and N^ε-(carboxyethyl) lysine (CEL) were measured by tandem mass spectrometry. Carotid intima-media thickness (IMT) - a marker of atherosclerosis, ankle-arm index (AAIx) - a marker of peripheral arterial disease, and large artery stiffness (compiled in a z-score of seven stiffness parameters, Hoorn Study only) were compared across genotypes with the use of ANCOVA (dominant, recessive and additive models). In addition, associations between the nine SNPs and blood pressure, glomerular filtration rate (GFR) - a marker of renal function and plasma AGE levels (CoDAM Study only) were performed. All analyses were adjusted for age, sex and glucose tolerance status.

Results: All genotyped SNPs were in Hardy Weinberg equilibrium. In the entire study population, no associations were found between all GLO-1 SNPs and IMT, AAIx and arterial stiffness. In addition, no associations were found with blood pressure, GFR and plasma levels of the AGEs CML and CEL. For example, in SNP rs2736654, carotid IMT in mm (mean value \pm SE) was 0.83 ± 0.01 , 0.82 ± 0.01 and 0.82 ± 0.01 for GG, GT and TT respectively; the AAIx was 1.16 ± 0.01 , 1.16 ± 0.01 and 1.16 ± 0.01 for GG, GT and TT respectively; and plasma CML in mmol/L was 1.78 ± 0.05 , 1.76 ± 0.03 and 1.79 ± 0.04 for GG, GT and TT respectively. Similar results were found when stratified analyses according to glucose tolerance status and study population were performed.

Conclusion: No associations were found between GLO-1 gene polymorphisms and markers of atherosclerosis, arterial stiffness and renal function and AGEs in normal-, impaired glucose tolerant, and type 2 diabetic subjects.

Functional analysis of the susceptibility haplotype in the receptor for advanced glycation end-products gene and its role in the hyperglycaemia-driven pathology

K. Kankova¹, P. Benes², S. Kuchtickova¹

¹Dept. of Pathophysiology, ²Dept. of Experimental Biology/Laboratory of Cell Differentiation, Masaryk University, Brno, Czech Republic

Background and aims: Receptor for Advanced Glycation End-products (RAGE) belongs to the class of transmembrane receptors recognizing AGEs produced in accelerated rate during hyperglycemia and uremia and contributing to the development of diabetic complications. Our previous studies have shown that second most frequent haplotype in the RAGE gene (denoted RAGE₂) conferred susceptibility to the development and accelerated onset of diabetic nephropathy in T2DM (frequency 21.7% in nephropathy vs. 12.8% in control diabetic, $P=0.015$, OR=1.65 [95% CI 1.08-2.5]). The aim of the study was to elucidate *in vitro* the functional role of the RAGE₂ susceptibility haplotype in the modulation of RAGE gene transcriptional activity.

Materials and methods: The two promoter and one SNP in intron 8 were identified as tagging variants for the RAGE₂ haplotype. A 788bp PCR fragment of the RAGE promoter region (-738 to +49 relative to the transcription start containing the -429T/C and -374T/A polymorphic variants) was amplified using genomic DNA of homozygous subjects to create all possible haplotypes present in our population (i.e. T/T, T/A, C/T) and cloned into reporter vector pGL3-Basic (Promega). Additionally, a 303bp sequence of the RAGE intron 8 was amplified from homozygotes for the 2184A/G and cloned into the enhancer site of the same vector in the combination with the promoter variants. All constructs were propagated in the competent *E. coli* and subsequently used for transfection of BAEC cell line by Lipofectamine (all experiments were run in triplicates). After incubation for 48 hrs at 37°C at 5% CO₂ at varying concentration of D-glucose (5 and 30 mmol/L) luciferase level was determined using Dual Luciferase Reporter Assay System (Promega).

Results: Luciferase activity (expressed in RLU) significantly differed between the three promoter haplotypes ($p<0.05$, ANOVA) with -429C/-374T giving the highest activity in both normo- and hyperglycemic conditions. Intron variant did not significantly influenced observed transcriptional activity of promoter variants in this assay system ($p>0.05$, ANOVA).

Conclusion: Using reporter gene assays we were able to elucidate functional impact of the RAGE promoter variants constituting previously identified risk haplotype for diabetic nephropathy. Speculated additional effect of the intron 8 variant as an enhancer factor/site was not proved. Functional effect of the RAGE variants further supports its significance in the pathogenesis of diabetic complications.

Advanced glycation end-products accelerate *in vitro* calcification of vascular cell via the AGE-RAGE pathway

X.M. Ren¹, H. Shao², N.F. Liu¹, Q. Wei¹, Z.L. Sun³

¹Institute for Cardiovascular Medicine, School of Clinical Medicine, ²Department of Clinical Pharmacology, Zhongda Hospital, ³Department of Endocrinology, Zhongda Hospital, Southeast University, Nanjing, China

Background and aims: Vascular calcification is common in people with diabetes and its presence predicts premature mortality. There is a growing body of evidence that advanced glycation end products (AGEs), senescent macroprotein derivatives formed at an accelerated rate in diabetes, play an important role in the pathogenesis of accelerated atherosclerosis in diabetes. Moreover, results of previous studies suggest that AGEs may modulate vascular calcification. Therefore, we hypothesized that AGEs may have a direct impact on the calcium-regulating system of vascular smooth muscle cells (VSMCs), resulting in deposition of calcium in vascular wall.

Materials and methods: In this study, we investigated the effect of glycated bovine serum albumin (AGE-BSA) and the receptor for AGEs (RAGE) on *in vitro* calcification by rat VSMCs. AGE-BSA was prepared by incubating BSA with high-concentration glucose. To induce calcification, VSMCs were incubated with AGE-BSA or non-glycated BSA in DMEM containing 10mmol/L β -glycerophosphate. Calcium deposition, Von Kossa staining, alkaline phosphatase (ALP) activity and mRNA, the osteoblast transcription factor core binding factor 1 (Cbfa-1), and its downstream protein osteopontin were used

to identify osteoblastic differentiation and mineralization in VSMCs induced by AGE-BSA. RAGE mRNA and protein were also detected by Real-time Polymerase Chain Reaction and Western blot analysis.

Results: AGE-BSA induced calcium accumulation in VSMCs in time- and dose-dependent manners. Treatment of VSMCs with 200 µg/ml AGE-BSA for 3 days caused a significant increase of calcium deposition as compared to non-glycated BSA culture (1.11 ± 0.1 vs 0.61 ± 0.06 µmol/mg; $p < 0.001$). After 10 days of AGE-BSA treatment, calcification in VSMCs was also dramatically increased, as shown by von Kossa staining. Mechanistic studies revealed that elevated AGE-BSA treatment of VSMCs enhanced ALP activity in a time-dependent manner (91.1 ± 11.4 vs 50.5 ± 12.3 U/g protein, day 3; 179.2 ± 11.4 vs 111.5 ± 15.1 U/g protein, day 6; $p < 0.01$). Similarly, 200 µg/ml AGE-BSA significantly increased ALP mRNA by 3.4-fold at 24 h, whereas in non-glycated BSA culture, VSMCs accumulated a slightly increase in ALP mRNA. AGE-BSA also increased the gene expression of Cbfa-1 and osteopontin by 4.1-fold and 1.8-fold, respectively, and osteopontin protein by 1.4-fold. We also showed that AGE-BSA increased RAGE mRNA and protein. Pretreatment of VSMCs with recombinant rat RAGE attenuated calcium deposition as well as ALP, osteopontin and Cbfa-1 mRNA induced by AGE-BSA.

Conclusion: These results suggest that AGEs enhances *in vitro* vascular calcification by promoting osteoblastic differentiation of vascular smooth muscle cells in part through AGE-RAGE pathway. Blockade of AGE-RAGE signaling may be a promising target for therapeutic intervention to prevent diabetic vascular calcification.

Linoleic acid upregulates the expression of the receptor for advanced glycation endproducts in glucose-treated human aortic endothelial cells

B.M. Haberberger¹, R. Graydon², J.M. Ames², A. Stitt³, L.A. Powell¹

¹Diabetes Research Group, United Kingdom, ²School of Biological Sciences, United Kingdom, ³Centre for Vision Science, Queen's University Belfast, United Kingdom

Background and aims: Diabetes is associated with changes in the blood vessel wall that lead to accelerated atherosclerosis, the main cause of increased mortality and morbidity in diabetes. Atherosclerosis is an inflammatory process initiated by endothelial dysfunction that involves the recruitment of circulating monocytes to the endothelium. This process is promoted by reactive oxygen species (ROS) and regulated by inflammatory mediators including RAGE, MAPK 1 and the cytokine TNF-α. In diabetes, in addition to disturbances in glucose homeostasis, there is impairment of fatty acid metabolism which results in increased free fatty acids in the bloodstream. The aim of this work was to analyze the effects of linoleic acid (the main dietary fatty acid in a Western diet) on the expression of inflammatory mediators in glucose-treated endothelial cells.

Materials and methods: Human aortic endothelial cells (HAEC) were cultured in 5 mM (NG) or 25 mM (HG) D-glucose (5% FCS) for 3 days prior to the addition of linoleic acid (0.2 mM) using fatty acid free-bovine serum albumin as a carrier (6:1). The cells were extracted after 24 h and 76 h and the relative mRNA expression analysed via quantitative RT-PCR. The cell permeable fluorescent probes 2', 7'-dichlorodihydrofluorescein diacetate (DCFH-DA, 10 µM) and dihydroethidium (DHE, 5 mM) were used to measure intracellular H₂O₂ and superoxide production respectively.

Results: After 24 h, linoleic acid treatment increased RAGE expression significantly in HG ($p < 0.05$) compared to the NG control. Further increases were observed in NG ($p < 0.001$) and HG ($p < 0.001$) after 76 h. TNF-α also increased significantly in HG after 76 h ($p < 0.05$) whereas maximal MAPK 1 expression was observed in HG after 24 h ($p < 0.01$) and remained constant until 76 h. These linoleic acid-induced changes in mRNA expression were preceded by increased intracellular superoxide and H₂O₂ generation ($p < 0.01$).

Conclusion: These results suggest that cellular ROS and AGEs generated by linoleic acid may mediate the upregulation of the inflammatory mediators MAPK1, TNF-α and RAGE.

RAGE deficiency induces a proinflammatory phenotype in bones and osteoblasts through PPAR-α suppression

S.K. Biswas¹, H. Li¹, F. Duttonhoefer¹, P.M. Humpert¹, C. Kasperk¹, M. Brownlee², P.P. Nawroth¹, A. Bierhaus¹

¹Department of Medicine I and Clinical Chemistry, University of Heidelberg, Germany, ²Department of Medicine and Pathology, Albert Einstein College of Medicine, New York, United States

Background and aims: AGE-RAGE interaction sustains inflammation and has been implicated in the pathogenesis of bone disease in diabetes. Remarkably, RAGE deficiency induces a proinflammatory phenotype in bones and osteoblasts, however, the physiologic role of RAGE in bone tissue is not clear. Therefore, we aimed to study the mechanism underlying inflammatory processes in RAGE deficient osteoblasts as well as signaling events that link RAGE deficiency and inflammation in bones from RAGE knock-out (RAGE^{-/-}) mice.

Materials and methods: Osteoblasts from wild type (WT, C57BL/6) and RAGE^{-/-} mice were transiently transfected with different plasmids and siRNA. Reporter gene assay, western blotting, PCR, immunoprecipitation and chromatin immunoprecipitation techniques were employed to study the expression and interactions of transcription factors and coactivators involved in the regulation of PPAR-α expression and nuclear translocation.

Results: The mild proinflammatory phenotype in bones and osteoblasts observed in RAGE^{-/-} mice was associated with a reduced gene expression and intranuclear translocation of the anti-inflammatory nuclear receptor PPAR-α. Moreover, PPAR-α activation by fibrates reduced inflammation in osteoblasts from RAGE^{-/-} mice, implying that the lack of PPAR-α in RAGE deficiency might contribute to the observed proinflammatory phenotype. We therefore analyzed the PPAR-α promoter which contains a series of Sp1 binding sites. PPAR-α promoter driven reporter gene expression was reduced in RAGE^{-/-} osteoblasts compared to WT osteoblasts. In addition, Sp1 overexpression significantly increased PPAR-α promoter activity in WT osteoblasts, but had only marginal effects in RAGE^{-/-} osteoblasts. Sequential promoter deletions confirmed a strong Sp1 dependency of PPAR-α expression in WT osteoblasts, that was not observed in RAGE^{-/-} osteoblasts. Suppression of Sp1 by siRNA transfection, however, decreased PPAR-α promoter expression by around 50% in both WT and RAGE^{-/-} osteoblasts. Remarkably, endogenous Sp1 gene and protein expression was similar in osteoblasts from WT and RAGE^{-/-} mice, suggesting that a qualitative or functional defect of Sp1 in RAGE^{-/-} osteoblasts might underlie the reduced PPAR-α gene expression in RAGE^{-/-} mice. Consistently, protein and chromatin immunoprecipitation demonstrated reduced Sp1 phosphorylation and a decreased Sp1 binding to the PPAR-α promoter in RAGE^{-/-} osteoblasts compared to WT osteoblasts.

Conclusion: The proinflammatory phenotype observed in bones and osteoblasts of RAGE^{-/-} mice is associated with a significant decrease in PPAR-α most likely due to dysfunctional Sp1 signaling and subsequent reduced PPAR-α expression.

Accelerated atherosclerosis in mice knockout for galectin-3 fed a high fat diet

S. Menini¹, C. Iacobini¹, C. Ricci¹, A. Scipioni¹, V. Sansoni¹, G. Mazzitelli¹, P. Simonelli¹, S. Cordone¹, M. Serino², M. Federici², F. Pricci³, G. Pugliese¹

¹Department of Clinical Sciences, La Sapienza University, ²Department of Internal Medicine, Tor Vergata University, ³Department of Cell Biology and Neurosciences, National Institute of Health of Italy, Rome, Italy

Background and aims: Galectin-3, a multifunctional lectin with (anti)adhesive and growth-regulating properties, was recently identified as a receptor for advanced glycation endproducts (AGEs)/advanced lipoxidation endproducts (ALEs) and modified LDLs promoting the uptake and removal of these harmful compounds. Clearance of AGEs/ALEs and modified LDLs via other receptors, including RAGE and scavenger receptors (SRs), is coupled to signaling pathways triggering macrophage activation and inflammation, ultimately leading to tissue injury. Galectin-3 expression was found to be increased in kidney and atherosclerotic lesions from both human patients and experimental animals. We previously showed that mice knockout (KO) for galectin-3 are more susceptible to develop glomerular disease induced by diabetes, AGEs and aging, as compared with the wild type (WT) mice.

Materials and methods: Coeval female galectin-3 KO and WT mice were fed for 8 months a high fat diet (HFD, 15% saturated fat, 1.25% cholesterol and 0.5% Na-cholate) or normal fat diet (NFD, 4% saturated fat). Metabolic parameters, morphometry of aortic lesions, apoptosis, inflammatory markers, AGEs/AGE-receptors and oxidative stress were assessed in these animals.

Results: Though serum cholesterol and triglyceride were increased in the 2 genotypes to the same extent, the HOMA-IR index was significantly increased only in WT-HFD mice (1.62 ± 0.37 vs. 0.88 ± 0.26 nei WT-NFD, $p < 0.01$) and the i.p. insulin tolerance test showed a lower reduction in blood glucose in WT-HFD vs. KO-HFD mice. Conversely, circulating AGE and isoprostan 8-epi-prostaglandin F_{2a} levels were higher in KO-HFD vs. WT-HFD mice. Blood pressure, as measured by arterial catheterism, was the same in the 2 genotypes and was unaffected by HFD. KO-HFD mice showed more extensive aortic lesions vs. WT-HFD mice, with significantly higher values ($p < 0.001$) of lesion area (66347 ± 6180 vs. $42973 \pm 8076 \mu\text{m}^2$) and length (583 ± 58 vs. $450 \pm 50 \mu\text{m}$). Aortic lesions of KO-HFD mice were also more complex, as shown by extensive lympho-monocyte infiltration (with higher F4/80 and exclusive CD3 staining), migration of smooth muscle cells from the media, and presence of cholesterol clefts and necrotic material surrounded by a fibrous cap, than those of WT-HFD, consisting only of fatty streaks. The gene and/or protein expression for activated caspase-3 (an index of apoptosis), monocyte chemoattractant protein, cyclooxygenase-2, vascular cell adhesion molecule-1, RAGE, SR-A1, SRB-1 e CD36 as well as the content of oxidized LDL, the glycoxidation and lipoxidation products N^ε-carboxymethyllysine and 4-hydroxy-2-nonenal, and nitrotyrosine were significantly higher in KO-HFD than in WT-HFD ($1.5\text{--}15\times$).

Conclusion: These data indicate that galectin-3 ablation favours the development of atherosclerotic lesions with a distinct inflammatory phenotype in the rodent model of lipid-induced atherogenesis. This suggests a protective role of galectin-3 in vascular injury associated with hyperlipidemia, which is related to a more efficient removal of AGEs/ALEs and modified LDLs and/or a blunted activation of pro-inflammatory pathways, at variance with RAGE.

Galectin-3 ablation protects from nonalcoholic steatohepatitis induced by high fat diet

C. Iacobini¹, C. Ricci¹, A. Scipioni¹, V. Sansoni¹, G. Mazzitelli¹, A. Frasheri¹, M. Serino², M. Federici², F. Pricci³, S. Menini¹, G. Pugliese¹

¹Department of Clinical Sciences, La Sapienza University, ²Department of Internal Medicine, Tor Vergata University, ³Department of Cell Biology and Neurosciences, National Institute of Health of Italy, Rome, Italy

Background and aims: Nonalcoholic steatohepatitis (NASH) is caused by lipid accumulation resulting in steatosis (non-alcoholic fatty liver disease, NAFLD), followed by an inflammatory and fibrotic response possibly leading to cirrhosis. Advanced glycation endproducts (AGEs) and advanced lipoxidation endproducts (ALEs), which are cleared mainly by the liver through receptors such as receptor for AGEs (RAGE) and galectin-3, may play a role in this response. Galectin-3 ablation was shown to accelerate renal injury induced by diabetes, aging and AGEs injection, but also to attenuate cirrho-

sis induced by CCl₄. This study was aimed at evaluating the role of gal-3 in the development of NASH in an animal model of insulin-resistance without obesity and diabetes.

Materials and methods: Mice knockout (KO) for galectin-3 and the corresponding wild type (WT) animals were fed for 8 months a high fat diet (HFD, containing 15% saturated fat, 1.25% cholesterol and 0.5% Na-cholate) or normal fat diet (NFD, containing 4% saturated fat). The presence of NASH was assessed in hematoxylin/eosin stained sections using the NAFLD score and its extent was then graded according to Brunt's criteria using Masson's trichromic staining for fibrosis. Metabolic parameters were assessed in these animals, together with inflammatory markers, AGEs/AGE-receptors and oxidative stress.

Results: Morphologic analysis showed NASH only in 3 out of 8 KO-HFD mice (class 3 NAFLD: micro/macrovessicular steatosis, with modest lobular inflammation and ballooning degeneration). Conversely, NASH (class 4 NAFLD: macrovesicular steatosis, portal and lobular inflammation, ballooning degeneration, Mallory's and acidophil bodies, fibrosis) was observed in all WT-HFD mice. NASH grading and staging showed grade/stage 1 NASH in the 3 KO-HFD and grade/stage 2 or 3 NASH in all the WT-HFD mice. Hepatic expression of F4/80, CD3, N^ε-carboxymethyllysine, RAGE, monocyte chemoattractant protein-1 and tumour necrosis factor- α was significantly higher in WT-HFD vs. KO-HFD mice. At the gene expression level, sterol regulatory element binding protein 1c (SREBP-1c) was up-regulated in WT-HFD, but not KO-HFD mice, which showed a down-regulation of both HMG-CoA reductase and fatty acid synthase, whereas only the former was down-regulated in WT-HFD mice. Though serum cholesterol and triglyceride levels were increased in the 2 genotypes to the same extent, the HOMA-IR index was significantly increased only in WT-HFD mice (1.62 ± 0.37 vs. 0.88 ± 0.26 in WT-NFD, $p < 0.01$) and the intraperitoneal insulin tolerance test showed a lower reduction in blood glucose in WT-HFD vs. KO-HFD mice. Conversely, circulating AGE and isoprostan 8-epi-prostaglandin F_{2a} levels were higher in KO-HFD vs. WT-HFD mice. Adipocyte diameter was higher and their number was lower in WT-HFD vs. KO-HFD mice; this difference between the 2 genotypes was observed also in the NFD-fed mice.

Conclusion: These data indicate that galectin-3 KO mice are protected from NASH, possibly due to a lower degree of insulin-resistance, resulting in a less marked steatosis (or viceversa) and impairment of removal of AGEs/ALEs, thus limiting pro-inflammatory and pro-fibrotic effects.

Atorvastatin downregulates monocyte CD36 scavenger receptor expression and nuclear NFkB levels in type 2 diabetic patients

E. Mandosi¹, M. Fallarino¹, A. Gatti¹, A. Carnovale¹, E. Lococo², B. Buchetti², S. Filetti¹, L. Lenti², S. Morano¹

¹Department of Clinical Sciences, ²Department of Experimental Medicine, "Sapienza" University, Rome, Italy

Background and aims: Type 2 diabetes increases the risk for cardiovascular disease and the 3-hydroxy-3-methylglutaryl coenzyme A (HMG-CoA) reductase inhibitors or statins reduce cardiovascular events in these patients. The benefits from statin therapy cannot be explained only by their lipid-lowering effect, but also by their anti-inflammatory properties. CD36 is a scavenger receptor expressed by many cell-types including monocytes; it is able to uptake oxidized low density lipoproteins (Ox-LDL) leading to foam cell formation and probably to Nuclear Factor- κ B (NFkB) activation. As known inflammatory processes play a major role in atherogenesis and NFkB regulates different genes involved in this condition. Given that monocytes play a major role in the atherogenesis processes, the aim of this study was to test the effect of atorvastatin therapy on CD36 scavenger receptor expression and NFkB levels in circulating monocytes from type 2 diabetic patients.

Materials and methods: Twenty-two type 2 Caucasian diabetic patients (17 male and 5 female, age 60.8 ± 7.1 years, BMI 28.9 ± 4.8 Kg/m², HbA1c $7.6 \pm 1.1\%$), were recruited and treated for 8 weeks with atorvastatin (20 mg/die). At baseline and after treatment a blood sample was collected for measurement of glucose, lipid profile (total cholesterol, HDL and LDL cholesterol, triglycerides), glycated hemoglobin (HbA1c), C-reactive protein (CRP) and for isolation of monocytes. CD36 surface protein expression (anti-CD36 fluorescein isothiocyanate-FITC), expressed as the mean of the median fluorescence, Arbitrary Units (A.U.), NFkB levels in monocyte lysate (Western blot analysis), nuclear and cytoplasm NFkB levels (immunoblot analysis), expressed as Relative Units (R.U.), were assessed in these cells.

Results: Atorvastatin therapy significantly decreased total (4.1 ± 1.0 vs. 5.2 ± 0.9 mmol/L, $p < 0.0001$) and LDL cholesterol (2.4 ± 0.9 vs. 3.2 ± 0.7 mmol/L,

$p < 0.002$) levels and increased HDL cholesterol (1.2 ± 0.2 vs 1.0 ± 0.2 mmol/L, $p = 0.02$) levels. CD36 surface protein expression was reduced (104.6 ± 20.1 vs 116.6 ± 16.0 A.U., $p < 0.02$) in circulating monocytes after atorvastatin therapy while in monocyte lysates NFkB levels were increased (22.9 ± 6.8 vs 18.4 ± 8.4 R.U., $p < 0.01$) in diabetic patients after statin treatment. To test whether the increase of NFkB levels was located into the nucleus or into the cytoplasm of monocytes, an immunoblot analysis of the nuclear and cytoplasmic fractions was performed. The immunoblot analysis showed a reduced nuclear NFkB (0.7 ± 0.1 vs 9.2 ± 0.2 R.U., $p < 0.05$) and an increased cytoplasm NFkB levels (26.5 ± 4.0 vs 17.9 ± 0.6 R.U., $p < 0.05$) after atorvastatin therapy.

Conclusion: These results suggest that, in addition to lowering serum cholesterol levels, atorvastatin therapy reduces the cardiovascular risk in treated patients by its anti-atherogenic and anti-inflammatory actions, through the decrease of the levels of molecules involved in endothelial dysfunction.

PS 130 Impairment and repair of endothelial function

1313

Forearm muscle blood flow after a mixed meal is impaired at all stages of type 2 diabetes

V. Lambadiari¹, G. Dimitriadis¹, P. Mitrou¹, E. Boutati¹, E. Maratou², T. Economopoulos¹, S.A. Raptis^{1,2};

¹2nd Dpt Internal Medicine and Research Institute, Athens University Medical School, "Attikon" University Hospital, ²Hellenic National Diabetes Center, Athens University Medical School, "Attikon" University Hospital, Athens, Greece.

Background and aims: Endothelial dysfunction is an important determinant of altered vascular reactivity and plays a decisive role in the pathogenesis of cardiovascular complications in diabetes. Microvascular disturbances can be present long before overt diabetes develops. This study was undertaken to investigate the existence of a de novo impairment in forearm muscle (FM) endothelial function, in the various stages of type 2 diabetes.

Materials and methods: A standard mixed meal was given to five groups of subjects, whose features are shown in Table 1. Blood samples were drawn from the radial artery (A) and from a vein (V) draining the FM at 30–60 min intervals for 6 h for the measurement of glucose and insulin. Simultaneous measurements of blood flow in FM were done with strain-gauge plethysmography. Glucose Flux (GFLUX) was calculated ($[G \text{ in (A-V)}] \times [BF]$).

Results: (a) GFLUX was higher in controls vs all other groups, (b) HOMA Index in controls was lower vs all other groups, (c) ISI Index was higher in controls vs all other groups, (d) peak-baseline BF was higher in controls vs all other groups (Table 1), (e) ISI was positively associated with peak-baseline BF (β -coefficient $4,962 \pm 2,147$, $p = 0,026$), (f) GFLUX was positively associated with peak-baseline BF (β -coefficient $66,120 \pm 29,3$, $p = 0,03$).

Conclusion: After meal ingestion, no response of insulin-stimulated blood flow was detected in the forearm muscles of relatives and patients with IGT, DM2-A, DM2-B. Consequently, postprandial glucose uptake was impaired, reinforcing glucose intolerance. Endothelial dysfunction combined with overt hyperglycemia will favor the development of microangiopathy.

Department of Internal Medicine, University of Pisa, Italy

Background and aims: A recent study has shown that in healthy subjects a low-dose insulin infusion severely impairs conductance arteries endothelial function suggesting a proatherogenic effect of hyperinsulinemia. This finding is in contrast with a wealth of *in vitro* and *in vivo* evidence showing that insulin facilitates both nitric oxide release and endothelium-dependent dilatation. The aim of this study was to try to replicate the above mentioned observation and evaluate to what extent the insulin effects on large arteries reactivity are modulated by the enhancement of adrenergic tone that typically occurs during the exogenous infusion of the hormone.

Materials and methods: In 20 healthy male volunteers (age: 27 ± 5 yrs), endothelium-dependent (FMD) and endothelium-independent (GTN) dilatation were evaluated by high-resolution ultrasound of the brachial artery with automatic edge detection system. FMD and GTN were expressed as percent maximal dilatation in response to 5 min of distal ischaemia or to the sublingual administration of 25 µg of glyceryl trinitrate, respectively. These meas-

Table	CONTROLS	RELATIVES	IGT	DM2-A	DM2-B

urements were serially taken at times -60 and -10 min and again after 120 and 240 min of either insulin (0.25 mUmin⁻¹kg⁻¹, n=10) or saline (n=5) intravenous infusion. Plasma glucose was maintained stable by means of a variable 20% glucose solution infusion according to the clamp technique. In 5 subjects, insulin infusion was preceded by an intravenous infusion of clonidine (0.0052 µgmin⁻¹kg⁻¹) started at time -40 min and continued throughout the 240 min of the study. Before each vascular test plasma samples were collected for the determination of insulin, glucose, adrenaline and noradrenaline.

Results: Insulin infusion raised plasma hormone concentrations from 63±4 to 210±22 pmol/l. Blood pressure, heart rate, brachial artery blood flow and plasma adrenaline remained stable in all studies. Basal artery diameter and post-ischemic flow increments were affected neither by insulin nor by clonidine. Plasma noradrenaline increased during insulin infusion from 260±40 to 333±62 pg/ml (p<0.05), while remained unchanged during combined insulin/clonidine infusion. As reported in the table, neither FMD nor GTN were affected by saline infusion. During insulin infusion no change in FMD was observed while the response to GTN showed a 25% decrease (p<0.05 by ANOVA). Infusion of clonidine alone resulted in a slight reduction in FMD (p=ns), which was not further changed by adding insulin. GTN was slightly increased by clonidine and further enhanced by insulin (p<0.05 by ANOVA).

Conclusion: A mild hyperinsulinaemia of 4-hour duration does not affect endothelium-dependent vasodilatation of conduit vessels but causes a decline in endothelium-independent vasodilatation that is entirely explained by the insulin-induced noradrenergic activation.

Fenofibrate protects microvascular endothelial cells through AMP-activated protein kinase activation and upregulation of eNOS

T. Atsuko, Y. Hattori, T. Okayasu, K. Suzuki, S. Hattori, K. Kasai
Endocrinology and Metabolism, Dokkyo University School of Medicine, Mibu, Japan

FIELD (Fenofibrate Interventon & Event Lowerig in Diabetes) showed that treatment with fenofibrate in individuals with type 2 diabetes mellitus not only reduced nonfatal coronary events but also reduced the need for laser treatment for diabetic retinopathy and inhibited the progress of diabetic nephropathy. The mechanism of the effect on this microangiopathy does not seem to be related to plasma concentrations of lipids. We hypothesized that AMP-activated protein kinase (AMPK) activity is a downstream mediator of the beneficial effects of fenofibrate on microvascular endothelial cells. Treatment of human glomerular microvascular endothelial cells (HGMEC) with fenofibrate resulted in transient activation of AMPK, as monitored by phosphorylation of AMPK and its down-stream target, acetyl-CoA carboxylase. Fenofibrate caused phosphorylation of Akt and eNOS, leading to increased production of NO, and also caused inhibition of cytokine-induced NF-κB activation, leading to suppression of expression of adhesion molecule genes. Significant decreases in eNOS activity and NO production in response to fenofibrate were observed in cells treated with AMPK siRNA or with AraA, a pharmacological inhibitor of AMPK. The attenuation of fenofibrate-induced inhibition of NF-κB activation was observed in cells treated with AMPK siRNA or with AraA. We demonstrated that TNFα stimulates IκB-α phosphorylation through induction of IKK activity, and that fenofibrate inhibits IKK activity and TNFα-induced IκB-α phosphorylation. Furthermore, fenofibrate upregulates eNOS expression, mainly through mechanism of stabilizing eNOS mRNA. Our findings suggest that the beneficial effects of fenofibrate on microvascular endothelial cells might be attributed to the induction of AMPK activation and upregulation of eNOS expression beyond its lipid-lowering actions.

Adiponectin stimulate endothelial nitric oxide synthase activation and nitric oxide production by activating AMP-activated protein kinase

Y. Long¹, Y. Yu²

¹Lab. of Endocrinology and metabolism, ²Division of Endocrinology and metabolism, West China Hospital of Sichuan University, Chengdu, China

Background and aims: Adiponectin, a hormone secreted by adipocytes, is involved in regulating energy homeostasis and glucose and lipid metabolism, and possesses potent protective effects against endothelial dysfunction. The current study investigated the action of globular adiponectin on endothelial nitric oxide synthase (eNOS), nitric oxide (NO) production, and tested the role of AMP-activated protein kinase in ser¹¹⁷⁷ phosphorylation of eNOS.

Materials and methods: Human umbilical vein endothelial cells (HUVEC) were cultured by DMEM of low glucose with 10% NBS. After 4 µg/ml recombinant human globular adiponectin stimulated for 15 minutes, phosphorylation of eNOS at ser¹¹⁷⁷, AMPK at thr¹⁷⁶ and AKT at ser⁴⁷³ were tested by immunocytochemistry. And the activity of eNOS were evaluated by measuring the production of nitrite and nitrate using high performance liquid chromatography (HPLC).

Results: The level of ser¹¹⁷⁷-eNOS Phosphorylation were increased significantly after globular adiponectin compared with control (IOD 16240.8 vs. 9159.5 p = 0.048), but not as high as which stimulated by 200 nmol/l insulin (IOD 23848.3 p = 0.034) and 20 mmol/l metformin (IOD 41472.91 p = 0.005). And globular adiponectin caused AMPK(thr¹⁷²) phosphorylation (IOD 26320.9 p = 0.003) but not AKT(ser⁴⁷³) (IOD 10671.24 p = 0.98). Globular adiponectin can stimulate more nitric oxide production although no statistical significance when compared with control (nitrite / nitrate 0.0285 vs. 0.0045, p=0.077).

Conclusion: Globular adiponectin can stimulated activation of eNOS and AMPK(thr¹⁷²) phosphorylation plays a crucial role in globular adiponectin-eNOS signal pathway.

Serum- and glucocorticoid-inducible kinase (SGK)-1 decreases human endothelial cell senescence

K. Basello¹, M.F. Lombardo¹, F. Ferrelli², D. Pastore¹, B. Capuani¹, A. Coppola¹, P. Sbraccia¹, M. Federici¹, M. Tesaro¹, G. Donadelli¹, D. Lauro¹
¹Internal medicine, University of Rome Tor Vergata, ²IRCCS, San Raffaele, Pisana, Rome, Italy

Background and aims: *In vitro* culture of vascular cell lines have a finite lifespan and, after several cell divisions, vascular cells enter in an irreversible growth arrest, called "cellular senescence". This process is accompanied by a specific set of phenotypic changes in morphology, gene and proteins expression and activity. Interestingly, the presence of senescent vascular cells has been demonstrated in human atherosclerotic lesions but not in non-atherosclerotic lesions. An increasing body of evidences have established a critical role for the telomere length and telomerase activity in inducing vascular cell senescence. Aging free radical theory suggests that reactive oxygen species (ROS) contribute significantly to senescent phenotype inducing molecular damages to lipids, proteins, and nucleic acids. It has been demonstrated that ROS production in human umbilical veins endothelial cell lines (HUVEC) is increased with increasing numbers of population doublings (PDL). SGK-1 is a serine/threonine protein kinase that is known to induce cell survival after different stress stimuli; SGK-1 transcription is induced by serum and glucocorticoid stimulation. The present study has been conducted to investigate the potential role of SGK-1 to delay the onset of senescence by counteracting the adverse effect of increased oxidative stress and/or other mechanisms involved in endothelial cell aging process.

Materials and methods: HUVEC have been used as experimental model. HUVEC have been infected with retroviral virus using pLPCX plasmid with

SGK-1wt or SGK-1D60 (deleted N 60 terminal amino acids) constructs. ROS production has been evaluated by FACS analysis using DHR123 probe. SGK-1 and hTERT expression have been measured by western blot and immunofluorescence analysis. SA-beta-galactosidase in situ staining has been used to determine the senescent status. OxyBlot technique has been used to detect and quantify carbonylated proteins that are induced by ROS. Telomerase activity has been quantified by immunofluorescence TRAP assay analysis.

Results: SGK-1 had a nuclear localization in SGK-1wt infected HUVEC cells, differently, there was a cytoplasmatic localization in SGK-1D60 infected cells and a barely detectable SGK-1 nuclear localization in HUVEC cells infected with mock (pLPCX). SGK-1 expression levels were higher in SGK-1D60 than SGK-1wt cell lines ($p<0.05$). Cells infected with SGK-1wt had a reduction of ROS production correlated to the increased numbers of PDL compared to mock ($p<0.05$). This result has been confirmed by a reduction in ROS-induced protein damage in SGK-1wt infected cells compared to mock and SGK-1D60 ($p<0.05$). It has been showed that cellular ageing decreased telomerase activity both in mock and SGK-1D60, differently, telomerase activity raised with increased numbers of PDL in SGK-1wt cell line ($p<0.05$). Finally, SGK-1wt infected cells had a reduced levels of SA-beta-Gal staining compared to mock and SGK-1D60, even in cell lines with higher PDL ($p<0.01$).

Conclusion: 1) In senescent endothelial cell lines increased expression of SGK-1 can reduce ROS production; 2) SGK-1 increased the telomerase activity in cell lines with higher PDL; 3) SGK-1 can decrease endothelial cell senescence.

Circulating endothelial progenitor cell number in long-standing type 1 diabetic patients

H. Reinhard¹, P.K. Jacobsen¹, L. Tarnov¹, A.-S. Astrup¹, M. Lajer¹, N. Pedersen¹, N. Billestrup¹, T. Mandrup-Poulsen^{1,2}, J. Kastrup³, H.-H. Parving⁴, P. Rossing¹

¹Research, Steno Diabetes Centre, Gentofte, ²Department of Biomedical Sciences, Core Unit for Medical Research Methodology, ³The Heart Centre, Rigshospitalet, Denmark, ⁴Medical Endocrinology, Rigshospitalet, Denmark

Background and aims: Circulating endothelial progenitor cells (EPC) are involved in neovascularisation and maintenance of vascular integrity. Decrease in number and dysfunction of EPC play a role in the progression of cardiovascular disease. Type 1 diabetic patients suffer from an increased risk of cardiovascular disease; underlying mechanisms are not well understood. The aim of our study was to evaluate EPC number in asymptomatic type 1 diabetic patients with and without diabetic nephropathy.

Materials and methods: We examined EPC number in 72 patients (M/F: 41/31) with long-standing type 1 diabetes without symptoms or history of cardiovascular disease (35 with normoalbuminuria and 37 with diabetic nephropathy). All patients were characterized regarding cardiovascular disease, including cardiac MR imaging. The number of EPC was assessed by *in vitro* cultures: Mononuclear cells were isolated from peripheral blood, using a Ficoll density gradient centrifugation. Cells were seeded on plates coated with human fibronectin in endothelial basal medium. After 7 days in culture, we counted double-stained cells for both UEA-1 and acLDL-DiI as EPC in 10 randomly selected fields in each patient.

Results: There was no difference in EPC number between patients with DN (120 SE (8)) and normoalbuminuric patients (108 (7)) or age-matched healthy controls (113 (5)). The 41 patients receiving simvastatin had higher number of EPC assessed by *in vitro* cultures, (133 (9)) cells per field compared to patients not receiving simvastatin, (100 (6)) cells per field, $p<0.02$. Similarly, the 17 patients treated with calcium-channel blocker (CCB), used as a third or fourth antihypertensive drug, also had more EPC, (138 (12)) cells per field compared to patients not treated with CCB (106 (6)) cells per field, $p<0.009$. Patients with systolic 24-hour blood pressure above the mean of 132 mmHg tended to have higher EPC number (125 (50)) cells per field compared to patients below the mean (106 (41)) cells per field, $p=0.078$. A multiple regression analysis confirmed these significant findings with estimates: 11 cells per field per 1% inverse change in HbA1c, 35 cells per field and 24 cells per field regarding therapy with simvastatin and calcium-channel blocker, respectively. ($R=0.507$). EPC number was not related to treatment with RAAS blockers or aspirin therapy, however patients with EPC number below the median (114, (SD 45)) were treated with a median of one antihypertensive drug compared to two in patients with EPC above the median, $p<0.02$. Only 4.2% of patients had coronary artery stenosis. The EPC number was not correlated to lipids, age, gender or coronary plaque burden.

Conclusion: In asymptomatic patients with longstanding type 1 diabetes, low EPC number is associated with poor metabolic control. Treatment with simvastatin is associated with increased number of EPC, independently of lipid levels. Treatment with calcium-channel blockers, reflecting higher blood pressure, is also associated with increased number of EPC. However in these patients with long diabetes duration but low level of coronary artery disease, EPC was not related to diabetic nephropathy and coronary plaque burden.

Endothelial progenitor cells and endothelial dysfunction in prediabetic and newly diagnosed type 2 diabetic subjects

L. Pucci¹, D. Lucchesi¹, R. Vanacore², M.C. Iorio², L. Ghiadoni³, R. Di Stefano⁴, M.C. Barsotti⁴, E. Storti¹, A. Balbarini⁴, S. Taddei³, R. Miccoli¹, G. Penno¹, S. Del Prato¹

¹Endocrinology and Metabolism, University of Pisa, ²Blood Bank, University of Pisa, ³Internal Medicine, University of Pisa, ⁴Cardio-Thorax Disease, University of Pisa, Italy

Background and aims: Circulating progenitor cells with endothelial phenotype (EPCs) contribute to functional integrity of endothelial monolayer. This integrity is essential to prevent local injuries-induced vascular leakage and to protect against initiation of atherogenesis. The concept of repair of damaged dysfunctional endothelial cell by EPCs has recently emerged. Reduction of circulating EPCs has been, indeed, associated with vascular dysfunction.

Materials and methods: We now investigated whether endothelial dysfunction is accompanied by quantitative alterations of the EPC pool in 34 subjects with impaired glucose regulation (IGR) or newly diagnosed (OGTT) type 2 diabetes (n. 18, naiveT2D) as compared to 26 normoglycaemic (NGT) individuals with (n. 13, NGT/Fam+) and without (n. 13, NGT/Fam-) first-degree family history for type 2 diabetes. Endothelial function (flow-mediated dilation, FMD) of brachial artery was assessed by ultrasound; number of circulating EPCs (CD34/KDR double positive cells) was determined by flow cytometry.

Results: IGR, naiveT2D and NGT did not differ for gender, BMI, waist circumference, diastolic BP, total- and LDL-cholesterol, apoA1 and apoB, serum creatinine, cistatin C, gammaGT, fibrinogen, hs-CRP, and SAA concentrations. However, IGR and naiveT2D were older (55 ± 5 and 58 ± 8 vs 45 ± 10 yrs, $p=0.001$), had higher systolic BP ($p=0.001$) and HbA1c values (6.0 ± 0.4 and 6.5 ± 0.6 vs $5.5\pm0.4\%$, $p<0.0001$), with not significant trend for lower HDL cholesterol ($p=0.07$) and higher triglycerides ($p=0.08$). Endothelium independent dilation (glycerol trinitrate, GTN) was not different, while FMD was lower in naiveT2D ($\Delta\%$ 4.4 ± 2.3 M \pm SD) compared with IGR ($\Delta\%$ 6.0 ± 2.8) and in both naiveT2D and IGR compared to NGT ($\Delta\%$ 7.9 ± 3.6 ; Kruskal-Wallis $p=0.0017$) with no differences between Fam+ and Fam-. The same pattern was observed for the FMD/GTN ratio, an expression of the selective endothelial function impairment. Both patterns are confirmed between genders and both in young (age 50 yrs, n. 51, $p=0.04$) subjects. Interestingly, EPCs pool was higher in NGT/Fam- (608 ± 87 cells/ml, M \pm SE) and similarly reduced in NGT/Fam+ (457 ± 68 cells/ml) and in IGR (479 ± 65 cells/ml), and even more reduced in naiveT2D (254 ± 51 cells/ml, Kruskal-Wallis, $p=0.01$). There were no gender-related or age-related differences.

Conclusion: Naive type 2 diabetic subjects showed depletion in the circulating EPC pool as well as impaired endothelium-dependent vasodilation. In subjects with non-diabetic hyperglycemia, reduction in FMD is paralleled by an intermediate depauperation of EPC pool. This impoverishment is already apparent in normoglycemic subjects with positive family history for diabetes suggesting that reduction in circulating EPCs may precede impairment in endothelial function.

1320

Kinin-mediated recruitment of progenitor cells is altered in diabetes

N. Kraenkel¹, V. Adams², M. Schoenauer³, R. Katare¹, C. Emanuelli¹, P. Madeddu¹

¹Bristol Heart Center, University of Bristol, United Kingdom, ²Heart Center Leipzig, University of Leipzig, Germany, ³Diabetologische Schwerpunktpraxis und Lehrpraxis der Universitaet Leipzig, Germany

Background and aims: Reduced recruitment of vasculogenic (VPC) and endothelial progenitor cells (EPC) is associated with an increased incidence of ischaemic complications in diabetic patients. In the past we and others

demonstrated an implication of the kallikrein-kinin-system (KKS) in reparative angiogenesis, mediated by mature endothelial cells. Here we investigated the hypothesis that bradykinin (BK) furthermore serves as a chemoattractant for VPC and EPC and that BK mediated recruitment of VPC is impaired in diabetic patients.

Materials and methods: EPC were cultured from peripheral blood mononuclear cells (PB-MNC) of non-diabetic (C, n=10) and type 2 diabetic donors (D, n=10). CD133⁺ and CD34⁺ VPC were isolated from PB-MNC by magnetic sorting. Expression of components of the KKS were analysed by qRT-PCR and flow cytometry. Migration of VPC and EPC towards BK was studied in the presence or absence of BK-receptor antagonists. BK-responsive cells were isolated from PB-MNC and the ability to give rise to EPC was studied in the BK-responsive (BK^{mis}) and non-responsive (BK^{non}) cell fractions. *In vitro* pro-angiogenic effects of BK^{mis} and BK^{non}-derived EPC were studied by matrigel assay. Homing of systemically injected B₂R-deficient or wild type MNC to the ischaemic limb of the recipient and support of blood flow recovery in the ischaemic leg was studied in a mouse hindlimb ischemia model. The abundance of CD133⁺ and CD34⁺ VPC co-expressing kinin receptors was analysed by flow cytometry in PB of healthy and diabetic donors.

Results: CD133⁺ and CD34⁺ VPC as well as cultured EPC expressed kininogens, tissue kallikrein and the constitutive B₂R. The inducible kinin B1 receptor (B₁R) was expressed only at low levels. CD133⁺ VPC and cultured EPC migrated dose-dependently towards BK. BK-induced migration was significantly reduced in the presence of B₂R antagonist HOE140 (reduced by 43.3±9.9% vs. BK, p=0.002) and PI3-kinase inhibitor LY294002 (reduced by 62.9±14.8% vs. BK, p=0.03). MNC migrating towards BK harboured a 3.9-fold higher number of CD133⁺ (p=0.01) and a 2-fold higher number of CD34⁺ VPC (p<0.05) and gave rise to 2.5-fold more EPC (p=0.01) as compared to BK^{non}. In contrast to BK^{non}, BK^{mis}-derived EPC facilitated tube formation in matrigel. B₂R-deficient (B₂R^{-/-}) EPC homed less well to ischaemic adductors as compared to WT MNC and blood flow recovery was significantly reduced when B₂R^{-/-} cells were injected. In diabetic subjects, the abundance of CD34⁺ and CD133⁺ VPC among kinin receptor expressing cells was decreased as compared to non-diabetic subjects.

Conclusion: BK induced migration of VPC might represent a novel alternative signalling pathway mediating circulating stem cell recruitment to facilitate vasculogenesis. Reduction of VPC and EPC among BK sensitive cells in diabetic patients suggests an imbalance among the spectrum of cells recruited by kinins.

Osteoprotegerin correlates with severity of peripheral artery disease in individuals with type 2 diabetes

E.P. O'Sullivan¹, D.T. Ashley², J. Kelly³, R.K. Crowley¹, A. Agha¹, C.J. Thompson¹, A.L. Leahy⁴, C.J. Kelly⁴, D. O'Gorman², P. Fitzgerald³, D. Smith¹

¹Diabetes and Endocrinology/RCSI Medical School, Beaumont Hospital, Dublin, ²School of Health and Human Performance, Dublin City University, ³Non-Invasive Vascular Lab/RCSI Medical School, Beaumont Hospital, Dublin, ⁴Department of Surgery/RCSI Medical School, Beaumont Hospital, Dublin, Ireland

Background and aims: Osteoprotegerin (OPG) is a member of the tumour necrosis factor receptor family and acts as an anti-resorptive agent in bone. Following the discovery that OPG knock-out mice develop severe vascular calcification in addition to osteoporosis, serum OPG has subsequently been shown to be associated with coronary artery calcification and cardiovascular mortality. Peripheral arterial disease (PAD) is also associated with vascular calcification and cardiovascular disease, yet the relationship between OPG and PAD in patients with diabetes has not been clarified. The aim of the study was to determine whether serum OPG correlates to severity of PAD, particularly in diabetes patients with non-compressible vessels, a clinical indicator of severe vascular calcification.

Materials and methods: 35 patients with type 2 diabetes and an age, gender and BMI-matched group of 29 without diabetes attending the vascular surgeons were enrolled into the study. All underwent assessment of PAD by means of ankle-brachial index (ABI). 63.9% had PAD, as defined by a resting ABI of <0.7, a drop in ABI post-exercise of >0.2, or toe pressures <0.6. ABIs were defined as non-compressible if the pulse could not be obliterated by inflation of a blood pressure cuff to >220mmHg. OPG was measured using a commercial ELISA assay. Statistical analysis was performed using the JMP IN 5.1 package.

Results: In the group as a whole, OPG was higher in those with PAD (7.8±0.3pmol/l), compared to those with normal ABIs (5.6±0.4pmol/l), p<0.0001; a relationship which remained statistically significant after correction for the fact that there were more patients with diabetes in the non-PAD group (81.5% vs. 50%, p=0.01). There was a negative correlation between OPG and result of ABI; r = -0.41, p=0.003. All but 1 of the 8 patients with non-compressible vessels had diabetes, and mean OPG was higher in these patients (8.1±0.8pmol/l) compared to those with compressible vessels (6.3±0.4pmol/l), p=0.04.

Conclusion: OPG is higher and correlates with the severity of PAD as defined by ABI. Whether OPG is simply a marker of underlying atherosclerotic disease or is directly involved in the pathogenesis of vascular calcification requires further research but the significant association of OPG and severe vascular calcification in patients with non-compressible vessels suggests that OPG plays a key role in pathogenesis.

Coronary atherosclerosis is characterised by more severe metabolic, inflammatory and endothelial alterations when compared to carotid atherosclerosis

E. Setola¹, L.D. Monti¹, P.C.G. Lucotti¹, E. Galluccio¹, M. Oldani¹, M.G. Pala², A. Rossodivita², M. Comola³, A. Poggi³, M. Marrocco-Trischitta², G. Comi³, R. Chiesa², E. Bosi¹, O. Alfieri², P.M. Piatti¹

¹Internal Medicine and Specialty Department, Scientific Institute San Raffaele, ²Cardiothoracovascular Department, Scientific Institute San Raffaele, ³Neurology Department, Scientific Institute San Raffaele, Milan, Italy

Background and aims: Several studies have demonstrated that patients affected by coronary or carotid atherosclerosis are at high risk of developing atherosclerotic lesions in other vascular districts, but there are no data available on the specific differences between coronary and carotid atherosclerosis. Therefore, aim of the present study was to evaluate which metabolic, hor-

monal and inflammatory alterations characterize coronary atherosclerosis compared to carotid atherosclerosis.

Materials and methods: We studied 66 patients affected by asymptomatic ischemic cardiopathy (Group 1) and 88 patients affected by carotid vasculopathy (Group 2). Group 1 included patients with a medical history of negative vascular events in other districts, in particular these patients were submitted to a carotid ultrasound that ruled out the presence of atherosclerotic lesions. In Group 2 patients presented a negative medical history for coronary events and a negative ECG for previous ischemic lesions. All patients did not have any known diabetes and fasting plasma glucose was below 126 mg/dl. The two groups were comparable by age, BMI, systolic and diastolic blood pressure, total cholesterol, HDL cholesterol and triglycerides. Plasma glucose, serum insulin and FFA levels were evaluated during an oral glucose load in all subjects and inflammatory and endothelial markers were evaluated in the fasting state.

Results: Fasting plasma glucose (107.1 ± 3.6 vs 96.1 ± 2.0 mg/dl; $p < 0.01$), HOMA index (2.90 ± 0.4 vs 1.93 ± 0.3 ; $p < 0.003$), NOx (18.7 ± 1.60 vs 11.7 ± 0.86 $\mu\text{mol/l}$; $p < 0.001$), IL-6 levels (4.04 ± 0.64 vs 2.79 ± 0.43 pg/ml; $p < 0.02$) and TNF- α levels (19.4 ± 0.13 vs 15.7 ± 1.7 pg/ml; $p < 0.05$) were significantly higher in Group 1 when compared to Group 2. After the oral glucose load, 26.5% of Group 1 patients presented normal glucose tolerance compared to 44.5% in Group 2 ($p < 0.05$). An altered glucose homeostasis, i.e. impaired glucose tolerance was found in 40.5% of Group 1 patients, while 33% evidenced type 2 diabetes mellitus. In Group 2, 35% of patients presented impaired glucose tolerance and 20% type 2 diabetes mellitus. FFA levels during the oral glucose load were higher in Group 1 than in Group 2 (60 min: 0.38 ± 0.03 vs 0.23 ± 0.01 $\mu\text{mol/l}$, $p < 0.01$; 120 min: 0.19 ± 0.02 vs 0.15 ± 0.01 mmol/l, $p < 0.03$). Furthermore, NOx levels during the oral glucose load were significantly lower in Group 1 compared to Group 2 ($\Delta\text{AUC NOx}$: -58.4 ± 28.2 vs -13.3 ± 12.1 $\mu\text{mol/l}$ (0–120 min); $p < 0.0001$). Performing a multiple regression analysis, 2h post load plasma glucose was independently related to vascular district ($p < 0.001$), AUC of FFA ($p < 0.01$), HDL cholesterol ($p < 0.003$), AUC of insulin ($p < 0.01$) and basal NOx ($p < 0.02$).

Conclusion: Coronary atherosclerosis is characterized by a higher prevalence of abnormal glucose tolerance and insulin resistance, a decreased antilipolytic activity of insulin, and a more proatherogenic profile than carotid atherosclerosis.

Role of ectodomain shedding activity from metabolic syndrome to carotid and coronary artery disease

M. Cardellini¹, S. Rizza¹, R. Menghini¹, E. Martelli², F. Clementi¹, A. Ippoliti³, F. Romeo¹, F. Folli⁴, M. Federici¹

¹Department of Internal Medicine, University of Rome Tor Vergata, Italy, ²Department of Cardiovascular Surgery, University of Rome, Italy, ³Department of Cardiovascular Surgery, University of Rome Tor Vergata, Italy, ⁴Internal Medicine, University of Texas Health Science Center SA, San Antonio, United States

Background and aims: The process of ectodomain shedding of transmembrane proteins has been recently involved in the regulation of inflammation in relation to atherosclerosis and diabetes vascular complications. Several studies suggested that soluble factors including sICAM-1, sVCAM-1, sIL6R and sTNFR1 are increased in various settings of metabolic diseases. All these factors are substrates of A Disintegrin and Metalloprotease Domain 17 (ADAM17).

Materials and methods: To elucidate the involvement of this system in the progression of atherosclerosis, we analyzed four cohorts including: 1. first degree relatives of type 2 diabetes patients (FDRs, $n=35$); 2. patients with chronic carotid artery stenosis (CTA, $n=32$); 3. patients with stable Coronary Artery Disease (CAD, $n=170$) all subjected to coronary angiography and/or cardio-TC and divided in monovessel and multivessel groups (CADmono $n=60$; CADmulti $n=110$) and 4. patient with carotid atherosclerosis who underwent to carotid endoarterectomy ($n=71$: NGT=39, IGT=19 and DM2=13). All the subjects underwent an OGTT at the beginning of the study and analysis of lipids and inflammatory markers. Ectodomain shedding process activity was performed by analysis of sICAM-1, sVCAM-1, sIL6R, sTNFR1 and sCXCL16, which is also shed by ADAM10, in cohorts 1,2 and 3. In the fourth cohort we also evaluated ADAM17 and TIMP1/2/3/4 mRNA expression levels by Real Time PCR and ADAM17 activity in the atherosclerotic plaques obtained from surgery.

Results: Results showed that sCXCL16 did not differ among groups although in CADmulti showed increased levels compared to CADmono group ($p=0.01$). sTNFR1 resulted increased only in CADmulti compared with FDR, CTA

and CADmono ($p < 0.001$). sIL6R was increased in CTA and CAD compared with FDR ($p < 0.001$) while sICAM-1 and sVCAM-1 significantly increased according to severity of vascular disease (FDRs < CTA < CAD monovessel < CAD multivessel, $p < 0.001$ Anova). Correlation of substrates with metabolic parameters in the different groups suggested that sICAM-1 was correlated with HOMA-IR in CAD ($p=0.002$, $r=0.24$) while sIL6R was correlated with HOMA-IR ($p=0.03$, $r=0.37$) and IMT ($p=0.003$, $r=0.54$) in FDRs. Our data suggest that ADAM17 activity is gradually increased in the progression of the atherosclerotic disease. To elucidate the mechanism that underlie this observation, we analyzed ADAM17 and TIMP1/2/3/4 RNA expression levels by Real Time PCR and ADAM17 activity in the 71 atherosclerotic plaques. In this subjects RNA expression levels of TIMP3 is significantly reduced in DM2 compared with NGT ($p < 0.01$) and significantly correlated with HbA1c ($R=-0.31$, $p < 0.02$) and LDL cholesterol ($R=-0.28$, $p < 0.03$). ADAM17 activity is increased in DM2 compared with NGT (NGT vs DM2 $p < 0.001$).

Conclusion: In conclusion our data suggest that the ectodomain shedding process is gradually involved in the progression of atherosclerosis from pre-clinical state to asymptomatic disease to clinically manifested disease, in relationship with the expression of TIMP3, which seems to be linked to factors correlated with glucotoxicity and hypercholesterolemia.

1324

Chronic low-grade inflammation mediates the association between body mass index and pulse pressure in women with type 1 diabetes: a 20-yr longitudinal study

P. Hovind^{1,2}, I. Ferreira^{3,4}, H.-H. Parving^{5,6}, C.G. Schalkwijk^{3,7}, C.D.A. Stehouwer^{3,7}, P. Rossing¹

¹Steno Diabetes Center, Gentofte, Denmark, ²Department of Clinical Physiology and Nuclear Medicine, Bispebjerg Hospital, Copenhagen, Denmark, ³Department of Medicine, University Hospital Maastricht, Netherlands, ⁴Department of Clinical Epidemiology and MTA, University Hospital Maastricht, Netherlands, ⁵Department of Medicinal Endocrinology, Rigshospitalet, Copenhagen, Denmark, ⁶Faculty of Health Science, University of Aarhus, Denmark, ⁷Cardiovascular Research Institute, University of Maastricht, Netherlands

Background and aims: With ageing, diabetic patients show a steeper increase in pulse pressure (PP; a marker of arterial stiffening) than non-diabetics, which may partially explain their increased cardiovascular risk. Increases in body fatness, and associated low-grade inflammation, may be one of the mechanisms underlying these increases in pulse pressure, but this has not been thoroughly examined among type 1 diabetic patients. We have therefore investigated, in a 20-yr prospective study, 1) whether the longitudinal development of BMI was associated with increases in PP and increases in a marker of low-grade inflammation (CRP); and 2) the extent to which CRP could explain any association between BMI and PP.

Materials and methods: Study population consisted of 277 type 1 diabetic patients (114 women) from an outpatient diabetic clinic (Gentofte, Denmark), who were consecutively admitted, upon diagnosis, between Sep'79-Aug'84 (mean age at diagnosis 27.5 ± 13.8 yrs; 216 adults). These patients attended the outpatient clinic every 3 or 4 months, throughout a total follow-up period of >20 yrs [median follow-up duration = 18 yrs (range 1.0–21.5)], as part of their routine evaluation. This included the assessments of BMI and blood pressure, as well as HbA1c, urinary albumin excretion rate (UAE), creatinine, cholesterol, and smoking status. PP was calculated as systolic - diastolic pressure. CRP was recently measured in blood samples collected throughout the whole longitudinal period. We used generalized estimating equations (GEEs) to investigate, longitudinally, the associations hypothesized and results hereby obtained are expressed in longitudinal regression coefficients (respective 95% CI). All analyses were adjusted for age and the other risk factors assessed (listed above).

Results: BMI and PP increased significantly throughout the longitudinal period: by 0.22 and 0.23 (kg/m² per year) and by 0.45 and 0.59 (mmHg/year), in men and women, respectively ($P < 0.001$ for all). BMI was positively associated with PP in women [$\beta=0.52$ (0.15; 0.89)], but not in men [$\beta=-0.04$ (-0.48; 0.40)]; BMI was positively associated with logCRP [$\beta=0.030$ (0.008; 0.053); $\beta=0.041$ (0.015; 0.046)], in both men and women, respectively. Finally, the association between BMI and PP observed in women was attenuated by about 29% for logCRP [$\beta=0.37$ (-0.10; 0.85)].

Conclusion: Life-course increases in body fatness are associated with increases in pulse pressure, a marker of arterial stiffness, in type 1 diabetic women (but not men). This association is, at least in part, mediated by the obesity-related increase in low-grade inflammation.

Gender difference in risk factors and mortality in patients with type 2 diabetes and myocardial infarction. A report from the DIGAMI 2 trial

A. Norhammar, K. Malmberg, L. Rydén

Unit of Cardiology, Institution of medicine, Karolinska University Hospital, Stockholm, Sweden

Background and aims: Diabetic women are in general at increased risk for cardiovascular disease compared to men. The impact of gender after myocardial infarction is, however, less well explored among such patients.

Materials and methods: The DIGAMI 2 trial included 837 men and 416 women with type 2 diabetes and myocardial infarction. Risk factor profile and outcome were analysed by gender. Predictors for outcome (previous myocardial infarction, heart failure, ventricular fibrillation, cardiogenic shock, smoking, age, creatinine, complications to diabetes, admission blood glucose, HbA1c and diabetes duration) were analysed by a stepwise logistic regression model.

Results: Women were older, had more frequently a history of heart failure and hypertension and were more often treated with diuretics at admission and discharge. Beta-blockers were given less often to women while ACE-inhibitors were used in a similar proportion of men and women. The combined end point (death, myocardial infarction and stroke) were more common in women (Figure). This difference disappeared after adjusting for age. Predictors for an event were previous heart failure and myocardial infarction, cardiogenic shock, creatinine, diabetes complications and blood glucose at admission.

Conclusion: The risk factor profile differs in men and women with type 2 diabetes and acute myocardial infarction with more previous heart failure and hypertension in women. Improved risk factor control may have a potential to improve the prognosis among female patients.

Apolipoprotein B/A1 ratio is independently associated with carotid intima media thickness in Korean diabetic patients with low LDL-cholesterol

Y. Choi¹, S. Choi², S. Park³, D. Kim⁴, C. Kim⁵, S.-H. Jee⁶, E.-J. Lee⁷, K. Huh¹

¹Endocrinology, Huh's Diabetes Center, Seoul, Republic of Korea,

²Endocrinology, Seoul National University Bundang Hospital, Seongnam,

³Endocrinology, Pochon Cha University, Seongnam, ⁴Endocrinology, Aju

University, Suwon, ⁵Endocrinology, Hallym University, Anyang, Republic

of Korea, ⁶Epidemiology, Yonsei University, Seoul, ⁷Endocrinology, Yonsei University, Seoul, Republic of Korea

Background and aims: The Apo B/Apo A1 ratio has been regarded as a useful predictor for cardiovascular events. Apo B measurement yields additional information on presence of atherogenic VLDL or small dense LDL, the type of dyslipidemia that is common in type 2 diabetes. In this study, we investigated whether Apo B/Apo A1 was associated with subclinical atherosclerosis in type 2 diabetic subjects with low LDL-cholesterol.

Materials and methods: Of 3777 patients with type 2 diabetes, who visited Huh's Diabetes Center from 2003 to 2007, we enrolled 1316 patient (mean age 57±10 yr, Male 55%) with low LDL cholesterol (<100 mg/dl). The Apo B/Apo A1 ratio was measured in all the subjects. Carotid artery intima media thickness (C-IMT) was measured bilaterally by high-resolution B-mode ultrasound and carotid atherosclerosis was defined as having a clearly isolated focal plaque or diffuse thickening of C-IMT≥1.1 mm.

Results: The Apo B/Apo A1 ratio was positively correlated with total cholesterol ($r=0.122$, $p<0.001$), triglyceride ($r=0.384$, $p<0.001$), LDL-cholesterol ($r=0.271$, $p<0.001$), fasting glucose ($r=0.059$, $p<0.05$), blood pressure ($r=0.055$, $p<0.05$), BMI ($r=0.173$, $p<0.001$) and negatively correlated with HDL-cholesterol ($r=-0.537$, $p<0.001$). The Apo B/Apo A1 represents high LDL/low HDL cholesterol in our study subjects. In multiple regression model, the Apo B/Apo A1 ratio was independently associated with C-IMT after adjusting for age, duration of diabetes, BMI, triglyceride, HDL cholesterol, systolic blood pressure, smoking in both sexes (men: $\beta=0.150$, $p<0.001$, women: $\beta=0.078$, $p<0.05$). The relative risk for carotid artery atherosclerosis was 1.76 (95% CI: 1.08, 2.88) in men and 2.18 (95% CI: 1.38, 3.44) in women with highest tertile of the Apo B/Apo A1 ratio compared with men and women with lowest tertile of the Apo B/Apo A1 ratio.

Conclusion: The Apo B/Apo A1 ratio could be a good predictor for carotid atherosclerosis in type 2 diabetics with low LDL-cholesterol.

Combination of resistin (RETN) polymorphism and serum resistin level may be a good risk marker for susceptibility of stroke in Japanese type 2 diabetic patients

E. Nakashima¹, A. Watarai¹, M. Tomita², T. Matsuki¹, T. Tsukahara¹, K. Naruse¹, H. Kamiya¹, T. Shibata¹, Y. Oiso¹, J. Nakamura¹

¹Endocrinology and Diabetes, Nagoya University, ²Information Systems and Mathematical Sciences, Nanzan University School, Nagoya, Japan

Background and aims: Diabetic macroangiopathy such as myocardial infarction, angina pectoris and cerebrovascular diseases are the major causes of mortality in diabetic patients. Resistin, an inflammatory cytokines, expressed in human monocytes and macrophages has reported to be elevated in the subjects with obesity and insulin resistance. Resistin has recently been also reported to have direct actions on arterial wall, and may contribute to the development of macroangiopathy. We previously reported that blood resistin levels were correlated with the inflammatory status and be associated with the prevalence of stroke in Japanese type 2 diabetic patients. But it also reported that the specific recognition of -420G allele by Sp1/3 transcription factor was reported to increase resistin gene (RETN) promoter activity, leading to increased serum resistin levels in human. In this study, therefore, we explored its other SNPs in correlation with its blood levels and examined the combination of resistin SNPs and its blood levels for the possibility as a risk marker of stroke in Japanese type 2 diabetic patients.

Methods: A total of 349 type 2 diabetic outpatients were enrolled in this study. Resistin were measured by an enzyme-linked immunoassay kit. Genotyping of polymorphisms at position -420G, -358, 188, and 299 were performed by polymerase chain reaction restriction fragment length polymorphism method. Statistical analyses were performed using the program SPSS. Data are presented as means ± SD. We also studied an association analysis of the model by diplotype-based QTL phenotype that is used estimated haplotypes.

Results: Serum resistin levels were significantly higher in patients with stroke than in those without stroke (19.6 ± 12.6 vs. 12.4 ± 7.8 ng/ml, $P<0.001$). The serum resistin levels were increased in a genotype-dependent fashion in all 4 genotypes. There was strong linkage disequilibrium among these 4 SNPs. The enrolled patients were divided by their serum resistin concentrations (high or low group) and their genotypes (CC, CG, GG at -420) into 6 groups. After adjustment for age, gender, body mass index, systolic blood pressure, and serum levels of triglycerides and creatinine, the multivariate logistic-regression analysis were done and each odds ratio against CC_Low group was calculated.

Figure

Conclusion: The serum resistin levels and its genotype were associated with the prevalence of diabetic macroangiopathy in Japanese type 2 diabetic patients. Our results suggest that the combination of RETN gene polymorphism and serum resistin levels might be a strong marker of susceptibility to stroke among Japanese type 2 diabetic patients.

Partial tissue kallikrein deficiency does not have a major impact on macrovascular complications in type 2 diabetic patients from the DIABHYCAR studyM. Fysekidis^{1,2}, N. Bellili³, R. Roussel^{1,2}, S. Madani-Maimaitiming³, F. Fumeron³, K. Mohammedi^{1,2}, M. Marre^{1,2}¹Diabetology, Nutrition and Endocrinology, Bichat Hospital, APHP, ²Inserm, U695, INSERM, ³INSERM, U695, INSERM, Paris, France

Background and aims: Tissue kallikrein known to cleave kininogen thus releasing kinins that have local vasodilator and diuretic effects is implicated in the regulation of renal hemodynamics and blood pressure. Subjects affected with the R53H polymorphism (5-7% of the caucasian population) were reported to have decreased enzymatic activity leading to eutrophic inward remodeling of the arterial wall and reduced arterial ability to adapt to shear stress. We have tested the impact of R53H on the risk for the occurrence of primary cardiovascular events such as myocardial infarction, stroke, cardiovascular death, heart failure, end stage renal disease or all of them combined in type 2 diabetic patients from the Non-Insulin-Dependent Diabetes, Hypertension, Microalbuminuria, Cardiovascular Events, and Ramipril (DIABHYCAR) study.

Materials and methods: The DIABHYCAR Study was a 6-year double-blind multicenter multinational clinical trial with 4,912 type 2 diabetic men and women selected from 1995 to 2001 from 16 European countries, aged 50 years or older with urinary albumin concentration (UAC) >20 mg/l. In the present study DNA samples were available for 3122 French type 2 diabetic patients. The tested hypothesis was that the 258 R53H and the 3 H53H would display a higher odds ratio (OR) for primary cardiovascular events than the 2861 R53R. Survival analysis was performed and adjustments were made using the Cox model.

Results: At baseline 44 from the 261 RH/HH subjects had a history of cardiovascular events and 502 from the 2861 RR group with no significant difference between the two groups (χ^2 RR vs RH/HH: 0.078, $p=0.778$). Age, sex ratio, HbA1c, blood pressure, smoking and diabetes duration were similar between groups and they were variables in the Cox model. During follow up 495 combined primary events occurred with 46 of them in the RH/HH group and the adjusted OR in the Cox model for participants with RH/HH genotypes vs RR was 1.3 (95% CI 0.94-1.79) with an attributable population risk at 2.3% (95% CI 0.0-8.0%). There were 13 congestive heart failure events OR 1.56 (95% CI 0.83-2.93), 11 strokes OR 1.45 (95% CI 0.77-2.72), 4 myocardial infarctions OR 0.54 (95% CI 0.17-1.70), 18 deaths of cardiovascular origin OR 1.54 (95% CI 0.91-2.60) and no end stage renal disease in the RH/HH group. No significant interactions with Angiotensin Converting Enzyme Insertion/Deletion polymorphism were found. Secondary event analysis for 37 amputations with 7 in the R53H group showed an OR of 2.66 (95% CI 1.01-6.55) with a log rank RH/HH vs RR: 6.63 ($p=0.018$) and a population attributable risk of 1.65% (95% CI 0.0-4.0%).

Conclusion: Partial tissue kallikrein deficiency in type 2 diabetic patients with the R53H polymorphism does not appear to have a major impact in the occurrence of mortality or macrovascular complications. The possible role in diabetic foot needs to be confirmed by further studies due to a small number of events and the lack of statistical power.

1329

The effects of adiponectin gene polymorphisms on the progression of carotid intima-media thicknessH.J. Kim¹, E.S. Kang², H.C. Lee²¹Internal Medicine, Medical College, Kwandong University, Goyang,²Internal Medicine, Medical College, Yonsei University, Seoul, Republic of Korea

Background and aims: Previous studies have documented environmental risk factors for the progression of carotid intima-media thickness (IMT); however, few have examined genetic risk factors for the progression of carotid IMT and none has specifically examined subjects with type 2 diabetes. This study examined the association between single nucleotide polymorphisms in the adiponectin gene and the progression of carotid IMT in patients with type 2 diabetes.

Materials and methods: We performed common carotid ultrasonography at baseline and 33-39 months later in 324 consecutive subjects with type 2 diabetes. The genotypes of the adiponectin gene were determined using a single base primer extension method.

Results: The A allele of -11426A/G ($P<0.05$), G allele of -10066C/G ($P=0.001$), A allele of -8564G/A ($P<0.01$), A allele of -450A/G ($P<0.05$), and G allele of 276G/T ($P<0.01$) were associated with progressive carotid IMT. In the haplotype analysis, the AC/AC haplotype combination in block 1, GAA/GAA haplotype combination in block 2, and GGA/GAG and GGA/TAG haplotype combinations in block 4 of the adiponectin gene were associated with progressive carotid IMT ($P<0.05$).

Conclusion: Variation in the adiponectin gene is associated with the rate of carotid IMT progression and is an important genetic factor for the progression of atherosclerosis in subjects with type 2 diabetes.

Prognostic value of osteoprotegerin for prediction of all-cause mortality in asymptomatic type 2 diabetic patientsA. Avignon¹, A. Sultan¹, J. Pochic¹, C. Boegner¹, C. Piot², D. Mariano-Goulard³, E. Renard⁴, A.-M. Dupuy⁵, J.-P. Cristol⁵
¹Metabolic disease, CHU Montpellier & Université Montpellier1, Montpellier CEDEX 5, France, ²Cardiology, ³Nuclear Medicine, ⁴Endocrinology, ⁵Biochemistry, CHU Montpellier & Université Montpellier1, France

Background and aims: Although intensive control of cardiovascular (CV) risk factors reduces mortality in diabetic patients (DP), this population still suffers from an excess mortality from CV diseases. The identification of DP likely to present an event could allow both to better target screening strategies and to further strengthen preventive measures, highlighting the need for improved methods to stratify residual risk within diabetic populations. In this regard, newer biomarkers like C-reactive protein, homocystein and fibrinogen among others have attracted attention but their value and appropriate use remain a source of debate. Very recently, osteoprotegerin (OPG) has emerged as a possible potent risk marker for CV disease. In DP, it has been shown to be associated with coronary atheroma, silent myocardial ischemia and CV events. However, no studies have evaluated usefulness of OPG for predicting all-cause death in DP which is the topic of the current study.

Materials and methods: A total of 356 consecutive type 2 DP (61±9 years; 61% male) free of symptoms of CV disease were evaluated by stress (exercise + dipyridamole) myocardial perfusion imaging. Risk factors, hs-CRP, homocystein, adiponectin, resistin and OPG levels were measured. Patients were followed up for death using telephone interview.

Results: Fourteen deaths occurred during a median follow-up of 34.3 [IQR 23.9-49.9] months. OPG at inclusion was higher in those patients who died compared to those who were alive at follow-up (11.7±4.2 vs 7.2±4.1 pmol/l, $P<0.0001$). After adjustment for age, predictors of mortality from the Cox proportional hazards model were smoking status ($P=0.04$), impaired renal function ($P=0.02$), peripheral arterial disease ($P=0.002$) and an OPG plasma value in the highest quartile, i.e. >8.7 pmol/l ($P=0.02$). None of the other classical or novel risk factors were significantly associated with time to death. In a multivariate model including all variables associated with time to death, an OPG plasma value in the highest quartile was the only independent predictor of death (HR, 4.39; 95% CI, 1.14-19.65; $P=0.03$). This remained true when further correcting for conventional risk factors. Predictive accuracy of OPG was evaluated using receiver-operator characteristic curve. Comparing the patients who were alive at the time of follow-up with those who had died gave an AUC (95% CI) of 0.82 (0.77-0.91; $P<0.0001$). The cut-off value of 8.7 pmol/L for plasma OPG corresponded to a negative predictive value of 99% (95% CI 97-100%) and a corresponding positive predictive value of 13% (6-22%) for the 34.3 months risk of death.

Conclusion: In asymptomatic type 2 DP, an OPG value in the highest quartile (>8.7 pmol/l) identifies increased risk for all-cause death. Importantly, an OPG plasma level below that threshold portends an extremely low risk of death. Hence, the addition of the measurement of OPG to conventional screening strategies may provide an improved method of identifying asymptomatic DP at risk for death.

1331

Cigarette smoking and high LDL-cholesterol concentrations are associated with two different but additive proinflammatory gene expression signatures in circulating mononuclear cells

I. Zavaroni¹, D. Ardigò¹, I. Steinfeld², E. Derlindati¹, R. Navon², L. Franzini¹, A. Dei Cas¹, V. Spigoni¹, T. Quertermous³, P. Tsao³, Z. Yakhini²

¹Internal Medicine, University of Parma, Italy, ²Agilent Technologies, Tel Aviv, Israel, ³Cardiovascular Medicine, Stanford University, Stanford, United States

Background and aims: Preliminary evidence indicates that the gene expression profile (GEP) of circulating white blood cells is significantly affected by the exposure to cardiovascular (CV) risk factors. However the few available studies have several limitations, including small sample size and narrow range of genes tested. Moreover, the interaction of multiple risk factors has not been investigated. The aim of the present study is to investigate GEP at whole-genome level in peripheral blood mononuclear cells (PBMC) of healthy volunteers in presence of cigarette smoking and/ or high LDL-cholesterol (LDL-c).

Materials and methods: To address this issue, PBMC's GEP was evaluated using Agilent whole genome oligonucleotide mRNA microarrays in 48 apparently healthy young-adults (20M/28F) with a median age of 35 years (IQR 7), all volunteers in a CV risk assessment study. Enrolled subjects were free of diabetes, CV and inflammatory diseases, and did not take pharmacological medications. Data analysis was performed using methods developed to address differential expression for quantitative phenotypes and enrichment of gene sets in ranked lists of genes.

Results: Despite the fact that regular smokers (N=8) had a similar clinical profile and comparable C-reactive protein levels to subjects who never smoked (N=28), their GEP was enriched with GO terms associated with the inflammatory response [Defense response, $p=10^{-9}$; Response to biotic stimulus, $p=10^{-9}$; Immune response, $p=10^{-9}$] and the over-expression of genes related to innate immunity. "B-cell receptor signaling" was the single molecular pathway most over-represented ($p = 1.6 \times 10^{-4}$) in genes differentially expressed in smokers. In addition, this signature was also correlated with weekly cigarette consumption.

In parallel, the presence of high LDL-c (140-197 mg/dL; 3rd LDL-c tertile) was also associated with a pro-inflammatory GEP compared to low LDL-c (40-104 mg/dL, 1st tertile) in absence of clinical differences between the two groups. However, the high LDL-c expression-signature was more characterized by the over-expression of genes associated with cell-mediated immunity [Antigen presentation $p=10^{-5}$, Antigen processing $p=10^{-5}$] and the most enriched cellular pathway found was the "antigen processing and presentation" through MHC class II ($p = 1.8 \times 10^{-4}$), whose key genes were all significantly up-regulated. Interestingly, in subjects who smoked and had high LDL-c compared to low LDL-c non-smokers, the transcriptomic profile was characterized by the co-presence of the two bio-signatures and the enrichment of both innate and cell-mediated immunity.

Conclusion: In conclusion, in apparently healthy young adults, both cigarette smoking and high LDL-c are associated with the over-expression of genes related to the inflammatory response. However, the two risk factors are characterized by two different transcriptomic "signatures", representative of innate and cell-mediated immunity respectively. The presence of both risk factors induces the expression of both these bio-profiles, suggesting an additive effect between the two in elevating the chronic sub-clinic inflammation associated with CV diseases.

Elevated adiponectin levels are independent of sex, adiposity, renal function and diabetes characteristics in normoalbuminuric type 1 diabetic patients

C. Abi Khalil^{1,2}, R. Aubert², R. Roussel^{1,2}, F. Travert¹, N. Emery², N. Bellili², G. Velho², F. Fumeron², S. Hadjadj³, M. Marre^{1,2}

¹Diabétologie-endocrinologie-nutrition, Hôpital Bichat, Paris, ²Faculté de médecine Xavier-Bichat, INSERM U695, Paris, ³Diabétologie-endocrinologie-nutrition, CHU Poitiers, France

Background and aims: Total adiponectin levels were reported elevated in type 1 diabetes T1D and related to nephropathy. As these patients are traditionally known to be "lean" individuals, we studied if specific adiponectin isoforms were elevated in normoalbuminuric T1D patients, and if their determinants differed from those in general population, especially adiposity and kidney function.

Materials and methods: Total, High-, Medium-, and Low-Molecular Weight (HMW, MMW, LMW) adiponectin levels were measured by ELISA in 33 consecutive normoalbuminuric, normotensive T1D subjects (19 M and 14 F, aged 35 ± 2 , T1D duration 13 ± 2 years) and in 33 age and sex matched controls. Body Mass Index (BMI), fat mass (impedancemetry), Glomerular Filtration Rate (GFR, ⁵¹Cr-EDTA clearance), and HbA1c were also measured.

Results: Total adiponectin was elevated in T1D vs controls (8.4 ± 0.8 vs 6.9 ± 0.7 $\mu\text{g/L}$, $p < 0.05$) with high HMW (4.1 ± 0.6 vs 3.1 ± 0.5 $\mu\text{g/L}$), MMW (1.8 ± 0.2 vs 1.7 ± 0.2 $\mu\text{g/L}$) and LMW (2.4 ± 0.2 vs 2.1 ± 0.2 $\mu\text{g/L}$). The T1D subjects had similar BMI (23.6 ± 0.9 vs 24.0 ± 0.7 kg/m^2), waist circumference (89 ± 2 vs 90 ± 2 cm), fat mass (23.1 ± 1.9 vs $23.4 \pm 2.1\%$ of weight), but higher GFR (127 ± 3 vs 106 ± 4 mL/min/1.73m^2), than controls. In T1D, total adiponectin levels were not different according to sex (M 7.7 ± 0.8 vs F 9.5 ± 1.4 $\mu\text{g/L}$), and not related to BMI ($p=0.06$; NS), waist circumference ($p=0.02$; NS), HbA1c ($p=0.05$; NS), GFR ($p=0.13$; NS), or diabetes duration ($p=0.30$; NS). In controls, total adiponectin was indeed different according to sex (M 4.9 ± 0.6 vs F 9.7 ± 1.0 $\mu\text{g/L}$, $p<0.001$), and inversely related to BMI ($p=-0.44$, $p<0.01$) and waist circumference ($p=-0.40$, $p<0.02$). Results were similar for all adiponectin isoforms.

Conclusion: The higher levels of all forms of ADPN in normoalbuminuric type 1 diabetic patients than in control patients were not explained by the difference in established determinants of adiponectin (adiposity, sex); neither by the T1DM characteristics (kidney function, diabetes duration). The nature of T1D effect on adiponectin levels remains unclear.

1333

The inflammation marker YKL-40 is elevated in patients with type 1 diabetes and increases with levels of albuminuria

C.N. Rathcke¹, F. Persson², L. Tarnow², P. Rossing³, H. Vestergaard^{1,3}

¹Dept. of Endocrinology, Herlev Hospital, Herlev, Denmark, ²Faculty of Health Sciences, University of Copenhagen, Denmark

Background and aims: The inflammation marker YKL-40 is independently associated with an increased cardiovascular (CV) mortality in individuals without diabetes and CV disease. It is associated with atherosclerosis and is also elevated in patients with type 2 diabetes (T2D) without diabetic complications where it correlates with insulin resistance. In the present study and for the first time, levels of YKL-40 are examined in patients with type 1 diabetes (T1D) with increasing levels of albuminuria, associated with an increased risk of CV disease.

Materials and methods: The study population consisted of 3 groups of Caucasian patients with T1D attending Steno Diabetes Center in 2004: 58 with normoalbuminuria (N)(u-albumin<30mg/24h), 46 with persistent microalbuminuria (MA)(30-300 mg/24h) and 45 with persistent macroalbuminuria/diabetic nephropathy (DMN)(≥300 mg/24h). Control group consisted of 55 healthy individuals (C). The groups were matched by gender and duration of diabetes, aged > 30 years.

Results: Median levels (range) of serum YKL-40 were significantly higher in N vs. C (C: 37 (14-100) ng/ml; N: 53 (14-255) ng/ml, $p<0.01$) and were increasing with increasing levels of albuminuria: MA, 74 (24-874) ng/ml; DMN: 117 (28-1106) ng/ml, $p<0.001$ for all comparisons). Levels of YKL-40 were correlated with urinary albumin/creatinine ratio (UACR) in the total group of participants ($r^2=0.25$, $p<0.001$). Significant, but weak, intercorrelations of YKL-40 were found with age, duration of diabetes, hemoglobin A1c and s-creatinine. After adjustment for significant covariates, albuminuria was significantly associated with levels of YKL-40, $p<0.001$.

Conclusion: Serum YKL-40 is elevated in patients with T1D with an independent association between increasing serum YKL-40 and increasing albuminuria. The present study is the first to suggest a role of YKL-40 in the gradually progressing vascular complications in patients with T1D.

Exercise restores coronary vascular function independent of myogenic tone or hyperglycaemic status in db/db mice

S. Ghosh¹, F.M. Afsari², M. Khazaei³, C.B. Verchere⁴, I. Laher⁵

¹Department of Pediatrics, Child and Family Research Institute, Vancouver, ²Department of Anesthesiology, Pharmacology and Therapeutics, University of British Columbia, Vancouver, ³Department of Anesthesiology, Pharmacology and Therapeutics, University of British Columbia, Vancouver, ⁴Department of Pathology and Laboratory Medicine, University of British Columbia, Vancouver, ⁵Department of Anesthesiology, Pharmacology and Therapeutics, University of British Columbia, Vancouver, Canada

Background and aims: Endothelial dysfunction is an early event in the development of diabetic vascular disease. Regulation of coronary function is important component in prevention of ischemic cardiac events, but remains poorly studied. Exercise is routinely recommended in the management of diabetes but the effects of this lifestyle modification on diabetic coronary function is relatively unknown. In this study, we investigated coronary artery myogenic tone and examined endothelial function, both of which are important determinants of maintaining vascular fluid dynamics in the myocardium. We hypothesized that exercise reduces pressure induced myogenic constriction of coronary arteries while at the same time also improving endothelial function *db/db* mice, a frequently used animal model of type 2 diabetes.

Materials and methods: We used pressurized mouse coronary arteries isolated from the hearts of control and *db/db* mice that were either sedentary or exercised for an hour a day on a motorized exercise wheel system (set at 5.2 meters/day, 5 days a week).

Results: Exercise caused a ~10% weight loss in *db/db* mice and decreased whole body oxidative stress as measured by plasma 8-isoprostane levels, but failed to improve hyperglycemia or plasma insulin levels. Exercise failed to alter myogenic regulation of arterial diameter stimulated by increased transmural pressure and did not alter smooth muscle responses to U-46619 (a thromboxane agonist) or sodium nitroprusside (endothelial independent dilator). However, exercise restored acetylcholine-stimulated, endothelial dependent coronary artery vasodilatation in *db/db* mice, accompanied by increased expression of manganese superoxide dismutase (MnSOD) and decreased nitrotyrosine levels in the hearts of *db/db* mice.

Conclusion: We conclude that the vascular benefits conferred by moderate levels of exercise were independent of changes in myogenic tone or hyperglycemic status, and primarily involved increased NO bioavailability in the coronary microcirculation.

e-Tracking (eT) as a new tool in the evaluation of early functional vascular changes in subjects without structural remodeling of carotid arteries in diabetes

Z. Bociaga¹, K. Loboż-Grudzien², M. Wilczyńska³, J. Jaroch¹, A. Kowalska¹, A. Wozwillo¹, E. Kruszyńska¹, M. Woda¹

¹Department of Cardiology, T.Marciniak Hospital, ²Public Health Department, Medical Academy Wrocław, ³Centre of Diabetic-Endocrinologic Care, Diabetic-Endocrinologic Care, Wrocław, Poland

Background and aims: Little is known about clinical application of e-Tracking (eT) in evaluation of early functional vascular changes in diabetes (D) without structural remodeling of carotid arteries (c.a.). We tested the hypothesis if eT indices of arterial stiffness (a.s.), with novel one-point pulse wave velocity-PWV among them, are an early marker of functional vascular abnormalities in D. The aim of the study was to compare eT indices in D and in healthy subjects (N). We also examined relationship between eT indices and clinical data (age, mean systolic and diastolic blood pressure (MSBP,MSDP)), c.a. intima-media complex (IMT) and echocardiographic left ventricular systolic and diastolic indices (l.v.s.i., l.v.d.i.).

Materials and methods: The study group consisted of 93 subjects (40 D and 53 N), mean age 52,5 years, 38 M and 55 F. eTracking of c.a. (a new built-in echo walltracking ALOKA system), B-Mode c.a. Doppler ultrasound, echocardiography and 24-ABPM were performed in each patient. From eT the following a.s. parameters (with blood pressure values introduced into formulas during examination) were calculated: Beta index (beta), Epsilon index (pressure-strain elasticity modulus, Ep), arterial compliance (AC), one-point pulse wave velocity (PWVβ), augmentation index (AI). From ECHO-Doppler and Tissue Doppler (T.D.): ejection fraction (EF) and l.v.d.i. were evaluated. From 24-ABPM: MSBP and MDBP were calculated. Glycated haemoglobin (HbA1c) was measured in each patient.

Results: All pts had normal IMT values and preserved LV systolic function. In D mean values of beta (10,7 +/- 3,3) were significantly higher ($p < 0,05$) than in N (8,3 +/- 2,61).

Mean values of Ep and PWV were also significantly higher in D than in N (146,8 vs 118,2; 6,86 vs 6,39 respectively). In D group 66% pts had higher than normal values of beta and 59% had higher than normal values of Ep and PWV (established as 9, 130 and 6,5 respectively, using ROC curve procedure in our normal population) while all of them had normal IMT value. Significant correlations between age and beta ($r = 0,33$, $p < 0,05$) were observed. MSBP and MDBP correlated with eT indices except AI. Among the l.v.d.i. only E' (early wave filling from T.D.) correlated with AC, AI, PWV. Significant correlations between HbA1c and beta index ($r = 0,39$, $p < 0,05$), Ep ($r = 0,46$; $p < 0,05$), AC ($r = -0,35$, $p < 0,07$) but not with IMT were noted.

Conclusion: e-Tracking carotid arterial stiffness indices can be useful in detection of early functional vascular changes that precede arterial structural remodeling in patients with diabetes which is supported by correlation between HbA1c and eT indices in diabetic patients with normal IMT.

Arrhythmogenesis and sympathetic activation in human obesity

F. Paleari¹, P. Gamba, F. Quarti-Trevano, R. Dell'Oro, L. Magni, M. Volpe, M. Colombo, G. Grassi, G. Mancina

Clinica Medica, Università Milano-Bicocca, Ospedale San Gerardo, Monza, Milan, Italy

Background and aims: Human obesity, particularly when complicated by obstructive sleep apnea is characterized by an increased risk of ventricular arrhythmias. Although this has been ascribed to neuroadrenergic mechanisms, no direct evidence is available on this issue in humans.

Materials and methods: We studied 51 obese normotensives (age: 49.7 ± 1.2 years, mean \pm SEM), of which 28 without (O-) and 23 with (O+) monofocal premature ventricular beats in Lown class < II. A polysomnographic evaluation allowed the O- subjects to be further classified as without (O-OSA-, n=12) and with (O-OSA+, n=16) sleep apnea. A similar procedure was done in O+ (O+OSA-, n=10 and O+OSA+, n=13). In each patient we measured, along with anthropometric and echocardiographic variables, beat-to-beat mean blood pressure (BP, Finapres), heart rate (HR, EKG) and muscle sympathetic nerve activity (MSNA, microneurography) at rest and during baroreflex stimulation and deactivation (vasoactive technique).

Results: O- and O+ subjects were age-matched and characterized by BP and echocardiographic values, which were in the normal range and superimpos-

able in the 2 groups. Anthropometric values were similarly altered in the 2 groups. When compared to O-, O+ showed a slight increase in HR but a significant elevation in MSNA (45.8 ± 1.9 vs. 68.2 ± 1.5 bs/100hb, $p < 0.001$). This increase was potentiated in presence of OSA. This was accompanied by a significant HR and MSNA baroreflex impairment which was evident in O+ (-24.5 ± 3.1 and $-19.4 \pm 2.9\%$) and potentiated in O+OSA+ (-35.1 ± 3.8 and $-28.7 \pm 3.1\%$).

Conclusion: Thus in human obesity neurogenic and reflex mechanisms participate at the development of ventricular arrhythmias. This participation, however, appears to be more pronounced when obesity is associated with OSA, indicating that in obesity not only baroreflex but also chemoreflex dysfunction may represent an important factor in the genesis of cardiac rhythm disturbances.

1337

Early detection of macrovascular complications in subjects with associated type 1 diabetes mellitus and coeliac disease

F. Martini¹, D. Pitocco¹, C. Smaldone², S. Giubilato¹, F. Zaccardi¹, V. Pezzano², A. Manto¹, L.M. Biasucci², G. Liuzzo², F. Crea², G. Cammarota¹, G. Ghirlanda¹

¹Internal Medicine, ²Cardiology, Catholic University, Rome, Italy

Background and aims: Immune system and inflammation seem to play a key role in the pathogenesis of type 1 diabetes (DM) and its complications. DM is often associated with other autoimmune diseases, like coeliac disease (CD). The aim of this study was: 1) To assess the effect of associated CD and Diabetes on early appearance of macrovascular complications, assessed through Carotid Intima-Media Thickness (CIMT), a well-known surrogate of cardiovascular disease; 2) To evaluate the role of inflammation (C reactive protein-CRP), immunity (CD4⁺CD28^{null} T-cells and CD4⁺CD25⁺ T-cells) and glycometabolic parameters on its pathogenesis.

Materials and methods: We enrolled 29 consecutive patients with DM and CD (12 males, mean age 35.72 ± 10.81); CD was diagnosed by intestinal biopsy and every patient with CD was on a gluten-free diet. We also enrolled patients with only DM (34, 21 males, mean age 34.50 ± 7.29) or CD (26, 6 males, mean age 32.64 ± 8.26) as control groups. Demographic and clinical data were collected. Blood samples were taken at time of enrollment. Serum level of CRP was measured using a high sensitivity immuno-nephelometric assay. CD4⁺CD28^{null} T-cells and CD4⁺CD25⁺ T-cells frequency was measured by flow cytometry.

Results: CIMT was significantly higher in patients with DM and CD (DM+DC = 0.60 ± 0.16 ; DM = 0.48 ± 0.12 ; CD = 0.48 ± 0.17 ; $p = 0.008$), as Total cholesterol (DM+DC = 190.41 ± 35.73 ; DM = 188.97 ± 34.68 ; CD = 163.89 ± 32.37 ; $p = 0.047$), LDL cholesterol (DM+DC = 120.12 ± 29.14 ; DM = 111.35 ± 27.14 ; CD = 93.77 ± 28.94 ; $p = 0.039$), Triglycerides (DM+DC = 80.59 ± 32.09 ; DM = 63.15 ± 21.09 ; CD = 87.74 ± 51.65 ; $p = 0.035$) and Glycated Hemoglobin (DM+DC = 7.88 ± 1.79 ; DM = 7.19 ± 0.52 ; CD = 4.83 ± 0.46 ; $p < 0.0001$). Serum levels of CRP were significantly higher in patients with T1DM and CD than in patients of control groups. No significant differences in CD4⁺CD28^{null} T-cells (2.195 ± 2.94 vs $2.565 \pm 2.05\%$) and CD4⁺CD25⁺ T-cells frequency (1.56 ± 0.64 vs $1.43 \pm 0.73\%$) were found.

Conclusion: Our study showed for the first time a higher CIMT in patients with DM and CD than in patients with DM or CD alone; furthermore, serum levels of CRP, marker of innate immune system activation, were higher in patients with T1DM and CD than in those with only one disease. It's also remarkable the different glycometabolic profile between DM+CD vs DM or CD. These results showed a possible enhanced activation of innate immune system and a worse glycometabolic pattern in T1DM and CD that can lead to a more severe CIMT- an inflammatory disease, whereas it seems that cellular-mediated immune system isn't involved.

1338

Long-term effect of anti-TNF treatment on atherosclerosis risk factors in rheumatoid arthritis patients

Y. Sayo¹, H. Dobashi², S. Matsubara², T. Ishida²

¹Internal medicine, Social Insurance Ritsurin Hospital, Takamatsu-city Kagawa, ²First Internal medicine, Faculty of Medicine, Kagawa University, 1750-1 miki-cho Kita-gun Kagawa,

Background and aims: The tumor necrosis factor alpha (TNF-alpha) is one of the adipocytokines, which are well known as the physiological activity substances of the fat cell origin. TNF-alpha interferes the phosphorylation of

intra-cellular domain in the insulin receptor on target organs, such as skeletal muscle and liver, which results in enhancement of insulin resistance. The expression of TNF-alpha on adipose tissue or skeletal muscle correlates with BMI in obese subjects. On the other hand, Rheumatoid arthritis (RA) is a chronic inflammatory disease induced by several inflammatory cytokines including TNF-alpha. TNF-alpha is considered as the most important cytokine in pathogenesis of RA. By using soluble TNF-alpha receptor for an insulin resistance model rat, TNF-alpha in blood can be neutralized and the insulin resistance of skeletal muscle can be decreased. TNF-alpha has been implicated in the progression of atherosclerosis through modulation of insulin resistance (IR) or other adipocytokines expression. We have already reported that anti-TNF treatment using Infliximab (IFX) or Etanercept (ETA) improved IR in RA patients. In both Annual European congress Rheumatology 2007 and annual meeting of the American College of Rheumatology 2007, the many reports that anti-TNF treatment decreased the risk of myocardial infarction, anti-TNF treatment might reduce the risk of cerebrovascular events in RA patients. There also reported increase of adiponectin might reduce the risk of arteriosclerosis RA patients. In this study, we examined the effect of anti-TNF treatment using IFX or ETA on IR or adipocytokine expression in RA patients during one year. We also investigated the change of visceral fat in anti-TNF treatment before and after.

Materials and methods: We prospectively followed 50 previously anti-TNF naive RA patients who received the anti-TNF treatment for one year or more. We analyzed the IR using the Homeostasis Model Assessment Insulin Resistance (HOMA-IR) at 0, 6, 22, 56 weeks. Serum IL-6, TNF-alpha, adiponectin, resistin and CRP were also examined to evaluate the change of RA activity. We used the Homeostasis Model Assessment Insulin Secretion (HOMA-beta) as for insulin secretion. We measured visceral fat area of all subjects before and after anti-TNF treatment using CT scanning and Fat scan (N2 system, Japan).

Results: The insulin resistance was decreased significantly in the first 6 weeks by both anti-TNF treatments. ETA could reduce IR continuously till the 22 weeks, however, IFX could not sustain the improvement. The enhancement of adiponectin and reduction of resistin were observed in both treatments. Additionally, the reduction of visceral fat area was indicated in RA patients treated with anti-TNF agents.

Conclusion: Anti-TNF treatment could reduce the risk of atherosclerosis progression in RA. However, this effect may be different between ETA and IFX treatment.

Direct medical costs for type 2 diabetes mellitus complications in the U.S. commercial payer setting: a resource for economic research

E.M. Pelletier¹, P. Smith¹, K.S. Boye², D.A. Misurski², S.L. Tunis³, M.E. Minshall³

¹Health Economics and Outcomes Research, IMS Consulting Services, Watertown, United States, ²Eli Lilly and Company, Indianapolis, United States, ³Health Economics and Outcomes Research, IMS Consulting Services, Noblesville, United States

Background and aims: The large and growing humanistic and economic burden of type 2 diabetes mellitus (T2DM) in the US has been widely documented. Medical complications are key drivers of costs among T2DM patients. Detailed information on the clinical and economic impacts of T2DM treatments remains in high demand for US healthcare payers and other stakeholders. An important unmet need for the accurate assessment of the economic impact of T2DM complications is a set of unit costs that are empirically based, clearly and consistently defined, and applicable to a large segment of US managed care patients. This study used a large, multi-payer US database to examine direct medical costs of T2DM complications.

Materials and methods: Health insurance claims were extracted from the PharMetrics Patient-Centric Database, which includes adjudicated medical and pharmaceutical claims from over 90 US health plans. Patients experiencing at least 1 of 24 T2DM complications from 1/2003 through 12/2004 and with a T2DM diagnosis prior to or on the date of the first (index) complication during the study window were identified. Complication cost data were extracted for 44,021 patients who had a minimum of 12 months follow-up enrollment; cost data for months 13-24 were extracted for a subset of patients with at least 24 months of follow-up ($n = 32,991$). Direct medical costs included both the amounts charged by medical providers for treating the complication and the health plan contracted allowed amounts. Costs were expressed as \$US 2007.

Results: The average age of the aggregate sample was 56 years and 52% were male; 75% were insured under a commercial plan and 17% had coverage from a public payer. During the first 12 months following the index complication, 74% of patients were on oral antidiabetics, 26% on insulins, 43% on ACE inhibitors, and 50% on antihyperlipidemics/statins. Table 1 shows the proportion of patients experiencing T2DM complications during the 12-month follow-up period and the corresponding average charged and allowed amounts; cost data for months 13–24 following the initial complication were provided for the patient subset. Allowed amounts for most complications were 30%–45% of charges. Congestive heart failure and myocardial infarction had the greatest fiscal impact because of the percentage of patients experiencing them and their associated costs.

Conclusion: These unit costing results provide an important resource for economic modeling and other types of costing research related to treating T2DM complications within the US managed care system.

Table 1. T2DM Complication Charged and Allowed Amounts in \$US 2007

T2DM Complication	%	First 12 Months		Months 13–24	
		Mean Charged	Mean Allowed	Mean Charged	Mean Allowed
Myocardial infarction	7.2	41,695	14,853	3,797	1,363
Angina pectoris	12.0	9,850	4,132	1,127	488
Congestive heart failure	14.0	30,066	11,257	10,802	3,905
Ischemic stroke	5.0	14,104	6,331	1,437	518
Peripheral vascular disease	10.6	9,800	3,623	3,460	1,289
Gangrene	1.0	25,125	10,094	3,582	1,057
Leg amputation	0.5	27,320	14,750	7,777	4,620
Foot ulcer	8.5	11,042	4,743	4,219	1,701
Kidney transplant	0.6	22,465	9,890	11,497	5,399
Hemodialysis	1.0	25,150	10,603	18,140	7,716
Peritoneal dialysis	0.2	29,609	15,893	26,667	13,694
Cataracts	0.3	1,094	558	71	60
Blindness	0.9	3,357	997	106	71

Hypoglycemic event	0.2	454	345	8	4
Lactic acidosis	1.2	24,344	9,929	1,627	198
Keto-acidosis	0.2	239	152	3	2

Supported by: Eli Lilly and Company, USA

Materials and methods: We used a centrally randomized clinical trial comparing CR with UC. Of 1614 eligible patients, 770 (47%) were randomized in ways of 390 patients receiving UC and 380 patients CR. A total of 151 patients (20%) had known diabetes at randomization and 75 patients were allocated to CR and 76 patients to UC. Patients randomized to CR received 6–12 weeks of an individually tailored, multi-disciplinary programme and clinical control after 3, 6 and 12 months. A composite blinded administrative register-based primary outcome measure included total mortality, myocardial infarction or first acute readmissions due to heart disease. For secondary outcomes we used acute re-admissions and acute length of stay. We used Cox-regression for analysing time-to-event and Poisson regression for analysing length of stay and number of re-admissions. The follow-up time was 3 years after randomisation.

Results: We find no difference in the composite outcome (CR versus UC; Hazard ratio: 0.87 95%CI: 0.75–1.13). There were no significant differences when looking separately at the components in the primary outcome. Amongst the CR and UC patients 57% and 62% were acute re-admitted at least once ($P=0.80$). There were 238 and 355 acute re-admissions for CR patients and UC patients ($P=0.17$) with mean length of stay of 5.8 days and 7.7 days respectively ($P<0.05$).

Conclusion: Although the DANREHAB study earlier has demonstrated significantly greater reduction in blood pressure as well as improvement in glycaemic control for patients with T2DM in CR compared to UC, these effects do not yet translate into the primary clinical endpoint at 3 years follow-up. Nevertheless there is a marginally significant reduction in acute length of stay for patients with diabetes in CR.

Comprehensive cardiac rehabilitation reduces length of stay in acute re-admissions for patients with diabetes. Three years results of the DANREHAB trial

A.B. Soja¹, A. Zwisler¹, S. Rasmussen², T.M. Melchior³, E. Hommel⁴, M. Madsen⁵, J. Fischer Hansen⁶

¹Department of Cardiology, Rigshospitalet, Copenhagen, ²Department of Epidemiology, National Institute of Public Health, University of Southern Denmark, Copenhagen, ³Department of Cardiology, Roskilde County Hospital, ⁴Steno Diabetes Center, Gentofte, ⁵Institute of Public Health Research, University of Copenhagen., ⁶Department of Cardiology, Bispebjerg University Hospital, Copenhagen, Denmark

Background and aims: Mortality and readmissions rates for ischemic events are high in patients with type 2 diabetes (T2DM). The Steno-2 study has shown an outstanding beneficial effect of multifactorial intervention in patients with T2DM and microalbuminuria. Although studies have reported beneficial impact of comprehensive cardiac rehabilitation (CR) on outcome in the overall population, little is known of the effect of CR in patients with T2DM. In this kind of population, preliminary results from the ACCORD study have given rise to some dispute, but we still hypothesize that patients with T2DM and macrovascular disease will benefit from CR receiving multifactorial intensified intervention. In a randomized clinical trial (The DANREHAB trial) on CR we found improvement in lifestyle and risk factor after 12 months compared to usual care (UC) among patients with T2DM. We now report if these effects are translated into clinical endpoints after 3 years.

Effect of desflurane on phosphorylation of Akt and GSK 3 beta proteins in the diabetic versus non diabetic human myocardium

S. Lemoine¹, G. Beauchef², L. Zhu¹, P. Galera¹, J.L. Gérard¹, J.L. Hanouz¹

¹Pole Anesthésie-Réanimation, ²Laboratoire de matrice extracellulaire et pathologie, CHU de Caen, France

Background and aims: The increasing incidence of diabetes mellitus worldwide results in an increase perioperative care of diabetic patients who are at high risk for perioperative ischemia reperfusion injury. Thus developing perioperative cardioprotective strategies are of importance in diabetic patients in Cardiovascular surgery. The aim of this study was to quantify the phosphorylation of Akt and GSK 3 beta (proteins which are known to mediate the cardioprotection) after exposure to desflurane (a volatile halogenated anesthetic which has capacity to protect non diabetic myocardium against ischemia reperfusion injury) in human myocardium with non insulin dependant diabetes mellitus (NIDDM).

Materials and methods: After the approval of local medical ethics committee, right atrial appendages were obtained during cannulation for cardiopulmonary bypass from patients scheduled for routine coronary artery bypass surgery and aortic valve replacement. Right atria diabetic NIDDM and non diabetic (ND) were pinned in a chamber (5 mL) containing Tyrode's modified solution, oxygenated with 95% O₂ and 5% CO₂ and maintained at 37 ± 0.5°C. Preparations were stimulated at a frequency of 1 Hz. In all groups, equilibration period was performed by oxygenated by 95% O₂-5% CO₂ during 60-min (Control groups); and followed by a 5-min exposure to desflurane 6% in Des groups.

After oxygenation (Control group) and after exposure to desflurane 6% (Des group), atria were frozen and stored at -80°C prior to protein extraction and western blot analysis. Frozen tissue samples were extracted into extraction buffer and protein concentration was determined using the BCA protein assay. Extracted protein samples from human atrial tissues were submitted to the western blot protocol. Then were incubated with antibodies recognizing phospho-Akt and phospho-GSK 3 beta. The western blots of each group were stripped and probed again with an antibody against beta-Tubulin to ensure equivalent loading. All band densities for protein of interest were then normalized to that of the band for beta-Tubulin in the same sample, then normalized to the mean of control tissues was defined as 1 arbitrary unit ± SD. Statistical comparison was made by analysis of variance.

Results: Brief administration of desflurane 6% significantly increased Akt phosphorylation in Des.ND et Des.NIDDM groups (2.37 ± 0.45 and 2.6 ± 0.12 -fold increase vs. Cont. ND et NIDDM, $P > 0.0001$); and GSK 3 beta phosphorylation in Des.ND and Des. NIDDM groups (1.98 ± 0.25 et 2.05 ± 0.12 -fold increase vs. Cont. ND and NIDDM, $P < 0.0001$). Phosphorylation of Akt and GSK 3 beta are equivalent in Des.ND and Des. NIDDM groups (no significant).

Conclusion: Brief administration of desflurane induced phosphorylation of Akt and GSK 3 beta, two proteins kinases of the Reperfusion Injury Salvage Kinase pathway, mediate the cardioprotective effect. Interestingly this effect is equivalent in diabetic and non diabetic myocardium. These results suggest that desflurane could be used in clinical practice as a cardioprotector agent of patients with non insulin dependant diabetes mellitus.

1342

MMP-9, inflammatory process activity and endothelial dysfunction in patients with STEMI and type 2 diabetes

D. Milosz¹, L. Czupryniak¹, M. Saryusz-Wolska¹, G. Zasadzinska¹, A. Borkowska¹, E. Cieplucha², K. Chizynski², J. Loba¹

¹Diabetology and Metabolic Diseases Dept, ²Cardiology Dept, Medical University of Lodz, Poland

Background and aims: The type 2 diabetes is an independent risk factor for coronary artery disease. Myocardial infarction has its onset as a result of the rupture of a vulnerable plaque and subsequent thrombus formation. Exogenous risk factors for rupture of a vulnerable plaque leading to an acute coronary syndrome include: the sudden increase in arterial blood-pressure, vasospasm reaction and inflammatory reaction, however the main "destabilizers of atherosclerosis plaque" are metalloproteinases. The aim of the study was to assess a relationship between MMP-9 and selected inflammatory

markers, endothelial dysfunction, and pronouncement STEMI in patients with type 2 diabetes.

Materials and methods: This study comprised 60 patients (27 women, 33 men, mean age 58 ± 8.5 years) with STEMI, who underwent percutaneous coronary angioplasty. Patients were divided into two groups. Study group consisted of 30 persons with type 2 diabetes treated with sulphonylureas derivatives, the control group were age-, gender- and body weight-matched 30 non-diabetes patients. Within 12 hours after ACS MMP-9, CRP, fibrinogen, leucocytosis, sVCAM, sICAM were evaluated in the patients. Lipids profiles were obtained after overnight fast condition. Severity of lesion in coronary arteries were obtained by Index Gensini Score. No significant differences in smoking status or non-diabetes medication were noted between the groups.

Results: Patients in the study group demonstrated more advanced lesions in the coronary vessels (Gensini Score 60.9 ± 33) as compared to the control group (Gensini Score 41 ± 21). Patients with STEMI and type 2 diabetes demonstrated higher concentrations of MMP-9 (1080 ± 351 vs 322.6 ± 209 ng/ml), CRP (5.9 ± 4.2 vs 3.9 ± 2.3 mg/l), fibrinogen (5.1 ± 1.9 vs 4 ± 1 g/l), leucocytosis (12100 ± 4200 vs 9800 ± 3400 per mcl), VCAM (1367 ± 1025 vs 930 ± 295 ng/ml), ICAM (848 ± 271 vs 722 ± 160 ng/ml) in comparison to the control group.

Conclusion: The study results suggest that diabetes is most important factor intensifying inflammatory process in the coronary vessels and arrangement of MMP-9 may play a significant role in destabilisation of atherosclerotic plaque and development of ACS in this group of patients.

Is there a role for PDGF-BB in in-stent restenosis in diabetes?

T. Poletti, A. Guildford, M. Santin, M. Harrison

School of Pharmacy & Biomolecular Sciences, University of Brighton, United Kingdom

Background and aims: Cardiovascular disease (CVD) represents a major complication and cause of death and is exacerbated in diabetes as a consequence of macrovascular changes. Formation of glycation products leads to atherosclerotic plaque deposition and structural changes in the vessel wall. Balloon angioplasty followed by stent deployment is the gold standard treatment. The outcome is adversely affected by *in-stent* restenosis (ISR) in 30% of cases. In diabetes, incidence increases to 60%. The growth factor PDGF-BB has been implicated as a major participant in the development and progression of ISR. The effective but costly use of drug-eluting stents (DES) can reduce the incidence of ISR to ~ 3%. There is an increased risk of late thrombosis and heart attack in patients treated with DES. Stent deployment is associated with tissue damage and protracted inflammatory response, which may be enhanced by the reported heightened inflammatory state in diabetes. Our established *in vitro* model of bare metal stent induced ISR was used to mimic the post-stent implantation environment and its effect on isolated mononuclear cell behaviour and phenotype. The isolated mononuclear cells (MC) from 3 cohorts [type 1 (T1), type 2 (T2) diabetes and controls (C)] were compared to characterize PDGF-BB production and MC population in the presence of the stent material (stainless steel-St.).

Materials and methods: Subjects were recruited at Royal Sussex County Hospital (Brighton, UK). Clinical data HbA1c, total cholesterol, BMI, HDL and age were recorded. MCs from peripheral blood were seeded onto pre-conditioned St discs for 24 hrs, 37°C, in physiological glucose. Supernatants from the incubation assay described above were analyzed for PDGF-BB by ELISA method. Cells were analyzed with Flow Cytometry for the following antibodies: CD45 (L; Leukocytes Common Antigen), CD3 (TL; T Lymphocytes), CD19 (BL; B Lymphocytes), CD14 (M; Monocytes), CD68 (AM; Activated Macrophages) and CD34 (HSC; Hematopoietic Stem Cells).

Results: Table 1: There was a significant difference in BMI observed between the groups. T2 were clinically obese whereas T1 and C had a normal BMI. No differences were observed in total cholesterol, HDL or HbA1c. CD14 (M) and CD19 (BL) were both elevated in diabetes. There were also differences in the proportion of cell populations between the T1 and T2 cohorts; There was a higher percentage of CD3 (TL) and CD45 (L) in the T2 cohort vs both T1 and C cohorts. CD68 (AM) percentage was higher in the T1 cohort than in the T2 and C. CD3 (TL) was lowest in C and increased in T1 but increased further in T2. Hematopoietic stem cells (CD34) were low in all groups. PDGF-BB was elevated in response to St. in control cells (0.59 pg/ml) but was unchanged in both diabetes cohorts.

Conclusion: The higher percentage of AM in both of the diabetes cohorts indicates a default pro-inflammatory state not witnessed in control cell popu-

Patients Data and cells population distribution.

lations. In conclusion, it is highly unlikely that PDGF-BB plays a significant role in ISR in diabetes.

1344**Assessment of the response to exercise of platelet reactivity in diabetic patients with angina and angiographically normal or stenotic coronary arteries**

P. Lamendola¹, D. Pitocco², F. Zaccardi², A. Sestito¹, S. Caputo², G.A. Lanza¹, F. Crea¹, G. Ghirlanda²

¹Cardiology, ²Internal Medicine, Catholic University, Rome, Italy

Background and aims: We previously demonstrated that in patients with cardiac syndrome X (effort angina, positive exercise stress test and normal coronary arteries at angiography [NCA]) platelet reactivity is reduced by exercise, in contrast with the increase observed in patients with obstructive coronary artery disease (CAD). However, patients with diabetes were excluded from these previous studies. Aim of this study was to investigate the effect of exercise on platelet reactivity in diabetic patients with angina and NCA at angiography.

Materials and methods: The study group included 17 patients (61±6 years; 6 men) with type 2 diabetes who referred because of effort angina and were found to have positive exercise stress test, but totally NCA at angiography. Two different comparison groups were studied: 1) 17 type-2 diabetic patients with effort angina and obstructive CAD at angiography (64±6 years, 15 men), and 2) 11 type-2 diabetic patients (controls, 61±9 years, 5 men) without any history of chest pain and no evidence or suspect of myocardial ischemia on maximal exercise stress test. All patients underwent, symptom-limited exercise stress test according to Bruce protocol. Platelet reactivity was measured before and 5 minutes after peak exercise by the platelet function analyzer (PFA)-100 system as the time for flowing whole blood to occlude a collagen-adenosine diphosphate ring (closure time).

Results: There were no differences among groups in exercise stress test capacity. ST-segment depression was induced during exercise test in 9 (54%) and in 8 (47%) patients in the NCA group and in the CAD group, respectively (P=1.0). At baseline, there was no difference among groups in closure time (NCA 108±24 s; CAD 124±47 s; controls 113±35 s; P=0.44). After exercise closure time was significantly reduced in CAD patients (to 93±27 s; P<0.01), whereas no significant changes were observed in NCA patients (103±21 s) and in controls (123±77 s). The group-exercise interaction was statistically significant (P=0.033).

Conclusion: In contrast to classical CSX patients, in type-2 diabetic patients with angina and NCA we found no significant changes in platelet reactivity with exercise, thus suggesting that the mechanisms involved in the improved platelet reactivity profile shown after exercise in non diabetic CSX patients are absent in diabetic patients with microvascular angina. Our data also suggest that diabetes by itself does not have any significant effect on basal and post-exercise platelet reactivity as assessed by the PFA-100 method.

1345**Does post-prandial glycaemia in non-diabetic patients with acute myocardial infarction give additional information for short-term prognosis?**

M.-C. Brindisi¹, C. Richard², L. Lorgis², P. Sicard², M. Zeller², B. Vergès¹, Y. Cottin²

¹Diabetologia, ²Cardiology, CHU, Dijon, France

Background and aims: Admission and fasting glycemia (FG) are both risk markers in patients with acute myocardial infarction (AMI). Over the last few

years, elevated postprandial glycemia (PPG) has emerged as a powerful predictor of cardiovascular disease in the population at large. However, the prognostic value of PPG in non-diabetic patients after AMI remains unknown.

Materials and methods: Between the 1st November 2005 and the 30th April 2007, 193 patients admitted to the coronary care unit for AMI were included. Patients with known diabetes or admission glycemia ≥ 11.1 mmol/l were excluded from the study. Blood samples were taken on admission, and to determine overnight fasting and PP (2h after a standardized meal) glucose levels on days 1 (FG1 and PPG1) and 3 (FG3 and PPG3) following admission. Six-month follow-up data were collected. The primary outcome was 6-month mortality or in-hospital heart failure.

Results: Median (IQR) admission glycemia was 6.9 (5.7-8.1) mmol/l. Median FG1 was 5.65 (5.02-6.37) mmol/l and FG3 was 5.20 (4.79-5.78) mmol/l. Median PPG1 was 7.41 (6.1-8.52) mmol/l and PPG3 was 7.39 (6.08-9.06) mmol/l. Median HbA1c taken on admission was 5.7 (5.5-5.9) %. Only FG3 and PPG3 were significantly related to the outcomes (OR (95% CI): 1.83 (1.29-2.61), p = 0.001 and 1.25 (1.08-1.44), p = 0.003, respectively). After adjustment for the GRACE (Global Registry of Acute Coronary Events) risk score and left ventricular ejection fraction, FG3 or PPG3 remained strong predictors of outcomes (OR (95%CI): 1.27 (1.07-1.51), p = 0.005, and 1.70 (1.14-2.54), p = 0.010, respectively). When both FG3 and PPG3 were introduced into the multivariate model, only FG3, but not PPG3, tended to be associated with the prognosis ((OR (95%CI): 1.19 (0.99-1.44), p = 0.065 and 1.43 (0.92-2.22), p = 0.116, respectively).

Conclusion: Our results show that in non-diabetic patients, both FG and PPG measured 3 days after admission for AMI are predictors of a poor short-term prognosis. However, our findings strongly suggest that the addition of PPG to FG does not significantly improve the prediction of risk.

1346**QTc interval and adiponectin in patients with type 2 diabetes mellitus**

R.Z. Timar, V. Serban, L. Diaconu, A. Vlad, B. Timar

Diabetes Clinic, University of Medicine "Victor Babes", Timisoara, Romania

Background and aims: QT prolongation has been shown to predict cardiac death in diabetic patients. QTc was used as a marker of atherosclerosis because previous studies have shown that QTc is affected by cardiac ischemia and correlates stronger with the carotid intima-media thickening than with cardiac autonomic neuropathy in patients with type 2 DM. Adiponectin, the only adipocytokine known to increase insulin sensitivity, also has anti-inflammatory and anti-atherogenic properties. The aim of our study were to evaluate the prevalence of QTc (QT corrected for heart rate) prolongation in patients with type 2 DM and to assess the relationship between QTc and plasma levels of adiponectin. We also evaluated the relation between QTc and HbA1c, HOMA-IR, inflammatory markers, plasma lipids, systolic blood pressure (SBP), diastolic blood pressure (DBP), body mass index (BMI), ischemic heart disease (IHD), microangiopathy, heart rate variability(HRV) and somatic neuropathy.

Materials and methods: The study enrolled 118 patients with type 2 DM. For each subject 100 consecutive heart beats were recorded on the resting ECG tracing. QT and RR intervals were measured with a ruler for 5 consecutive beats on V5 lead on the resting ECG tracing. QTc was calculated according to Bazett's formula. QTc for each subject was considered the mean value of 5 calculated intervals. QTc > 0.44s was considered abnormally prolonged. After measuring RR intervals for all 100 consecutive beats on V5 lead, the index HRV was calculated according to the formula = (standard deviation of RR/mean RR) X 100.

Results: The prevalence of prolonged QTc interval was 27.1% in patients with type 2 DM.

Table 1. Study subjects characteristics by the presence or absence of QTc prolongation

Parameter	QTc in normal ranges	QTc prolonged > p 0.44s	
N(%)	86 (72.9)	32 (27.1)	–
Age (years)	54.2±12.1	59.14±11.3	0.047
Sex M n(%)	42(48.8)	15(53.1)	NS
Duration of DM (years)	12.1±4.4	15.0±5.4	0.003
HbA1c (%)	7.5±1.4	7.9±2.8	NS
BMI (kg/m ²)	27.3±3.1	29.24±4.5	0.012
DBP(mmHg)	76.2±7.2	85.14±7.5	<0.001
SBP(mmHg)	138.5±11.0	143.5±11.1	0.031
Triglycerides (mg/dL)	217.1±20.2	228.3±19.4	<0.001
Cholesterol (mg/dL)	204.2±24.3	210.3±31.4	NS
HDLc (mg/dL)	45.26±5.42	38.6±6.6	<0.01
HOMA IR	3.50±1.12	4.92±1.81	<0.001
Adiponectin (µg/mL)	13.6±1.6	7.1±0.8	< 0.001
Leptin (ng/mL)	7.4±3.5	12.6±2.4	< 0.001
TNF-α (pg/mL)	6.5±1.2	8.4±1.4	< 0.001
IL-6 (pg/mL)	3.2±0.5	4.5±0.6	< 0.001
hs-CRP (mg/L)	5.4±0.6	7.4±0.9	< 0.001
Fibrinogen (mg/dL)	232.9±40.7	345.2±44.2	< 0.001

Data are mean±SD or n(%). P was calculated with Student's t test or with chi-square test.

Patients with prolonged QTc had significantly higher age, diabetes duration, BMI, waist circumference, SBP, DBP, higher plasma triglycerides, lower HDLc plasma levels and increased prevalence of IHD than patients without QT abnormalities. Serum adiponectin was strongly and significantly negatively correlated with QTc ($r = -0.76$, $p < 0.0001$), after adjusting for age, sex, diabetes duration, BMI, waist circumference, HbA1c, plasma lipids. QTc was also correlated with HOMA-IR ($r = 0.58$, $p < 0.001$), BMI ($r = 0.52$, $p < 0.05$), waist circumference ($r = 0.56$, $p < 0.001$), the presence of IHD ($r = 0.63$, $p < 0.001$). A significant, but weak negative relationship was found between QTc and HRV ($r = -0.36$, $p < 0.01$). Also, QT prolongation was associated with increased plasma levels of leptin and of inflammatory markers. No relationship between was observed between QTc and gender, HbA1c, diabetic retinopathy, diabetic nephropathy, somatic neuropathy.

Conclusion: Low plasma levels of adiponectin were strongly and independently correlated with prolonged QTc and the presence of IHD. Our findings suggest that both hypoadiponectinemia and prolonged QTc could be cost-benefit advantageous methods of identifying diabetic patients with increased risk for atherosclerotic cardiovascular diseases.

Effect of glucose-insulin-potassium infusion (GIK) on stress-induced myocardial ischaemia

B. Boldrini¹, S. Di Marco², U. Conti², F. Lattanzi², C. Morgantini¹, E. Ferrannini¹, A. Natali¹

¹Department of Internal Medicine, University of Pisa, Italy, ²Division of Cardiovascular Medicine, Hospital of Pisa and Pescia, Italy

Background and aims: Clinical trials using Insulin and GIK in the treatment of acute coronary syndrome have given conflicting results. In experimental animal models, however, pre-treatment with insulin or GIK has been shown to consistently improve left ventricular perfusion and function during both acute and chronic ischaemia through metabolic and vascular preconditioning of the myocardial tissue. The aim of this study is to verify whether in order to exert its protective effect, insulin must be present before the ischemic event occurs. Data *in vivo* in man in this setting are lacking.

Materials and methods: Eleven non-diabetic patients with clinical and ECG evidence of inducible myocardial ischaemia and normal left ventricular function underwent a dipyridamole-atropine echocardiography test (stress echo). Another 11 non-diabetic patients with regional contractility defects and evidence of inducible ischaemia (on exercise ECG test) were submitted to a ²⁰¹Tl myocardial perfusion exercise scintigraphy. Each test (stress echo and ²⁰¹Tl scan) was done twice (within 14 days), once preceded by 60 minutes of normal saline, the other by 60 minutes of GIK infusion (500 ml of a 20%

glucose solution with KCl 30 mEq and insulin 15U) at the rate of 2 ml/kg/h. Hyperglycaemia was accurately avoided either by adding extra insulin or by shifting on a 10% glucose solution. For the stress echo the extent of ischemia was evaluated by using an ischemia score (IS) calculated as the number of left ventricle segments multiplied by their wall motion score change divided by the duration (proportional to the dose) of the dipyridamole/atropine infusion. For the ²⁰¹Tl scan the analysis was done on the difference in perfusion score in the 20 segments of the left ventricle among the 3 conditions of stress, rest and reinjection. A global perfusion score was calculated as the sum of all the 16 segments perfusion score of all patients.

Results: GIK infusion in both tests was well tolerated and resulted in a plateau of plasma insulin concentration of 1,120±84 pmol/l and in a stable plasma potassium and glucose concentration throughout the tests (3.7±0.5 mEq/l and 6.1±1.7 mmol/l, respectively). On the stress echo, GIK infusion was associated with a 35% reduction in the severity of ischaemia (IS Saline: 0.55±0.09, IS GIK: 0.36±0.09). On ECG ergometry, GIK infusion slightly increased the time to ischaemia (+0.6 min, $p=0.07$) but the higher workload (+8%) was achieved at a similar rate-pressure plateau (Saline: 22,250±1,055 vs GIK 22,539±1,194 mmHg x bpm). On the ²⁰¹Tl scan, an increase in number of ischaemic segments (+48%, $p<0.05$) was observed mainly to the detriment of viable (but non-ischaemic) and non-viable segments, which were reduced by 60% ($p<0.01$). When the perfusion pattern was analysed using the global perfusion score, the main effect of GIK was to enhance the reversibility of acute post-stress perfusion defects (+94%, $p<0.01$), while stress-induced left ventricular underperfusion was only marginally affected (+13%, $p=ns$).

Conclusion: In non-diabetic patients with inducible myocardial ischaemia acute GIK pre-treatment directly attenuates the effects of ischaemia on myocardial contractility, slightly improves exercise tolerance through systemic hemodynamics and causes a more rapid and diffuse recovery of exercise-induced myocardial perfusion defects.

1348

A low-dose treatment with atorvastatin for one year improves arterial stiffness in patients with type 2 diabetes mellitus

P. Grigoropoulou¹, N. Tentolouris¹, D. Perrea², C. Zoupas¹, I. Eleftheriadou¹, K. Alexiadou¹, N. Katsilambros¹

¹1st Department of Propaeudetic Medicine, Athens University Medical School, Laiko Hospital, ²Laboratory of Experimental Surgery and Surgical Research, Athens University Medical School, Athens, Greece

Background and aims: Type 2 diabetes mellitus (T2DM) is associated with a two to four-fold increased risk for coronary heart disease. Dyslipidaemia is a modifiable atherogenic risk factor in patients with T2DM, and low LDL cholesterol (LDLc) levels with the use of statins have demonstrated beneficial effects in the reduction of cardiovascular diseases in large primary and secondary prevention clinical trials. Increased arterial stiffness, assessed by pulse wave velocity (PWV), has also been emerged as an independent predictor for cardiovascular events. The aim of this prospective, open, intervention, parallel group study was to evaluate the effect of atorvastatin administration for 1 year on arterial stiffness, assessed by determination of PWV at the carotid-femoral (PWVcf) and the carotid-radial (PWVcr) arteries, in patients with T2DM.

Material and methods: A total of 54 patients with T2DM were recruited, 31 patients (11 men, 20 women, mean age 60.77±8.752 years, diabetes duration 6.94±6.175 years) were assigned to 12-months atorvastatin therapy (10 mg daily) and a low fat diet, and 23 patients (8 men, 15 women, mean age 58.55±8.445, diabetes duration 5.58±5.004) to low-fat diet only. The two groups were comparable at baseline in terms of total cholesterol, LDLc, body mass index, and HbA1c. The main inclusion criteria were age between 40 and 75 years, LDLc ≥100 mg/dl, and absence of clinically apparent macrovascular disease. PWV was determined by applanation tonometry (SphygmoCor Vx, AtCor Medical, Sydney, Australia). Plasma lipids, HbA1c, and PWV were evaluated prospectively at baseline, 3, 6, and 12 months in both groups.

Results: Total cholesterol and LDLc declined significantly in the atorvastatin-treated group at the examined time intervals. In the same group a significant reduction in PWVcr and PWVcf was observed 3 months post-intervention (4.59 %, $p<0.001$, and 9.18 %, $p<0.001$), which was maintained at 6 (6.55 %, $p=0.007$, and 12.99 %, $p<0.001$) and 12 months (9.9%, $p=0.01$, and 12.43%, $p=0.003$, respectively). In the untreated group, a small non-significant improvement in lipid profile was observed; however, no significant changes in PWVcr and PWVcf were found.

Conclusion: Beyond the lipid-lowering effects, a low dose of atorvastatin improves arterial stiffness in patients with T2DM. The improvement starts 3 months after intervention and continuous for 1 year.

1349

Does multiple injection therapy with a rapid-acting insulin analogue prevent cardiovascular disease in type 2 diabetes? The NICE-study: a prospective, randomised, open-label, blinded endpoint study

H. Nishimura¹, M. Shintani¹, K. Maeda¹, I. Hanaoka², H. Kuzuya³

¹Division of Diabetes and Endocrinology, Osaka Saiseikai Nakatsu Hospital, Osaka, ²Division of Diabetes, Wakayama Red Cross Center, Wakayama,

³Division of Diabetes and Kidney Disease, National Hospital Organization, Kyoto Medical Center, Kyoto, Japan

Background and aims: Diabetes mellitus is recognized to be one of the major risk factors for macrovascular disease. However, the effect of postprandial metabolic control by rapid-acting insulin analogues on macrovascular disease has not been investigated in type 2 diabetes. We, therefore, investigated whether multiple injection therapy with a rapid-acting analogue insulin aspart prevents cardiovascular disease in type 2 diabetes, and conducted the “Nippon ultrarapid Insulin and diabetic Complication Evaluation-study (NICE-study)”.

Materials and methods: Three hundred and seventy-four type 2 diabetes patients on multiple injection therapy with insulin from 11 medical institutions (aged 20–84 years) were randomised into 2 treatment groups, (ultra)rapid-acting analogue insulin aspart (U) and short-acting human regular insulin (R). As necessary, intermediate-acting or long-acting insulin was used (40% of the U group and 42% of the R group). The primary endpoint was cardiovascular events (myocardial infarction, angina pectoris, PCI/CABG and TIA/cerebral infarction). During the observation period, aspirin, ARBs, and statins were administered to patients according to guidelines with usual daily dosing. Statistical analyses were based on intention to treat. The study was registered at ClinicalTrials.gov with the identifier NCT00575172 and conducted from January 2003 to December 2007.

Results: There was no difference in the baseline characteristics between the 2 groups (age, BMI, gender, duration of disease, HbA_{1c}, blood pressure or LDL-cholesterol). After a median follow-up of 4.5 years (range 3.5–5.0), hazard ratios were calculated and adjusted for age, BMI, gender, blood pressure, LDL-cholesterol, and smoking. A significant decrease of 43% was found in the cumulative cardiovascular event rate between the U group, 6.4% (12.8/1000/year), and the R group, 11.1% (22.2/1000/year) (HR=0.57, CI: 0.34–0.95, P<0.02). However, there were no differences in cardiovascular and overall mortality. Total dosages of basal and bolus insulin in the two groups was not different at the start point (Bolus: 27.7 ± 6.2 in the U group vs. 26.8 ± 8.2 in the R group, Basal: 12.2 ± 4.0 vs. 12.6 ± 4.5 U/day, respectively). At the end point, however, the bolus dosage was increased significantly in the U group (Bolus: 34.8 ± 8.3 vs. 28.3 ± 4.8, p<0.01, Basal: 14.6 ± 3.4 vs. 14.2 ± 4.1 U/day, p>0.05, respectively). A significant decrease was seen in the 90 min. postprandial plasma glucose levels of the U group vs. the R group, (142 ± 58 vs. 226 ± 48 mg/dl, respectively, P<0.02). A statistically significant difference was not found between the groups in fasting plasma glucose levels (128 ± 42 vs. 133 ± 54 mg/dl, respectively), HbA_{1c} (7.5 ± 0.7 vs. 7.5 ± 0.7%, respectively), or in the use of concomitant hypertensive/dyslipidemia/anticoagulation treatments.

Conclusion: Treatment with rapid-acting insulin analogue showed an improvement in postprandial plasma glucose and a reduction in the risk of cardiovascular events. The results may be mediated not only by the improvement in postprandial glucose levels but also by unknown mechanisms of the rapid-acting insulin analogue.

Effects of a rehabilitation programme on large and small artery elasticity, in cardiac patients. Comparison between diabetic and non-diabetic patients

P.R. Blanc¹, A. Boussuges², S. Maunier¹, S. Chopra¹, X. Debussche³

¹Cardiac rehabilitation, Sainte Clotilde center, Sainte Clotilde, Reunion,

²Université de la Méditerranée et IMNNSA, Faculté de Médecine Nord et

IMNNSA, Marseilles, France, ³Service de diabétologie, CHD Félix Guyon, Sainte Denis, Reunion

Background and aims: Impairment in arterial compliance is associated with diabetes. Arterial stiffness is related to the cardiovascular disease risk. Treatments allowing arterial compliance increase should be relevant to improve prognosis. Previous studies have demonstrated that rehabilitation programs were able to improve arterial compliance in cardiac patients. In the present study, we have assessed the effect of a 6-week rehabilitation program on arte-

rial compliance in diabetic patients (DP) in comparison with non-diabetic patients (NDP) with heart disease.

Materials and methods: 134 type 2 DP and 160 NDP engaged in aerobic training and multidisciplinary educational interventions five days per week. DP and NDP were matched appropriately for age (respectively 57.5 vs 56.5 years), sex ratio (29% vs 25% women) and type of heart disease. Sixty one percent of DP was treated by insulin. Baseline HbA_{1c} was greater than 6.6% in 64% of cases. Retinopathy and microalbuminuria were detected in respectively 31% and 36% of subjects. Large (C1) and small artery (C2) elasticity indices were measured using the HDI/PulseWaveTM CR-2000 Research CardioVascular Profiling System (Hypertension Diagnostics TM, Inc) before and after rehabilitation.

Results: Before exercise training C2 was lower in DP in comparison with NDP (3.3 vs 3.6 -p<0.02) whereas C1 was similar (15.7 vs 15.3 -p=0.6). After training, significant increases in C1 and C2 were found in the two groups. In diabetic patient a +9% increase in C1 (16.6 -p=0.01) and a 21% increase in C2 (4.2 -p<0.001) were found. This increase was assessed to +7% for C1 (16.7 -p=0.002) and to +18% for C2 (4.3 -p<0.001) in NDP. The percentage of increase in C1 and C2 was not statistically significant between DP and NDP.

Conclusion: Small artery elasticity is lower in diabetics compared with non diabetics. A 6-week aerobic training and multidisciplinary educational program improves both large and small artery elasticity in DP and NDP.

The metabolic syndrome, angiographically determined stable coronary artery disease, and subclinical inflammation

M. Woess¹, C. Saely^{1,2}, S. Beer¹, P. Rein¹, A. Vonbank¹, C. Boehnle¹, V. Jankovic¹, H. Drexel^{1,2}

¹VIVIT Institute, Feldkirch, Austria, ²Medicine, University for Human Sciences, Triesen, Liechtenstein

Background and aims: The metabolic syndrome (MetS) and stable coronary artery disease (CAD) frequently coincide; the individual contributions of these entities to subclinical inflammation have not been investigated yet. We therefore aimed at investigating markers of inflammation in patients with the MetS, in patients with CAD, and in patients who had both, the MetS and CAD.

Materials and methods: We enrolled 935 consecutive patients undergoing coronary angiography for the evaluation of suspected or established stable CAD. The MetS was defined according to National Cholesterol Education Programme Adult Treatment Panel III criteria; coronary stenoses with lumen narrowing $\geq 50\%$ were considered significant.

Results: From our patients 520 (55.6%) had significant coronary stenoses; the prevalence of the MetS was higher in our patients with significant stenoses than in those without such lesions (39.0% vs. 32.8%; $p = 0.048$). The inflammatory markers hsCRP and white blood cell count (WBC) were significantly higher in MetS patients than in those without the MetS both among patients with significant coronary stenoses (0.49 ± 0.71 vs. 0.42 ± 0.88 mg/dl; $p = 0.004$ and 7.0 ± 1.8 vs. 6.5 ± 1.8 G/l; $p = 0.003$, respectively) and in subjects who did not have such lesions (0.44 ± 0.51 vs. 0.37 ± 0.54 mg/dl; $p = 0.004$ and 7.1 ± 1.8 vs. 6.4 ± 1.8 G/l; $p < 0.001$, respectively). In contrast, these inflammatory markers were not significantly elevated in patients with significant stenoses among subjects with the MetS ($p = 0.776$ and $p = 0.713$, respectively) nor among those who did not have the MetS ($p = 0.882$ and $p = 0.119$, respectively). Similar results were obtained with the International Diabetes Federation definition of the MetS.

Conclusion: We conclude that subclinical inflammation is strongly and significantly associated with the MetS but not with angiographically determined stable CAD.

Cardio-vascular risk factors and mortality in a geriatric population; is there a “reverse metabolic syndrome”?

U.M. Vischer¹, F. Herrmann¹, M. Safar², J. Blacher²

¹Dept of Rehabilitation and Geriatrics, Geneva University Hospitals, Thônex/Geneva, Switzerland, ²Diagnosis and Therapeutic Center, Hôtel-Dieu Hospital, Paris, France

Background and aims: Diabetes or insulin resistance, overweight, arterial hypertension and dyslipidemia are strong risk factors for cardio-vascular (CV) disorders in young adults. We investigated the predictive value and hierarchy of these risk factors in elderly high-risk subjects.

Materials and methods: Two-year total mortality was determined in a prospective cohort study of 331 elderly (mean age \pm SD): 85 ± 7 years) high-risk patients admitted to two geriatric wards.

Results: Two-year total mortality was predicted by age, diabetes, low BMI, low diastolic blood pressure (DBP), low total and HDL-cholesterol, and previous CV events. The effect of diabetes was accounted for by previous CV events. In non-diabetic patients, total mortality was also predicted by high insulin sensitivity (low HOMA-IR and high QUICKI indexes). In multivariate analysis, the strongest predictors of mortality were a low BMI, low HDL-cholesterol and previous myocardial infarction. Low serum albumin, a marker of malnutrition, was associated with low blood pressure, total and HDL-cholesterol and HOMA-IR index. CRP, a marker of inflammation, was associated with low total and HDL-cholesterol values and high HOMA-IR index.

Conclusion: In elderly patients, malnutrition and/or chronic disorders generate a “reverse metabolic syndrome” in which, paradoxically, low BMI, low

DBP, low total and HDL-cholesterol and high insulin sensitivity predict total mortality. These inverse associations limit the value of conventional risk factors in elderly patients. Along with previous CV events, HDL-cholesterol remains a strong, coherent mortality risk factor. Future intervention studies should determine whether and when the prevention and treatment of malnutrition in the elderly should be incorporated into conventional cardiovascular prevention.

The association of serum adipocyte fatty acid-binding protein with coronary artery severity in Korean adults

E.-J. Rhee¹, E.-S. Choi¹, J.-H. Kim¹, J.-C. Won¹, C.-Y. Park¹, W.-Y. Lee¹, K.-W. Oh¹, B.-J. Kim², K.-C. Sung², B.-S. Kim², J.-H. Kang², S.-W. Park¹, M.-H. Lee², S.-W. Kim¹

¹Endocrinology and metabolism, ²Cardiology, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea

Background and aims: Adipocyte fatty acid-binding protein (A-FABP), also known as aP2 or FABP4, is abundantly expressed in adipocytes and plays a role in glucose homeostasis. As there are increasing evidences that FABP4 might play an important role in inflammation and metabolic derangements in human body, we analyzed the relationship between the coronary artery disease and serum FABP4 levels in Korean adults.

Material and methods: In total 234 Korean adults (mean age 58.2 years) in whom coronary angiograms were performed due to chest pain, anthropometric measurements were done and fasting glucose and lipid profiles were measured. The severities of coronary artery disease were classified in 4 groups according to the number of stenotic vessels, that is, normal, 1-vessel, 2-vessel and 3-vessel disease. Serum FABP4 levels were measured with enzyme-linked immunosorbent assay. The presence of metabolic syndrome was diagnosed according to AHA/NHLBI criteria with body mass index substituted for waist circumference.

Results: Among the subjects, 137 subjects (58.5%) were male and 97 subjects (41.5%) were female. 74 subjects (31.6%) had diabetes, and 110 subjects (47%) had metabolic syndrome. Regarding the severity of coronary artery disease, 99 subjects (42.4%) were normal, 81 subjects (34.6%) had 1-vessel disease, 32 subjects (13.7%) had 2-vessel disease, and 22 subjects (9.4%) had 3-vessel disease. Mean serum FABP4 levels were not different between the subjects with or without metabolic syndrome, but showed significantly higher levels in subjects with diabetes (16.44 ± 13.3 vs. 12.78 ± 11.0 ng/mL; $p = 0.042$). When the metabolic parameters were compared according to each groups, age, fasting glucose and serum FABP4 levels increased significantly as the numbers of stenotic vessel increased from normal to 3-vessel disease (Mean values for FABP4, 12.81 ± 9.4 , 12.84 ± 12.8 , 14.39 ± 8.8 and 22.40 ± 18.1 ng/mL for normal, 1-vessel, 2-vessel and 3-vessel groups; $p = 0.005$). In post-hoc analysis, mean values for serum FABP4 levels showed significant differences between normal, 1-vessel and 3-vessel groups ($p < 0.05$). However, these significances were attenuated after adjustment for age and fasting glucose ($p = 0.060$).

Conclusion: Serum FABP4 levels increased as the numbers of stenotic coronary artery increased, but these differences were lost after adjustment for age and fasting glucose levels, suggesting that the relationship of serum FABP4 levels with the severity of coronary artery disease might be affected strongly by age and fasting glucose levels.

Do different definitions of the metabolic syndrome equally identify patients at risk for cardiovascular disease in type 1 diabetes?

L.M. Thorn^{1,2}, C.M. Forsblom^{1,2}, J. Wadén^{1,2}, M. Saraheimo^{1,2}, N. Tolonen^{1,2}, D. Gordin^{1,2}, O. Heikkilä^{1,2}, K. Hietala^{1,2}, J. Kyto^{1,2}, M. Rosengård-Bärlund^{1,2}, P.-H. Groop^{1,2}

¹Department of Medicine, Division of Nephrology, Helsinki University Central Hospital, ²Department of Diabetes Genetics, Folkhälsan Research Center, Helsinki, Finland

Background and aims: The prevalence of the metabolic syndrome varies between 15–70% in patients with type 1 diabetes, depending on age, glycemic control, presence of diabetic complications, and diagnostic criteria. The role of the syndrome as a predictor for cardiovascular disease and diabetes-related mortality in type 1 diabetes is not clear. The aim was therefore to assess its predictive value regarding new cardiovascular events and mortality in patients with type 1 diabetes using different definitions of the syndrome.

Materials and methods: 3,743 adult patients with type 1 diabetes attending the prospective, nation-wide Finnish Diabetic Nephropathy Study were assessed. At baseline, mean age was 37.3 ± 11.8 yrs, duration of diabetes 22.6 ± 12.1 yrs, 52% were male, and 20% had diabetic nephropathy. The metabolic syndrome was defined according to the WHO, NCEP, and IDF criteria. Complete data on mortality were retrieved from death certificates and data on cardiovascular end-points from medical files (available in 64%, $n=2,392$). A cardiovascular event was defined as myocardial infarction, coronary revascularization, or stroke during follow-up.

Results: The prevalence of the metabolic syndrome at baseline was 44%, 34%, and 36% with WHO, NCEP, and IDF criteria, respectively. After a median follow-up of 5.8 (IQR 4.1–6.9) years, 219 patients suffered a new cardiovascular event and 245 died, of whom 199 (81%) died of cardiovascular or diabetes-related causes.

The metabolic syndrome according to WHO and NCEP criteria independently predicted new cardiovascular events [HR 3.52 (2.45–5.06) and 1.80 (1.36–2.39), respectively], adjusted for age, sex, LDL cholesterol, smoking, and HbA_{1c}. After further adjustment for previous cardiovascular events, WHO and NCEP were still independent predictors [HR 2.84 (1.96–4.12) and 1.59 (1.20–2.12)], while after adjustment for diabetic nephropathy only WHO remained significant [HR 2.08 (1.47–2.95)]. For cardiovascular and diabetes-related mortality, both WHO and NCEP criteria were independent predictors [HR 7.37 (4.51–12.05) and 2.02 (1.49–2.74)], adjusted for age, gender, LDL cholesterol, smoking, and HbA_{1c}. After further adjustment for diabetic nephropathy, only WHO was an independent predictor [HR 2.71 (1.56–4.69)]. IDF criteria neither predicted new cardiovascular events nor diabetes-related mortality.

Conclusion: In type 1 diabetes, the metabolic syndrome independently predicts, not only cardiovascular morbidity, but also cardiovascular and diabetes-related mortality. Notably, the WHO criteria, which include microalbuminuria, was the strongest predictor followed by NCEP, while IDF was not a significant predictor in type 1 diabetes.

Alanine aminotransferase and gamma glutamyl transferase are associated with the metabolic syndrome but not with angiographically determined coronary atherosclerosis

L. Risch¹, C.H. Saely^{1,2}, A. Vonbank¹, P. Rein¹, M. Woessl¹, S. Beer¹, C. Boehnel¹, V. Jankovic¹, S. Aczel¹, H. Drexel^{1,2}

¹VIVIT Institute, Feldkirch, Austria, ²Medicine, University for Human Sciences, Triesen, Liechtenstein

Background and aims: We aimed at investigating the respective associations of the metabolic syndrome (MetS) and of angiographically determined coronary atherosclerosis with liver enzymes.

Materials and methods: We enrolled 1000 consecutive patients undergoing coronary angiography for the evaluation of suspected or established stable coronary artery disease (CAD). The MetS was defined according to Adult Treatment Panel III criteria; significant CAD was diagnosed in the presence of coronary stenoses with lumen narrowing $\geq 50\%$.

Results: Serum alanine aminotransferase (ALT), the ALT / aspartate aminotransferase (AST) ratio, and serum gamma-glutamyl transferase (GGT) were significantly higher in patients with the MetS than in subjects without the MetS (34 ± 21 vs. 29 ± 20 U/L; $p < 0.001$; 1.16 ± 0.39 vs. 1.00 ± 0.36 , $p < 0.001$; and 53 ± 88 vs. 43 ± 57 U/L, $p = 0.001$, respectively). In contrast, these parameters of liver function were similar in patients with significant CAD and in those who did not have significant CAD ($p = 0.592$; $p = 0.731$, and $p = 0.716$, respectively). Analysis of covariance after multivariate adjustment including alcohol consumption confirmed that ALT, the ALT/AST ratio, and GGT were significantly and independently associated with the MetS ($F = 13.87$, $p < 0.001$; $F = 19.94$, $p < 0.001$; and $F = 8.55$, $p = 0.004$, respectively) but not with coronary atherosclerosis ($p = 0.317$, $p = 0.741$, and $p = 0.151$, respectively).

Conclusion: ALT, the ALT / AST ratio, and GGT are associated with the MetS but not with angiographically determined coronary atherosclerosis.

Effects of noninvasive ventilation on cardiovascular risk profile in patients with metabolic syndrome and obstructive sleep apnea

R. Tkacova¹, Z. Dorkova², D. Petrasova³, A. Molcanyiova⁴, I. Tkac⁵

¹Dept. of Respiratory Disorders, Medical Faculty, PJ Safarik University,

²Dept. of Respiratory Disorders, Medical Faculty, PJ Safarik University,

³Institute of Experimental Medicine, Medical Faculty, PJ Safarik University,

⁴Dept. of Biochemistry, Labmed, ⁵Dept. of Internal Medicine 4, Medical

Faculty, PJ Safarik University, Kosice, Slovakia

Background and aims: The increased risk of atherosclerotic morbidity and mortality in patients with the metabolic syndrome and obstructive sleep apnea (OSA) has been linked to arterial hypertension, insulin resistance, systemic inflammation, and oxidative stress. In these patients, intermittent hypoxia is the strongest predictor of the nuclear factor- κ B dependent pathways activation resulting in increased serum tumor necrosis factor- α (TNF- α) levels. In contrast, obesity rather than OSA drive raised serum C-reactive protein (CRP), interleukin 6 (IL-6), or leptin concentrations. We aimed to determine the effects of 8-weeks therapy using noninvasive ventilation with continuous positive airway pressure (CPAP) on glucose and lipid profile, systemic inflammation, oxidative stress, and the global cardiovascular disease (CVD) risk in patients with severe OSA and metabolic syndrome.

Materials and methods: In 32 patients, serum cholesterol, triglycerides, high density lipoprotein (HDL) cholesterol, fibrinogen, apolipoprotein A-I (ApoA-I), apolipoprotein B (ApoB), high sensitivity CRP, IL-6, TNF- α , leptin, malondialdehyde (MDA) and erythrocytic glutathione peroxidase (GPx) activity were measured at baseline and after 8 weeks of CPAP. Insulin resistance index (HOMA-IR) was based on the homeostasis model assessment method, the CVD risk was calculated using the multivariable risk factor algorithm. No patient changed hypolipidemic and/or antihypertensive medication, or changed weight ($>5\%$) during the follow-up.

Results: In patients who used CPAP for ≥ 4 h.night⁻¹ ($n=16$), noninvasive ventilation reduced the number of apneas and hypopneas during sleep (from 64.7 ± 23.3 to 3.8 ± 2.1 events.hr⁻¹, $p < 0.001$), and increased the lowest nocturnal SaO₂ (from 66.5 ± 15.6 to $89.5 \pm 12.6\%$, $p < 0.001$). Abolition of OSA was associated with reductions in systolic and diastolic blood pressure (from 148.6 ± 19.6 to 129.4 ± 15.6 mm Hg, $p = 0.001$; from 91.7 ± 13.5 to 79.5 ± 8.2 mm Hg, $p = 0.006$, respectively), reductions in total cholesterol (from 8.80 ± 1.55 to 7.75 ± 1.63 mmol/l, $p = 0.002$), ApoB (from 1.15 ± 0.29 to 0.99 ± 0.20 g/l, $p = 0.009$), and HOMA-IR (from 4.73 ± 3.18 to 2.93 ± 1.77 , $p = 0.031$). In addition, serum MDA and TNF- α were reduced (from 1.73 ± 0.26 to 1.49 ± 0.22 nmol/ml, $p = 0.004$; from 2.13 ± 0.98 to 1.79 ± 0.69 pg/ml, $p = 0.037$, respectively), while erythrocytic GPx activity increased (from 29.2 ± 8.1 to 36.3 ± 12.5 U/g Hb, $p = 0.015$). Serum high sensitivity CRP, IL-6 and leptin concentrations remained unchanged ($p = 0.196$, $p = 0.984$, $p = 0.526$, respectively). Importantly, the calculated global CVD risk was reduced from 18.8 ± 9.8 to $13.9 \pm 9.7\%$ ($p = 0.001$). In contrast, no significant changes in any parameter under investigation were observed in 16 patients whose OSA was not abolished by CPAP (use for < 4 h.night⁻¹).

Conclusion: In patients with the metabolic syndrome and severe OSA, abolition of sleep apnea by effective therapy using noninvasive ventilation improved insulin sensitivity, reduced oxidative stress markers and serum TNF- α concentrations, and reduced the global CVD risk.

High-dose atorvastatin provides sustained benefit in reducing risk of cardiovascular disease among patients with diabetes or metabolic syndrome

P. Deedwania¹, J.C. LaRosa², J. Shepherd³

¹Division of Cardiology, VA Central California Healthcare System, Fresno, United States, ²Department of Medicine, State University of New York Health Science Center, New York, United States, ³Department of Biochemistry, University of Glasgow, United Kingdom

Background and aims: Randomized clinical trials generally restrict the analyses to occurrence of first endpoint event. However, this approach precludes much potentially useful clinical and health economic information because a significant number of patients in long-term trials experience multiple subsequent events. Based on analyses of time to first event, the TNT trial showed that intensive lipid lowering with atorvastatin (ATV) 80 mg significantly reduced the risk of CV events compared with ATV 10 mg both among stable CHD patients with type 2 diabetes (T2D) and among those with metabolic

syndrome (MetS). In this analysis, we evaluated the effect of treatment with ATV 80 mg vs 10 mg among patients with T2D or MetS during the follow up period after the occurrence of a first CV event.

Materials and methods: In TNT, 5854 stable CHD patients with either diabetes or MetS (270 T2D/no MetS; 4352 MetS/no T2D; 1232 T2D & MetS) were randomized to double-blind therapy with ATV 10 or 80 mg and followed for 4.9 years. Time-to-event analysis was used to estimate the treatment hazard ratios separately for time to first, second, third, fourth, and fifth occurrences of any CV event (defined as: any coronary event [CHD death, nonfatal MI, resuscitated cardiac arrest, revascularization procedure, procedure-related MI or documented angina]; a cerebrovascular event [fatal or nonfatal stroke, TIA]; PAD; hospitalization with primary diagnosis of CHF).

Results: A total of 2002 patients with T2D or MetS experienced the first CV event. The numbers with second, third, fourth, and fifth CV events were 1004, 478, 237 and 141, respectively. Among patients with T2D or MetS receiving ATV 80 mg the relative risk of a first as well as subsequent CV events was significantly reduced compared with those receiving ATV 10 mg (Fig).

Conclusion: In patients with either T2D or MetS who had survived the first CV event the treatment with ATV 80 mg (compared to ATV 10 mg) significantly reduced the risk of subsequent CV events during the entire follow-up period.

The clinical value of metabolic syndrome and its components in established type 2 diabetes mellitus: the FIELD trial

R. O'Brien¹, R. Scott², J. Best², M.-R. Taskinen², C. Pardy², C. Ehnholm², A. Keech²

¹NHMRC Clinical Trials Centre, University of Sydney, Australia, ²on behalf of the FIELD study investigators

Background and aims: In the randomised placebo-controlled FIELD trial of long-term fenofibrate among 9795 patients with type 2 diabetes mellitus, almost 1300 first cardiovascular (CVD) events accrued over 5 years. This provides an opportunity to assess whether the constellation of characteristics comprising metabolic syndrome (MS) have clinical value in the setting of type 2 diabetes mellitus.

Materials and methods: All subjects were classified in pre-specified analyses according to the presence of each individual criterion of metabolic syndrome (i) elevated blood pressure or treated hypertension, (ii) gender-specific low HDL cholesterol (HDLc) levels, (iii) elevated triglycerides (TG), (iv) increased waist circumference, and (v) impaired glucose tolerance or diabetes, according to the modified ATP III definitions, and whether metabolic syndrome was present (at least 3 criteria present). Marked hypertriglyceridaemia (TG levels ≥ 2.3 mmol/L) was also examined. Total cardiovascular event rates were estimated among those with and without each feature.

Results: 84% of subjects fulfilled the criteria for having MS: 84% had elevated blood pressure, 68% increased waist, 59% low HDLc and 52% high TG. Marked hypertriglyceridaemia was present in 25%, and in 20% combined with low HDLc. In those with MS, or any individual feature of MS (except for increased waist; $p=ns$), the cardiovascular event rates were at least 3% higher in absolute terms than among those without MS ($p<0.001$) or without the same feature. The highest event rates were seen in those with marked hypertriglyceridaemia plus low HDLc. The CVD event reductions with fenofibrate

over 5 years in those with and without MS were proportionally (11% versus 12% respectively) and in absolute terms (1.4%; number needed to treat [NNT] = 71 versus 1.6%; NNT = 63) very similar. In contrast, the proportional risk reduction was 27% ($p=0.005$) when marked dyslipidaemia (marked high TG plus low HDLc) was present (absolute reduction 4.3%, NNT = 23) compared with 6% ($p=0.32$) among all others (absolute reduction 0.8%, NNT = 143; p value for treatment by group interaction = 0.053). In risk modelling adjusted for age, gender, prior CVD and HbA1c, low HDLc and elevated blood pressure were independent risk contributors (both $p<0.001$), whereas increased waist ($p=0.52$) and elevated TG ($p=0.069$) were not.

Conclusion: Even in the presence of established type 2 diabetes mellitus, the presence of MS or any of its features, except increased waist, increases risk for CVD events significantly. The effects of fenofibrate were similar with or without MS being present, but markedly greater among those at greatest risk, with marked hypertriglyceridaemia plus low HDLc. Marked diabetic dyslipidaemia is an especially important marker of CVD risk and benefit from fenofibrate therapy.

Hyperglycaemia and its effect after acute myocardial infarction on cardiovascular outcomes in patients with type 2 diabetes mellitus (HEART2D)

I. Raz¹, P. Wilson², K. Strojek³, I. Kowalska⁴, V. Bozиков⁵, A. Gitt⁶, G. Jermendy⁷, B. Campaigne⁸, L. Kerr⁹, Z. Milicevic⁸, S. Jacober⁸

¹Internal Medicine, Hadassah Hospital, Jerusalem, Israel, ²Endocrinology, Emory Univ, Atlanta, United States, ³Internal Diseases, Diabetology and Nephrology, Silesian Medical Univ, Zabrze, Poland, ⁴Endocrinology, Medical Univ of Bialystok, Bialystok, Poland, ⁵Endocrinology, Diabetes and Metabolic Diseases, Univ Hospital Dubrava, Zagreb, Croatia, ⁶Ludwigshafen Institut, Heidelberg Univ, Germany, ⁷Medical Dept, Bajcsy-Zsilinszky Teaching Hospital, Budapest, Hungary, ⁸Eli Lilly & Co, Indianapolis, United States

Background and aims: Outcomes of clinical trials on patients with type 2 diabetes (T2D) have shown reduced microvascular complications but inconsistent results regarding macrovascular complications. HEART2D was a multinational, randomized, controlled trial designed to compare the impact of a prandial insulin strategy (PRANDIAL) vs a basal insulin strategy (BASAL) on cardiovascular (CV) outcomes in T2D patients after acute myocardial infarction (AMI). Primary aim was to determine the difference between insulin regimens on time from randomization to first combined CV event (CV death, nonfatal MI, nonfatal stroke, hospitalization for acute coronary syndromes, coronary revascularization procedures planned after randomization).

Materials and methods: Patients (≥ 30 yrs of age) diagnosed with T2D at least 3 months before study admission were randomly assigned (21 days post AMI) to achieve targeted $HbA_{1c} < 7.0\%$ by either (1) PRANDIAL of 3 pre-meal doses of insulin lispro and targeted 2-h postprandial (PP) blood glucose (BG) < 7.5 mM or (2) BASAL of NPH BID or insulin glargine once-daily and targeted fasting/premeal BG < 6.7 mM. Investigators intensified insulin regimen if $HbA_{1c} > 8.0\%$ by: addition of bedtime NPH for PRANDIAL and conversion to human insulin 30/70 twice-daily for BASAL. Patients were studied initially for 18 months followed by an extended period until patient discontinued or the study was stopped by the sponsor. The study was stopped for futility after implementation at 4th interim analysis.

Results: 1115 patients were randomized to either PRANDIAL (N=557) or BASAL (N=558) and took at least one study drug dose (intent to treat). Average days patients were on study drug was 963 (2.7 yrs [1 day minimum, 1078 days (3.0 yrs) maximum]). Patients in the PRANDIAL experiencing a combined adjudicated CV event was similar to the BASAL (N=174, 31.2% vs N=181, 32.4%; HR= 0.98; 95% CI [0.8, 1.21]). Mean (\pm SD) HbA_{1c} did not differ between strategies (7.6 ± 2.5 vs $7.6 \pm 2.4\%$; $p=0.48$) during the study. Regimen intensification occurred in both groups (prandial 28 vs basal 21%; $p=0.005$). Approximately 47% of patients in PRANDIAL achieved BG target of < 7.5 mM for daily mean PP BG and 46% in BASAL achieved daily mean FBG/pre-meal BG < 6.7 mM. Endpoint BG profiles in PRANDIAL showed lower daily mean PP BG (8.1 ± 2.2 vs 8.7 ± 2.2 mM; $p<0.001$), and mean 2-h PP BG excursion (0.1 ± 1.1 vs 1.2 ± 1.3 mM; $p<0.0001$) compared to BASAL. Endpoint fasting BG (FBG) and daily mean of FBG/pre-meal BG were significantly lower for BASAL (8.4 ± 2.3 vs 6.9 ± 1.9 mM; $p<0.0001$ and 8.0 ± 2.0 vs 7.4 ± 2.0 mM; $p<0.0001$, respectively).

Conclusion: Differences in PP and fasting BG were achieved between insulin treatments that targeted fasting/premeal or PP BG; however, rate of combined CV outcomes and HbA_{1c} were similar in these T2DM patients who recently experienced an AMI.

Impaired glucose tolerance significantly increases the risk for cardiovascular events in patients undergoing elective coronary angiography

H. Sourij¹, C.H. Saely², S. Aczel², R. Zweiker³, P. Langer², P. Passler¹, T. Marte², G. Hoefle², W. Benzer², T.C. Wascher^{1,4}, H. Drexel^{2,5}

¹Internal Medicine, Metabolism and vascular biology research group, Medical University of Graz, Austria, ²Department of Medicine, Academic Teaching Hospital Feldkirch, Vorarlberg Institute For Vascular Investigation and Treatment (VIVIT), Feldkirch, Austria, ³Department of Internal Medicine, Div. of Cardiology, Medical University of Graz, Austria, ⁴Department of Internal Medicine, Hanusch Krankenhaus, Vienna, Austria, ⁵University of Human Science, Triesen, Liechtenstein

Background and aims: Prevalence of impaired glucose tolerance (IGT) in patients undergoing coronary angiography for suspected coronary artery disease has been shown to be high. Until now it is unclear whether IGT is associated with increased risk for future cardiovascular events in this population or not.

Materials and methods: We enrolled 1040 patients (374 female, 666 male, mean age 63.7 ± 10.2 years) undergoing elective coronary angiography for suspected coronary artery disease. In patients without previously known diabetes mellitus, an oral glucose tolerance test (oGTT) was performed. Cardiovascular events were recorded prospectively over 3 years.

Results: 394 patients had normal glucose tolerance, 190 suffered from IGT and 456 were diabetics (244 previously known and 212 newly diagnosed by the oGTT). The incidence of vascular events was significantly higher in patients with IGT (14.9%, $p=0.029$) and patients with diabetes mellitus type 2 (13.4%, $p=0.004$) compared to normal glucose tolerant patients (8.9%). No difference between IGT and diabetes mellitus type 2 regarding cardiovascular event rate could be observed ($p=0.778$).

Hazard ratios in multivariate adjusted Cox-Regression analysis were 1.89 (95%-CI 1.11-3.24], $p=0.020$) for patients with IGT and 1.73 ([1.10-2.74], $p=0.019$) for diabetic patients.

Conclusion: IGT and diabetes mellitus type 2 are associated with the same risk for future cardiovascular events in patients undergoing elective coronary angiography. We therefore strongly recommend performing an oGTT in these patients to access the real cardiovascular risk.

The prognostic ability of troponin after the introduction of hs-CRP and HOMA index in different groups of abnormal glucose regulation patients with acute coronary syndrome

A. Koutsovasilis¹, A. Melidonis¹, D. Levisianou¹, G. Koukoulis², I. Skoularigis², M. Zairis³, S. Foussas³, F. Triposkiadis²

¹Diabetes Center, Tzanio General Hospital, Piraeus, ²Cardiology Department, Larissa University Hospital, Larissa, ³Cardiology Department, Tzanio General Hospital, Piraeus, Greece.

Background and aims: Cardiac troponins are considered the “gold standard” measurements for diagnosing myocardial damage in patients with or without chest pain. The presence of elevated levels of serum high-sensitivity C-reactive protein (hs-CRP) is widely accepted as a significant risk factor of cardiovascular event patients while insulin resistance with hyperinsulinemia is an independent risk factor for ischemic heart disease. The aim of this study was to examine the prognostic ability of TnI combined with hs-CRP and insulin resistance HOMA index as to the end points during the first year after hospitalization for Acute Coronary Syndrome (STEMI or NSTEMI) in patients with abnormal glucose regulation.

Materials and methods: Longitudinal, prospective, observational unicenter study. 448 consecutive patients who were admitted to the coronary care unit (CCU) and discharged from February 2006 through January 2007 were included in this study. First-year end points were: death (of cardiovascular cause), myocardial infarction, cardiac failure (clinical and echocardiographic determination) and unstable angina after hospitalization. Non-diabetic patients went through an Oral Glucose Tolerance Test (OGTT) three months after discharge and IGTs were categorized.

Results: Diabetes was previously diagnosed (Group A) in 133 (29.7%) patients, newly diagnosed (Group B) in 43 (9.6%) patients, an IGT (Group C) was ob-

served in 91 (20,3%) patients while 181 (40,4%) were patients with normal glucose regulation (Group D). The incidence of one-year complications was 22.6%, 16.3%, 12.1% and 11.6% in groups A, B, C and D respectively ($p=0.022$). Between hs-CRP and HOMA, hs-CRP had the strongest association with the one-year outcome, since HR of patients with both TnI and hs-CRP in the top quartile was 2.85 (95%CI: 1.28–5.41, $p<0.001$), 2.62 (95%CI: 1.34–4.81, $p<0.001$), 2.18 (95%CI: 1.30–3.96, $p<0.001$) and 2.05 (95%CI: 1.41–4.66, $p<0.001$) compared with those with TnI and hs-CRP in the bottom quartile while patients' HR with TnI and HOMA in the top quartile was 2.59 (95%CI: 1.33–6.31, $p=0.012$), 2.36 (95%CI: 1.29–5.99, $p=0.016$), 1.84 (95%CI: 1.31–6.44, $p=0.033$) and 1.92 (95%CI: 1.23–6.13, $p=0.036$) compared with those in the bottom quartile for A, B, C, D Group respectively (after adjustment to age, sex, waist circumference, triglycerides, HDL, total cholesterol and smoking). Individuals with all these three biomarkers in the top quartile had a HR 3.56 (95%CI: 1.49–6.36, $p<0.0001$), 3.02 (95%CI: 1.55–5.98, $p<0.0001$), 2.48 (95%CI: 1.38–6.44, $p<0.001$), and 2.49 (95%CI: 1.32–6.16, $p<0.001$) compared with those with all these biomarkers in the bottom quartile for A, B, C and D Group respectively.

Conclusion: In this population of patients with Coronary Artery Disease, patients with known diabetes are at high risk for complications during hospitalization while newly diagnosed diabetic patients are at intermediate risk. The main finding is that the introduction of hs-CRP modifies more strongly the prognostic value of TnI, compared to the introduction of HOMA, in all patient groups.

1362

Lipid predictors of cardiovascular events in statin-treated coronary patients with diabetes mellitus

H. Drexler^{1,2}, S. Aczel¹, T. Marte¹, A. Vonbank¹, C.H. Saely^{1,2}

¹VIVIT Institute, Feldkirch, Austria, ²Medicine, University for Human Sciences, Triesen, Liechtenstein

Background and aims: Statins are a cornerstone in the treatment of diabetic patients with coronary artery disease (CAD), but vascular risk in these patients remains high. We therefore aimed at identifying which lipid parameters drive vascular risk in this important patient population despite statin treatment.

Materials and methods: We recorded vascular events over 5.6 years in 491 consecutive statin-treated patients with angiographically proven stable CAD, covering 2750 patient-years.

Results: Low HDL cholesterol (standardized adjusted hazard ratio (HR) 0.73 [0.60–0.89]; $p=0.001$), low apolipoprotein A1 (HR 0.77 [0.65–0.92]; $p=0.003$), a small LDL particle diameter (0.76 [0.64–0.91]; $p=0.002$), and high triglycerides (1.20 [1.05–1.38]; $p=0.007$) significantly predicted vascular events, but not total cholesterol ($p=0.995$), LDL cholesterol ($p=0.961$), or apolipoprotein B ($p=0.077$). Patients with T2DM ($n=116$) were at a higher vascular risk than non-diabetic subjects (38.6% vs. 24.1%; $p<0.001$). Importantly, like in the total population, low HDL cholesterol (HR = 0.58 [0.41–0.82]; $p=0.002$), low apolipoprotein A1 (HR = 0.70 [0.51–0.95]; $p=0.002$), a small LDL particle diameter (0.67 [0.50–0.91]; $p=0.010$), and high triglycerides (1.30 [1.11–1.53]; $p=0.001$) predicted vascular risk in statin-treated coronary patients with T2DM, whereas total cholesterol ($p=0.822$), LDL cholesterol ($p=0.235$), and apolipoprotein B ($p=0.366$) did not.

Conclusion: The pattern of low HDL cholesterol, low apolipoprotein A1, small LDL particles, and high triglycerides is the main lipid risk factor in statin-treated coronary patients with T2DM.

Multivariate biochemical basis of vascular complications and mortality in 4,197 patients with type 1 diabetes

V.-P. Mäkinen^{1,2}, C. Forsblom¹, L.M. Thorn¹, J. Wadén¹, D. Gordin¹, O. Heikkilä¹, K. Hietala¹, J. Kytö¹, M. Rosengård-Bärlund¹, M. Saraheimo¹, M. Parkkonen¹, K. Kaski², M. Ala-Korpela^{1,2}, P.-H. Groop, FinnDiane Study Group¹

¹Folkhälsan Research Center, Folkhälsan Institute of Genetics, Helsinki,

²Department of Biomedical Engineering and Computational Science, Helsinki University of Technology, Espoo, Finland

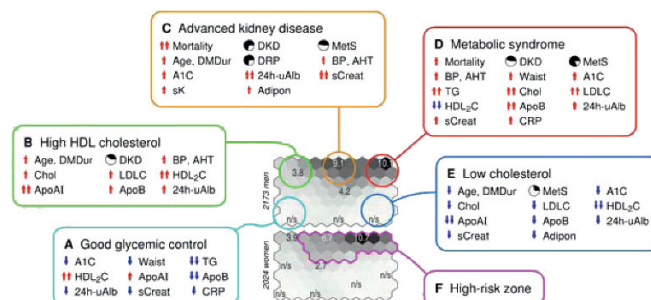

Background and aims: Risk assessment of diabetic complications is challenging due to the gradual disease processes and the lack of accurate metabolic

phenotypes. Here the focus is on the latter problem: to reveal the multi-variate biochemical features behind the clinical outcomes and premature deaths in a set of Finnish patients with type 1 diabetes.

Materials and methods: Baseline biochemical and clinical data were collected for 2173 men and 2024 women with type 1 diabetes (age at onset below 35 years, insulin treatment within a year of onset) from the Finnish Diabetic Nephropathy Study. The vitality status was obtained after an average of 6.5 years of follow-up (25,714 patient years, 295 deaths). Clinical records and measurements of 20 biochemical variables (lipoprotein subfractions, apolipoproteins, serum and urine creatinine, inflammatory markers and 24h-urine albumin) were collected by standardized questionnaires and laboratory methods. The data were analysed by a self-organizing map (SOM), and visualized separately for males and females with computational significance estimates and confidence intervals. The metabolic phenotypes revealed by the SOMs were then compared against the observed all-cause mortality.

Results: Two sides of the diabetic complications cluster were revealed: a metabolic syndrome profile of insulin resistance, low HDL2C, and abdominal obesity, and a high-adiponectin, high-LDL2C, high-HDL2C profile associated with microvascular complications. A 10.1-fold [CI95%: 7.3–13.1] population adjusted risk of death in males, and a 10.7-fold [CI95%: 7.9–13.7] risk in females was observed at the intersection of the two metabolic states.

Conclusion: The SOM approach offers a visual way of incorporating multivariate biochemical datasets into clinical decision making, as demonstrated in this study by the dissection of diabetic complications into a metabolic continuum between two characteristic phenotypes. We expect this type of computational medicine to be crucial not only for cultivating the scientific understanding of multifactorial metabolic disorders, but also for enabling tailored treatments of complex diseases.

Discovery of biomedical markers of early diagnosis of diabetic complications with proteomic analysis

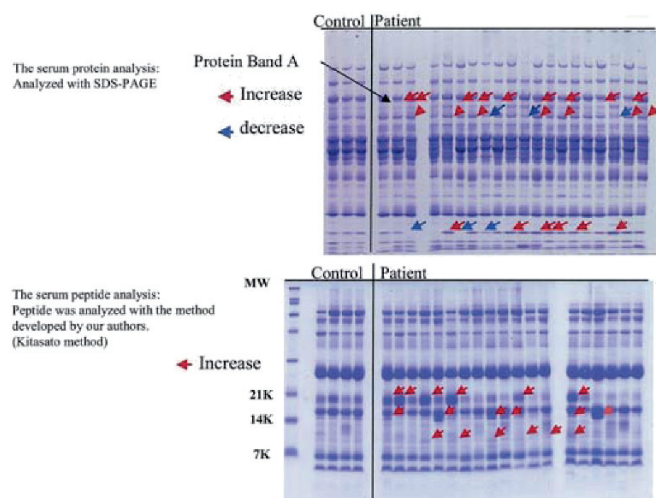

T. Takada¹, T. Hosaka¹, K. Tanaka¹, T. Moriya¹, M. Oh-Ishi², Y. Kodera², T. Maeda², Y. Fujita¹

¹Department of Endocrinology, Diabetes & Metabolism, ²Department of Physics, Kitasato University, Kanagawa, Japan

Microangiopathy of diabetes represents one of the most serious consequences of the disease. Particularly, retinopathy, nephropathy, and possibly peripheral neuropathy exhibit significant pathology. To find diabetic complications in the early stage of the disease, we need biomedical markers high in specificity and sensitivity. The only available biomedical marker in recent years has been microalbuminuria for the diagnosis of diabetic nephropathy. Proteomic analysis is a useful tool for the identification of altered protein expressions in various pathologic conditions. Although tissue biopsy and cytology is an ideal sample for analyses, it is invasive and costly to patients. Therefore, we analyzed serum samples to find the biomedical markers for early diagnosis of diabetic complications. Serum samples were taken from 17 type 1 diabetic patients (male/female, 6/11; mean age: 52.0±19.7), 41 type 2 diabetic patients (male/female, 22/19; mean age: 56.8±14.5), and 8 healthy subjects (male/female, 5/3; mean age: 28.7±0.8) as a control. Mean HbA1c value was 8.9±2.3% in type 1 and 9.6±2.3% in type 2 diabetic patients. The serum samples were analyzed with sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE) and two-dimensional electrophoresis. Fractions of albumin and globulin that interfere with proteomic analysis were removed. Low molecular weight proteins defined as less than 20 kDa (peptide) was analyzed with the method developed by three of our authors (Oh-Ishi, Kodera, Maeda). Pro-

tein and peptide were identified with mass spectrometry and tandem mass spectrometry.

As a result of SDS-PAGE, a protein band was increased in 36 diabetic patients (10 in type 1, 26 in type 2). Among these patients, glycemic controls of 26 patients were poor regardless of diabetic type. As a result of peptide analysis, peptide band of approximately 10 KDa was increased in 6 diabetic patients (2 in type 1, 4 in type 2). We identified the apolipoprotein C-III in this peptide band. In addition, a peptide band of approximately 14 KDa was increased in 6 patients (3 in type 1, 3 in type 2). We also identified a preplatelet basic protein in this peptide band. We found several altered protein expressions in the serum of diabetic patients with hyperglycemia regardless of the type of diabetes. Our results suggest that these protein expressions may become biomarkers for early diagnoses of diabetic complications. Further studies are warranted to clarify the relationship between these protein expressions and the development of diabetic complications.

Performance of the UKPDS Risk Engine and the Framingham risk equations in estimating cardiovascular disease in the EPIC-Norfolk cohort

R.K. Simmons¹, R.L. Coleman², H.C. Price², R.R. Holman², K.-T. Khaw³, N.J. Wareham¹, S.J. Griffin¹

¹MRC Epidemiology Unit, Institute of Metabolic Science, Cambridge, ²Diabetes Trial Unit, Oxford University, ³Clinical Gerontology, University of Cambridge, United Kingdom

Background and aims: Individuals with type 2 diabetes have a 2 to 4 fold increased risk of cardiovascular disease (CVD) compared to those without diabetes. Multifactorial treatment can significantly reduce this risk. Multivariate equations such as Framingham are used to estimate CVD risk in order to target therapy to those at highest absolute risk, and to provide patients and practitioners with prognostic information. This study examines the performance of the UKPDS Risk Engine (version 3) and the Framingham risk equations in estimating CVD incidence in three population sub-groups: (i) individuals with known diabetes (DM); (ii) individuals with non-diabetic

hyperglycaemia, defined as $HbA_{1c} \geq 6.0\%$ (HG); and, (iii) individuals with $HbA_{1c} < 6.0\%$ (normoglycaemia) (NG).

Materials and methods: The data are from a population-based prospective cohort (EPIC-Norfolk). Participants aged 40–79 years recruited from UK general practices attended a health examination (1993–1998) and were followed for CVD events/death until April 2007. CVD risk estimates were calculated for 10,138 individuals with complete data on age, sex, ethnicity, smoking status, diabetes, total cholesterol, HDL-cholesterol, systolic blood pressure and HbA_{1c} using the UKPDS Risk Engine and Framingham CVD risk equation. Estimation of events by each score was compared using the area under the receiver operating characteristic curve (aROC) and the Net Reclassification Improvement (NRI) statistic.

Results: Over 10.5 years of follow-up there were 69 CVD events in the 272 individuals with diabetes, 160 in the 906 with non-diabetic hyperglycaemia and 732 in the 8,960 with normoglycaemia (Table 1). The estimated CVD 10-year risk in individuals with diabetes was 26% and 28% using the UKPDS and Framingham scores respectively. In the HG group, estimated CVD risk was 28% and 31% respectively, and for the NG group, 19% and 23% respectively. In the DM and HG groups, there was no significant difference in the ability of the two risk scores to either discriminate between or correctly reclassify individuals at different risk of CVD events (Table 1). The discrimination of both scores was poor in the NG group.

Conclusion: The UKPDS and Framingham risk equations perform reasonably well at estimating CVD risk in individuals with diabetes in EPIC-Norfolk. These scores can therefore assist with targeting of therapy to those at highest absolute risk. The UKPDS Risk Engine unsurprisingly overestimates risk in those without diabetes. The overestimates of risk in those without diabetes by the Framingham score confirm previous findings. Our results highlight that care is still needed when using scores to communicate risk information to individuals.

Benefits of long-term fenofibrate therapy on amputations in type 2 diabetes mellitus in the FIELD trial

P. Colman¹, K. Rajamani², L.-P. Li², M. D'Emden², M. Voysey², A. Keech², ¹NHMRC Clinical Trials Centre, University of Sydney, Australia, ²on behalf of the FIELD study investigators.

Background and aims: In the FIELD trial in 9795 patients with type 2 diabetes mellitus, fenofibrate reduced total cardiovascular events and retinopathy requiring laser therapy, suggesting effects on both macrovascular and microvascular complications. The study provided an opportunity to explore in detail the nature and predictors of amputations, which were also significantly reduced by treatment.

Materials and methods: All on-study non-traumatic amputations were reviewed in blinded fashion by 2 clinicians. Amputations of digits and forefoot were classified as having a presumed microvascular basis provided that no prior or concurrent large vessel disease (including angioplasty and bypass surgery) in that same limb, or evidence of causative embolism, was present. Larger amputations or those with evidence of embolism or existing vascular disease in the affected limb were classified as macrovascular or mixed. All analyses of the effects of treatment were by intention-to-treat.

Results: Compared with patients suffering any other cardiovascular event or no event during 5 years of follow-up, those with an amputation had a significantly longer duration of diabetes, higher systolic blood pressure, more current smoking, more prior vascular disease, more male gender, more microvascular disease and more baseline insulin use (all $p < 0.0001$). Com-

Table 1: Actual and estimated CVD risk using UKPDS and Framingham scores in EPIC-Norfolk

	Individuals with prevalent diabetes (n=272)	Individuals with non-diabetic hyperglycaemia (n=906)	Normoglycaemic individuals (n=8,960)
Actual mean CVD risk, %	25.4	17.7	8.2
Estimated CVD 10-yr risk: UKPDS score, % (95% CI)	26.4 (25.5 - 27.3)	27.5 (27.0 - 28.0)	19.2 (19.1 - 19.3)
Estimated CVD 10-yr risk: Framingham score, % (95% CI)	27.6 (26.8 - 28.4)	31.4 (30.9 - 31.9)	23.1 (23.0 - 23.2)
aROC* (95% CI) for the UKPDS score	0.61 (0.53 - 0.69)	0.65 (0.60 - 0.70)	0.53 (0.51 - 0.55)
aROC (95% CI) for the Framingham score	0.60 (0.52 - 0.68)	0.67 (0.62 - 0.71)	0.52 (0.49 - 0.54)
NRI** (%), p-value comparing UKPDS and Framingham models	-7.0%, p=0.290	-6.9%, p=0.111	-9.7%, p<0.001

*Area under the receiver operating characteristic curve

**The NRI refers to the net gain in correct reclassification. A positive NRI indicates an improvement in classification, while a negative NRI corresponds to a worsening in classification. The negative NRIs in the table above indicate that the UKPDS risk engine correctly reclassified risk of CVD events in more individuals than the Framingham score

pared with subjects classified as having a macrovascular amputation, those with presumed microvascular amputations were slightly younger ($p=0.03$), heavier ($p<0.001$), had slightly higher HbA1c ($p=0.07$) and with more other microvascular disease at baseline, including known retinopathy, peripheral neuropathy and albuminuria ($p=0.002$).

Effects of fenofibrate on amputations

	Relative risk reduction	95% confidence interval	p value
Microvascular amputations	47%	8-70%	0.025
Macrovascular amputations	23%	-21-51%	0.26
All first amputations	38%	10-57%	0.011

Conclusion: Compared with amputations associated with large vessel limb disease, small digit (presumed microvascular) amputations occur in a population with higher levels of established microvascular complications of diabetes. The measured effects of fenofibrate on amputations were particularly striking in this group, further supporting important clinical benefits with fenofibrate treatment on microvascular disease in type 2 diabetes mellitus.

ERM proteins mediate the effects of Na/H exchanger activation in diabetic rat hearts

A. Darmellah, C. Rucker-Martin, D. Feuvray

Hôpital Marie Lannelongue, UMR CNRS 8078, Université Paris-Sud XI, Le Plessis Robinson, France

Background and aims: To further investigate molecular linkers between NHE1 and Akt activity previously identified in hypertrophied left ventricular (LV) myocytes from diabetic GK rats.

Materials and methods: Individual myocytes were isolated from the LV wall of perfused hearts. Intracellular acidification (by the ammonium pulsing method) was induced to activate NHE1. Fluorescence microscopy was used to detect immunocytochemical localisation of phosphorylated (activated) ezrin/radixin/moesin (ERM) proteins and whole-cell lysates were used to measure their levels, as well as levels of several phosphorylated kinases.

Results: ERM proteins were localised predominantly at the intercalated disk regions under basal conditions. Profound change in activated ERM were observed in acidified cells, with immunolabelling detected in regions corresponding to the transverse tubules. This correlated with a marked increase in phospho-ERM levels, which was blocked by NHE1 inhibitor treatment. Levels of phospho-Akt paralleled those of phospho-ERM under the various experimental conditions used. Moreover, the pattern of GSK-3 β phosphorylation was strikingly similar to that observed for Akt activity under the conditions used.

Conclusion: Activated ERM proteins mediate the effects of acid-induced NHE1 activation in LV myocytes. Akt is a downstream effector in the cascade activated by NHE1/ERM interaction. In addition, GSK-3 β phosphorylation is required for downstream effects of Akt-NHE1/ERM signalling. Our findings provide insight into mechanisms explaining the role of NHE1 activation in cardiac hypertrophy in the GK model of type 2 diabetes.

Rat diabetic heart does not respond to ischaemic preconditioning: the role of methionine-centered redox cycle

V. Vinokur¹, B. Bulvik¹, E. Berenshtein¹, R. Eliashar², M. Chevion¹

¹Cellular Biochemistry and Human Genetics, Hebrew University of Jerusalem, ²Department of Otolaryngology, Hadassah Hospital, Jerusalem, Israel

Background and aims: Diabetes is associated with increased risk of cardiovascular morbidity and mortality. While the non-diabetic heart responds to ischemic preconditioning (IPC) and acquires protection against subsequent prolonged ischemia, the diabetic heart often fails to get protected by IPC. The role of methionine-centered redox cycle (MCRC) in IPC response of diabetic heart compared to the normal one was analyzed. The aims of the current study was to characterize the effect of IPC on heart function in diabetic hearts as compared to non-diabetic ones, and monitor the changes in MCRC proteins relate to cardioprotection.

Materials and methods: Rats were made diabetic by streptozotocin injection (70 mg/kg, i.p.). After 4 weeks, hearts were isolated and retrogradely perfused according to Langendorff. The hearts were subjected to IPC (2 min. ischemia and 3 min. (re)perfusion, 3 cycles) followed by prolonged ischemia (35 min.). Heart hemodynamics, contractile function and MCRC proteins e.g. thioredoxin 1 (Trx), thioredoxin reductase 1 (TrxR) and methionine sulfoxide reductase A and B isoforms concentrations were measured.

Results: The post-ischemic recovery of function in diabetic hearts was markedly better than that in controls. However, unlike the control ones, the diabetic hearts did not improve their post-ischemic recovery following the IPC procedure. No alterations in the Trx concentration were detected in the control hearts during IPC, as well as during ischemia or reperfusion. On the other hand, the diabetic hearts have demonstrated a significant 2.3 fold decrease at the end of ischemia preceded by IPC. During the reperfusion the Trx concentration has restored. The hearts from the control and diabetic groups have demonstrated a significant increase in MsrA concentration at the end of post-IPC ischemia, 2.5 and 1.9 fold respectively. This increase was

followed by down-regulation to the initial level during the reperfusion. In TrxR and MsrB concentrations no changes were observed in any stage of the experiment neither in control hearts nor in diabetic ones.

Conclusion: We hypothesize that the inability of the diabetic heart to maintain the required level of thioredoxin, one of the most important proteins in cellular redox balance regulation, underlies the heart inability to be protected by IPC. Moreover, the MsrA concentration in control hearts has shown much more considerable increase in response to IPC followed by ischemia than diabetic ones, demonstrating better protection. Studies aimed at bringing the light on MCRC involvement in better post-ischemic recovery of diabetic hearts are in progress.

Ethanol exposure decreases the expression of AMP-activated protein kinase and GLUT4 in rat cardiac myocytes

X.L. Sun¹, X.B. Wei², H. Ding², X.J. Zhang¹, L. Feng¹, L.M. Tian¹, L. Gao³, J.J. Zhao¹

¹Endocrinology, Provincial Hospital affiliated to Shandong University,

²Department of Pharmacology, Shandong University School of Medicine,

³Scientific Center, Shandong Provincial Hospital, Jinan, China

Background and aims: We and other studies found that chronic ethanol intake may cause lower expression of Glucose transporter 4 (GLUT4) in skeletal muscles, adipocytes and livers. It is well known that GLUT4, a signal at the end of insulin signaling pathway, is regulated by insulin signal and contributes to glucose metabolism. Recently, a few studies have addressed that AMP-activated protein kinase (AMPK) is necessary for GLUT4, and this effect may be occurred in a independent - insulin signaling pathway manner. Studies on skeletal muscles showed that effect of AMPK on GLUT4 was mediated by myocyte enhancer factor-2 (MEF2), a muscle-specific regulator for GLUT4 gene transcription. GLUT4 promoter has a MEF2 binding element located between -473 and -464. Our aims of the current study were to investigate whether there existed the effects of AMPK on MEF2 and GLUT4 in rat cardiac muscles. If so, whether this event was involved in ethanol action.

Materials and methods: (1) *In vivo*, male Wistar rats weighing 180±5g were randomly divided into two groups: AICAR (an AMPK activator) group and control group. AICAR-treated rats were received a subcutaneously injection with 0.8 mg AICAR/g body weight. Control animals were injected with a corresponding volume of 0.9% NaCl. Treatment for 2 hours, all rats were anesthetized and the heart ventricles were dissected out for an analysis of the mRNA levels of MEF2A and 2D subtypes as well as GLUT4 by RT-PCR (normalized to GAPDH). (2) *In vitro*, cardiomyocytes were prepared from ventricles of neonatal Wistar rats (1-3-day-old). After culture, cardiomyocyte specific proteins, α -cardiac muscle actinin, were identified by immunofluorescence. The cells were treated with 100 mM edible ethanol or 1 mM AICAR. Treatment for 4 hours, total proteins were gained for analyzing the expression of phospho-AMPK α (the activated AMPK) and GLUT4 by Western blotting (normalized to β actin) and total RNA was extracted for determining the mRNA levels of GLUT4 by RT-PCR (normalized to GAPDH), respectively.

Results: (1) Compared with control rats, AMPK activator, AICAR, obviously up-regulated the mRNA levels of MEF2A and GLUT4 ($p < 0.05$). We, however, failed to detect the significant change of MEF2D mRNA level, which is in agreement with a previous report of strong MEF2A while weak MEF2D expression in heart tissues. (2) In the cardiomyocyte experiments *in vitro*, AICAR increased significantly the expression of phospho-AMPK α protein ($p < 0.05$), while ethanol exposure decreased markedly the activated AMPK levels ($p < 0.05$). Like the experiment above *in vivo*, the AICAR-mediated AMPK activity increase was associated with the up-regulation of GLUT4 expression at both mRNA and protein levels ($p < 0.05$). However, ethanol exposure to rat cardiac myocytes could decrease the GLUT4 expression not only at the mRNA but also at the protein levels relative to control ($p < 0.05$).

Conclusion: AICAR may enhance AMPK activity and increase the expression of MEF2A and GLUT4 in rat cardiac myocytes. While ethanol is able to decline AMPK activity associated with a decrease in GLUT4 expression in rat cardiac myocytes. This maybe partly indicate that ethanol impairs insulin sensitivity in rat heart muscle via, at a certain extent, decreasing the expression of AMPK activity, MEF2A and GLUT4.

Changes of adrenergic and cholinergic coronary circulation regulation in dogs induced by multiple insulin administration

A. Nescheret

Laboratory of Diabetes Mellitus Epidemiology, Institute of Endocrinology and Metabolism, Kiev, Ukraine

Background and aims: Recently we have shown that in experiments on dogs both acute hyperinsulinemia and insulin deficiency (alloxane diabetes) modulate adrenergic and cholinergic heart function regulation and circulation reactions to acute myocardial ischemia. Nevertheless the mechanisms of the coronary tone physiological and pathophysiological effects of insulin in the heart circulation have not been fully elucidated. The purpose of this study was to assess whether multiple high dose insulin administrations may be involved in the pathophysiology of diabetic neuropathy and deterioration of coronary circulation and heart function regulation.

Materials and methods: During 30 days of chronic experiments on healthy conscious dogs (ID) insulin administrations (1.0 IU/kg in muscle of hind leg) were carried out. Every morning animals were injected with insulin 4 hours before feeding. Final investigations of neurohormonal coronary artery (CA) tone and heart function regulation were fulfilled in acute experiments on 20 anesthetized dogs (alpha-chloralose, 50-100 mg/kg, i.v.). Control physiological investigations of circulation were performed on 10 clinically healthy dogs (HD). Catheterization and programmed autoperfusion of left CA, catheterization and continuous drainage of coronary sinus, heart and main vessels catheterization were performed without opening the chest. Cardiohaemodynamics, CA perfusion pressure (CAPP) with another clinical and biochemical parameters were registered. Test-reactions of CA and femoral artery (FA) resistance were provoked by bolus injection of epinephrine (E, 5.0 mkg), norepinephrine (NE, 5.0 mkg) and acetylcholine (Ach, 1.0 mkg) into arterial blood stream.

Results: Due to multiple insulin administrations the dog's body masses and venous blood glucose levels augmented (from 15.1±1.4 to 18.0±1.5 kg, $P < 0.05$, and from 3.36±0.6 to 4.7±0.8 mmol/l, $P < 0.05$, resp.). But the levels of venous blood pH, pCO_2 , pO_2 , as well as blood pressure and other cardiohaemodynamics parameters did not change significantly. In ID group E and Ach induced more pronounced decrease of CAPP in comparison with HD group (-5.7±0.4 kPa; -5.6±0.4 kPa; $P < 0.05$; and -4.5±0.3 kPa; -4.3±0.3 kPa; $P < 0.05$, resp.). Meantime no differences between ID and HD groups were observed in circulation reactions to NE (-4.6±0.5 kPa and -4.5±0.4 kPa; $P > 0.5$). Also in ID group after bolus injection of E into FA stream but not after NE the elevation of FA perfusion pressure (FAPP) was significantly augmented in comparison with HD group (+8.0±0.6 kPa; +6.1±0.4 kPa; $P < 0.05$ and 6.3±0.8 kPa; +6.3±0.7 kPa; $P > 0.05$, resp.). Besides that the degree of decrease of FAPP to Ach in ID group was increased in comparison with HD (-7.3±0.2 kPa and 6.6±0.1 kPa; $P < 0.05$).

Conclusion: These findings suggest that multiple high dose insulin administrations to healthy animals can provoke the development of typical for our previously observed early diabetic states in experiments on dogs changes of coronary circulation and heart function regulation deterioration: augmentation of coronary vessels and heart reactivity to adrenergic and cholinergic nervous systems stimulation.

1371

High-fat diet-induced atherosclerosis was alleviated by lithium chloride, a glycogen synthase kinase-3 (GSK3) inhibitor, in apolipoprotein E-deficient mice

H.-J. Jang¹, S.-E. Choi¹, H. Kwon², J. Jung¹, H. Kim¹, D. Kim¹, Y. Kang³, K. Lee¹

¹Endocrinology and metabolism, Ajou University, ²Endocrinology and metabolism, Kwon's Endo Im Clinic, ³Institutes for Medical Sciences, Ajou University, Suwon, Republic of Korea

Background and aims: Glycogen synthase kinase-3 (GSK-3) is a serine/threonine kinase with roles in multiple biological functions, including cell fate determination, metabolism, proliferation, and carcinogenesis. However, the role of GSK-3 in atherosclerosis has not been elucidated. The present study was performed to investigate the role of GSK-3 in atherosclerosis using lithium chloride (LiCl), an inhibitor of GSK-3, in apolipoprotein (apo) E-deficient mice.

Materials and methods: Ten-week-old male mice were divided randomly into baseline, vehicle, and treatment groups. Mice in the vehicle and treat-

ment groups were fed a typical western diet (*i.e.*, 20% fat, 0.5% cholesterol) for 14 weeks without or with LiCl (10 mg/kg/day).

Results: LiCl treatment had no effect on glucose tolerance but improved insulin tolerance and body weight. Examination of plasma lipid profiles indicated that total cholesterol levels were significantly decreased by LiCl treatment as compared with the vehicle group ($P<0.05$). However, there were no differences in triglycerol, HDL-cholesterol, or free fatty acid levels between the groups. In comparison with vehicle-treated controls, LiCl-treated apolipoprotein (apo) E-deficient mice showed 60% and 40% reductions in atherosclerotic lesion areas in the aorta and aortic valves, respectively ($P<0.05$). LiCl treatment also decreased macrophage infiltration into atherosclerotic lesion areas of the aortic valves.

Conclusion: These results indicated that LiCl, an inhibitor of GSK-3, reduces total plasma cholesterol levels, atherosclerotic lesion areas in the aorta and aortic valves, and macrophage infiltration into atherosclerotic lesions in apolipoprotein (apo) E-deficient mice. The results of the present study provided experimental evidence for a novel strategy of atherosclerosis treatment using GSK-3 inhibitors.

The influence of the presence of retinopathy on the circulating endothelial progenitor cell counts, endothelial function and carotid intima-media thickness in type 1 diabetes

L. Sibal^{1,2}, A. Jones², A. Aldibbiat¹, G. Mitchell³, C. Oates³, J. Weaver¹, J.A.M. Shaw^{1,2}, P.D. Home^{1,2};

¹School of Clinical Medical Sciences-Diabetes, The Medical School, Newcastle University ²Department of Diabetes, Newcastle upon Tyne Hospitals, ³Medical Physics, Newcastle upon Tyne Hospitals, United Kingdom

Background: The relationship of retinopathy to cardiovascular (CV) risk is controversial. Endothelial dysfunction (measured as flow mediated dilatation, FMD) and increased carotid intima-media thickness (CIMT) predate clinical CV disease, while circulating endothelial progenitor cells (EPCs) are reduced in the presence of CV risk factors. We have determined how abnormalities of FMD, CIMT and EPCs in type 1 diabetes (T1DM) are affected by the presence of diabetic retinopathy.

Methods: FMD, CIMT and EPCs were measured in 74 young adults with T1DM without microalbuminuria or arterial disease and 80 healthy controls. EPCs were quantified in the lymphocyte gate and CD14-positive gate by flow-cytometry with matching isotype control antibodies to reduce background noise. Retinopathy was graded from digital photography.

Results: FMD was comparable in those with T1DM with ($4.8\pm 3.0\%$) and without ($5.3\pm 2.9\%$) retinopathy, though significantly reduced compared to controls ($9.0\pm 3.4\%$; $p<0.001$). CIMT was higher in T1DM people (0.62 ± 0.00 vs controls 0.50 ± 0.00 mm; $p<0.001$) and in those with retinopathy compared with those without (0.64 ± 0.01 vs 0.59 ± 0.01 mm, $p=0.009$). The median EPC and CV progenitor counts (cells/ 10^6 -events) in T1DM without and with retinopathy and controls were: CD34+ cells (108, 291, 418, $p=0.018$ to 0.002 respectively); CD133+ cells (49, 159, 213, NS to $p=0.012$ respectively) and CD34+/VE-Cadherin (67, 155, 216, $p=0.008$ to 0.001 respectively). Within the T1DM group CD34+/VEGFR2 count was lower in those without retinopathy (3 vs 10, $p=0.042$).

Conclusion: CIMT was higher in those with retinopathy suggesting possible association with macrovascular pathology while the reduced number of circulating EPCs in those with T1DM compared to healthy controls was significantly attenuated in the presence of retinopathy. Further studies of the mechanisms influencing EPC number and function will be required to fully elucidate their role in the pathogenesis of microvascular and macrovascular complications of diabetes and their value as a marker of CV risk in this complex heterogeneous population.

Relationship between post-occlusive forearm skin reactive hyperaemia and diabetic microangiopathy or macroangiopathy in patients with type 2 diabetes - a novel index for detecting microvascular dysfunction using laser Doppler flowmetry

R. Suganuma, Y. Aso, T. Inukai

Internal Medicine, Dokkyo Medical University, Koshigaya Hospital, Koshigaya, Japan

Background and aims: To investigate the relationship between post-occlusive forearm skin reactive hyperemia (PORH) and macro- and microangiopathy, or serum high molecular weight (HMW) adiponectin.

Materials and methods: We studied 20 age-matched healthy control subjects and 104 patients with type 2 diabetes. Cutaneous blood flow (flux) in response to 5-min arterial occlusion in the forearm was measured using laser Doppler flowmetry. We defined the PORH-index as the ratio of the area under the curve (AUC) 1 min after the release of the cuff relative to the AUC of a 1-min period before the cuff inflation. The flux in response to arterial occlusion was divided morphologically into three patterns: normal peak, early non-dominant peak, and early dominant peak. Brachial-ankle pulse wave velocity (baPWV), an index of arterial stiffness, was measured.

Results: The PORH-index was markedly lower in diabetic patients than in control subjects. The prevalence of an early dominant peak pattern was significantly higher in diabetic patients than in control subjects. The PORH-index correlated negatively with urinary albumin and baPWV in diabetic patients. We found no significant relationship between serum HMW adiponectin and PORH-index or the three morphologic patterns of flux in diabetic patients. The PORH-index was an independent determinant of cardiovascular disease in diabetic patients.

Conclusion: The PORH-index may be the most sensitive indicator for microvascular and macrovascular function among the various measures of PORH in patients with type 2 diabetes. However, the measures of PORH, including the PORH-index, were not associated with the serum HMW adiponectin concentrations in patients with type 2 diabetes.

Microvascular reactivity in acute hyperglycaemia in type 1 diabetes

M. Prázný, E. Horová, J. Škrha

3rd Dept. of Internal Medicine, 1st Faculty of Medicine, Prague, Czech Republic

Background and aims: High plasma glucose variability and excursions are considered as a risk factor for macrovascular complications in diabetes. Less is known about microvascular damage. The aim of the study was to evaluate skin microvascular reactivity (MVR) in type 1 diabetic patients during isoglycemic and hyperglycemic hyperinsulinemic clamps to test the effect of acute hyperglycemia. Lipid parameters, fibrinogen and the cell adhesion molecules were evaluated, too.

Materials and methods: 20 type 1 diabetic patients (mean age 51 ± 7 years, BMI 25 ± 3 kg.m⁻², diabetes duration 24 ± 7 years, HbA_{1c} $7.8\pm 0.9\%$) were studied initially during isoglycemic (2 hours) and consequently hyperglycemic (2 hours) hyperinsulinemic clamps and after following next two weeks during appropriate intravenous volume load as control examination to exclude non-specific factors, especially hemodilution. Skin MVR was measured by laser Doppler flowmetry continually during clamps and after post-occlusive (PORH) and thermal hyperemia (TH) at the end of isoglycemic and hyperglycemic phases. Maximal perfusion (max), time to maximal perfusion (tmax), velocity of perfusion increase (max/t) and percentage of baseline increase (%) were calculated. Paired t-test, ANOVA, Wilcoxon test and Pearson correlation were used for statistical analysis of data using Statistica for Windows software.

Results: Venous blood glucose was 6.5 ± 1.9 mmol.l⁻¹ in isoglycemic and 12.0 ± 1.6 mmol.l⁻¹ in hyperglycemic phase of the clamp, respectively. Maximal perfusion in PORH increased in hyperglycemic phase compared to basal value and the same was true for the velocity of perfusion increase which was increased in isoglycemic phase, too. Negative relationship was found between plasma insulin concentration and time to maximal flow during PORH ($r=-0.7$, $p=0.007$; $y=193.6-2.5\cdot x$). No other changes in microvascular reactivity were observed during clamps. No changes in microvascular reactivity were observed in control test. Generally, the cell adhesion molecules concentration declined at the end of both clamps and in the control test. Similar was true for lipid parameters. Results of post-occlusive reactive hyperemia and cell adhe-

Microvascular reactivity and cell adhesion molecules. a- $p<0.001$, b- $p<0.01$, c- $p<0.05$

	CLAMP (n=20)			CONTROL TEST (n=20)	
	baseline	ISO	HYPER	baseline	end
PORHmax (PU)	40±16	39±19	47±16 ^b	32±12	35±12
PORHtmax (s)	13.5±5.1	6.1±4.7 ^a	10.4±8.4	11.8±6.0	11.3±9.0
PORHmax/t (PU/s)	2.6±1.5	11.2±14.9 ^c	10.4±16.5 ^c	2.7±2.4	3.7±3.0
PORH% (%)	385±165	328±309	392±219	303±104	394±28
E-selectin (ng.ml ⁻¹)	29±12	–	27±11 ^a	29±15	28±14 ^b
P-selectin (ng.ml ⁻¹)	132±50	–	93±34 ^a	126±50	111±27
ICAM-1 (ng.ml ⁻¹)	251±48	–	215±41 ^a	237±40	212±33 ^b
VCAM (ng.ml ⁻¹)	812±183	–	673±117 ^a	815±203	665±165 ^a

sion molecules are shown in the table. Fibrinogen was slightly increased at the end of hyperglycemic phase of the clamp (3.6 ± 0.8 vs 3.4 ± 0.9 g.l⁻¹, $p<0.01$) but was declined in control test (3.2 ± 0.9 vs 3.4 ± 1.0 g.l⁻¹, $p<0.05$). No relationship was observed between parameters measured during both clamps and control tests.

Conclusion: Microvascular reactivity was probably modulated by vasodilatory effect of hyperinsulinemia during clamps. The fibrinogen increase at the end of the clamp documents hypercoagulability in hyperglycemia. Decline in the cell adhesion molecules concentration was probably caused by non-specific effect (hemodilution). No relationship was observed between acute hyperglycemia ($+5.5$ mmol.l⁻¹) and microvascular reactivity in type 1 diabetic patients.

Supported by: Ministry of Education of Czech Republic

respectively 7%, 8%, 17% and 18%). HbA1c was significantly correlated with AI ($p=0.007$), $t_{1/2}$ ($p=0.037$) and y_{thr} ($p=0.002$).

Conclusion: The combination of hct and $t_{1/2}$ is able to model viscosity in lowest shear rates, whereas the combination of hct and y_{thr} approximates real viscosity in higher shear rates. A cross-over point exists around 2.19 s⁻¹. This difference is probably due to the fact that y_{thr} reflects the tendency for aggregation whereas $t_{1/2}$ displays the aggregation kinetics. Furthermore both parameters are associated with HbA1c. Our findings indicate the relevance of aggregation in WSS calculations, which increases with increasing HbA1c.

³Laboratory for Clinical Hemorheology, Academic Medical Center,

Amsterdam, ⁴Dept. of Physiology, Academic Medical Center, Amsterdam,

⁵Dept. of Nephrology, Leiden University Medical Center, Netherlands

Background and aims: Low wall shear stress (WSS) modulates the endothelium and in the long-term contributes to the development of atherosclerotic lesions. Viscosity is an important determinant of WSS. In order to take into account the non-Newtonian viscosity of blood in computational fluid dynamics, one needs a constitutive equation which defines the relationship between viscosity and shear rate. Previous studies showed that for high shear rates a model with hematocrit (hct) in the exponent is able to approximate real viscosity. However, at lower shear rates this model becomes inadequate, as red blood cell (RBC) aggregation differs between individuals. Especially patients diagnosed with type 2 diabetes mellitus (T2DM) are known for their heightened RBC aggregation. The aim of this study was to test improvement of viscosity modeling by addition of aggregation parameters.

Materials and methods: Hct, aggregation- and viscosity measurements were performed in duplicate in subjects diagnosed with an asymptomatic plaque in the carotid artery (intima media thickness > 0.08 cm and stenosis < 70%, measured by duplex ultrasonography) (n=56, 43 - 79 yrs, 63% male, 50% T2DM). Aggregation parameters include amplitude, half time ($t_{1/2}$), aggregation index (AI), fit error, Tfast, Tslow and threshold shear rate (y_{thr}). Viscosity was measured on following shear rates: 0.87 s⁻¹, 2.19 s⁻¹, 5.49 s⁻¹, 10.15 s⁻¹, 47.1 s⁻¹ and 87 s⁻¹. A forward linear regression analysis (inclusion criterion $p<0.05$) was performed to investigate improvements with various aggregation parameters and hct for modeling of viscosity on the six mentioned shear rates. Influence from gender and age was tested. A linear regression analysis was performed to test correlations of HbA_{1c} with aggregation parameters.

Results: Hct was significantly correlated with viscosity in all instances. Gender was correlated with viscosity, but not after adjustment for hct. Age was not correlated with viscosity. Both were not correlated with HbA_{1c} or any of the aggregation parameters. Viscosity modeling on 0.87 s⁻¹ was improved by addition of only $t_{1/2}$ (standard error decreased with 8%). Viscosity modeling on 2.19 s⁻¹ was improved by addition of both $t_{1/2}$ and y_{thr} (standard error decreased with 14%). Viscosity modeling on 5.49 s⁻¹, 10.19 s⁻¹, 47.1 s⁻¹ and 87 s⁻¹ was improved by addition of only y_{thr} (standard error decreased with

Comprehensive evaluation of coronary arteries by multidetector-row cardiac computed tomography according to the glucose tolerance status of asymptomatic subjects

S. Lim¹, S. Choi¹, K. Park², Y. Koo², H. Lee², H. Jang¹

¹Internal Medicine, Endocrinology and Metabolism, Seoul National University Bundang Hospital, Seongnam, ²Internal Medicine, Endocrinology and Metabolism, Seoul National University College of Medicine, Seoul, Republic of Korea

Objective: Cardiovascular disease is a major cause of mortality in subjects with diabetes. There is an increasing need to detect early atherosclerosis before cardiac events occur through noninvasive techniques. We performed multidetector-row computed tomography (MDCT) to investigate the status of coronary artery stenosis (CAS) and plaque characteristics, which has been limited in asymptomatic subjects.

Research design and methods: The number of diseased vessels, the extent of stenosis ($\geq 50\%$ luminal narrowing), the composition of plaques (noncalcified, mixed, or calcified), and the coronary artery calcium score (CACS) were measured by MDCT in 1043 asymptomatic subjects (mean \pm SD) age = 49.2 ± 9.5 years). Anthropometric parameters and metabolic profiles were also measured.

Results: 20.8% of subjects had plaques and 5.1% had significant CAS. The mean (\pm SD) of CACS was 17.2 ± 81.2 in this study group. Subjects with impaired fasting glucose (IFG, $n = 215$, 20.6%) or diabetes ($n = 112$, 10.7%) had more CAS, a greater plaque burden, and higher CACS than those of normal subjects (all $P < 0.01$). More vulnerable (noncalcified and mixed) plaque was observed in subjects with diabetes (19.4%) and IFG (11.3%) than in normal (6.6%). After adjustment for confounding factors, impaired glucose metabolism was strongly associated with significant CAS and a greater vulnerable plaque burden.

Conclusion: Considering the relatively high prevalence of vulnerable-plaque in IFG or diabetes, even when they are asymptomatic, MDCT could be considered as a useful diagnostic tool for detecting early coronary atherosclerosis in prediabetes and diabetes.

Lower bone mineral density is associated with higher coronary calcification by multi-detector row coronary computed tomography in women independently from cardiovascular risk factors

S. Choi¹, J. An¹, S. Lim¹, K. Park², H. Lee², H. Jang¹, C. Shin²

¹Internal Medicine, Endocrinology and Metabolism, Seoul National University Bundang Hospital, Seongnam, ²Internal Medicine, Endocrinology and Metabolism, Seoul National University College of Medicine, Seoul, Republic of Korea

Background and aims: There are growing concerns about the direct association between bone mineral density (BMD) and vascular calcification, which is related to cardiovascular disease. Coronary multi-detector row computed tomography (MDCT) is recently developed as a non-invasive tool for coronary status and evaluate coronary calcification more precisely. To evaluate the relationship between the BMD and coronary calcification by using MDCT

Design: We had enrolled 815 subjects who received their routine check up in health care center. After excluding subject who had factors affecting altered bone mechanism and cardiovascular disease, the data of 462 subjects were finally analyzed. We measured the coronary calcification with MDCT, BMD, anthropometric, and metabolic parameters.

Results: The BMD of femur area and lumbar spine are negatively associated with coronary calcium score in both premenopausal and postmenopausal women, but not in men after adjustment for age and BMI. This inverse correlation was getting stronger with longer year since menopause, in femur area than lumbar spine ($r = -0.37$, $P < 0.05$), and in postmenopausal women with osteoporosis and osteopenia than normal BMD ($r = -0.49$, $P < 0.05$).

Conclusion: The increased coronary calcium score by MDCT is associated with a low BMD in pre- and postmenopausal women, independently from cardiovascular risk factors, age, and BMI.

Noninvasively measured subendocardial viability ratio and ejection duration were impaired in newly diagnosed type 2 diabetes

H.-J. Kim, K. Han, B. Koo, H.-J. Kim, K. Pak, K. Min, E. Kim

Internal medicine, Eulji University School of Medicine, Seoul, Republic of Korea

Background and aims: Heart failure of ischemic or non-ischemic origin is a significant source of morbidity and mortality in diabetes. With an increase in aortic or ventricular chamber pressure, especially during diastole, endocardial perfusion can be compromised, which will reduce in myocardial contractility. This study was conducted to investigate whether the propensity for myocardial ischemia expressed as subendocardial viability ratio (SEVR, %) and ejection duration (ED, %) from central artery pressure analysis is increased in prediabetic stage or newly diagnosed type 2 diabetic patients.

Materials and methods: Three hundred and forty-three subjects were included [30–80 years, (M:F 45.8%:54.2%)] and divided into three groups (control, $n = 131$; prediabetes, $n = 93$; newly diagnosed diabetes, $n = 119$). Diabetes was diagnosed by ADA criteria and prediabetes was defined as having impaired fasting glucose or impaired glucose tolerance after 75g OGTT. Augmentation index (AIx, %) by pulse-wave reflection, SEVR, and ED were calculated from the wave pattern of the central artery by applanation tonometry using SphygmoCor[®]. Other cardiovascular risk factors such as obesity, lipid profiles and smoking pack-years were also evaluated. General linear model (GLM) analysis was used to identify the determining factors of AIx, SEVR, and ED from multivariate.

Results: HbA1c and fasting plasma glucose (FPG) were significantly higher and HDL-cholesterol significantly lower in newly diagnosed diabetic patients than other two groups ($P < 0.05$, respectively). BMI and triglyceride were significantly higher in both of prediabetic and diabetic subjects than control ($P < 0.05$, respectively). While AIx was not different (control, $25 \pm 11\%$; prediabetes, $23 \pm 10\%$; newly diagnosed diabetes, $24 \pm 12\%$; $P = ns$), SEVR was decreased and ED was increased significantly in diabetic patients compared to control or prediabetes (SEVR- $151 \pm 26\%$ vs. $160 \pm 27\%$ or $158 \pm 24\%$, $P < 0.05$; ED- $37 \pm 4\%$ vs. $35 \pm 4\%$ or $35 \pm 4\%$, $P < 0.05$, respectively). From GLM analysis with group and sex as factors, AIx had a significant association with age, height and LDL cholesterol ($P < 0.001$, $P = 0.043$ and $P = 0.005$, respectively), but not with glucose level or blood pressure. By contrast, in ED, only age, BMI and HbA1c but not lipid profile showed a significant association with ED ($P = 0.015$, $P = 0.001$ and $P < 0.001$, respectively). While BMI and HbA1c were also significantly associated with SEVR ($P < 0.001$ in both), age showed no significant association with it.

Conclusion: Even though aortic stiffness was not significantly increased in prediabetes or newly diagnosed diabetic patients, SEVR and ED were significantly impaired in newly diagnosed diabetic patients, but not in prediabetic condition. These results imply that the propensity for myocardial ischemia is increased in newly diagnosed type 2 diabetic patients.

1379

Screening unrecognised peripheral arterial disease using ankle-brachial index: ELLIPSE STUDY diabetics group results

D. Huet¹, Investigators of the ELLIPSE Study

¹Diabetology, Endocrinology, Groupe hospitalier Paris Saint Joseph, Paris, France

Aims: Peripheral arterial disease (PAD) is often underdiagnosed, in lack of symptoms and increase the major cardiovascular (CV) event risk. ELLIPSE is a multicentric, epidemiological, french study to investigate prevalence of undiagnosed PAD in high risk CV patients including diabetics.

Materials and methods: From April to November 2007: 2444 inpatients, age > 55 y, without PAD but with coronary or cerebrovascular disease or at least one of CV risk factors (diabetes, smoking, hypertension, dyslipidemia,) where enrolled by 244 trained investigators for measurement of ankle brachial index (ABI). Diabetes + was defined as patient taking insulin or any oral hypoglycemic agents. PAD + patients was defined by an ABI < 0.9 .

Results: 2129 patients investigated by (22 % cardiologists, 22 % diabetologists, 23 internists, 14 % neurologists and 15 % geriatrists) are included in the primary analysis (all ABI values available). In this population, 942 diabetes + patients was younger than the 1187 diabetes - patients 69.8 years (± 9.5) vs 74.8 (± 10.6) $p < 0.05$, and had less frequently symptomatic arterial disease (coronary 21.5% vs 30.3% - cerebrovascular 11.8% vs 28.2% or both 5.5% vs 8.1%) $p < 0.05$ but more frequently only CV risk factors (61.1% vs 35.4%).

Diabetes + patients present significantly more hyperlipemia (54.2% vs 38.5%) and hypertension (77.1% vs 73.1%). The mean ABI was 0.92 ± 0.22 (range 0.13 - 2.75) in diabetics patients and did not differ from the global population PAD was diagnosed in 41.7% for diabetes + vs 40.9% for diabetes - NS 4.9% ABI < 0.5 3.3% ABI > 1.3

Conclusion: Prevalence of undiagnosed PAD is important in PAD asymptomatic diabetic's patients: **43.1 %**. The extend of systematic ABI (examination simple, rapid, reproducible) in diabetics patients will increase support aggressive secondary prevention care in the event of PAD +, especially in patients without coronary or cerebro-vascular disease.

Screening of peripheral arterial disease in asymptomatic diabetic patients

R. Da Ros¹, R. Assaloni², G. Zuodar³, S. Pressoni³, M. Deotto³, A. Ceriello⁴

¹Distretto 4, Ass1 Triestina, Trieste, Italy, ²Casa Di Cura, Foot and Ankle Clinic, Abano Terme, Italy, ³University of Udine, Internal Medicine, Italy,

⁴University Hospital of Coventry and Warwickshire, Centre of Excellence in Diabetes and Endocrinology, Coventry, United Kingdom

Background and aims: Peripheral arterial disease (PAD) is an important complication of diabetes, with consequences on quality of life and survival. PAD is a risk factor for increasing mortality and cardiovascular events. ADA and AHA indicate every year screening for PAD in patients with type 2 diabetes and over 40 years old, but literature data show that screening is underutilized and PAD underdiagnosed. The most used screening test is ankle brachial index (ABI), it requires about 15 minutes to be performed and it has demonstrate low sensitivity in asymptomatic diabetic patients. Moreover alternative tests like pulse oximetry and toe pressure failed to demonstrate better efficacy and usefulness compared to ABI. Aim of the study: to compare accuracy of screening tests in asymptomatic diabetic patients and to evaluate efficacy of arterial sound interpretation like a new proposed diagnostic test.

Materials and methods: 324 limbs, in 162 diabetic asymptomatic consecutive outpatients presented in a primary care service, were evaluated. We investigate all the limbs with: transcutaneous oximetry; pulse oximetry at rest and after uplift of the limb, ABI at rest and after walking test, temperature and a new test: the arterial sound interpretation at ankle level and Doppler waveform analysis. We defined PAD as monophasic waveforms on waveform analysis.

Results: Prevalence of PAD was 18%. Patients with peripheral arterial disease were older than patients without, with a longer history of diabetes, and higher prevalence of hypertension, cardiovascular disease and renal failure (all $p < 0.01$). Diagnostic test specificity, sensitivity and K test values for agreement with color-duplex, are reported in table 1.

Test	Sens	Spec	K-test	Test	Sens	Spec	K-test
ABI	58	82	0.35	TcPO2 < 50mmHg	62	68	0.21
ABI after walking test	38	91	0.31	TcPO2 < 40mmHg	48	82	0.20
Pulse-oximetry hand/foot	24	75	0.01	Temperature difference hand/foot >2	83	36	0.09
Pulse-oximetry after elevation	37	84	0.20	Arterial sound interpretation	90	95	0.81

Conclusion: This study, according to literature data, confirm low ABI sensitivity for PAD screening in diabetic asymptomatic patients and found fair agreement with color duplex. Transcutaneous oximetry, pulse oximetry and ABI after walking test are not effective for PAD screening. Arterial sound interpretation presents good sensitivity and sensibility, very good agreement with color duplex and short performing time. This test, if data will be confirmed in a larger number of people, can be proposed for screening of diabetic patients.

1381

Clinically relevant peripheral arterial occlusion is associated with a high as well as a low-pressure ankle-to-brachial ration index (ABI)

L. Potier¹, F. Bouilloud¹, J.-L. Golmard², M. Dadon³, J. Le Doeuff³, C. Deybach¹, M. Halbron¹, G. Ha Van¹, A. Grimaldi¹, A. Hartemann-Heurtier¹

¹Diabetes department, ²Biostatistics Unit, ³Vascular Surgery Department, University Pierre et Marie Curie-Paris 6, School of Medicine, Paris, France

Background and aims: The importance of peripheral vascular calcification in causing luminal narrowing remains uncertain. Defining clinically relevant peripheral arterial occlusion on an ABI threshold of <0.9 may misclassify patients with an increased artery rigidity if the latter results in "falsely" high pressure and obscures underlying occlusion. The aim of this study was to compare the severity of peripheral arterial occlusive disease (PAOD) between diabetic patients with a high, normal or low-pressure ABI.

Materials and methods: Observations were undertaken in a single diabetes department as part of routine assessment of all patients admitted for further investigation and treatment of suspected PAOD, with or without an associated foot ulcer. Patients with previous revascularisation procedure were excluded from this study. 160 lower limbs from 81 diabetic patients had TcPO2 and ABI measurements performed as well as colour duplex imaging (CDI). ABI was measured using a hand-held Doppler probe with the systolic pressure being recorded in the dorsalis pedis or, if undetectable, in the posterior tibial artery. The severity of arterial occlusion was scored on CDI according to an adapted version of a validated published angiographic score (0=no significant arterial lesion, 1=at least one significant stenosis to 21=maximal severity). The relationship between ABI and time to healing was studied as an indicator of PAOD severity in the subset of 35% limbs that had foot ulcer.

Results: ABI was > 1.3 in 13.8% limbs (incompressible arteries=group 1), between 0.9 and 1.3 in 37.6% (group 2), and < 0.9 in 37% (group 3). CDI showed no significant arterial lesion in 15% patients in group 3 (false positive ABI), and significant lesion in 57% patients in group 2 (false normal ABI) and in 60% patients in group 1. TcPO2 from group 1 (36 ± 19 mm Hg) was not different from group 3 (36 ± 20 , $p=0.28$) but significantly lower than TcPO2 from group 2 (42 ± 16 , $p<0.02$). Duplex score in presence of PAOD from group 1 (8.0 ± 3.9) was significantly higher than duplex score from group 2 (4.8 ± 2.7 , $p<0.05$) and even than duplex score from group 3 (7.4 ± 3.7 , $p<0.0001$). Wound healing time was not different between group 1 and 3, but significantly shorter in group 2 ($p<0.003$).

Conclusion: In presence of clinical suspicion of PAOD, lower limbs with incompressible arteries show a lower prevalence of confirmed PAOD than IPS < 0.9, but when present indicators of PAOD severity are comparable or even higher.

1382

The performance of pulse wave velocity for the diagnosis of peripheral vascular disease in patients with type 2 diabetes mellitus

I. Eleftheriadou¹, V. Dianas¹, P. Grigoropoulou¹, C. Arapostathi¹, D. Perrea², N. Katsilambros¹, N. Tentolouris¹

¹1st Department of Propaedeutic Medicine, Athens University Medical School, Laiko General Hospital, ²Laboratory of Experimental Surgery and Surgical Research, Athens University Medical School, Athens, Greece

Background and aims: Pulse wave velocity (PWV) of the carotid-femoral (cf) arteries has emerged as a new method by which total cardiovascular risk can be assessed. Increased PWVcf reflects arterial stiffening and is an important predictor of cardiovascular events. In the present study we examined the validity of PWV for the diagnosis of peripheral vascular disease (PVD) in patients without and with type 2 diabetes mellitus (T2DM). In addition, we examined whether the presence of either peripheral (PN) or cardiac autonomic neuropathy (CAN) alters the validity of PWV for the diagnosis of PVD in patients with T2DM.

Materials and methods: A total of 155 patients (82 with T2DM and 73 without diabetes, mean age 65.8 ± 8.8 and 62.4 ± 8.5 years; male/female 48/34 and 27/46, respectively) were examined. Diagnosis of PVD was based on the presence of either biphasic, monophasic or blunted waveforms in the artery posterior tibial. PWV was measured at the carotid-femoral (cf) and femoral-posterior tibial (ft) segments. Diagnosis of PN was based on neuropathy symptom score (NSS), neuropathy disability score (NDS) and vibration perception threshold (VPT), while of CAN on the battery of the autonomic function tests.

Results: Higher values of PWVcf and PWVft have high specificity but low sensitivity for the diagnosis of PVD in both diabetic and nondiabetic patients. Presence of PN does not affect the performance of PWV, but presence of CAN reduces its specificity for the diagnosis of PVD in subjects with T2DM (table).

Conclusion: High values of PWV almost confirm the presence of PVD both in diabetic and nondiabetic patients, irrespective of the presence of PN. However, presence of CAN reduces the specificity of PWV in the subjects with T2DM.

Short-term QT interval variability in patients with long-standing type-1 diabetes mellitus

C. Lengyel¹, A. Orosz², R. Takács¹, T.T. Várkonyi¹, I. Baczkó², T. Wittmann¹, J.G. Papp³, A. Varró^{2,3}

¹1st Department of Medicine, University of Szeged, Hungary, ²Department of Pharmacology and Pharmacotherapy, University of Szeged, Hungary,

³Division for Cardiovascular Pharmacology, Hungarian Academy of Sciences, Szeged, Hungary

Background and aims: Determination of short-term QT-interval variability (QTV) is an intensively investigated new and non-invasive method for assessment of proarrhythmic risk. Several studies have demonstrated that temporal QTV is a more sensitive predictor of ventricular arrhythmias than the parameters of conventional QT-measurements. The aim of the present study was to evaluate the QTV in patients with long-standing type 1 diabetes mellitus (DM).

Patients and methods: 21 DM patients (age: 33.7±2.7 years, male/female ratio: 11/10, duration of DM: 16.9±2.8 years, HbA1c: 8.6±0.4%, BMI: 25.1±0.9 kg/m²; mean±SEM) and 21 healthy controls (age: 33.3±2.0 years, male/female ratio: 11/10, HbA1c: 5.2±0.1%, BMI: 24.4±0.9 kg/m²) were enrolled into the study. ECGs were continuously recorded and all leads acquired by an ECG signal processing system. After analogue-to-digital conversion, the data were stored to hard disk and analyzed off-line using SPEL Advanced Haemosys software (v3.0, Experimetria Ltd.). The RR and QT intervals were measured as the average of 31 consecutive beats. To characterize the temporal instability of beat-to-beat repolarization, Poincaré plots of the QT intervals were constructed, where each QT value is plotted against its former value. QTV was calculated using the following formula: $QTV = \sum |QT_{n+1} - QT_n| / (30 \times \sqrt{2})^{-1}$. Autonomic function was assessed by means of five standard cardiovascular reflex tests.

Results: DM patients have an increased heart rate compared to the controls (78.1±3.1/min vs 69.2±1.4/min, $p < 0.05$, respectively). Comparison of the two groups (DM vs control) revealed no difference in the QTc interval (433±7.2 ms vs 437±4.1 ms). The QTV, however, was increased in the DM patients relative to those for the control group (4.61±0.29 ms vs 3.19±0.22, $p < 0.05$). In the DM group, the mean autonomic score was 1.6±0.3, and there were no significant correlations between the QTV values and the parameters of the five cardiovascular reflex tests.

Conclusion: The short-term QT variability may be elevated in long-standing type 1 diabetes mellitus despite of unchanged QTc interval. This enhanced temporal QT variability may early indicate the increased instability of cardiac repolarization.

Endothelial function, artery stiffness and coronary artery disease in type 2 diabetic patients

A. Belhadj-Mostefa^{1,2}, M. Henouda³, F. Touati¹, J.R. Attali⁴, D. Roula¹, P. Valensi⁴

¹Medicine, Department of Internal Medicine, Constantine, Algeria, ²Health, ANDRS, Oran, Algeria, ³Medicine, Department of Cardiology, Constantine, Algeria, ⁴Medicine, Department of Endocrinology Diabetology Nutrition Jean Verdier Hospital, Bondy, France

Background and aims: Impairment of endothelium function and artery stiffness have been shown to be predictive of cardiovascular events. The aim of this study was to determine whether these disorders might be considered as markers of silent myocardial ischemia (SMI) or silent coronary stenoses (SCS) in type 2 diabetic patients.

Materials and methods: One hundred patients, 54.6 ± 8.1 years, with type 2 diabetes since 8±6.5 years, were assessed for SMI by an ECG stress test. Coronary angiography was performed in patients with SMI. A post-ischemia reactive hyperaemic test was performed, and changes in blood flow (F2/F1) and diameter (D2/D1) of the brachial artery which account mostly for the reactivity of downstream microvasculature and for endothelium function, respectively, were evaluated by pulsed Doppler velocimetry. Artery stiffness was assessed by measuring pulse wave velocity (PWV) between the carotid and femoral arteries using the Complior device.

Results: SMI was found in 27 patients and SCS in 16 of them. D2/D1 (SMI-: 1.06±0.05 and SMI+: 1.05±0.04), F2/F1 (SMI-: 4.72±1.65 and SMI+: 4.5±2.03) and PWV (SMI-: 11.75±2.76 and SMI+: 11.73±2.06) did not differ significantly between patients with or without SMI. Compared with patients without SCS, patients with SCS had significantly lower D2/D1 (1.04±0.04 vs 1.07±0.06; $p < 0.05$), lower F2/F1 only in the normotensive subgroup (2.96±0.59 vs 4.25±1.5; $p = 0.06$ NS; domage) and not in the hypertensive one (4.85±2.28 vs 4.78±1.48; $p = 0.56$), and significantly higher PWV (11.7±1.89 vs 10.2±1.4; $p = 0.03$).

Conclusion: This study suggests that in type 2 diabetic patients more severe impairments in peripheral endothelium function and artery stiffness, and microcirculation function in normotensive patients, might be considered as markers for silent coronary stenoses.

Strong association between capillary recruitment and forearm glucose uptake following acute per oral phosphodiesterase-5 inhibition in type 2 diabetes patients

P.-A. Jansson¹, G. Murdolo^{1,2}, L. Strindberg¹, B. Nyström³, M. Sjöstrand¹, P. Lönnroth¹

¹The Lundberg Laboratory for Diabetes Research, Dpt of Molecular and Clinical Medicine, University of Gothenburg, Sweden, ²Dpt of Internal Medicine, Perugia University, Italy, ³Dpt of Cardiology, University of Gothenburg, Sweden

Background and aims: Impaired blood flow in skeletal muscle may contribute to a dysregulated metabolism in the insulin resistant state. The aim of this open non-randomized study was to test whether phosphodiesterase-5 inhibition (PDE5Inh), first line therapy against erectile dysfunction, could improve recruitment of nutritive capillaries and ameliorate forearm glucose uptake (FGU) in insulin resistant subjects.

Materials and methods: Eight non-smoking postmenopausal female type 2 diabetic patients (T2D) without significant complications (Diabetes duration: 12±9 yrs (Mean±SD); Medication: Life style treatment: 2/8; Oral Hypoglycemic Agents: 3/8; Insulin treatment: 3/8; Blockers of the type 1 angiotensin-II receptor : 2/8; Statins: 3/8) and eight age-matched, medication and nicotine free, non-diabetic, healthy control subjects (C) (Age: 62±2 vs 59±4 yrs (Mean±SD), $p = ns$; BMI: 31.9±4.6 vs 25.1±4.7 kg/m², $p < 0.001$; Waist/Hip-ratio: 0.94±0.04 vs 0.80±0.10, $p < 0.001$; HbA1c: 6.2±1.4 vs 4.3±0.2%, $p < 0.003$; fP-Glucose: 8.8±2.2 vs 5.2±0.4 mmol/l, $p < 0.001$; fS-Insulin: 15±9 vs 10±11 mU/l, $p = ns$, respectively) were studied after fasting overnight. Microdialysis measurements in m brachioradialis in situ, recording of muscle blood flow (MBF) by plethysmography and concomitant sampling of forearm arterial and venous blood was performed before and 3 hrs after oral intake of 10 mg tadalafil. Substrate balance studies and equations according to Fick and Renkin enabled us to estimate FGU and capillary recruitment (PS glucose: permeability surface area, ml/100g x min) in response of acute per oral selective PDE5Inh in the fasting state.

Results: At baseline, PS for glucose was lower in T2D compared to C (median (25th; 75th percentiles): (0.09 (0.04;0.25) vs 0.28 (0.18; 0.51) ml/100g x min, $p<0.0001$), and after PDE5Inh PS increased 4.4-fold in T2D ($p<0.05$) and 1.3-fold in C subjects ($p=ns$). FGU was lower in T2D 0.39 (0.19; 0.55) vs 0.63 (0.43; 0.94) $\mu\text{mol}/100\text{g} \times \text{min}$, $p<0.001$) and increased 2.4-fold ($p=ns$) and 1.7-fold ($p=ns$) after PDE5Inh in T2D and C, respectively. Moreover, PDE5Inh induced a 1.3-fold increase of MBF after 90–150 min ($p<0.05$) in both groups and, interestingly, a strong association revealed between AUC PS glucose and AUC forearm glucose uptake in T2D (r_s : 0.96, $p<0.002$), but this was not seen in C (r_s : 0.33, $p=0.15$). During the study period circulating levels of glucose and insulin did not change in C, whereas glucose decreased ca 1.2 mmol/l ($p<0.05$) and insulin tended to go down in T2D subjects. S-FFA remained stable in both groups.

Conclusion: This open non-randomized study implies for the first time acute positive effects of PDE5Inh on capillary recruitment and its close relationship with FGU in insulin resistant skeletal muscle. We suggest further studies to elucidate whether PDE-5 inhibitors has the potential to become novel anti-hyperglycemic agents in type 2 diabetes.

Postprandial modifications of HDL particle characteristics and endothelial function following 3 consecutive meals in men with and without type 2 diabetes

P.G. Scheffer¹, M.E. Tushuizen², R.P. Vermue¹, C. Rustemeijer², R.J. Heine², M. Diamant²

¹Clinical Chemistry, ²Endocrinology / Diabetes Centre, VU University Medical Centre, Amsterdam, Netherlands

Background and aims: Type 2 diabetes (T2DM) is associated with low-grade inflammation and oxidative stress, leading to cardiovascular damage. Postprandial dyslipidaemia, which is exaggerated and prolonged in T2DM, has also been associated with cardiovascular disease. We studied the effect of 3 consecutive meals on the composition and function of HDL in men with and without T2DM during a 24-h period.

Materials and methods: Fourteen men with T2DM (mean \pm SD: age 55.5 \pm 4.0 yrs; BMI 32.7 \pm 4.1 kg/m²; HbA1c 7.2 \pm 1.1 %), and 14 age-matched healthy men were given 3 standardized high-fat mixed meals (900 kcal; 50g fat, 75g carbohydrate, 35g protein) as breakfast (t=0), lunch (t=4h) and dinner (t=8h). Blood sampling was performed just before the meals, and 12h and 16h after breakfast. Flow-mediated dilation (FMD) of the brachial artery was measured by ultrasound before each blood collection. The triglyceride (TG), cholesterol, and protein content were determined in HDL, which was isolated by ultra-centrifugation. HDL particle size was measured by high performance gel-filtration chromatography. The anti-oxidative function of HDL was assessed by monitoring its capacity to inhibit the oxidation of dichlorodihydrofluorescein by oxidized 1-palmitoyl-2-arachidonoyl-phosphatidylcholine.

Results: Postprandial glucose and TG responses were increased in T2DM patients compared with controls. In T2DM, glucose peaked at t=2h (11.1 \pm 3.2 mmol/L) and TG peaked at t=6h (3.5 \pm 2.0 mmol/L). At baseline, T2DM, relative to controls tended to smaller HDL particles (8.87 \pm 0.28 versus 9.04 \pm 0.35 nm; $P=0.18$). In the fasting state, HDL from T2DM versus controls contained more TG (94.2 \pm 27.5 vs. 65.0 \pm 18.3 nmol/g; $P<0.01$) and less cholesterol (0.67 \pm 0.11 vs. 0.92 \pm 0.15 mmol/g; $P<0.01$). HDL-TG content increased postprandially in both groups reaching the highest level after two consecutive meals (123.3 \pm 41.0 nmol/g for T2DM and 97.5 \pm 24.0 nmol/g for controls, both $P<0.001$). The cholesterol content of HDL derived from T2DM was significantly decreased in the postprandial state at t=4h (0.63 \pm 0.12 mmol/g; $P<0.05$) and t=8h (0.62 \pm 0.10 mmol/g; $P<0.05$), but not in controls. FMD at baseline was lower in T2DM compared to controls (5.0% vs. 7.6%; $P<0.01$), and decreased postprandially in both groups after breakfast and only in T2DM after dinner (all $P<0.05$). At baseline, the anti-oxidative function of HDL was similar in patients and controls. In both groups, a non-statistically significant decrease in the anti-oxidative capacity of HDL occurred postprandially. In controls, this effect occurred only after the first meal whereas in T2DM it was observed especially after the third meal which was paralleled by a decreased FMD. Subsequently, HDL functionality returned to baseline levels in both groups.

Conclusion: The real-life exposure to 3 consecutive meals and the prolonged study-period allowed us to uncover the full scope of alterations in HDL composition and function in T2DM. Fasting HDL from T2DM had a higher TG-content, whereas HDL from both groups showed a relatively stronger postprandial rise in TG- than cholesterol-content. Postprandially, HDL from T2DM showed a delayed decline in anti-oxidative capacity relative to control HDL, paralleled by endothelial dysfunction.

Treat-to-target strategy for LDL-cholesterol improvement in type 2 diabetes: post-hoc analysis of data from the 2-year follow-up of the MIND.IT study

D. Ardigo¹, M. Trovati², A.A. Rivellese³, O. Vaccaro³, F. Cavalot², R. Miccoli⁴, P.P. De Feo⁵, L. Franzini¹, C. Di Loreto⁵, M. Boemi⁶, L. Patti³, I. Zavaroni¹

¹Internal Medicine, Parma University, ²Internal Medicine, University of Torino, Italy, ³Clinical and Experimental Medicine, University Federico II, Napoli, ⁴Endocrinology, University of Pisa, ⁵Internal Medicine, University of Perugia, Italy, ⁶Internal Medicine, INRCA-IRCCS, Ancona, Italy

Background and aims: The Multiple Intervention in type 2 diabetes. ITaly (MIND.IT) study is a multi-centric, randomized, nationwide, two-parallel

arm trial involving 1461 type 2 diabetic patients (759M/702F, age 61 ± 5 years) at high cardiovascular (CVD) risk, as defined by 2 or more CVD risk factors. The study compares the Usual Care (UC) of CVD prevention with a multi-factorial treat-to-target Intensive Care (IC) strategy, following the indications of national and international guidelines. The pre-planned ad-interim analysis after the completion of the first 2 years of follow-up showed a consistent improvement of all major CVD risk factors in the IC arm compared to UC, including LDL-cholesterol (LDL-c). The present work investigates the characteristics of the statin treatment operated by the two groups.

Materials and methods: Ten Italian centers for treatment of diabetes were randomized to the UC or IC arm. As far as the LDL-c is concerned, IC investigators were requested to achieve values <100 mg/dL with a step-wise treat-to-target approach, but leaving the freedom to choose drug's molecule and dose. To compare results observed with different statins, daily dose was converted to the Atorvastatin-equivalent dose adopting the following proportion: 10 mg Atorva = 40 mg Prava = 20 mg Simva = 5 mg Rosuva. Lipid profile was assessed at peripheral level, but laboratory performance was certified by an external quality control system and systematic differences among laboratories were corrected before statistical analysis.

Results: Average LDL-c decreased from 144 ± 35 to 108 ± 31 mg/dL in IC and from 142 ± 28 to 118 ± 32 mg/dL in UC (p for interaction "intervention*time" < 0.0001). This striking difference between the two groups was associated with a significant increase of statin prescription in out-of-target patient in IC compared to UC (45% vs 14% within the 1st year, $p < 0.001$), and with a significantly lower withdrawal from treatment (28 vs 61% respectively, $p < 0.001$). However, in the out-of-target patients who started statin treatment in the first year, the average prescribed dose was similar between the two groups (mode=10 mg/day in 45% of UC and 49% of IC, $p = \text{NS}$), resulting in an equivalent target achievement in treated patients (33% UC and 27% IC, $p = \text{NS}$). In addition, IC investigators did not tend to increase dose nor to change drug in patients out-of-target during treatment.

Conclusion: The application of a multi-factorial treat-to-target intervention strategy is associated with a significant improvement in LDL-c beyond what achieved by the usual practice in diabetes care. However, at least in our cohort, the change in LDL-c appears to be more related to an increased number of treated patients and a decreased treatment withdrawal, than to a true treat-to-target approach. The general attitude of physicians to start treatment without increasing the dose or changing active principle when the target is not reached may account for the high percent of patients who remain out of target during "intensive" treatment.

Lipid-altering efficacy of extended-release niacin/laropiprant in dyslipidaemic patients with metabolic syndrome

H.E. Bays¹, D.L. Maccubbin², A.K. Shah², J. Lin³, C.M. Sisk², J.F. Paolini²

¹Endocrinology & Metabolism, Louisville Metabolic and Atherosclerosis Research Center Inc. (L-MARC), Louisville, United States, ²Merck & Co., Inc., Rahway, United States

Background and aims: Patients with metabolic syndrome (MetS) are at increased risk for atherosclerotic coronary heart disease (CHD). Current guidelines recommend reducing LDL-C as the primary lipid target to reduce CHD risk. Improvement in other dyslipidemias may further reduce CHD risk, such as increasing HDL-C and lowering triglyceride (TG) levels. Niacin is a lipid-altering drug that is underutilized due to flushing. Laropiprant (LRPT) reduces niacin-induced flushing, and in combination with extended-release

niacin (ERN/LRPT), significantly improves multiple lipid parameters in dyslipidemic patients. This *post-hoc* subgroup analysis evaluated the efficacy and safety of ERN/LRPT in dyslipidemic patients with MetS, vs. those without MetS, in a Phase III randomized, double-blind, placebo-controlled, 24-week study ($n=1613$).

Materials and methods: Patients were randomized 3:2:1 to ERN/LRPT 1g, ERN 1g, or placebo. After 4 weeks, active treatment doses were doubled to 2g (2 tablets) for the remaining 20 weeks.

Results: Relative to placebo, ERN/LRPT significantly lowered LDL-C and raised HDL-C to a similar degree in MetS vs. non-MetS cohorts (Table). ERN/LRPT also significantly lowered TG vs. placebo (Table). The placebo-adjusted differences in percent change from baseline in TG were slightly greater in patients with MetS (-30.2% [$-36.0, -24.6$]) vs. those without MetS (-22.2% [$-27.1, -17.4$]), which may be due to the higher baseline median TG levels in the MetS group. For all lipid parameters, similar magnitude changes were observed with ERN/LRPT and ERN. ERN/LRPT produced less flushing than ERN during initiation and maintenance of therapy; this effect appeared to be consistent across MetS and non-MetS subgroups. ERN/LRPT was well-tolerated and had a safety profile similar to ERN. ERN/LRPT and ERN similarly resulted in small median increases in fasting blood glucose levels in MetS (2.0 and 4.0 mg/dL, respectively) and non-MetS (4.0 mg/dL for both treatment groups) patients, consistent with the known effects of niacin.

Conclusion: In conclusion, ERN/LRPT effectively improves LDL-C, HDL-C and TG levels in patients with and without MetS.

Significance of metabolic components of metabolic syndrome in African American women: HDL-C/Triglyceride ratio and insulin resistance paradox

K. Osei, T. Gaillard

Division of Endocrinology, Diabetes and Metabolism, The Ohio State University, Columbus, United States

Background: Metabolic Syndrome (MetS), defined by The Adult Treatment Panel (ATP) III criteria includes 5 factors that are associated with increased cardiovascular risks. However, whether the 3 metabolic components (serum glucose, triglyceride and HDL-C) carry similar CVD risk burden is unknown. Therefore, we investigated CVD risk factor clusters, prevalence of the components of MetS as well as the prevalence of MetS associated with each of the 3 metabolic components of MetS in nondiabetic, overweight and obese African American women (AAW).

Methods: We studied the clinical and metabolic CVD risk factors of 258 AAW (mean age 42.0 ± 7.7 yrs and mean BMI, 33.3 ± 8 (kg/m²). Fasting serum insulin, glucose and c-peptide levels were obtained in each subject. Waist circumference (WC), systolic (SBP) and diastolic (DBP) blood pressure were measured. Insulin sensitivity (Si), and insulin resistance (IR) (homeostasis model assessment (HOMA) were calculated. We examined the clusters of CVD risk factors of each tertile of the 3 metabolic components of MetS.

Results: As a group, MetS was 35.5 % in our AAW. Mean age and BMI did not differ with the worsening of any of the metabolic parameters. Increased WC was associated with increased metabolic risks irrespective of metabolic parameters. The prevalence of MetS increased 3 fold from 1st to 3rd tertile of serum glucose, 14.1% and 42.3%, respectively. The 1st HDL-C tertile was associated with increased MetS vs 3rd HDL-C tertile (42.3% vs 1.2%, respectively). Comparing 3rd with 1st tertile of triglyceride (17% vs 7%, respectively), there was no significant increase in MetS in our AAW. In contrast, when compar-

Table. Baseline → On Treatment mg/dL (Percent Change[§] from Baseline in Lipid Parameters) by MetS Subgroup

Parameter	Patients with MetS [*]			Patients without MetS		
	ERN/LRPT (n=304)	ERN (n=190)	Placebo(n=106)	ERN/LRPT (n=392)	ERN (n=244)	Placebo(n=151)
LDL-C ^{**}	102→83 (-17.5%)	100→84 (-17.0%)	103→102 (0.3%)	123→97 (-19.9%)	116→93 (-18.7%)	122→119 (-0.7%)
HDL-C ^{**}	45→54 (22.2%)	43→53 (22.7%)	46→46 (1.1%)	56→65 (17.1%)	55→65 (18.7%)	56→54 (-1.9%)
TG [†]	172→122 (-28.1%)	171→120 (-28.0%)	160→149 (1.8%)	107→89 (-16.9%)	112→85 (-18.7%)	107→115 (3.7%)

^{*}Patients were classified as having MetS if they met ≥ 3 of the following criteria: waist circumference >102 cm for men and >88 cm for women; fasting glucose ≥ 100 mg/dL or history of type 2 diabetes; TGs ≥ 150 mg/dL; HDL-C <40 mg/dL for men and <50 mg/dL for women; and systolic blood pressure ≥ 130 mmHg and/or diastolic blood pressure ≥ 85 mmHg or currently taking antihypertensive medication.

[§]Least squares mean for LDL-C and HDL-C and median for TG; ^{**}Mean; [†]Median

ing the 3 metabolic components, the prevalence of MetS was higher in the 3rd tertile for glucose (43.2%), 1st tertile of HDL-C (42.3%) and least with the 3rd tertile of triglyceride (17%). While WC was increased with worsening of the 3 metabolic components, BMI, Si and HOMA-IR as well as BP did not differ among the tertiles.

Conclusion: We found that serum glucose and HDL-C were more predictive of MetS, each yielding at least 40% of MetS, while triglyceride, BP and insulin resistant indices had the least impact on MetS in our overweight/obese AAW. We propose 1) that the 3 metabolic parameters for MetS defined by ATP III should be **weighted** differently with respect to their potential for CVD risks and 2) that nondiabetic overweight/obese AAW in our 3rd tertile of serum glucose (>100 mg/dl) and/or 1st tertile of HDL-C (<40mg/dl) should be targeted for screening for MetS.

Inadequate attainment of lipid levels in patients with or without type 2 diabetes and/or cardiovascular disease

G.A. Nichols¹, B.M. Ambegaonkar², V. Sazonov², J.B. Brown¹

¹Center for Health Research, Kaiser Permanente, Portland, ²Merck & Co., Inc., Whitehouse Station, United States

Background and aims: High density lipoprotein cholesterol (HDL-C) and triglycerides (TG) are secondary treatment targets for reduction of coronary heart disease risk in certain patient populations. However, these targets are often not addressed. Our objective was to document lipid recommended level attainment before and after initiation of dyslipidemia pharmacotherapy in patients with vs. without type 2 diabetes (T2DM) and/or cardiovascular disease (CVD).

Materials and methods: We identified 5158 patients who initiated lipid modifying therapy (LMT) between July 2004–June 2006, were age ≥35 years, continued LMT for ≥1 year, and had full lipid panels 12 months pre- and 9–15 months post LMT initiation date. LDL-C goals and recommended levels for TG and HDL-C were defined according to updated NCEP ATP III guidelines. We classified patients into 4 groups: T2DM+CVD, n=261; T2DM only, n=1661; CVD only, n=698; NEITHER condition, n=2538. We calculated the proportion in each group that met LDL-C, HDL-C and TG goals/recommended levels pre and post LMT initiation. Logistic regressions predicted lipid target attainment adjusting for age, sex, BMI, hypertension, mean statin dose, and baseline lipid levels.

Results: Overall, mean age was 62.5 years and 50% were women. Prior to LMT initiation, 33% of T2DM+CVD met LDL-C goals, compared to 20%, 22% and 24% of T2DM, CVD, and NEITHER, respectively (p<0.001 for all 3 comparisons). About 60% of all T2DM patients were at recommended TG level compared to 77% of CVD and 68% of NEITHER (p<0.001). Only 36% of T2DM+CVD, 40% of T2DM, 54% of CVD, and 59% of NEITHER were at recommended HDL-C levels (p<0.001 between all groups). A majority of the patients (96% in each group) initiated statin monotherapy. Following 1 year of LMT, 89% of T2DM+CVD, 75% of T2DM, 72% of CVD, and 81% of NEITHER had attained LDL-C goal (p<0.001 all comparisons except T2DM vs. CVD). After multivariate adjustment, T2DM+CVD were significantly less likely to attain LDL-C goal relative to NEITHER (odds ratio 0.60, 95% CI 0.38–0.94), as were the T2DM (0.27, 0.22–0.33) and CVD (0.26, 0.20–0.33) groups. Attainment of recommended TG level improved among all patients (66% pre-LMT vs. 80% post-LMT), with little difference between groups. Neither T2DM nor CVD status predicted TG recommended level attainment. Attainment of recommended HDL-C levels did not improve with LMT. Only about 33% of T2DM+CVD, 39% of T2DM, 51% of CVD, and 58% of NEITHER had HDL-C above recommended levels post-LMT (p<0.001 except T2DM+CVD vs. T2DM). Relative to NEITHER patients, T2DM+CVD (0.58, 0.39–0.86) and T2DM patients (0.82, 0.68–0.99) were less likely to attain recommended HDL-C levels.

Conclusion: Patients initiating dyslipidemia pharmacotherapy often achieved LDL-C goals, probably due to emphasis on statin therapy. However, HDL-C was largely unaddressed, especially among patients with T2DM and known CVD.

Goal/Recommended Level Attainment Before and After Lipid Modifying Therapy (LMT)

	T2DM+ CVD (n=261)	T2DM Only (n=1,661)	CVD Only (n=698)	Neither Condition (n=2,538)	Total (n=5,158)
% Attainment Before LMT					
LDL-C	32.6%	20.2%	22.3%	23.7%	22.8%
Triglycerides	60.5%	59.7%	76.9%	68.2%	66.3%
HDL-C	36.0%	40.2%	54.9%	58.8%	51.1%
% Attainment After LMT					
LDL-C	88.9%	74.5%	71.9%	80.6%	77.9%
Triglycerides	77.0%	76.3%	87.4%	81.0%	80.1%
HDL-C	32.6%	39.0%	50.9%	58.0%	49.7%

Cholesterol does not predict mortality in patients with type 2 diabetes of old age (ZODIAC-12)

S.T. Houweling^{1,2}, N. Kleefstra^{1,2}, S.J.J. Logtenberg¹, G.W.D. Landman³, A.M. Kamper³, K.H. Groenier⁴, H.J.G. Bilo^{1,5}

¹Diabetes Centre, Isala clinics, Zwolle, ²Medical Research Group, Langerhans, Zwolle, ³Internal Medicine, Isala clinics, Zwolle, ⁴General Practice, UMCG, Groningen, ⁵Internal Medicine, UMCG, Groningen, Netherlands

Background and aims: Large intervention studies have been undertaken to study the effects of lipid lowering drugs in patients with type 2 diabetes (T2DM). In many of these studies 75 years (yrs) is the maximum age of inclusion. In daily diabetes practice we treat a lot of patients above 75 yrs of age and often the questions arises whether a poor lipid profile is associated with increased risk in these higher age categories, and whether there is a benefit of statins. Therefore, we analyzed mortality risk in association with total cholesterol to HDL-cholesterol ratio (Chol/HDL) in patients with T2DM both below and above the age of 75 yrs.

Materials and methods: The ZODIAC study started in 1998 as part of a large shared care diabetes project in the Netherlands. Data on mortality were assessed after 5.8 yrs. We used Cox proportional hazard modeling to investigate the association between Chol/HDL and (cardiovascular and all-cause) mortality. The following variables were included in the model as confounders: Gender, smoking (yes, previous or no), duration of diabetes, estimated glomerular filtration rate, BMI, systolic blood pressure, macrovascular complications (yes or no), use of statins (yes or no) and albuminuria (yes or no).

Results: Our study population consisted of 653 women and 490 men. Median (interquartile range (IR)) HbA_{1c} at baseline was 7.3% (6.6–8.3), 7.3% (6.6–8.3) and 7.2% (6.5–8.2) for the total group, group ≤75 yrs and group >75 yrs, respectively. Mean (SD) Chol/HDL was 5.24 (1.59), 5.34 (1.56) and 4.93 (1.64) for the total group, group ≤75 yrs and group >75 yrs, respectively. During follow up, 330 patients died. There were 851 patients aged ≤75 yrs at baseline of whom 153 died (18%) during follow up. There were 292 patients aged >75 yrs at baseline of whom 177 died (61%) during follow up. Below or above the age of 75, 13.2% and 4.5% of patients were on lipid lowering therapy, respectively. Hazard ratios (HRs) with 95% confidence intervals (95%CI) of Chol/HDL as a continuous variable for all-cause and cardiovascular mortality, without adjustment for confounders were 1.09 (1.03–1.14) and 1.14 (0.99–1.32), respectively at age ≤75 yrs. For subjects aged >75 yrs, HRs (95%CI) were 0.99 (0.88–1.11) and 1.07 (0.95–1.21) for all-cause and cardiovascular mortality, respectively. When adjusted for selected confounders HRs (95%CI) were 1.10 (1.04–1.16) and 1.17 (0.99–1.38) for all-cause and cardiovascular mortality, respectively at age ≤75. For those aged >75 yrs, these HRs (95%CI) were 0.95 (0.83–1.09) and 0.98 (0.84–1.14), respectively. HRs (95%CI) for having a lipid lowering drug were 1.25 (0.99–1.59) and 2.00 (0.83–4.78) for all-cause and cardiovascular mortality, respectively, at age ≤75. For age >75 yrs, these HRs (95%CI) were 0.69 (0.43–1.74) and 0.38 (0.09–1.64), respectively.

Conclusion: In patients with T2DM above the age of 75 yrs, Chol/HDL does not seem to predict (cardiovascular) mortality. There were too little patients in this study on lipid lowering treatment to draw definite conclusions about long-term effect of statins in this age category. Intervention trials with statins, especially in elderly patients with T2DM, are needed to further evaluate the efficacy of statins in this specific patient category.

Genetic interaction between CETP and LIPC genes in risk of type 2 diabetes in the canary population: the Telde study

L. López Ríos¹, A.M. Wäagner¹, M. Boronati¹, F. Varillas¹, D. Marrero¹, N. Pérez¹, Y. García¹, R. Chirino², J. Nóvoa¹

¹Endocrinology, Hospital Universitario Insular de Gran Canaria,

²Physiology, Universidad de Las Palmas de Gran Canaria, Spain

Background and aims: Diabetic dyslipidaemia is common in type 2 diabetes (T2D) and insulin resistance (IR) and often precedes the onset of T2D. It includes elevated triglycerides (TG), low high-density lipoprotein (HDL) cholesterol (c) and small, dense low-density lipoprotein (LDL) particles. In addition, an increase in free-fatty acids is associated with IR and lipotoxicity, which may play a role in the development of T2D. Thus, genes involved in lipoprotein metabolism may be good candidates for the risk of T2D. In normotriglyceridaemia Cholesteryl Ester Transfer Protein (CETP) balances cholesterol and TG content in LDL, VLDL and HDL particles. In hypertriglyceridaemic conditions, CETP leads to an enrichment of LDL and HDL particles in TG. This makes them more prone to hydrolysis by hepatic lipase (HL), leading to the production of small, dense particles. LDL particles become more atherogenic and HDL, less protective. The Taq1B polymorphism in CETP is associated with increased enzyme activity and reduced HDLc. In addition, the G-250A polymorphism in LIPC (the gene encoding HL) is associated with changes in enzyme activity and lipid concentrations. Our aim was to assess the effects of Taq1B CETP and G-250A LIPC polymorphisms on changes of lipid profile and their influence on T2D.

Materials and methods: A population-based sample of 1030 people from the city of Telde (Gran Canaria, Canary Islands, Spain) was classified according to the results of a glucose tolerance test and assessed for the presence of cardiovascular risk factors. A total of 116 patients with T2D, 115 patients with impaired glucose regulation (impaired glucose tolerance and/or impaired fasting glucose) (IGR) and 226 controls matched for gender and age were genotyped. The Taq1B polymorphism was determined using RFLP-PCR while the G-250A LIPC was analysed with ARMS-PCR. For statistical analysis, we used chi-square test and logistic regression.

Results: The frequency of the B1B1 genotype increases with worsening glucose metabolism (42.5% controls, 46.1% in IGR and 54.3% diabetic population; $p=0.042$). Although the GG genotype from LIPC was not significantly different between the groups, its frequency tended to increase with worsening glucose metabolism (47.13 % control, 49.5 % in IGR and 53.1 % diabetic population; $p>0.1$). To analyse the independent effect of each polymorphisms on diabetes prevalence, multinomial logistic regressions were used. After adjustment for age, sex, BMI, waist and B1B1 genotype of Taq1B CETP were associated with an increased risk of diabetes (OR: 1.828; IC 95%: 1.12-2.99; $p=0.016$), but not of IGR (OR: 0.525; IC95%: 0.68-1.74; $p=ns$). The LIPC polymorphism was not associated with diabetes. Regarding genetic interaction, LIPC polymorphism did not influence the risk of diabetes in non-B1B1 carriers. However, in B1B1 genotype carriers, the presence of the minor allele in the LIPC polymorphism (A allele) reduced the risk of having diabetes (OR: 1.32; IC95%: 0.71-2.44), while its absence increased this risk (O.R: 2.42; IC95%: 1.30-4.50) ($P=0.036$).

Conclusion: The presence of the B1B1 Taq1B CETP genotype contributes to the risk of T2D, independently of age, sex, BMI and waist. However, among carriers of B1B1, allele A of the -250 LIPC polymorphism reduces this risk.

Increased hippocampal neurogenesis in a spontaneous model of type 2 diabetes (T2D), the Goto-Kakizaki (GK) rat

F.E. Saravia¹, J. Beauquis¹, J. Coulaud², P. Roig¹, B. Portha², F. Homo-Delarche², A.F. De Nicola¹

¹Neuroendocrine Biochemistry, Institute of Biology and Experimental Medicine, Buenos Aires, Argentina, ²Cnrs umr 7059, Paris-Diderot University, Paris, France

Background and aims: Diabetes, regardless of the type, is associated with central nervous system (CNS) complications. Indeed, metabolic and vascular consequences of diabetes induce cognitive impairment and increase the risk of depression, stroke, dementia and Alzheimer disease. The hippocampus, part of the limbic system, is a particular CNS target of diabetic alterations, both in patients and animal models. More precisely, the dentate gyrus (DG) of the hippocampus is one of the rare brain areas, where new neurons -associ-

ated to memory and learning process- are generated during adulthood. We previously showed that adult hippocampal neurogenesis is altered in animal models of type 1 diabetes. Here, we explored hippocampal neurogenesis, and vascularisation, as a key component of the neurogenic microenvironment in a spontaneous model of T2D, the GK rat.

Materials and methods: Four-month-old GK and control male Wistar (W) rats were used, $n=4-5$. Bromodeoxyuridine (BrdU, 250 mg/kg BW) was administered i.p. 21 days before cardiac perfusion with 3% paraformaldehyde. DG containing brain sections (vibratome) were used for immunohistochemistry with the following markers: 1) Ki67 (cellular proliferation); 2) BrdU (cell survival); 3) doublecortin (DCX, neuronal differentiation); and 4) von Willibrand factor (vWF, endothelium). Data were evaluated by computer-assisted image analysis.

Results: The number of proliferative Ki67⁺ DG cells was twice in GK than in W rats: 3309 ± 362 and 1496 ± 227 , respectively, $p<0.02$. BrdU⁺ cell number -indicator of cell survival- was slightly increased in GK vs W. Neuronal maturation of new DG cells followed the same pattern: DCX⁺ cells were twice as much in diabetic animals as compared to controls: 15776 ± 745.3 and 9923 ± 1356 respectively, $p<0.01$. Finally, the ratio vWF⁺ vessel area /DG area was decreased by more than 50% in diabetic animals: GK: 0.033 ± 0.004 , W: 0.078 ± 0.013 , $p<0.05$.

Conclusion: A net increase in hippocampal neurogenesis, together with increased cell proliferation and survival, was observed in type 2 diabetic GK rats. Interestingly, high neurogenesis rates have been observed in pathological situations, such as brain trauma, seizures and ischemia and diabetes is correlated with augmented risk of cerebrovascular disease. Macro- and microangiopathy have been described in GK rats in the cerebrovasculature and the islet of Langerhans, respectively. Therefore, cerebrovascular remodelling induced by chronic hyperglycemia/hyperlipidemia in GK rats might be responsible for their high DG neurogenesis, as corroborated by our data showing a markedly diminished blood vessel area.

Effect of oral glucose load on triglyceridaemia and cholesterolaemia: does insulin sensitivity make a difference and is increasing post oral glucose load insulinaemia beneficial?

A. Major-Pedersen¹, H. Dominguez², T.S. Hermann³, N. Ihlemann⁴, B. Kveiborg², B. Christiansen⁵, L. Køber⁴, C. Torp-Pedersen⁶

¹Endocrinology M, Odense University Hospital, Denmark, ²Cardiology, Gentofte University Hospital, Denmark, ³Cardiology Clinic Y, Bispebjerg Hospital, Bispebjerg, Denmark, ⁴Cardiology, Rigshospitalet University Hospital, Copenhagen, Denmark, ⁵Cardiology, Gentofte University Hospital, Odense C, Denmark, ⁶Cardiology, Gentofte University Hospital, Copenhagen, Denmark

Background and aims: Dyslipidemia is an independent risk factor for cardiovascular disease, even before the development of overt diabetes. We investigated the action of oral glucose load on triglyceridemia in both insulin sensitive and insulin resistant individuals, and whether acute and chronic stimulation of first phase insulin secretion (with nateglinide) modified the postprandial triglyceride response. We also investigated the effect of chronic insulin secretion stimulation on total cholesterol and sub-classes.

Materials and methods: We assessed post oral glucose load triglyceridemia (at 0, 15, 30, 60, 120, 180, 240 minutes) in 56 insulin resistant subjects randomized to intervention/ control groups [Homeostasis Model Assessment (HOMA) 6.41 ± 0.7], at baseline, "BL day", and after 3 months nateglinide treatment/observation, "Closing day". Postprandial triglyceridemia was assessed on two additional days in the intervention group: On "Acute day" where an initial dose of nateglinide was administered before oral glucose load, and on "Acute+chronic day" where the intervention group met for a last nateglinide dose. We examined post-oral glucose triglyceridemia in 9 healthy, insulin-sensitive subjects [HOMA 0.65 ± 0.13]. Total cholesterol and sub-classes were measured in the healthy group and on BL and Closing days in intervention and control groups. Change in triglyceride concentrations between the different time points, within the same day, was analyzed with paired Student's t-test.

Results: Glucose load in the healthy group provoked a sharp fall in triglyceridemia at 2 hours post oral glucose load [(1.11 ± 0.07) vs (0.65 ± 0.08) , $p=0.0001$]. We found no difference in triglyceridemia when we compared post oral glucose load values to pre glucose load values, in the intervention group on BL and Closing days. On Acute day, triglyceridemia at 2 hours post glucose load

decreased compared to pre-load values. $[(1.59 \pm 0.15) \text{ vs } (1.49 \pm 0.15), p=0.05]$. On Acute+chronic day, 2 hour post load triglyceride values were increased $[(1.38 \pm 0.11) \text{ vs } (1.47 \pm 0.20) p=0.05]$. In the control group, there was no change in post load vs pre load triglyceridemia on Closing day. High density lipoprotein cholesterolemia decreased in the intervention group: BL day vs Closing day respectively $[(1.14 \pm 0.04) \text{ vs } (1.09 \pm 0.04), p=0.04]$. No other cholesterol changes were observed.

Conclusion: Our findings suggest that acute stimulation of first phase insulin secretion decreases triglyceridemia in insulin resistant individuals, mimicking the beneficial glucose load effect on triglyceridemia we observed in insulin-sensitive individuals. Surprisingly, however, repeated insulin stimulation in insulin resistant individuals not only seems to augment triglyceridemia, but seems to reduce high density lipoproteinemia. These findings could impact the choice of blood glucose regulating therapeutic agents in the presence of insulin resistance, especially in light of the increased cardiovascular risk that accompanies this state.

PS 139 Non-classical risk factors and markers of inflammation

1395

Nonclassical cardiovascular risk factors in young and apparently healthy, nonobese subjects with low insulin sensitivity

M. Straczowski, I. Kowalska, M. Karolczuk-Zarachowicz, A. Adamska, M. Karczewska-Kupczewska, A. Nikolajuk, M. Gorska

Department of Endocrinology, Diabetology and Internal Medicine, Medical University of Bialystok, Poland

Background and aims: Insulin resistance is an important risk factor for type 2 diabetes and cardiovascular disease. Both conditions are associated with chronic low-grade inflammation and endothelial dysfunction. Proinflammatory cytokines, like IL-18, and adhesion molecules, like soluble intercellular adhesion molecule 1 (sICAM-1), are predictors of type 2 diabetes and are considered as 'nonclassical' risk factors for cardiovascular disease. The aim of the present study was to estimate serum concentrations of IL-18, sICAM-1, monocyte chemoattractant protein 1 (MCP-1) and high-sensitive C-reactive protein (hsCRP) in young and apparently healthy nonobese subjects with low insulin sensitivity.

Materials and methods: The study group consisted of 102 apparently healthy, young (age at examination between 18 and 30 years), nonobese ($\text{BMI} < 30 \text{ kg} \times \text{m}^{-2}$) subjects, 51 men and 51 women. All participants had fasting plasma glucose below 100 mg/dl and all had normal glucose tolerance in the OGTT according to the WHO criteria. Anthropometric and biochemical parameters and serum concentrations of IL-18, sICAM-1, MCP-1 and hsCRP were measured. Insulin sensitivity was estimated with the euglycemic hyperinsulinemic clamp technique. Then, subjects were divided into 3 groups according to their insulin sensitivity (high, medium and low insulin sensitivity). The tertiles of insulin sensitivity were calculated for men and women separately. In statistical analysis, we used one-way ANOVA to assess differences between the groups and Pearson product-moment correlation and multiple regression analysis to assess the relationships between variables. Parameters, which did not have normal distribution, were log-transformed before analyses.

Results: The study groups did not differ in anthropometric and serum lipid parameters. In the entire group, we observed significant differences in serum IL-18 (high insulin sensitivity, 210.21 ± 69.63 ; medium, 239.59 ± 111.96 ; low, $295.52 \pm 106.28 \text{ pg/ml}$; $p=0.0008$), sICAM-1 (high insulin sensitivity, 235.66 ± 39.15 ; medium, 258.15 ± 57.29 ; low, $277.10 \pm 38.55 \text{ ng/ml}$; $p=0.0015$) and hsCRP (high insulin sensitivity, 1.37 ± 0.39 ; medium, 1.60 ± 0.68 ; low $1.86 \pm 0.55 \text{ mg/l}$; $p=0.002$) concentrations between the groups. Additionally, we found differences in serum IL-18 ($p=0.008$) in the male group and in serum sICAM-1 ($p=0.01$) and hsCRP ($p=0.0038$) in the female group, with the highest values in subjects with low insulin sensitivity. Serum MCP-1 did not differ between the study groups. Serum IL-18, sICAM-1 and hsCRP were inversely related to insulin sensitivity in the entire study group ($r=-0.33$, $p=0.001$; $r=-0.32$, $p=0.001$ and $r=-0.28$, $p=0.005$, respectively). These associations were independent of potential confounding factors. No correlation between serum MCP-1 and insulin sensitivity was found.

Conclusion: Our data indicate that in young, nonobese subjects with low insulin sensitivity, there is an accumulation of nonclassical cardiovascular risk factors. Early detection of insulin resistance might be useful in identifying subjects at risk of cardiovascular disease.

Insulin resistance and metabolic disturbances are inversely related to lung function in Japanese

S. Jimba¹, T. Nakagami¹, J. Wada¹, S. Fukushima¹, M. Hasegawa¹, T. Wasada², Y. Iwamoto¹

¹Diabetes Center, Tokyo Women's Medical University, Tokyo, ²Department of Internal Medicine, Saitama-ken Saiseikai Kurihashi Hospital, Saitama-ken, Japan

Background and aims: Recently, it has been reported that lung dysfunction expressed by declined forced vital capacity (FVC) or forced expiratory volume in one second (FEV1) is a risk factor for cardiovascular events and death. Some prospective studies show that middle-aged individuals with lung dysfunction have increased risk of developing hypertension (HT), insulin resistance (IR) and diabetes (DM). However, there are very few studies showing

the relationship between lung function with IR and metabolic disturbances in a large general population. Thus, our aim of this study is to examine whether lung dysfunction is independently associated with IR and several metabolic disorders among healthy Japanese adults.

Methods: This is a cross-sectional study in a general health examination programme at S.S.K Hospital from Oct '06 to Sep '07. We examined the data of 2,195 subjects (men: 67%, mean age: 51 ± 9 years) who did not have previous DM, cancer, endocrine, respiratory and congestive heart disease or were not under pharmacological treatments for HT or dyslipidemia. FVC and FEV1 were measured by spirometer. The homeostasis model assessment (HOMA) was calculated as: fasting immuno reactive insulin (F-IRI)($\mu\text{U/mL}$) \times fasting plasma glucose (FPG)(mmol/L) / 22.5 among those with fasting plasma glucose ≤ 6.10 mmol/L. Smoking status and physical activity were asked by questionnaires. The multivariate linear regression models were used to evaluate whether lung function (FVC, FEV1) is independently associated with metabolic variables, F-IRI and HOMA.

Results: The average FVC and FEV1 were $109 \pm 14\%$ and 2.87 ± 0.65 L. FVC was correlated with age (Spearman's correlation coefficients: -0.142), BMI (-0.129), waist circumference (Wc) (-0.117), systolic blood pressure (sBP) (-0.124), diastolic blood pressure (dBP) (-0.095), FPG (-0.081), HbA1c (-0.130), triglyceride (TG) (-0.143), high density lipoprotein cholesterol (HDL-C)(0.128). FEV1 was also significantly correlated with those variables. The multiple linear regression analysis showed that FVC was related with HbA1c ($\beta = -0.002$, $p=0.001$), TG ($\beta = -0.332$, $p=0.001$), sBP ($\beta = -0.077$, $p=0.001$), HDL-C ($\beta = 0.078$, $p=0.000$), F-IRI ($\beta = -0.030$, $p=0.000$) and HOMA ($\beta = -0.007$, $p=0.000$) after adjusting for age, sex, Wc, smoking status and physical activity. Further additional analysis adjusting for F-IRI showed that these relations were not changed in HbA1c, sBP, HDL-C. FEV1 was also associated with HbA1c ($\beta = -0.080$, $p=0.000$), TG ($\beta = -11.937$, $p=0.000$), sBP ($\beta = -2.609$, $p=0.001$), dBP ($\beta = -1.323$, $p=0.027$), HDL-C ($\beta = 3.381$, $p=0.000$), F-IRI ($\beta = -0.823$, $p=0.000$) and HOMA ($\beta = -0.183$, $p=0.000$) after adjusting for age, sex, Wc, smoking status and physical activity. These associations were not changed in TG, sBP, dBP, and HDL-C, even after additional adjusting for F-IRI.

Conclusion: Decline in FVC or FEV1 was related with the deterioration of blood pressure, lipids and glucose metabolism, independently of IR. This may suggest that hypoxia and inflammation induced by lung dysfunction cause metabolic disorders with or without mediation of IR.

Chronic obstructive pulmonary disease prevalence and severity in type 2 diabetic patients correlate to glycometabolic control and the presence of complications and co-morbidities

M.E. Lunati¹, T. Cappelletti², B. Masserini¹, L.F. Sburlati¹, V. Valenti³, F.B. Blasi², L. Allegra², P. Beck-Peccoz², E. Orsi¹

¹Department of Medical Science, Endocrinology and Diabetes Unit, IRCCS, Foundation Policlinico, Mangiagalli e Regina Elena, ²Institute of Respiratory Disease, IRCCS, Foundation Policlinico, Mangiagalli e Regina Elena,

³Institute of Respiratory Disease, IRCCS, Policlinico San Donato Milanese, Milan, Italy

Background and aims: Chronic Obstructive Pulmonary Disease (COPD) and diabetes mellitus are worldwide chronic diseases that represent leading causes of morbidity and mortality related to cardiovascular diseases. COPD is associated with low-grade systemic inflammation with increased levels of pro-inflammatory cytokines (TNF- α , IL-6, IL-8). Increasing evidence points toward a role of these cytokines in the pathogenesis of insulin resistance, type 2 diabetes and its correlated complications. The aim of this study was to determine the prevalence of COPD in outpatients with type 2 diabetes and to assess a possible correlation with glycometabolic control, micro/macrovacular complications and co-morbidities such as dyslipidemia and obesity.

Materials and methods: We enrolled 152 consecutive type 2 diabetic outpatients attending the Endocrinology and Diabetes Unit (M:F 78:74, (mean \pm SD) age 65 ± 10 , BMI 29 ± 5 , fasting glycaemia 139 ± 40 , HbA1c 7.04 ± 0.99). Spirometry was performed in all patients and COPD severity was classified according to GOLD guidelines. Patients were divided in subgroups depending on the degree of glycometabolic control (HbA1c $\leq / > 7\%$) and the presence of long-term complications and co-morbidities (yes/no).

Results: We identified 18 patients (prevalence 11.8%, which is much higher than that reported in the general population in Italy, i.e. 3.6%) with COPD (FVC $72 \pm 15\%$, FEV1 $55 \pm 17\%$). In patients with good glycometabolic con-

trol COPD was lower than in those with less tight control (8.4% vs 15.9%, $p=0.008$). COPD prevalence in the subgroup of patients with complications was 15.8% compared to 7.9% in the subgroup without complications ($p=0.017$). In particular, COPD prevalence was significantly increased in diabetics with microalbuminuria, isolated or associated with cardiovascular events such as acute myocardial infarction and/or stroke, versus non-complicated subjects (18% vs 7.9%, $p<0.001$ and 31% vs 7.9%, $p<0.05$ respectively). Moreover, the subgroup with complications showed a worse respiratory function than that without (FVC: $66 \pm 12\%$ vs $82 \pm 15\%$, $p=0.028$ and FEV1: $49 \pm 16\%$ vs $68 \pm 12\%$, $p=0.023$). Conversely, diabetic patients with dyslipidemia showed a lower COPD prevalence than non-dyslipidemic subjects (10% vs 20%, $p<0.001$) and the percentage of COPD was also lower in obese patients, as compared to normal-weight subjects (7% vs 28%, $p<0.01$). The severity of obstruction did not appear to be significantly affected by the presence of these co-morbidities.

Conclusion: Our data show an increased prevalence of COPD in type 2 diabetic patients with less tight glycometabolic control, long-term vascular complications and possibly worse nutritional status. We also found a correlation between the severity of obstruction and the presence of chronic complications. These findings might be related to the higher oxidative stress and low-grade inflammatory state which play an important role in both disease conditions.

1398

Adenovirus induced decorin transfection inhibits pulmonary fibrosis in diabetic rats

H. Li, F.P. Zheng, F. Wu, W.N. Lu, Y. Ruan, F.-B. Zhang

Endocrinology and Metabolism, Sir Run Run Shaw Hospital, College of Medicine, Zhejiang University, Hangzhou, China

Background and aims: To investigate the relation between proteoglycan II (Decorin, DCN) and transforming growth factor- β 1 (TGF- β 1) in the lung of diabetic rats and to evaluate the effect of adenovirus induced DCN transfection on diabetic pulmonary fibrosis in different stages.

Materials and methods: 84 SD rats were divided into 4 groups at random: the diabetic group (diabetes was induced by a single intraperitoneal injection of 65 mg/kg streptozotocin (STZ), group D), the decorin recombinant adenovirus transfection group (diabetic rats treated with a intraperitoneal injection of decorin recombinant adenovirus every other week starting 4 weeks after the diabetic model established, group AD-DCN), the Lac-Z recombinant adenovirus transfection group (diabetic rats treated with AD-LacZ as above, group AD-LacZ) and the normal control group (group N). The blood glucose variation and the pulmonary pathological changes were observed at 8, 12, 16 and 20 weeks after the induction of diabetes models. The mRNA and protein expressions of DCN, TGF- β 1 and type IV collagen were examined by RT-PCR and immunohistochemistry.

Results: (1) The blood glucose levels of AD-DCN, AD-LacZ and D groups were increased significantly ($p<0.01$). There were no statistical differences in the blood glucose levels among the groups of AD-DCN, AD-LacZ and D ($p>0.05$). (2) Compared with N and AD-DCN groups, the D and AD-LacZ groups showed increased thicknesses of alveolar septum and capillary basement membrane by HE staining and increased expressions of collagen fibers in alveolar septum, capillary basement membrane and bronchiole by Masson staining. (3) The mRNA and protein expressions of DCN, TGF- β 1 and type IV collagen in lung tissues of the AD-DCN, AD-LacZ and D groups were increased significantly compared with those in the N group at all observed time points ($p<0.01$ or $p<0.05$). (4) The mRNA and protein expressions of TGF- β 1 and type IV collagen in lung tissues were increased along with the diabetic course in the AD-LacZ and D groups (12th, 16th, 20th week vs 8th week, $p<0.01$ or $p<0.05$). Adenovirus mediated DCN transfection downregulated the over-expression of TGF- β 1 and type IV collagen (compared with D and AD-LacZ groups, $p<0.01$ or $p<0.05$), but did not reached to the normal levels.

Conclusion: (1) The mRNA and protein expressions of TGF- β 1 and type IV collagen in the lung of diabetic rats were increased with the progress of diabetes. (2) AD-DCN transfection could significantly decrease the expression of TGF- β 1 and type IV collagen, thus improves the lung fibrosis changes in streptozotocin-induced diabetic rats.

Haemodynamic alteration and lung injury induced by endotoxin in streptozotocin-induced diabetic ratsC.-H. Hung¹, J.T. Cheng², C.N. Chang¹, Y.W. Chen³¹Department of Physical Therapy, National Cheng Kung University, Tainan,²Department of Pharmacology, National Cheng Kung University, Tainan,³Department of Physical Therapy, China Medical University, Taichung, Taiwan

Background and aims: Wound healing is difficult in type I diabetic patients, which may easily contribute to further threatening infections. As a systemic infection, endotoxemia frequently leads to septic shock, including cardiac depression and multiple organ failures. However, the severity of cardiopulmonary dysfunctions during endotoxemia in type I diabetes remains unclear. The objective of this study is designed to know this change using type I-like diabetic rats under endotoxin-induced endotoxemia.

Materials and methods: Adult male Wistar rats were randomly assigned to control group and the group treated with streptozotocin to induce type I diabetic animal model. The survival time and cardiovascular parameters, including mean arterial pressure, heart rate, cardiac output, and stroke volume were continually monitored in animals receiving the intravenous infusion of endotoxin (lipopolysaccharide; LPS) or saline. At the 3rd hour after LPS injection, we determined arterial blood gas, Tumor necrosis factor- α (TNF- α) level in serum and bronchoalveolar lavage fluid, histopathology of lung tissue, albumin content in lavage, and wet/dry weight ratio of lung.

Results: Before LPS administration, the mean arterial pressure of diabetic rats was significantly higher than normal control (93.22 ± 4.96 mmHg versus 74.38 ± 6.08 mmHg, $P = 0.015$) although other hemodynamic parameters were no difference between two groups. Since the body weights of streptozotocin-induced diabetic rats were significantly lower than that of normal rats

(376 ± 11 gm versus 262 ± 10 gm, $P < 0.05$), cardiac output index and stroke volume index of diabetic rats were significantly higher than those of normal rats in the controlled situation of saline administration (cardiac output index = 14.34 ± 0.87 ml·min⁻¹·100g⁻¹ versus 10.81 ± 0.81 ml·min⁻¹·100g⁻¹, $P = 0.004$; stroke volume index = 0.04 ± 0.0033 ml·beat⁻¹·100g⁻¹ versus 0.031 ± 0.0025 ml·beat⁻¹·100g⁻¹, $P = 0.004$). After administration of LPS, the heart rate, cardiac index and stroke volume index dropped in diabetic rats were more marked than that in normal group (all $P < 0.05$). Also, the increased level of TNF- α in serum and lavage by LPS treatment were significantly higher in diabetic rats than those in normal rats (Fig. 1). However, the arterial blood gas, albumin content, and wet/dry weight ratio of lung were indistinguishable between diabetic and normal rats. Then, the survival time in diabetic rats was significantly shorter than that in normal rats after LPS application (303.22 ± 28.58 min versus 420.78 ± 38.99 min, $P = 0.027$).

Conclusion: These results indicate that the cardiopulmonary dysfunction during endotoxemia is more marked in type I diabetic rats as compared to normal rats. The greater increase of TNF- α in diabetic rat seems related to the higher mortality rate.

Soluble CD40 ligand in essential hypertensive men: relationship with the metabolic derangementE. Storti¹, L. Pucci¹, D. Lucchesi¹, G. Dell'Omo², E. Russo¹, F. Caricato¹, R. Miccoli¹, G. Penno¹, S. Del Prato¹, R. Pedrinelli², A. Solini³¹Endocrinology and Metabolism, ²Cardio-Thorax Disease, ³Internal Medicine, University of Pisa, Italy

Background and aims: Elevated levels of sCD40L have been consistently reported in subjects with diabetes. Furthermore, soluble CD40L levels were also higher in subjects with impaired glucose tolerance (IGT), metabolic syndrome, obesity, and insulin resistance. Patients with hypertension showed higher sCD40L levels with no significant differences between hypertension grades and in absence of any additional cardiovascular risk factors. It is therefore conceivable that metabolic abnormalities highly frequent in subjects with essential hypertension might account for the increased levels of sCD40L.

Materials and methods: To address this issue, we analyzed the metabolic correlates of sCD40L levels (ELISA assay) in a group of non-diabetic hypertensive patients. Albumin excretion rate, hs-CRP (ELISA), ambulatory blood pressure monitoring and carotid ultrasonography to measure intima-media thickness (IMT) were also performed.

Results: In the 90 never-treated essential hypertensive men, mean sCD40L level was 8.8 ± 4.9 ng/ml (95%CI for the mean: 7.7–9.8 ng/ml). On the basis of sCD40L, subjects were divided by tertiles (thresholds at 6.6 and 11.0 ng/ml). The three groups did not differ for age, BMI, percentage of current smokers, systolic, diastolic and pulse BP as well prevalence of non-dippers (39%, 33%, and 39%) as assessed by ambulatory blood pressure monitoring, serum lipid and lipoprotein pattern, and fibrinogen concentration. Furthermore, the three groups had similar clinical and laboratory characteristics as far as creatinine and cystatin-C serum levels, eGFR, AER and distribution of microalbuminuric subjects. Finally, mean IMT (0.79 ± 0.22 , 0.83 ± 0.29 and 0.85 ± 0.30 mm) and percentage of subjects with wall thickening (IMT > 0.9 to < 1.3 mm: 23%, 27%, and 27%, respectively) were superimposable in the three groups. No differences were observed in hs-CRP levels and no correlation emerged between sCD40L and hs-CRP ($r = 0.01$, $p = 0.93$). Area under the curve (AUC) for glucose (122 ± 30 , 134 ± 38 and 139 ± 37 mg/min; ANOVA $p = 0.16$) and insulin (61 ± 35 , 77 ± 33 and 76 ± 34 microU/min, $p = 0.27$) showed a trend, although not significant, towards an increase with sCD40L tertiles. A similar trend emerged for basal insulin (11.2 ± 5.6 , 14.7 ± 7.7 and 16.8 ± 13.5 microU/ml, $p = 0.10$), while significant was the increase in fasting glucose (95 ± 11 , 103 ± 16 , and 105 ± 14 mg/dl, $p = 0.028$). Consistently, along the increase in sCD40L, it was observed a worsening in insulin sensitivity expressed as HOMA%S (99 ± 52 , 77 ± 43 , and 72 ± 35 , $p < 0.05$), ISIcomp (Matsuda index: 5.11 ± 2.65 , 3.61 ± 1.98 , and 3.28 ± 1.87 , $p = 0.025$) or OGIS (oral glucose insulin sensitivity index: 421 ± 67 , 386 ± 90 , and 362 ± 72 , $p = 0.004$).

Conclusion: In male subjects with newly diagnosed essential hypertension, sCD40L levels increase as insulin sensitivity decreases, with no correlation with blood pressure levels, other cardiovascular risk factors, nor the degree of sub-clinical atherosclerosis as assessed by carotid IMT. Caution is necessary in attributing to sCD40L an independent role as a cardiovascular risk factor in hypertensive subjects.

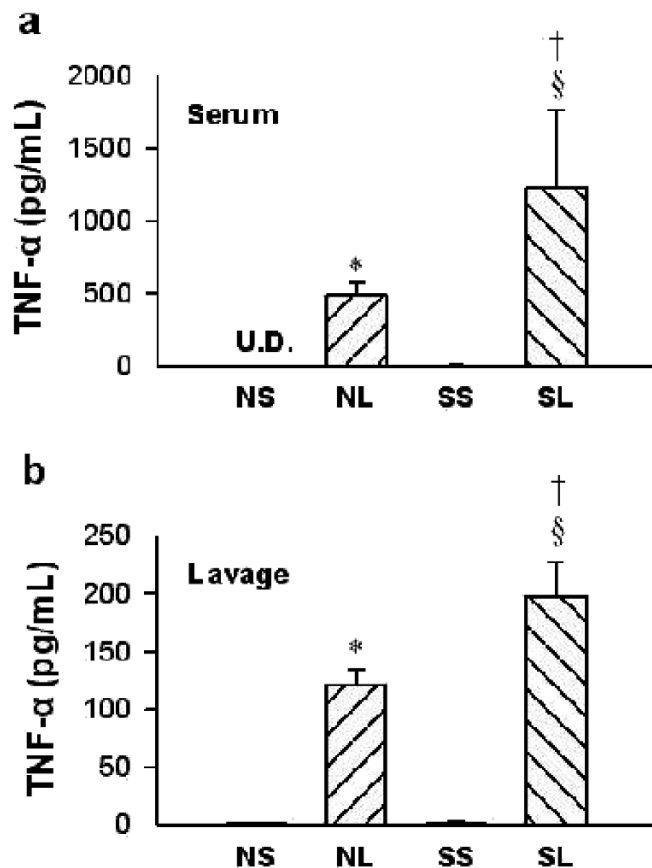

Fig. 1 The serum and lavage TNF- α levels in different groups of rats. NS, normal rats injected with saline; NL, normal rats injected with LPS; SS, STZ-induced diabetic rats injected with saline; SL, STZ-induced diabetic rats injected with LPS; U.D., undetectable. Data are expressed as mean \pm S.E.M. ($n = 7$). * $P < 0.05$, compared with the NS group; † $P < 0.05$, compared with the NL group; § $P < 0.05$, compared with the SS group (one-way ANOVA)

MCP-1 reduction by Krüppel-like factor 5 siRNA is associated with NFκB p50 in endothelial cells

G. Fukuda, M. Kume-kawa, K. Konno, S. Shimizu, T. Miwa, A. Kanazawa, Y. Notoya, M. Odawara

The 3rd department of Internal Medicine, Tokyo Medical University, Japan

Background and aims: Diabetic macroangiopathy is first initiated by the endothelial disorder through hyperglycemia and cytokines. Damaged endothelial cells produce endothelin (ET)-1, monocyte chemoattractant protein (MCP)-1 and begin to develop atherosclerotic changes. Vascular smooth muscle cells are also influenced and transformed their shape from contractile phenotype to synthesizing phenotype modulation. We have already reported that an embryonic form of myosin heavy chain (SMemb) increased in human umbilical vein endothelial cells (HUVECs) cultured by high concentration of glucose with parallel association of ET-1 expression. Krüppel-like factor (KLF) 5 is one of the important transcriptional factors and known to regulate SMemb expression. We investigated whether KLF5 inhibition may lead a beneficial effect on the prevention from atherosclerosis in HUVECs.

Materials and methods: The control siRNA and KLF5 siRNA were designed without showing any off-target effect, and determined the appropriate concentration of siRNA. HUVECs were transfected with 2.5 nM control siRNA or 2.5 nM KLF5 siRNA. The experiments were classified into 4 groups including (1) a control group with control siRNA, (2) an experimental group with KLF5 siRNA, (3) an experimental group with 10 ng/ml tissue necrosis factor (TNF)-α and control siRNA, and (4) an experimental group with 10 ng/ml TNF-α and KLF5 siRNA. Total RNA, culture medium and nuclear proteins were isolated from HUVECs. Real-time PCR was carried out for 18S, MCP-1, ET-1, SMemb mRNA quantification. Each mRNA level was compared by arbitrary ratio to 18S ribosomal RNA. The protein level of the MCP-1 in culture medium was measured by ELISA-based assay. The extracted nuclear protein was used to observe the effect of KLF5 siRNA on nuclear factor kappa B (NFκB). The binding activity of p50 subunit was measured by EZ-Detect NFκB p50 Transcription Factor Kit (Pierce). One-way ANOVA was used for the statistical analysis.

Results: HUVECs grew linearly in either control siRNA or KLF5 siRNA without cytotoxic effect. The KLF5 mRNA level was reduced extensively in HUVECs when the cells were treated with KLF5 siRNA for 24 hours. The MCP-1 mRNA level was not altered when cells were treated with KLF5 siRNA alone. However, the MCP-1 mRNA level was increased 10 times when treated with TNF-α ($p < 0.01$). This augmentation was decreased in the presence of KLF5 siRNA ($p < 0.05$). KLF5 siRNA did not significantly affect the ET-1 mRNA expression but significantly decreased the SMemb mRNA expression. SMemb mRNA level was further decreased when treated with TNF-α. The MCP-1 protein was extensively increased by the treatment with TNF-α in the conditioned medium ($p < 0.05$). It was attenuated significantly in the presence of KLF5 siRNA ($p < 0.05$). The binding activity of NFκB p50 subunit was 2.4 times significantly increased in the nuclear protein with TNF-α treatment ($p < 0.01$) as compared to that without TNF-α. This augmentation was attenuated by KLF5 siRNA as low as control siRNA without TNF-α ($p < 0.01$).

Conclusion: Present results suggest that KLF5 may work as a regulator of cytokines related to develop atherosclerotic changes observed in diabetes mellitus through NFκB regulation. It would be important to consider KLF5 as a new target for the treatment of diabetes as well as metabolic syndrome where TNF-α plays a trigger of inflammation intervened by MCP-1 and cardiovascular remodeling.

Human C-peptide exerts anti-inflammatory activity in LPS-stimulated monocytes through stimulation of PPAR-γ

V. Cifarelli, J. He, M. Trucco, P. Luppi

Pediatrics, University of Pittsburgh Medical School, Pittsburgh, United States

Background and aims: Inflammatory changes at the level of both the endothelium and the circulating monocytes are important factors in the pathogenesis of vascular complications in type 1 diabetes (T1D). Monocytes of T1D patients are activated, secrete inflammatory cytokines and interact with vascular lesions, leading to atherosclerotic plaque development. In recent years, the biological activity of C-peptide has been revisited by showing that this peptide displays anti-inflammatory activities and improves endothelial dysfunction in conditions of hyperglycemia. The potential anti-inflammatory

effect of C-peptide on activated monocytes, however, has not been investigated. The purpose of this study, therefore, was to investigate whether C-peptide may afford anti-inflammatory effects in lipopolysaccharide (LPS)-activated monocytes and whether these effects are associated with activation of peroxisome proliferators-activated receptor-γ (PPAR-γ), a nuclear transcription factor that plays a regulatory role in inflammation and atherosclerosis. We also tested whether activation of PPAR-γ was associated with modulation of extracellular signal regulated kinases (ERK)-1 and 2 activation.

Materials and methods: The human monocytic cell line U-937 was exposed to high glucose (30mM) and lipopolysaccharide (LPS; 1ng/μL) in the presence or absence of human C-peptide for 4 hours. Expression of PPAR-γ and phosphorylated-ERK1/2 in cellular extracts of U-937 was determined by Western blot analyses. Secretion of inflammatory cytokines in the culture supernatants was determined by Luminex. Flow cytometry was used to evaluate expression of the PPAR-γ-regulated CD36 scavenger receptor on U-937.

Results: We found that C-peptide per se stimulated PPAR-γ expression in U-937 under high glucose for 4 hours (see Figure of Western blot). This C-peptide effect was associated with up-regulation of the specific PPAR-γ-monocyte marker CD36. When cells were treated with LPS in the presence of C-peptide (1-10nM), PPAR-γ activity was also stimulated as compared to LPS-treated U-937 cells in the absence of C-peptide (see Figure of Western blot). Furthermore, C-peptide significantly inhibited secretion of the inflammatory cytokines IL-1β, IL-6, IL-8, MCP-1, MIP-1α, MIP-1β by LPS-stimulated U-937 cells. A similar effect of C-peptide was also observed on LPS-stimulated monocytes isolated from T1D patients. Finally, C-peptide stimulatory effect on PPAR-γ was associated with a modulatory activity in the phosphorylated, active form of ERK1/2.

Conclusion: C-peptide exerts anti-inflammatory (and potentially anti-atherogenic) effects on LPS-activated monocytes under conditions of hyperglycemia. These effects are associated with activation of the nuclear factor PPAR-γ, which is considered a major controller of susceptibility to vascular injuries and diseases.
