

MINUTES OF THE 43rd GENERAL ASSEMBLY OF THE EUROPEAN ASSOCIATION FOR THE STUDY OF DIABETES

held in Amsterdam, The Netherlands on 20 September 2007 at 18:15

Present:	Drs.	E.	Ferrannini	(President)
		G.	Spinas	(Honorary Treasurer)
		D. L.	Eizirik	(Honorary Secretary)
		E.	Gale	(Editor-in-Chief, Diabetologia)
		V.	Jörgens	(Executive Director)

The President welcomed everyone to the 43rd General Assembly.

1. MINUTES, 42nd GENERAL ASSEMBLY 2006

Since there were no comments, the minutes were approved unanimously and officially signed as a correct record.

2. REPORTS

a) President

Dr. Ferrannini reported that Dr. DeFronzo would give the Claude Bernard Lecture in 2008.

The President reported that the European Foundation for the Study of Diabetes (EFSD) was continuing to be very successful, with many partnerships being maintained.

The President announced that Dr. R. Heine would not be standing for President from 2008-2011 and that he had resigned from the Board of the European Foundation for the Study of Diabetes with immediate effect. The election of the EASD President for the term of office 2008-2011 will take place in the 87th Council meeting before the Annual Meeting in Rome.

The President reported that Dr. P. Cryer had requested co-operation with EASD regarding the preparation of a Clinical Practice Guideline entitled 'Evaluation and Management of Adult Hypoglycemic Disorders' which is organised by the European Society of Endocrinology. He explained

that the Executive Committee had unanimously decided to expand the remit of EASD to include issuing of consensus statements, formulating guidelines etc. To achieve this, ad hoc committees composed of expert colleagues from Europe and USA will be set up to evaluate the issues critically. Dr. Ferrannini said a communication strategy was needed and that the EASD membership would be informed so that anyone who was especially interested could contact the relevant committee. The information will also be put on the web pages of EASD and in Diabetologia.

Dr. Ferrannini reported on the ad hoc committee meeting for clinical trials which had taken place in Düsseldorf on 5-6 September and had been chaired by Dr. D. Matthews. He said the Executive Committee had unanimously decided to change the ad hoc committee into a sub-committee, which should consist of Drs. B. Charbonnel, J. Ludvigsson, D. Matthews [Chair], M. Nauck, A. Scheen, A. Siebenhofer, C. Tack and S. Heller.

The President reported on relations with the European Agency for the Evaluation of Medicinal Products (EMA). EMA is presently inviting a number of professional organisations to participate in discussions and to provide advice on clinical trials and pharmacovigilance. Dr. Ferrannini said that Dr. Smith had attended 3 meetings with EMA. Dr. Smith reported that it had been decided that more European clinical trials were needed and he suggested that EASD had an important role to play in this matter. Dr. Ferrannini reported that the Executive Committee had unanimously decided to set up a sub-committee to be chaired by Dr. Smith and to include Drs C. Bailey, A. Barnett and J. Nolan. It was

further decided that all information should be sent to Dr. Gale.

b) Honorary Treasurer

Dr. Spinas reported that income had decreased slightly due to a decrease in registration fees and donations. On the expenditure side, salary costs decreased slightly as there were no costs for copy-editing in Düsseldorf. At the end of 2006 EASD transferred 2.5 million Euro to EFSD to support diabetes research.

Dr. Spinas brought his report to an end by thanking the EASD staff, in particular Mrs. A. Klee, for the professional administration of the accounts.

The President thanked the Honorary Treasurer for his diligence and asked if there were any questions. There were none.

c) Honorary Auditors

The President asked the Honorary Auditors to formally discharge the accounts. Drs. Tiedge and Katsilambros confirmed that the accounts had been checked carefully and were in perfect order. Dr. Ferrannini asked for the vote to accept the accounts.

The accounts were accepted unanimously (one abstention).

d) Honorary Secretary

Dr. Eizirik reported that in 2007 2179 abstracts had been received, an increase of 249 compared to the previous year. The main countries submitting abstracts are the UK, USA, Germany and Italy. In 2006, a trial questionnaire had been introduced which produced positive feedback and which would be continued in a simpler form, the goal being to have a more representative sampling. In 2007, an Evening Poster Reception had been introduced, when there would be the opportunity for one-to-one discussions. For the Annual Meeting in 2007, 183 applications for Travel grants had been received and 138 accepted in the value of €76,094. A total of 23 Stayment Grants were awarded.

Dr. Eizirik said future challenges included maintaining and improving the academic traditions of the founding members and preserving the unique transparency and scientific quality of EASD Annual Meetings.

Dr. Eizirik closed his report by thanking all members of the EASD staff for their outstanding help and support with the organisation of the EASD Annual Meetings during the past three years. He wished his successor, Dr. M. Stumvoll, good luck.

Dr. Ferrannini thanked Dr. Eizirik for the meticulous and enthusiastic work he had done.

e) Editor-in-Chief, Diabetologia

Dr. Gale reported that a total of 1742 articles had been submitted to Diabetologia, an increase of 18%. The largest number of submissions in 2006 originated from the USA, followed by the UK, Japan and Germany. The acceptance rate for all articles was 20.8% and that for original articles had decreased to 18.6%. The Impact Factor in 2006 was 5.247. The Editor-in-Chief said the journal was coming out on time. He expressed his thanks to his team in Bristol.

Dr. Ferrannini thanked Dr. Gale for the excellent work he had done. He said a sub-committee had been appointed by the Executive Committee to evaluate potential candidates for the position of Editor-in-Chief.

f) Chair, Postgraduate Education Sub-committee

Dr. Nolan reported that two postgraduate courses (in Jena and Loipersdorf) had been held since the Annual Meeting in Copenhagen and three were planned for 2008 (in Jena, Wrocław and Belgrade). Possible future courses included Bulgaria, Turkey, Latvia, Romania and Bosnia-Herzegovina.

Dr. Nolan reported that one course had been organised in St Petersburg and he particularly thanked Dr. Boulton for the excellent organisation. Dr. Nolan reported that Dr. Boulton, as Chair of the Extra-European Postgraduate Courses, was scheduling the Third Joint EASD/ADA/IDF Advanced Clinical Postgraduate Course in the Management of Diabetes and its Complications in the South American Region, Brasilia from 1-3 November 2007.

Dr. Nolan said the committee was working on developing a new web-based CME series of initiatives which would start in 2007. The educational sessions will be prepared for viewing on the website. As this initiative develops, it is hoped to arrange debates between experts at short notice on controversial topics as they arise.

Dr. Nolan thanked Dr. Czupryniak for his close co-operation.

Dr. Ferrannini thanked Dr. Nolan for his valuable work.

3. ELECTIONS

a) Honorary Secretary 2007-2010

The Council's election of Dr. M. Stumvoll was unanimously approved with one abstention.

b) Editor-in-Chief extension until 2009

The extension of the Editor-in-Chief's term of office until 2009 was unanimously approved with one abstention.

c) Council Members 2008-2011

The following Council Members were unanimously elected by the General Assembly:

Drs. T. Battelino (Slovenia) – two abstentions,
D. Matthews (UK) – one abstention,
J. Philippe (CH) – one abstention and
J. Zierath (S) – one abstention.

4. STUDY GROUPS

Dr. Eizirik reported that there were 15 Study Groups, 13 of which had attended the Study Group Forum in 2006. All Study Groups are allowed to make proposals for symposia, with the Programme Committee making the final choice. The Honorary Secretary reiterated the rule that under no circumstances should a meeting of a Study Group be held during the period of the EASD Annual Meeting. A Study Group on cardiovascular disease which was introduced to the membership last year is now officially endorsed as a Study Group of the Association. Another group of researchers asked for a Study Group on genetics and diabetes. The group was asked to describe their activities in an article in the News Section of Diabetologia. The matter will be on the agenda of the 87th Council meeting and the 44th General Assembly.

5. HONORARY MEMBERSHIP

Drs. L. Orci and G. Reaven were unanimously elected by the General Assembly.

6. ANY OTHER BUSINESS

There was no other business.

Dr. Ferrannini thanked the outgoing member of the Executive, Dr. D. L. Eizirik, for his dedication and presented him with the Albert Renold Medal.

Dr. Ferrannini also thanked the outgoing members of the Council: Drs. K. Dahl Jørgensen, R. J. Heine, B. Mankovsky and S. Sasson.

Dr Ferrannini thanked the industry for their support. He also expressed his sincere gratitude to the Local Organising Committee, in particular to Drs. Heine and Tack and Mrs. L. van 't Hull for their outstanding contribution to the organisation of the 43rd EASD Annual Meeting. He again thanked Dr. D. L. Eizirik and the members of the Programme Committee for their hard work with regard to the scientific programme. The President warmly thanked the EASD team in Düsseldorf for their kind and efficient help.

Dr Ferrannini brought the General Assembly to a close at 19:00.

Agenda for the 44th General Assembly of the European Association for the Study of Diabetes

to be held in the Da Vinci Hall at the Nuova Fiera di Roma, Rome, Italy on 10 September 2008 at 18:15 hours

1. Minutes of the 43rd General Assembly, Amsterdam, the Netherlands 2007

2. Reports

- | | |
|---|---------------------|
| a) President | Dr. E. Ferrannini |
| b) Honorary Treasurer | Dr. G. Spinas |
| c) Honorary Auditors | Dr. N. Katsilambros |
| | Dr. M. Tiedge |
| d) Honorary Secretary | Dr. M. Stumvoll |
| e) Editor in Chief, Diabetologia | Dr. E. Gale |
| f) Chair, Postgraduate Education
Sub-committee | Dr. J. Nolan |

3. Elections

- | | |
|-----------------------------------|---|
| a) President
2008-2011 | in place of
Dr. E. Ferrannini |
| b) Vice President
2008-2011 | in place of
Dr. U. Smith |
| c) Editor-in-Chief
2009-2010 | Extension:
Dr. E. Gale |
| d) Honorary Auditors
2008-2011 | in place of
Drs N. Katsilambros and
M. Tiedge |
| e) Council Members
2009-2012 | in place of
Dr. V. Pirags (Latvia)
Dr. F. Pociot (DK)
Dr. M. Porta (I) |

4. Study Groups

5. Honorary Membership

6. Membership Fee. Members joining on 1 July to pay for 18 months, thus, giving access to reduced Annual Meeting registration fees for 2 years.

7. Any other business

44th EASD Annual Meeting of the European Association for the Study of Diabetes

Rome, Italy, 8 – 11 September 2008

Abstracts

Index of Oral Sessions

- OP 1 New treatments in type 2 diabetes
- OP 2 Genome-wide scans in type 2 diabetes
- OP 3 Continuous glucose monitoring system
- OP 4 Mechanisms and new markers of macrovascular disease
- OP 5 Beta cell development and regeneration
- OP 6 Fat traffic and parking
- OP 7 Novel oral agents for type 2 diabetes
- OP 8 Nephropathy: development and treatment
- OP 9 Prediction of diabetes
- OP 10 High glucose, oxidative stress and cellular signalling
- OP 11 Genetics: type 2 diabetes
- OP 12 Inflammation, metabolism, cross-talk
- OP 13 DPP-IV inhibitors
- OP 14 Obesity: new insights and new therapies
- OP 15 Molecular mechanisms in insulin signalling
- OP 16 Nephropathy: experimental treatments
- OP 17 Dynamics of beta cell exocytosis
- OP 18 Type 1 diabetes mellitus epidemiology
- OP 19 Cardiomyopathy and dysfunction of the heart
- OP 20 Diabetes in childhood
- OP 21 Incretins: action and secretion
- OP 22 Brain and peripheral metabolism
- OP 23 Lipotoxicity in beta cells
- OP 24 Genetics of type 1 diabetes and complications
- OP 25 GLP-1 based therapies
- OP 26 Health care models across Europe
- OP 27 Microangiopathy: glucose toxicity and inflammation
- OP 28 The triumvirate gets fatty
- OP 29 Glucagon and effects of other hormones
- OP 30 Metabolic signals in beta cells
- OP 31 Insulin and analogue treatment
- OP 32 Type 2 diabetes mellitus epidemiology
- OP 33 Retinopathy: experimental treatments
- OP 34 Adipokines: from bone to heart
- OP 35 Endothelium cross-talk
- OP 36 Apoptotic mechanisms in beta cells
- OP 37 Thiamine and microangiopathy
- OP 38 Prevention of type 2 diabetes
- OP 39 Hypoglycaemia and the brain
- OP 40 Classical and sophisticated education
- OP 41 Experimental and clinical immunology
- OP 42 Monogenic diabetes
- OP 43 Neural pathways and neuropathy

- OP 44 Nutrition and diet
- OP 45 Insulin signalling and glucose transport
- OP 46 Low grade inflammation and endothelial function
- OP 47 Novel mechanisms in insulin secretion
- OP 48 Programming of metabolism

Index of Poster Sessions

- PS 1 Genetics of autoimmunity
- PS 2 Genetics of type 1 diabetes
- PS 3 Monogenic diabetes
- PS 4 Single gene influence on type 2 diabetes risk
- PS 5 Multiple gene influence on type 2 diabetes risk
- PS 6 Genetic regulation of insulin action
- PS 7 Genetic influence on beta cell function
- PS 8 Genetic influence on insulin sensitivity
- PS 9 Prediction of type 1 diabetes
- PS 10 Environmental factors and diabetes
- PS 11 Screening and prediction of type 2 diabetes
- PS 12 Animal models for type 2 diabetes
- PS 13 Classification of type 1 diabetes
- PS 14 Incidence of type 1 diabetes
- PS 15 Cardiovascular risk
- PS 16 Glycated haemoglobin and diabetes management
- PS 17 Epidemiology and genetics of body weight
- PS 18 Epidemiology of type 2 diabetes complications
- PS 19 CVD and mortality in diabetes
- PS 20 Diabetes and ethnicity
- PS 21 Quality of life and diabetic complications

OP 01 New treatments in type 2 diabetes

1

XOMA 052, an anti-IL-1 β antibody, in a double-blind, placebo-controlled, dose escalation study of the safety and pharmacokinetics in patients with type 2 diabetes mellitus - a new approach to therapy

M.Y. Donath¹, C. Weder¹, J. Whitmore², R.J. Bauer², K. Der², P.J. Scannon², C.A. Dinarello³, A.M. Solinger²

¹Endocrinology & Diabetes, University Hospital Zurich, Switzerland,

²Clinical Development, XOMA (US) LLC, Berkeley, United States,

³University of Colorado Health Sciences Center, Denver, United States

Background and aims: The cytokine interleukin-1 β (IL-1 β) is involved in the pathology of many inflammatory diseases, and blocking of the IL-1 pathway shows efficacy in both animal and human disease. Recent evidence points to the role of elevated IL-1 β in glucose-induced beta-cell apoptosis and dysfunction. Clinical data has also shown IL-1 receptor inhibition improving glycemic control and beta-cell function, thus validating this pathway as a target for therapy. The Human Engineered™ anti-IL-1 β antibody, XOMA 052, was developed for the treatment of inflammatory diseases and has a very high affinity ($K_D = 300$ fM) and activity for human IL-1 β (hIL-1 β).

Materials and methods: Two clinical studies in Type 2 Diabetes Mellitus patients with inadequate control of their hyperglycemia (FBS > 126 mg/dL and HgA1c $\geq 7.5\%$ but $\leq 12\%$) evaluated a total of 72 subjects after single IV slow infusions of XOMA 052 over a dose range beginning at 0.01 mg/kg and escalating at half-logs in six equal cohorts. Each 6-subject treatment cohort in the two parallel studies contained 5 active drug-treated subjects and 1 placebo-treated subject. Each subject was evaluated for safety, pharmacokinetics of the study drug, and various diabetes- and inflammation-related parameters for 2-3 months after their single infusion. These parameters will be used to assess clinical activity and include inflammatory markers such as CRP and IL-6 levels, and key measures of glucose control such as FBS and HgA1c.

Results: Infusion of study drug was well tolerated without any evidence of any serious or drug-related adverse events during the study. Clearance of study drug was consistent with that for a human IgG with a 15-21 day T $_{1/2}$.

Conclusion: In this first-in-disease study of XOMA 052, an anti-IL-1 β antibody, no evidence of safety or pharmacokinetic issues for XOMA 052 was present. This therapeutic agent with the projected profile may be able to be used on a once every month or longer schedule. Further investigation of dosing schedule and initial clinical signals will need to be performed.

2

Improvement in glycaemic control by Gastric Electrical Stimulation (TANTALUS™) in overweight subjects with type 2 diabetes (T2DM)

B. Guerci¹, E. Renard², R. Prager³, B. Ludvik⁴, A. Hamann⁵

¹Hopital Jeanne-d'Arc, Nancy, France, ²Hopital Lapeyronie, Montpellier, France, ³Hietzing Hospital, Vienna, Austria, ⁴Medical University of Vienna, Austria, ⁵Diabetes Klinik, Bad Nauheim, Germany

Background: The TANTALUS System (MetaCure Ltd.) is a minimally invasive implantable gastric stimulation modality that does not exhibit malabsorptive or restrictive characteristics. The device automatically detects food intake and applies GCM (Gastric Contractility Modulation) signals to the stomach antrum to induce early satiety. Retrospective analysis of previous studies indicated that T2DM subjects poorly controlled with oral anti-diabetic medication are likely to benefit from the treatment.

Aims: To prospectively investigate the potential effect of the TANTALUS System therapy on glycemic control and weight change in obese T2DM subjects.

Clinical characteristics and methods: In this European multi-center, open-label pilot study, 19 T2DM obese subjects (12 M, 7 F, Age: 53 \pm 2 years, BMI: 38.1 \pm 0.8 kg/m², HbA1c 8.0 \pm 0.1% (Mean \pm SEM) treated with oral anti-diabetic medications, but with poor glycemic control, were implanted laparoscopically with the TANTALUS System.

Results: To date, 16 out of 19 subjects have completed 3 months of treatment and show a mean significant reduction in HbA1c from 8.0 \pm 0.1% to 6.8 \pm 0.2% ($P < 0.01$). This was accompanied by a mean significant decrease in body weight from 109.6 \pm 4.5 Kg to 105.5 \pm 4.7 Kg ($P < 0.01$), and in waist cir-

cumference from 123.3 \pm 2.8 cm to 118.4 \pm 2.9 cm ($P < 0.01$). The HbA1c reduction was sustained also after 6 months of treatment ($N = 7$). R² of the correlation between changes in body weight and HbA1c was 0.31 ($P = 0.02$). Weight reduction contributed only 31% of the decrease in HbA1c.

Conclusion: Interim results with the TANTALUS System suggest that this stimulation regime can potentially improve glucose homeostasis and induce weight loss in obese T2DM subjects on oral anti-diabetic therapy with poor glycemic control. As weight reduction was only minimally associated with major HbA1c decrease the observed beneficial TANTALUS effects might be associated with weight-independent mechanism(s).

3

Rimonabant improves glycaemic control and associated cardiometabolic risk factors in insulin-treated type 2 patients

P.A. Hollander¹, A. Amod², L.E. Litwak³

¹Baylor Endocrine Center, Baylor University Medical Center, Dallas, United States, ²Centre for Diabetes, Endocrinology and Metabolic Diseases, Chatsmed Garden Hospital, Durban, South Africa, ³Department of Endocrinology, Hospital Italiano de Buenos Aires, Argentina

Background and aims: Rimonabant, the first selective cannabinoid type-1 (CB₁) receptor antagonist, has demonstrated a significant beneficial effect on a comprehensive set of cardiometabolic risk parameters in patients with type 2 diabetes (T2DM) naïve to antidiabetic therapy or treated with metformin or sulphonylurea. To further evaluate rimonabant 20 mg/day in an advanced stage of T2DM, rimonabant was studied in patients receiving insulin monotherapy.

Materials and methods: Entry criteria for this 48-week, double-blind, placebo-controlled trial included HbA1c $\geq 7\%$, insulin monotherapy for ≥ 3 months; there was no requirement for BMI. Primary outcome was change from baseline in HbA1c. Secondary outcomes included change in high-density lipoprotein (HDL)-cholesterol, triglycerides, body weight and waist circumference.

Results: In total, 368 patients were randomised between rimonabant (181) and placebo (187). At baseline: mean body mass index (BMI), 34.6 kg/m²; mean total daily insulin dose (MTDID), 83.5 \pm 50.5 IU; T2DM duration, 14.4 \pm 7.7 years; insulin treatment, 6.2 \pm 4.9 years. In the intention-to-treat population, mean baseline HbA1c (9.1 \pm 1.5%) was reduced significantly more with rimonabant vs placebo (-0.89 \pm 1.34% vs -0.24 \pm 1.13%; $p < 0.0001$). There was significantly greater improvement in high-density lipoprotein cholesterol ($p < 0.0001$) and triglyceride ($p = 0.02$) levels, weight ($p < 0.0001$) and waist circumference (WC) ($p < 0.0001$) with rimonabant vs placebo (Table). The observed effect on HbA1c appeared consistent in additional analysis across baseline BMI strata (Figure). The safety profile of rimonabant was consistent with previous studies in T2DM with more gastrointestinal (nausea 11.0% vs 1.6%, diarrhoea 7.3% vs 6.4%), nervous system (dizziness 10.1% vs 8.1%) and psychiatric (anxiety 14.0% vs 4.3%, depressed mood 10.1% vs 4.3%) events reported with rimonabant vs placebo. Similar rates of serious adverse events were reported in both treatment groups.

Conclusion: This study in patients with advanced T2DM, receiving insulin, confirmed the clinically significant effect of rimonabant on glycaemic control and associated cardiometabolic risk factors.

Mean (SD) changes from baseline

Outcome		Placebo n=186	Rimonabant 20 mg n=179
HDL-C, mM	Baseline	1.32 (0.4)	1.32 (0.3)
	% change	-7.1 (13.4)	3.1 (13.5)
Triglycerides, mM	Baseline	2.7 (4.4)	2.7 (3.9)
	% change	7.6 (40.6)	-4.0 (53.0)
Weight, kg	Baseline	95.3 (20.5)	97.4 (20.7)
	Change	0.1 (3.5)	-2.5 (4.0)
WC, cm	Baseline	110 (15)	112 (14)
	Change	0.2 (6.9)	-2.8 (8.6)

4

Repeat-dosing of oral insulin (Capsulin) in persons with type 2 diabetes

T.P. Broke-Smith¹, S.D. Luzio², A. Lockett¹, R.R.C. New¹, D.R. Owens²
¹Diabetology Limited, Cobham, ²Diabetes Research Unit, Cardiff University, Penarth, United Kingdom

Background and aims: A 10 day repeat dose study to investigate twice-daily dosing with the oral insulin (CapsulinTM) in the treatment of type 2 diabetes. **Materials and methods:** 16 subjects (12 male) participated; mean (SD) age 60.2 (5.5) years, BMI 28.3 (3.4) kg/m², HbA1c 7.5 (1.3) %. All subjects received 150U Capsulin BID given approximately one hour prior to breakfast and the evening meal for 10 consecutive days, during which self-monitored blood glucose (SMBG) readings were conducted 5-times a day (fasting, 2-hr after breakfast, before dinner, 2-hr after dinner, at bedtime). Prior to study entry, subjects were on stable doses of oral hypoglycaemic agents (OHA) for at least 3 months and had suboptimal glycaemic control. During the study, all OHAs apart from metformin were withdrawn (9 out of 16 subjects dropped at least one OHA; 14 remained on metformin; 2 were treated with Capsulin alone). Pre-study and post study screening occurred around 5 days prior and post the dosing period respectively.

Results: During the repeat dosing period SMBG readings remained within the recommended range (6–11 mmol/L). Daily fluctuations in SMBG as assessed by the mean amplitude of glycaemic excursion (MAGE) analysis were reduced over the study period. Analysis of postprandial glucose (PPG) excursions indicated that by day 10 the proportion of post-meal values which fell within the ADA recommended range (<8.9 mmol/L) had increased from 9.7% (day 2) to 35.5% (day 10) ($p=0.027$). This effect was more pronounced during the evening meals where the proportion of data points that fell within the recommended range increased from 6.3% (day 2) to 43.8% (day 10) ($p=0.009$). These observations were associated with significant improvements in HbA1c ($7.38\pm1.14\%$ to $7.16\pm0.86\%$, $p<0.05$), weight (84.9 ± 11.9 to 84.2 ± 11.6 kg, $p<0.05$) and triglycerides (1.83 ± 0.88 to 1.53 ± 0.60 mmol/L, $p<0.05$) between pre-study screen and study close. No serious adverse events and no hypoglycaemia were reported.

Conclusion: The ability for Capsulin to potentially improve glycaemic control throughout the day (including mealtimes) without inducing hypoglycaemia may be due to its route of delivery via the hepatic portal system, thereby mimicking endogenous insulin secretion.

5

An open label, two period, placebo controlled, multiple dose study to evaluate the effect of food on pharmacokinetic and pharmacodynamic of IN-105 10 mg in type 2 diabetes mellitus patients

H. Iyer¹, A.P. Khedkar¹, S. Suryanarayan^{1,2}, A. Anand¹, A. Vedala¹, S. Krishnamurthy¹, A.S. Arvind³, A. Eshwaraiah³, S. Savale³, K.M. Prasanna Kumar⁴, S.R. Arvind⁵, S.S. Srikanta⁶

¹Research and Development, Biocon Limited, Bangalore, India, ²Visiting faculty, Department of Molecular Medicine and Surgery, Karolinska Institute, Stockholm, Sweden, ³Clinical research, Clinigene International limited, Bangalore, India, ⁴M.S.Ramaiah Medical College and Hospital, Bangalore, India, ⁵Diacon Hospital and Research Centre, Bangalore, India, ⁶Diabetology, Samatvam Science and Research for Human Welfare Trust, Bangalore, India

Background and aims: IN-105 is a modified insulin analog which, on oral administration, showed glucose lowering activity in normal healthy volunteers. The aim of this study was to evaluate safety and effect of meal on pharmacokinetics and pharmacodynamics of IN-105 in type II diabetics.

Materials and methods: 14 type II diabetic patients, with HbA1c between 7.5 to 9.5%, were enrolled in an open label, two treatment, two period placebo-controlled study, conducted to assess pharmacokinetics and pharmacodynamics of multiple doses of “IN-105” tablets [10 mg dose]. In period 1, subjects were given placebo tablets 20 min prior to meal and a metformin tablet was given 30 min post meal. 3 tablets were administered during the single day period: one each prior to breakfast, lunch and dinner. A washout period of 7 days was maintained between period 1 and period 2. In period 2, the same patients were dosed with 10 mg IN-105 prior to breakfast, lunch and dinner at the same times as in period 1. The patients were given 600 kcal meal for breakfast, lunch and dinner and 200 kcal after the final sample of the day was collected. Immunoreactive insulin levels in plasma were measured along with the c-peptide and glucose levels.

Results: A significant drop in plasma glucose levels was observed after each dose of IN-105 as compared to that of placebo. Average maximum % drop in glucose after administration of morning, afternoon and evening doses of IN-105 tablets (10 mg dose) were 16, 23 and 18% respectively. The corresponding values for drop in glucose after administration of placebo were 2, 5 and 7%. Further average T_{min} values for corresponding doses of IN-105 were between 30–40 min. The average C_{max} for total insulin obtained after administration of morning, afternoon, evening doses of IN-105 (10mg) were 137 ± 33 , 112 ± 21 , 69 ± 13 mIU/L. The corresponding values of C_{max} for total insulin after administration of placebo were 46.54, 53.42, 42.65 mIU/L. The C_{max} values for total insulin, in period 2, reduced in the order of morning > afternoon > evening dose. The data on C_{max} and C_{min} for C-peptide after administration of morning, afternoon and evening doses of IN-105 and placebo treatment indicates that the higher levels of total insulin after administration of IN-105 tablet are due to the absorption of IN-105 administered orally. The IN-105 tablet formulation (10 mg dose) administered three times a day was well tolerated in presence of multiple meals administered 20 min after each dose in type II diabetes mellitus patients.

Conclusion: IN-105, 10 mg dose was well tolerated by type II diabetic patients. Glucose lowering effect was found to be proportional to insulin exposure. The plasma exposure of IN-105 was reduced from morning to evening. The glucodynamic effect was however, was similar for morning and evening dose.

6

Effects of grapeseed extract in type 2 diabetic subjects: a double blind randomised placebo controlled trial looking at the effects upon inflammatory and metabolic markers

P. Kar¹, D. Laight², K.M. Shaw¹, M.H. Cummings¹

¹Academic Department of Diabetes & Endocrinology, Queen Alexandra Hospital, Portsmouth, ²School of Pharmacy, University of Portsmouth, United Kingdom

Background: Vascular inflammation is thought to be a possible contributor to the pathology of type 2 diabetes and cardiovascular disease. Recent attention has focused upon the beneficial effect of plant-based products containing flavonoids, which have been shown to have anti-inflammatory properties. Studies have also highlighted the potentially beneficial platelet-dependent antithrombotic and anti-inflammatory properties of flavonoid rich products such as grape seed extracts (GSE). Moreover experimental work in animal models have suggested GSE improves metabolic markers such as cholesterol.

Aim: This study aimed to test the hypothesis that GSE may improve inflammatory and metabolic markers of vascular risk in high-risk cardiovascular subjects with T2DM.

Methods: 32 T2DM patients, diet or tablet controlled, were given 600mg GSE and placebo, for 4 weeks each, in a double-blinded randomized crossover trial. Markers of inflammation (hsCRP; Urinary ACR) and metabolism (fructosamine, lipid profile) were measured at baseline and after intervention with GSE or placebo.

Results: Baseline characteristics of patients (16 M, 16F): Age 61.81 ± 6.36 years (mean \pm 1SD); BMI 30.24 ± 5.92 kg/m²; diabetes duration 5.92 ± 2.14 years; HbA1c 6.81 ± 1.04 %; total cholesterol of 4.51 ± 0.95 mmol/l, HDL-cholesterol 1.88 ± 1.01 mmol/l and triglycerides 1.19 ± 0.3 mmol/l. Significant reductions were noted in fructosamine ($282.2 \pm 40.87 \mu\text{mol/l}$ vs. $272.87 \pm 50.19 \mu\text{mol/l}$; $p=0.0004$) and hsCRP ($3.22 \pm 3.65 \text{mg/l}$ vs. $1.95 \pm 2.2 \text{mg/l}$; $p=0.0006$), post GSE intervention. A reduction in total cholesterol ($4.51 \pm 0.96 \text{mmol/l}$ vs. $4.33 \pm 0.99 \text{mmol/l}$) was also observed ($p=0.05$). Triglyceride ($1.88 \pm 1 \text{mmol/l}$ vs. $1.69 \pm 0.99 \text{mmol/l}$; $p=0.2957$), HDL-cholesterol ($1.19 \pm 0.3 \text{mmol/l}$ vs. $1.22 \pm 0.32 \text{mmol/l}$; $p=0.1441$) and urinary ACR levels (1.1 ± 0.5 vs. 1.2 ± 0.5 ; $p=0.4734$) did not show any significant changes. Multiple correlation analysis did not show any correlation between the GSE mediated changes shown in vascular and metabolic markers.

Conclusion: GSE significantly improved inflammatory and metabolic markers in high-risk cardiovascular subjects (T2DM) over a 4-week period. Large prospective studies are required to examine whether these changes in short term surrogate markers of vascular risk with GSE translate into beneficial clinical outcome implications in T2DM patients. Analysis of genome-wide scans identifies potential novel common susceptibility loci for central obesity

C.M. Lindgren¹, I.M. Heid², J.C. Randall¹, C. Lamina², E.K. Speliotes³, The GIANT Consortium

¹Wellcome Trust Centre for Human Genetics, University of Oxford, United Kingdom, ²German Research Center for Environmental Health, Helmholtz Zentrum Muenchen, Institute of Epidemiology, Neuherberg, Germany, ³Harvard University and MIT, Broad Institute, Boston, United States

Background: Recently, FTO and one other locus located 188 kilobases downstream of MC4R were the first loci identified harboring common variants with an unequivocal impact on common obesity predisposition. In contrast, no specific associations have been reported to central obesity (in particular the amount of visceral/abdominal fat), which is especially relevant to metabolic disease (Type 2 Diabetes, Cardiovascular Disorder etc.). Anthropometric measures of central obesity can be used as physiological proxies of fat distribution and are more directly correlated to adverse metabolic outcomes including diabetes risk than BMI. Due to imperfect correlation with overall obesity ($r^2 \sim 0.8$), measures of central obesity can be used to identify genetic variants specific to regulation of fat distribution. Heritability estimates are still $\sim 60\%$ for waist circumference (WC) and $\sim 45\%$ for waist-hip ratio (WHR) after correcting for BMI. Thus we set out to undertake global identification of common genetic variants and pathways influencing individual patterns of fat distribution and central obesity through large-scale genome-wide association meta-analysis of WC and WHR.

Methods: We have carried out a meta-analysis of 13 GWA scans across $\sim 29,000$ individuals of European ancestry and include individuals from Germany (KORA), Sweden and Finland (DGI, FUSION), the US (PLCO, NHS), the UK (WTCCC T2D, HT, CHD, BC58, NBS and GEM-EPIC), Switzerland (CoLaus), and Italy (SardiNIA). First we excluded SNPs with HWE1% and high imputation quality scores (>3 MACH2QTL-R2HAT, >9 posterior probability, >4 SNPTEST proper_info). The meta-analysis of the association results was performed using METAL.

Results: The analysis of the waist-related phenotypes has identified several novel loci associated with fat distribution phenotypes; we observed 15 independent loci for WC and 3 for WHR with p -values $< 1 \times 10^{-6}$. We strongly confirmed the association of the FTO and MC4R, which accounted for the best p -values for WC ($p < 5 \times 10^{-13}$ and $p < 2 \times 10^{-8}$, respectively) but was less associated with WHR ($p < 5 \times 10^{-6}$ and $p < 2 \times 10^{-5}$, respectively). Several of the nominally associated loci have strong biological credentials and appear to be distinct from BMI signals. For example, at least two variants that show an association with WHR ($p < 2 \times 10^{-5}$ and $p < 3 \times 10^{-5}$) are involved in the central neuronal signalling pathways.

Conclusion: Our results suggest there are genetic variants with a primary effect on central obesity (WC/WHR) that differ from those with an effect on overall obesity (weight/BMI). We are currently expanding the GWA meta-analysis to other cohorts attempting to replicate our findings ($n \sim 27,000$). These results indicate that multiple common variants influence central obesity in humans and that genome-wide association analysis with large numbers of individuals will aid in the identification of such variants.

8

Meta-analysis of genome-wide association data for weight from over 32000 individuals

J.C. Randall¹, C.M. Lindgren¹, E.K. Speliotes², S. Li³, The GIANT Consortium

¹Wellcome Trust Centre for Human Genetics, University of Oxford, United Kingdom, ²Broad Institute, Harvard and MIT, Boston, MA, United States, ³Epidemiology Unit, MRC, Cambridge, United Kingdom

Background and aims: Obesity is increasingly prevalent worldwide, and is reaching epidemic levels in some western countries. Health risks associated with obesity have long been established and include an increased risk of de-

veloping a number of metabolic diseases as well as a shortened life expectancy. Adult weight is highly heritable (heritability ~70%), but the genetic variants that predispose to this trait are not yet well-characterized, and those loci that have been identified have had modest effects. To increase power to detect common variants with modest effect sizes, we performed a meta-analysis of 13 genome-wide association studies that each contributed association data on anthropometric measures as part of the GIANT consortium.

Materials and methods: All the populations studied are of European ancestry and include individuals from Germany (KORA), Sweden and Finland (DGI & FUSION), the USA (PLCO & NHS), the UK (WTCCC BC58, CHD, HT, NBS, T2D; & GEM EPIC), Switzerland (CoLaus), and Italy (SardiNIA); and together constitute more than 32,000 individuals. Each study excluded SNPs with HWE < 10⁻⁶ and then imputed to obtain probable genotypes for approximately 2.5 million SNPs in the CEU HapMap reference panel. Each study then inverse-normal transformed the weight data separately for each gender before performing gender-stratified association testing, in which each SNP was tested for association with the transformed weight phenotype using an additive model with age as a covariate. We then performed QC on those results and excluded SNPs with a minor allele frequency < 1% or with low imputation quality scores. Finally, we performed a meta-analysis of the association results using METAL to generate a single summary p-value for each SNP.

Results: This meta-analysis represents the largest whole-genome association study of weight performed to date. Our preliminary analysis has identified 18 independent loci associated with adult weight at levels of genome-wide significance ($p < 1 \times 10^{-6}$). Top hits include *FTO* ($p < 6 \times 10^{-15}$), *HMG2* ($p < 6 \times 10^{-10}$), *MC4R* ($p < 8 \times 10^{-9}$), *ZBTB38* ($p < 2 \times 10^{-7}$), and *GDF5* ($p < 4 \times 10^{-7}$), confirming previously known associations at these loci for BMI (*FTO*, *MC4R*) and showing novel associations with weight for several loci previously shown to be associated with height (*HMG2*, *ZBTB38*, *GDF5*). A number of the remaining 13 loci identified by our meta-analysis as being associated with weight also have modest levels of association with either BMI or height, while a handful appear to be unique to weight. Of those, several of the strongest hits are implicated in biologically interesting pathways such as lipid metabolism, glycogen storage, and neural signaling. Additionally, gender-stratified meta-analyses indicate strong sexual dimorphism for some loci.

Conclusion: These results are consistent with previously known associations for obesity and height, with the most associated locus for weight being a known BMI locus and the second most associated being a height locus. Loci that share a high level of association between weight and height may in fact be associated with overall body size. The numerous additional associated loci found continue to support the hypothesis that multiple common variants influence body weight and that genome-wide association analysis with large numbers of individuals can identify such variants.

First-generation scan of genome-wide association data allowing for epistasis prioritises multiple interacting candidate loci in T2D

J.T. Bell¹, N. Timpson¹, N.W. Rayner¹, E. Zeggini¹, A.P. Morris¹, M.I. McCarthy², Wellcome Trust Case Control Consortium, UK, UK Type Two Diabetes Consortium

¹Wellcome Trust Centre for Human Genetics, ²Oxford Centre for Diabetes, Endocrinology and Metabolism, Oxford University, United Kingdom

Background and aims: Genome-wide association (GWA) provides an opportunity to discover genetic variation involved in complex human traits and has yielded evidence of novel genes associated with T2D. GWA data allow for a systematic search of joint genetic effects including epistasis, though such analyses are computationally and methodologically challenging. We undertook a series of interaction analyses within data from the Wellcome Trust Case Control Consortium (WTCCC) for T2D (1924 cases and 2938 controls) with the aim of developing interaction analysis as a strategy for prioritising pairs of markers for follow-up.

Materials and methods: We first took novel T2D loci implicated by GWA analyses and assessed pairwise interaction within these and between these and previously known T2D loci. We then performed a two-dimensional, genomewide, gene/gene effect scan using a joint two-locus test of association (including main and epistatic effects) in a subset of 70,236 markers tagging common SNP variation at r^2 of >0.2 and MAF \geq 0.05. These were derived

from the tagging of 393,242 SNPs from WTCCC Affy chip data which passed initial stringent quality control. Top results from this were assessed for additive-by-additive epistasis alone (1df test PLINK).

Results: There was no evidence for interaction between novel loci for T2D from GWA analysis or between these and previously known T2D loci (p -value \leq 0.05). In stage two, we examined 2.34×10^9 comparisons involving pairs of inter-chromosomal SNPs and found that 79 pairs show evidence for two-locus association at a Bonferroni-corrected P -value \leq 0.05 (uncorrected P -value $\leq 2.14 \times 10^{-11}$). All of the 79 pairs involved loci that showed evidence for joint effects on T2D in cooperation with *TCF7L2* (rs11196205), which has strong single-locus effects. Within these, 4 loci showed association results suggestive of epistasis, where the two-locus association results independent of the main effect at *TCF7L2* were significant (p -value $< 10^{-5}$), but contrasted with the single point main-effects at the 4 loci (p -value $> 10^{-2}$). Three of these were genic; contained within coding regions for *BMP7* (rs1998190), *GNAQ* (rs10512091) and *FYCO1* (rs1552489). Other SNPs of biological interest were found within *GLP1R* (rs910171), *FTO* (rs1421090/rs9926289), *KCNJ6* (rs6517434) and *CDK5R1* (rs9348440). Relaxing significance thresholds to a Bonferroni-corrected P -value \leq 0.15, exposed further evidence for joint effects involving rs9926289 in *FTO*, in cooperation with SNPs on chromosomes 2 and 5. In further analysis of the top 79 pairs, 5 exhibited p -values $< 10^{-5}$ for additive-by-additive epistasis alone. The strongest evidence for epistatic effect with *TCF7L2* in this stage (p -value 2.9×10^{-5}) was found with *RFPL4B* (rs1935683), a locus not previously implicated in T2D aetiology.

Conclusion: Our findings allow us to prioritize pairs of markers for a second stage scan, involving more detailed epistatic models in an extended data set of additional SNPs and independent samples.

Stratified analysis of the Wellcome Trust Case Control Consortium scan for type 2 diabetes reveals susceptibility loci that may affect age of diagnosis

I. Fernandez-Cadenas^{1,2}, I. Prokopenko², N.J. Timpson^{2,3}, V. Boraska^{2,4}, N.W. Rayner², A.T. Hattersley⁵, T.M. Frayling⁵, E. Zeggini², C.M. Lindgren^{2,6}, M.I. McCarthy^{2,6}

¹Neurovascular Research Laboratory, Institut de Recerca, Vall d'Hebron Hospital, Barcelona, Spain, ²Wellcome Trust Centre for Human Genetics, University of Oxford, United Kingdom, ³Translational Epidemiology, MRC Centre for Causal Analyses in Translational Epidemiology, Bristol University, United Kingdom, ⁴Department of Biology, University of Split, Department of Biology, Croatia, ⁵Peninsula Medical School, Exeter, United Kingdom, ⁶Oxford Centre for Diabetes, Endocrinology and Metabolism (OCDEM) University of Oxford, United Kingdom

Background and aims: We hypothesized that age of diagnosis (AOD) in type 2 diabetes (T2D) may be genetically influenced.

Materials and methods: We used the Wellcome Trust Case Control Consortium genome-wide association (GWA) scan data for T2D (1,924 T2D cases and 2,938 controls, typed on the 500k Affymetrix chip). We analyzed 529 subjects with AOD < 45 years vs. controls, 1395 subjects with AOD \geq 45 years vs. controls. In addition, we analyzed the difference between effect estimates in cases with AOD < 45 vs. cases with AOD \geq 45 years. The cut-off of AOD of 45 years was used in keeping with previously published studies. We used PLINK and STATA software for the analysis of these data sets.

Results: The T2D-associated genes *FTO* and *TCF7L2* were associated with T2D regardless of AOD stratum. In cases with AOD < 45 years, the strongest association with T2D was identified ~10kb downstream from *THBS2* (rs10806665, $p = 4.6 \times 10^{-10}$), followed by a locus ~10kb downstream from *TSHZ2* (rs6068566, $p = 4.8 \times 10^{-7}$). In addition we found a new intergenic region ~150kb upstream from *MYR8* and *TNFSF13B* in AOD < 45 cases associated with T2D (rs1924340, $p = 2.2 \times 10^{-6}$). In cases with AOD \geq 45 years, the strongest signals of association with T2D were identified in *TCF7L2* (rs7901695, $p = 9.24 \times 10^{-12}$), followed by an intergenic region ~25kb upstream from *TSPAN8* (rs1495377, $p = 8.33 \times 10^{-7}$). Both of these are established T2D gene regions. When we compared differences in T2D association signals between cases with AOD < 45 vs cases with AOD \geq 45 years, the locus close to *TSHZ2* showed statistical evidence for difference in T2D association between AOD strata (rs6068566, $p_{\text{diff}} = 1.38 \times 10^{-5}$).

Conclusion: Stratified analysis of T2D association by AOD appears to yield differential profiles of genetic association indicating a genetic predisposition associated with age. This may have importance for the design and interpretation of future association studies for T2D.

11

Genome-wide association (GWA) analysis in 4000 members of a Finnish birth cohort identifies common variants associated with fasting insulin levels and related metabolic traits

M. Kaakinen¹, I. Prokopenko², W.N. Rayner², C. Lindgren², N. Timpson², A. Pouta¹, A. Ruokonen¹, A.-L. Hartikainen¹, N. Freimer³, P. Elliott⁴, M. Daly⁵, C. Sabatti⁶, L. Peltonen^{7,8}, M.-R. Järvelin⁴, M.I. McCarthy²
¹Institute of Health Sciences, University of Oulu, Finland, ²WTCHG, University of Oxford, United Kingdom, ³Center for Neurobehavioral Genetics, University of California, Los Angeles, United States, ⁴Dept of Epidemiology and Public Health, Imperial College London, United Kingdom, ⁵Massachusetts Institute Of Technology, The Broad Institute, Boston, United States, ⁶Depts. of Human Genetics and Statistics, University of California, Los Angeles, United States, ⁷Institute of Molecular Medicine, Biomedicum Helsinki, Finland, ⁸Sanger Institute, Wellcome Trust Genome Campus, Hinxton, United Kingdom

Background and aims: Identification of genetic variants influencing the concentrations of fasting insulin levels and related metabolic traits may deepen our understanding of the genetic pathways regulating metabolic traits relevant to the development of type 2 diabetes (T2D).

Materials and methods: 6007 individuals from the Northern Finland Birth Cohort of 1966 (NFBC1966) representing a homogeneous population, underwent exhaustive phenotypic and clinical characterisation at age 31. Of these, genomewide association data (Illumina 370K) were available for 4628. After excluding subjects with established diabetes, pregnant woman, non-fasting subjects and outliers ($\pm 3SD$) for fasting glucose or insulin, a final set of 316870 SNPs and 4042 subjects were available for analysis. Insulin, HOMA-B and HOMA-IR values were log transformed: association analyses evaluated the additive model and were adjusted by gender.

Results: GWA analysis of fasting insulin levels showed the strongest association at rs2969344, ($p=4.4 \times 10^{-7}$) on chromosome 2, approximately 15kb from the nearest predicted transcript [GenBank accession BG259880]. Additional association signals of interest were found within the *SYN3* (synapsin III isoform IIIa, chr.22, $p=2.7 \times 10^{-6}$) and *PANK1* (pantothenate kinase 1 isoform beta, chr.7, $p=1.1 \times 10^{-5}$) genes. Unsurprisingly, given the strong correlation between fasting insulin and HOMA-IR, these same SNPs showed associations of similar strength with HOMA-IR measures ($p=1.2 \times 10^{-6}$ and 2.2×10^{-6} respectively). For HOMA-B (beta-cell function), the most promising novel association was observed at rs132689 ($p=2.0 \times 10^{-7}$), close to the *APOL3* (apolipoprotein L3 isoform 3) gene. An additional signal for beta-cell function was detected close to the *G6PC2* gene (rs563694: $p=5.8 \times 10^{-6}$), this being driven by the strong (and previously-reported) association with fasting glucose levels seen in this sample (rs560887, $p=4 \times 10^{-9}$). The *PANK1* SNPs showing modest association with insulin levels were also significantly ($p \sim 4 \times 10^{-5}$) associated with HOMA-B. None of the known T2D-susceptibility genes showed strong signals for HOMA-B (eg *TCF7L2*, rs7903146 $p=0.04$).

Conclusion: GWA analysis of these three related metabolic traits, in over 4000 young non-diabetic adults has revealed several promising association signals distinct from those previously shown to be involved in predisposition to T2D. Further replication and meta-analysis efforts are underway to substantiate these findings, but the indications are that analyses of quantitative traits such as these will allow identification of additional loci impacting on metabolic regulation in human populations.

Meta-analysis of genome-wide association data involving 6,100 adults of European origin identifies common variants associated with fasting glucose levels

I. Prokopenko^{1,2}, Y. Aulchenko³, M. Kaakinen⁴, A. Dehghan³, S. Service⁵, N. Freimer³, P. Elliott⁶, M.-R. Jarvelin⁶, L. Peltonen^{7,8}, C.M. van Duijn³, M.I. McCarthy^{1,2}

¹WTCHG, University of Oxford, United Kingdom, ²Ocdem, University of Oxford, United Kingdom, ³Dept. Epidemiology & Biostatistics, Erasmus MC, Rotterdam, Netherlands, ⁴Institute of Health Sciences, University of Oulu, Finland, ⁵Center for Neurobehavioral Genetics, University of California, Los Angeles, United States, ⁶Dept. of Epidemiology and Public Health, Imperial College of London, United Kingdom, ⁷Biomedicum, Institute of Molecular Medicine, Helsinki, Finland, ⁸Sanger Institute, Wellcome Trust Genome Campus, Hinxton, United Kingdom

Background and aims: Identification of common variants influencing fasting glucose concentrations will provide novel clues to the mechanisms involved in the maintenance of glucose homeostasis, and complement case-control association approaches for the detection of the genes influencing risk of type 2 diabetes.

Materials and methods: We analysed genome-wide association (GWA) data from ~6,100 European individuals of Caucasian origin. GWA data were available from 4042 subjects from the Northern Finland Birth Cohort (NFBC1966) who had been tested for fasting glucose levels at age 31 (Illumina 370k), and 2058 subjects from the ERGO sample, a population-based cohort study in the Netherlands (mean (SD) age: 64.06(\pm 5.89); Illumina 317K). Those with established diabetes, pregnant woman, non-fasting subjects and outliers ($\pm 3SD$) had been excluded from the analysis. Association analyses were adjusted by gender and age (ERGO sample) and glucose values log-transformed. Meta-analysis was performed using the inverse-variance weighted method with a fixed effects model.

Results: In these samples, we were able to replicate two previous associations with fasting glucose. At rs2971671, close to the glucokinase gene (~230kb from the variants previously described), we detected a per-allele effect of ~0.06mmol/l ($p=4.8 \times 10^{-7}$). An effect of similar size was also detected at SNP rs560887, near to *G6PC2* (glucose-6 phosphatase catalytic subunit 2) ($p=6.8 \times 10^{-10}$). The most striking association pointing towards a novel quantitative trait locus was observed near to the *MTNR1B* gene encoding the melatonin receptor 1b (per-allele effect ~0.06mmol/l in NFBC1966 and ~0.11mmol/l in ERGO, $p=3.7 \times 10^{-11}$). Other promising signals (both $p \sim 3 \times 10^{-6}$) were observed for SNPs in the vicinity of the *CNTNAP2* (contactin associated protein-like 2) and *PBX1* (pre-B-cell leukemia transcription factor 1) genes, both of which have substantial functional credibility as candidates. Evidence of association for known T2D-susceptibility genes was muted, the strongest signal being for rs7903146 within *TCF7L2* ($p=1.8 \times 10^{-5}$): this effect was stronger in the (more elderly) Rotterdam cohort than in the Finnish sample (per-allele effect ~0.09 and ~0.03mmol/l respectively).

Conclusion: As well as confirming previous associations, these GWA data have identified several novel signals related to fasting glucose. Efforts at large-scale replication and meta-analysis of these findings currently underway should reveal which of these have a robust, genuine effect on glucose levels in adults. Both physiological (glucose-sensing) and pathological (diabetes-related) mechanisms seem to be implicated in the determination of glucose levels.

Effectiveness of continuous glucose monitoring during pregnancy: results of a randomised clinical trial

H.R. Murphy¹, G. Rayman¹, K. Lewis¹, S. Kelly², B. Johal², D. Fowler¹, K. Duffield³, R.C. Temple⁴

¹Diabetes centre, Ipswich Hospital, ²Obstetrics and Gynaecology, Ipswich Hospital, ³Elsie Bertram Diabetes centre, Norfolk and Norwich University Hospital NHS Trust, Norwich, United Kingdom, ⁴Elsie Bertram Diabetes centre, Norfolk and Norwich University Hospital NHS, United Kingdom

Background and aims: To evaluate the effectiveness of Continuous Glucose Monitoring (CGM) during pregnancy on maternal glycaemic control, infant birth weight and risk of macrosomia in women with type 1 and type 2 diabetes.

Materials and methods: A prospective, open label randomised controlled trial comparing standard antenatal care with and without CGM in 2 secondary care multidisciplinary obstetric diabetes clinics in the United Kingdom. CGM was used as an educational tool to inform decision making and future therapeutic changes at 4–6 weekly intervals during pregnancy. All other aspects of antenatal care were equal between the 2 groups. 71 women with type 1 (n=46) and type 2 (n=25) diabetes were randomised to antenatal care with CGM (n=38) or without supplementary CGM (n=33). All statistical analyses were performed on an intention-to-treat basis.

Results: Women randomised to CGM had lower mean HbA1c between 32–36 weeks gestation compared to women in standard care ($5.8\% \pm 0.6$ versus $6.4\% \pm 0.7$; $p=0.007$). Compared to infants of standard care mothers, infants of the CGM mothers had a lower median birth weight centile (69% versus 93%; $p=0.009$) and reduced risk of macrosomia (Odds ratio 0.36, 95% Confidence Interval 0.13 to 0.98; $p=0.05$).

Conclusion: Use of CGM during pregnancy is associated with improved glycaemic control, lower infant birth weight and reduced risk of macrosomia. This is the first trial to demonstrate the effectiveness of continuous glucose monitoring on glycaemic control and pregnancy outcome.

Figure. Distribution of the individual customised birth weight centiles for 67/69 infants of mothers randomised to supplementary continuous glucose monitoring (CGMS) or standard antenatal care. Lines mark the medians (thick lines) and interquartile range (thin lines)

Glycaemic rises after waking up in response to an alarm clock during the night in type 1 diabetic patients can be avoided by experienced nurses drawing blood in a hospital setting as shown by continuous glucose monitoring (GlucoDay®)

C. Berndt¹, L. Köthe¹, B. Nawrodt¹, B. Mraz², A. Patzelt-Bath³, M.A. Nauck¹;

¹Diabeteszentrum, Bad Lauterberg im Harz, Germany, ²A. Menarini Diagnostics, Berlin, Germany, ³Diagnostica, Berlin-Chemie AG, Berlin, Germany

Background and aims: It is not known, to which degree waking up in response to an alarm clock evokes a stress reaction that may lead to acute elevations in glucose concentrations and to false estimates of overnight glucose profiles. Therefore, it was the aim of the present study, to compare, by use of continuous glucose monitoring, overnight glucose profiles obtained by patients with type 1 diabetes themselves (i.e. waking up in response to an alarm clock, and performing glucose self-measurements), or by experienced nurses, in a prospective, randomized trial.

Materials and methods: 30 type 1 diabetic patients participated. They were 49 ± 13 years old (21 male and 9 female patients), their BMI was 27.7 ± 4.2 kg/m², and their diabetes had been diagnosed 24 ± 11 years earlier. Treatment was with continuous subcutaneous insulin infusion (n = 9) or intensified conventional regimens (n = 21), daily insulin doses were 43.7 ± 17.6 IU/d. In randomized order, each participant participated (a) in one night, during which they were instructed to set their alarm clock for glucose measurements to be performed by the patient themselves at midnight, 2 a.m., and 4 a.m., and (b) in another night, when an experienced nurse was scheduled to perform capillary blood glucose determinations as gently as possible (dimmed light, little noise etc.). (c) The night between these two experiments, the patients were left undisturbed. In addition, venous blood was taken for the analysis of stress hormones. Throughout the study, patients were equipped with a GlucoDay® device for continuous glucose monitoring (CGM; 2 periods of 48 h). CGM data obtained between 15 min before and 30 min after the times specified for glucose measurement were analysed by repeated-measures analysis of variance.

Results: After waking up in response to an alarm clock, CGM-determined glucose concentrations rose by 15.7 ± 6.1 mg/dl after 9 min at 2 a.m. and by 17.7 ± 6.3 mg/dl at 4 p.m. ($p = 0.0003$), whereas only minor increments were elicited with gently taking blood by nurses (4.8 ± 4.4 mg/dl at 2 a.m. and 0.0 ± 3.8 mg/dl at 2 and 4 a.m.). Pulse rates and adrenaline concentrations were higher ($p < 0.05$) in response to alarm clocks.

Conclusion: Waking up in response to an alarm clock leads to a stressful arousal reaction that will lead to erroneously high glucose concentrations. Exact night-time glucose profiles may require hospitalization and gentle procedures for taking blood avoiding such conditions. Continuous glucose monitoring with GlucoDay® is able to demonstrate short-lived increments in glucose concentrations in response to stressful arousal.

A cross over study on patient reported outcomes of continuous glucose monitoring (CGM) comparing real time access to glucose values with retrospective analysis

N. Hermanns¹, G. Gulde¹, B. Kulzer¹, H. Eberle¹, E. Pradler², A. Patzelt-Barth³, T. Haak¹

¹Research Institute of Diabetes Academy Mergentheim, FIDAM, Bad Mergentheim, Germany, ²Menarini, diagnostics, Berlin, Germany, ³Berlin-Chemie, AG, Berlin, Germany

Background and aims: The results of CGM can be reported to patients either in real time or retrospectively. This randomized cross over trial examines the effect of CGM with real time access to glucose data (RTA) vs. a CGM with a retrospective analysis (RA) of glucose data on satisfaction with CGM and other patient reported outcomes

Materials and methods: Participants used the CGM device (GlucoDay®, Menarini Diagnostics, Florence, Italy) twice. In one condition patients got real time access to current glucose values and in the other condition glucose values were only reported retrospectively. The order of these two conditions was randomized. At baseline, after the first and the second trial, subjects completed questionnaires about perceived satisfaction with CGM (CGM-SAT, with a total score of satisfaction with CGM, with a perceived benefit scale and a perceived disadvantage scale). They also completed the Problem Areas in Diabetes (PAID), and the state anxiety scale (State Version STAI).

Results: In this study 50 type 1 diabetic patients (age 41.7 ± 12.3 yrs., diabetes duration 14.75 ± 11.9 yrs., 48 % female, A1c $8.1\% \pm 1.5\%$, years of education 10.3 ± 2.1 yrs) participated. At baseline patients perceived CGM as rather advantageous, after RA and RTA the perceived benefits were reduced (baseline: 47.8 ± 10.5 ; RA: 38.4 ± 17.2 ; RTA: 37.0 ± 16.8 , $p < .01$), but there was no significant difference between RA and RTA. Interestingly the same was true for perceived disadvantages of CGM (Baseline: 22.9 ± 10.6 ; RA: 18.7 ± 10.6 ; RTA: 19.3 ± 12.6 $p < .05$). The total scale of the GCM SAT showed a similar course (Baseline: 101.0 ± 16.0 ; RA: 95.7 ± 20.2 ; RTA: 93.6 ± 22.8 $p > .01$). There was also no significant effect on diabetes related distress or state anxiety.

Conclusion: After the experience of CGM the possible benefits were perceived as a little bit less positive and potential disadvantages were perceived less negative. Thus experience of CGM corrected expected benefits and disadvantages. But there was no specific significant negative or positive effect of RA vs. RTA on satisfaction with CGM. Furthermore CGM with RA or RTA had no significant effect on the course of diabetes related distress or state anxiety. Exposing type 1 diabetic patients to their current glucose values doesn't seem to have a specific negative impact on the appraisal of CGM or more generic patient reported outcomes.

Assessing glycaemic excursions by continuous glucose monitoring system (CGMS) in patients with type 2 diabetes treated with insulin secretagogues

Y. Li¹, L. Xu¹, J. Shen², J. Ran³, Y. Zhang³, M. Wang², L. Yan¹, Z. Fu¹

¹Department of Endocrinology, Sun Yat-Sen Memorial Hospital,

²Department of Endocrinology, Southern Hospital, ³Department of Endocrinology, Guangzhou Red Cross Hospital, Guangzhou, China

Background and aims: Patients with similar HbA_{1c} may differ in glycemic excursion profiles. The aim of this study was to explore glycemic excursions in patients who had similar glycemic control when treated with different insulin secretagogues.

Materials and methods: A total of 60 newly diagnosed patients were enrolled into this multi-center, open-labelled, parallel study and randomly (1:1:1) assigned to receive repaglinide (Rg), glimepiride (Gm) and gliclazide (Gli). The initial dosage for Rg, Gm and Gli were 1 mg tid, 1 mg qd, and 30mg qd, respectively, and were titrated to reach the fasting blood glucose (FBG) target of ≤ 7 mmol/L. Glucose concentration was monitored by CGMS for 72 hours at the end of a 4-week treatment period.

Results: Patients' age, BMI, FBG, HbA_{1c} and glycosylated serum protein were comparable among the three treatment groups at baseline. After treatment, mean glycemic values during 72 hours were similar in the three groups. Mean amplitude of glycemic excursions (MAGE) was significantly lower in Rg as compared with Gm and Gli ($p = 0.006$ and 0.007 , respectively), and no difference existed between Gm and Gli ($p = 0.581$). The same tendency was found in mean maximal glycemic values (Rg vs. Gm, $p = 0.016$; Rg vs. Gli, $p = 0.016$; Gm vs. Gli, $p = 0.948$). Mean minimal glycemic values were similar in the three groups. The percentages of time when patients experiencing hypoglycemia (< 3.9 mmol/L) and hyperglycemia (> 7.8 and > 11.1 mmol/L) were comparable. The exposure to hyperglycemia tended to be the shortest with Rg.

Conclusion: Despite similar glucose control, glycemic excursion profiles can be different with different insulin secretagogues. Repaglinide causes less gly-

emic excursions than glimepiride and gliclazide. CGMS can be used as a tool to monitor glycemic excursions and help patient to achieve accurate glycemic control.

Diabetes and sleep apnoea - lessons learnt from continuous glucose monitoring in type 2 diabetic patients with sleep-disordered breathing

M. Pallayova, V. Donic, Z. Tomori

Department of Physiology and Sleep Laboratory, PJ Safarik University School of Medicine, Kosice, Slovakia

Background and aims: There is compelling evidence that severe sleep-disordered breathing (SDB) and coexisting diabetes significantly increase cardiovascular morbidity and mortality. Given the enormous cardiovascular consequences of type 2 diabetes it is important to understand the development of the hyperglycemic state and to develop identification and intervention strategies. Our aim was to discern the glycemic consequences of sleep apnea in type 2 diabetic state.

Materials and methods: Thirty type 2 diabetic patients on diet or stable oral hypoglycemic therapy (19 men; mean age 55.5 ± 7.8 years, BMI 34.7 ± 7.4 , duration of diabetes 3.0 ± 1.7 years, HbA_{1c}/HPLC method $7.1 \pm 0.79\%$) with objectively assessed SDB of various grades of severity underwent continuous glucose monitoring (CGM) for several days. Subjects were divided into four subgroups according to their apnea-hypopnea index (AHI): [A] normal with an AHI $< 5/h$, [B] with mild SDB (AHI $5-15/h$), [C] with moderate SDB (AHI $15-30/h$), and [D] with severe sleep apnea (AHI $\geq 30/h$). The primary study outcome measures included indices of nocturnal glucose variability (overnight glucose standard deviation $SD_{\text{overnight}}$, coefficient of variance CV, mean of nocturnal glucose differences MOND) and mean nocturnal glucose values. The differences between groups were tested using ANOVA. Correlations between two continuous variables were analyzed using Spearman's rank correlation.

Results: 111 nocturnal glucose profiles showed the most stable overnight glucose control in [A] ($n=11$; 38 nocturnal CGM profiles; AHI $1.6 \pm 1.0/h$, BMI 31.7 ± 8.7 , $SD_{\text{overnight}}$ 0.53 ± 0.22 , CV $9.35 \pm 3.92\%$, MOND 2.16 ± 0.87 mmol/l, mean nocturnal glycemia 5.8 ± 1.08 mmol/l). The most labile nocturnal glucose control was observed in [D] ($n=10$; 32 nocturnal CGM profiles; AHI $57.8 \pm 16.0/h$, BMI 36.9 ± 6.5 , $SD_{\text{overnight}}$ 1.02 ± 0.4 , CV $12.81 \pm 4.91\%$, MOND 3.96 ± 1.55 mmol/l, mean nocturnal glycemia 8.15 ± 1.76 mmol/l). ANOVA showed significantly increased nocturnal glucose variability in [C] as compared to [A] ($p=0.008$), in [D] as compared to [B] ($p=0.01$), and in [D] as compared to [A] ($p<0.001$). Despite no significant difference in HbA_{1c} be-

	Repaglinide (Rg)	Glimepiride (Gm)	Gliclazide (Gli)	p-value
Mean glycemic values (mmol/L)	6.55 ± 1.17	7.13 ± 1.79	6.71 ± 1.28	0.463
MAGE (mmol/L)	4.28 ± 1.02	5.54 ± 1.55	5.94 ± 2.37	0.011
Mean maximal glycemic values (mmol/L)	11.73 ± 1.56	13.84 ± 2.92	13.53 ± 3.02	0.028
Mean minimal glycemic values (mmol/L)	3.28 ± 1.03	3.57 ± 1.01	3.44 ± 0.72	0.658
Percentage of time (%)				
BG < 3.9 mmol/L	2.0 (0 - 44)	0.0 (0 - 58)	1.0 (0 - 35)	0.699
BG > 7.8 mmol/L	18.0 (1 - 52)	27.0 (2 - 91)	18.5 (2 - 95)	0.749
BG > 11.1 mmol/L	1.0 (1 - 11)	3.0 (0 - 40)	2.5 (0 - 35)	0.168

Values are presented as Mean \pm SD or Median (min-max).

If $p < 0.05$, there is a difference among three groups; If $p \geq 0.05$, there is no difference among three groups.

tween subgroups, ANOVA showed significant difference in mean nocturnal glycemia between [A] and [D], [A] and [C], [B] and [D], and [B] and [C]. Evaluation of CGM- and parallel sleep and respiratory data showed strong positive correlations between AHI and parameters of nocturnal glucose variability ($p<0.005$) and a strong positive correlation of AHI with mean nocturnal glucose values ($r=0.6$; $p<0.001$). We observed strong negative correlations of mean nocturnal glucose values with both mean oxygen saturation ($r=-0.59$; $p<0.001$) and minimum oxygen saturation levels ($r=-0.54$; $p<0.001$).

Conclusion: The results suggest that moderate to severe sleep apnea accompanied by severe oxygen desaturation is associated with significantly increased nocturnal glucose variability and worse overnight glucose control as compared to type 2 diabetic state without SDB. Our findings emphasise need for multidisciplinary approach to diabetes care with early diagnosis and treatment of comorbidities, which might aggravate glucose control. With the rapid increase in incidence of coexisting diabetes and sleep apnea, it is important to ensure that patients are treated as effectively as possible in order to achieve sustained glycemic control and, thereby, minimise the impact of the condition.

Reduced circulating endothelial progenitor cell number in young adult insulin-resistant healthy subjects

A. Dei Cas¹, V. Spigoni¹, D. Ardigo¹, G. Pedrazzi², L. Franzini¹, E. Derlindati¹, L. Monti³, L. Gnudi⁴, I. Zavaroni¹

¹Department of Internal Medicine and Biomedical Sciences, University of Parma, Italy, ²Department of Public Health, University of Parma, Italy, ³Department of Internal Medicine, Istituto Scientifico San Raffaele, Milan, Italy, ⁴Department of Diabetes and Endocrinology, Cardiovascular Division, King's College, London, United Kingdom

Background and aims: Insulin-resistance (IR) associates with a cluster of metabolic and hemodynamic abnormalities, endothelial dysfunction and increased cardiovascular (CV) risk. Circulating Endothelial Progenitor Cells (EPCs) are considered to play a key role in vessel repair following endothelial damage. The number of EPCs inversely correlates with the presence of glucose intolerance, diabetes, cardiovascular risk factors, CV morbidity and mortality. However, it remains unclear whether the presence of insulin-resistance is associated to a variation in the number of EPCs in healthy subjects with normal glucose tolerance.

Materials and methods: To address this issue, circulating EPC number was determined in 122 healthy subjects (73M/49F; age 37 ± 8 yrs; BMI 24.6 ± 4.2 Kg/m²). All subjects were normotensive and not taking any medication. Glucose tolerance test was performed in all subjects with the determination of plasma glucose and insulin. Subjects were classified as insulin resistant on the basis of fasting plasma insulin as a surrogate marker of insulin resistance. Fasting blood samples were drawn in all subjects for the determination of EPC number, lipid profile, white blood count (WBC), high sensitive C-reactive protein (hsCRP), uric acid and PAI-1. EPCs were identified as cell positive for CD34, CD133 and Kinase insert Domain Receptor (KDR) cell-surface antigens by flow cytometry analysis. Isotype Immunoglobulins (IgG1) were used as controls. EPC number is expressed respectively as percentage of cells positive for KDR within the CD133+ cells (early EPCs) and KDR+ within the CD133+ and CD34+ cells (triple EPCs) within the lymphomonocyte population. Data were analysed with Spearman correlation and differences among groups were evaluated with non parametric tests for ordered alternatives (Jonkheere-Terpstra) and χ^2 test.

Results: Early EPC number was greater in female ($p<0.05$) and significantly inversely correlated with BMI ($r=-0.18$; $p<0.05$), waist circumference ($r=-0.2$; $p<0.05$), diastolic and systolic blood pressure ($r=-0.23$; $p<0.01$; $r=-0.21$; $p<0.05$), creatinine ($r=-0.18$; $p<0.05$), uric acid ($r=-0.24$; $p<0.005$), gGT ($r=-0.24$; $p<0.005$), PAI-1 ($r=-0.197$; $p<0.05$) and fasting insulinaemia ($r=-0.2$; $p<0.05$). The number of triple EPCs inversely correlated with body weight ($r=-0.18$; $p<0.05$), monocytes ($r=-0.2$; $p<0.05$), uric acid ($r=-0.28$; $p<0.005$), gGT ($r=-0.3$; $p<0.005$), GPT ($r=-0.2$; $p<0.05$) and insulinaemia ($r=-0.2$; $p<0.05$). By dividing in tertiles the subjects on the basis of fasting plasma insulin, subjects belonging to the third tertile (insulin resistant) showed reduced EPC number with respect to the first tertile (insulin-sensitive) ($p<0.05$). Insulin tertiles were inversely associated with EPC tertiles ($p<0.05$).

Conclusion: Insulin resistant subjects showed reduced EPC number which inversely correlated also with the cluster of abnormalities linked to the insulin resistance syndrome. These data suggest a possible role for EPCs as early markers of CV risk in insulin-resistant subjects.

Diminished endothelial progenitor cells are related to glycaemic control in type 1 diabetic children

G.H. Schernthaner¹, B. Rami², M. Satler¹, F. Hoellerl¹, C. Höbaus¹, E. Schober³, G. Schernthaner⁴

¹Medicine II, Medical University of Vienna, ²Pediatrics and Adolescent Medicine, Medical University of Vienna, ³Pediatrics and Adolescent Medicine, Medical University of Vienna, ⁴Medicine I, Rudolfstiftung Hospital Vienna, Austria

Background and aims: The risk of dying of cardiovascular disease (CVD) before the age of 40 is increased nearly 20-fold in patients with type 1 diabetes

mellitus (T1DM) compared with nondiabetic subjects. One main contributor to the increased CVD risk might be unsatisfactory glycemic control, which emerges from the very beginning of T1DM, thus in childhood. However, the mechanisms mediating this increased risk are not completely understood. Endothelial progenitor cells (EPC) are bone marrow derived cells circulating in the peripheral blood. They are involved in animal adult neovascularisation and (animal and human) endothelial homeostasis and may predict CVD morbidity and mortality in humans. Thus, we performed a longitudinal study in T1DM children, enumerated EPC and studied the associations of the latter.

Materials and methods: In total, 120 children, 90 with T1DM and 30 control children (CO), were included. The patients and controls were carefully matched and did not differ for age (13.5 ± 2.8 years), gender (48.5 % female) and BMI (21.2 ± 3.6 kg/m²). Circulating pluripotent progenitor cells (CPC; CD34+/CD133+) and EPC (CD34+/CD133+/CD309+) were enumerated by flow cytometry out of peripheral blood specimen. All laboratory tests were performed at the beginning of the study and one year thereafter, when the patients were scheduled for their routine follow up examination. Statistical analysis included unpaired and paired student's t test, correlation analysis as well as multivariate linear regression modelling, as appropriate. In order to analyse changes of variables during the one year observation time, delta values were calculated.

Results: EPC were significantly reduced in children with T1DM compared to CO (607 ± 368 vs 1037 ± 504 , $p < 0.001$). Other significant differences were found in systolic blood pressure (112 ± 14 vs 101 ± 8 mmHg, $p < 0.001$) and glucose levels (150 ± 77 vs 90 ± 8 mg/dl, $p < 0.001$), each T1DM vs CO. Multivariate regression analysis revealed that HbA1c was the strongest independent predictor of EPC levels (Beta = -0.319, $p = 0.003$). The overall glycemic control at the beginning as well as at the end of the study was satisfying, and not different (7.8 ± 1.2 vs 7.8 ± 1.2 rel.%, $p = \text{ns}$) and in our 90 patients with T1DM none presented with neuropathy, nephropathy, retinopathy or CVD. However, looking up the patients individually, we had changes of HbA1c levels during the one year follow up of -4.30 and +3.10 rel. %, respectively. When calculating the mean change of EPC per 0.10 rel. % HbA1c, we obtained an increase of mean EPC in 93 cells per each reduction of HbA1c of 0.1 rel % and vice versa.

Conclusion: In conclusion, this is the first study providing evidence for diminished numbers of endothelial progenitor cells in children with type 1 diabetes mellitus. Since low endothelial progenitor cells are important predictors of future cardiovascular morbidity and mortality in nondiabetic high risk patients, these new findings could be relevant for the understanding of the high cardiovascular risk of type 1 diabetic children. The observed significant increase of EPC in diabetic children with improved diabetic control within 1 year suggest that optimization of glycemic control could be relevant in reducing the high CVD burden in these patients.

Circulating progenitor cells in the natural history of type 2 diabetes mellitus

G. Fadini, S. de Kreutzenberg, C. Agostini, A. Tiengo, A. Avogaro
Dept Clinical and Experimental Medicine, University of Padova, Italy

Background and aims: Cardiovascular disease (CVD) in type 2 diabetes is attributed to the biochemical effects of hyperglycemia and to the coexistence of additional risk factors. Depletion of bone marrow-derived circulating progenitor cells has been recently proposed as another mechanism of CVD induction in diabetes. The present study was undertaken to describe quantitatively progenitor cell de-modulation during the natural history of type 2 diabetes.

Materials and methods: CD34+ cells were chosen as the simplest phenotype of circulating immature cells likely derived from the bone marrow. We searched our database for subjects having circulating CD34+ cell count determined and carbohydrate metabolism status known. We identified 425 individuals, which were divided into 7 categories according to carbohydrate metabolism status (normal glucose tolerance, NGT; impaired fasting glucose, IFG; impaired glucose tolerance, IGT; newly diagnosed type 2 diabetes, „DM new“) and diabetes duration (0-9; 10-19; ≥ 20 years). These categories were examined as ideally describing the natural history of type 2 diabetes development and progression. Rough data of CD34+ cell count were plotted as variation with respect to NGT patients. Adjusted CD34+ cell variation was derived from non-standardized regression coefficients of a multivariable analysis taking into account all possible confounders.

Results: The analysis of rough data (continue line) revealed that, in comparison with NGT, CD34+ cells were significantly (*) reduced as early as in IGT subjects, and had a first nadir at time of diagnosis. In patients with 0-19 years of diabetes duration a slight increase or stabilization of CD34+ cell count was recorded. A second deeper nadir was evident after 20 years of diabetes. Full adjustment to clear out possible confounders from this trend (including age, concomitant risk factors, prevalent cardiovascular disease, and medications), confirmed that CD34+ cell count are deeply reduced at time of diagnosis (+), partially recover during the subsequent 0-19 years, and dip again after at least 20 year of diabetes duration (dashed line).

Conclusion: This study describes the time course level of CD34+ progenitor cells, likely to be derived from bone marrow, across categories of patients reflecting the natural history of type 2 diabetes. A sort of bone marrow “stunning” may mark the clinical onset of type 2 diabetes. While a partial recovery occurs during subsequent years, bone marrow reserve is exhausted in the long term. Recognition and treatment of this early abnormality may help preserving longer marrow function, thus preventing CVD.

22

Increased levels of endothelial microparticles CD144 positives in type 2 diabetic patients with coronary noncalcified plaques evaluated by multidetector computed tomography

S. Bernard¹, R. Loffroy², A. Sérusclat², L. Boussel², E. Bonnefoy³, C. Thévenon⁴, D. Revel², P. Moulin¹, P. Douek²

¹Endocrinology Diabetology, Cardiovascular Hospital-HCL, Bron, ²Radiology, Cardiovascular Hospital-HCL, Bron, ³Intensive Care Unit, Cardiovascular Hospital-HCL, Bron, ⁴Cecil, Université Claude Bernard Lyon I, France

Background and aims: The combination of both morphological and cellular markers of subclinical atherosclerosis, in addition to conventional risk factors, may help to improve cardiovascular prevention in type 2 diabetic patients. The aim of our cross-sectional study was to evidence a putative increase in endothelial (EMP) or platelet (PMP) microparticles, in type 2 diabetic patients with coronary noncalcified plaques detected by multidetector CT (MDCT).

Materials and methods: Microparticles and coronary MDCT were assessed in 56 type 2 diabetic patients with different cardiovascular risk levels. EMP and PMP were detected by cell-specific monoclonal antibodies using flux cytometry.

Results: Both EMP ($p = 0.35$, $p = 0.022$) and PMP ($p = 0.34$, $p = 0.022$) were correlated with CRP. EMP were elevated in patients with acute coronary syndromes (ANOVA, $p = 0.034$). EMP count was significantly higher in presence of noncalcified plaques (ANOVA, $p = 0.01$). This increase in EMP in noncalcified plaque carriers remained significant ($p = 0.05$) after adjustment for coronary heart disease and hsCRP. By contrast, there was no association of PMP count with noncalcified plaques and no difference in PMP count between patients with and without acute coronary syndrome. No significant association between either EMP and PMP counts and mixed or calcified plaques was observed.

Conclusion: We report for the first time an association between plasma EMP-CD144+ and coronary noncalcified plaques assessed by MDCT in a population of type 2 diabetic patients. EMP might be used as a surrogate marker

of unstable plaques, and might help to improve cardiovascular prediction in diabetic patients with intermediate risk.

Retinal microvascular changes and risk of coronary heart disease in hypertensive diabetic and non-diabetic individuals: an ASCOT substudy

C. Stettler^{1,2}, N. Witt², R. Tapp², A. Stanton², S. Thom², S. Allemann^{1,3}, T. Tillin², A.D. Hughes², N. Chaturvedi²

¹University Hospital Bern, Division of Endocrinology, Diabetes and Clinical Nutrition, Bern, Switzerland, ²Imperial College London, International Centre for Circulatory Health, NHLI, United Kingdom, ³University of Bern, Institute of Social and Preventive Medicine, Switzerland

Background and aims: The role of arteriolar retinal changes as a marker of cardiovascular disease is widely accepted, but the importance of venular changes has only recently been emphasised. We aimed to assess differences in the retinal microvasculature between diabetic and non-diabetic hypertensive individuals with multiple cardiovascular risk factors, and to assess whether their prognostic value differs between diabetic and non-diabetic individuals.

Materials and methods: This was a substudy of the Anglo-Scandinavian Cardiac Outcomes Trial (ASCOT), a randomised controlled multicenter trial assessing the effect of two antihypertensive regimens on coronary heart disease (CHD) endpoints. In addition to hypertension, individuals had to have at least 3 additional risk factors out of: diabetes mellitus (DM); left-ventricular hypertrophy; ECG abnormalities; peripheral arterial disease; previous stroke or transient ischaemic attack; male sex; age > 55 years; micro- or proteinuria; smoking; dyslipidemia; family history of premature CHD. Retinal analyses were performed on digital 30° images of superior and inferior temporal fields. Multiple linear regression was used to compare DM and non-DM groups, logistic regression was used to assess the association of retinal parameters with CHD events, all models were adjusted for age, sex, body mass index, smoking, antihypertensive and lipid-lowering treatment.

Results: The study included 720 individuals (160 DM, 560 non-DM) with 44 CHD events. Mean age±SD was 61.4±8.4 and 61.5±7.7 years (p=0.88), body mass index was 30.5±5.4 kg/m² and 28.8±4.3 kg/m², respectively (p<0.001). Antihypertensive treatment was equally distributed across the two groups but more patients used a lipid-lowering agent in the non-DM group (56.6 vs. 32.5%, p<0.001). Venular length to diameter ratio (LDR) was smaller in DM compared with non-DM (10.6±5.0 vs 11.4±5.0 pixels, p=0.04), venular vessels being shorter in DM compared with non-DM (461.5±184.1 vs 495.3±196.9 pixels, p=0.04), while diameters were comparable (42.5 ±5.7 and 41.9±4.9 pixels, p=0.18). Arteriolar LDR also differed between DM and non-DM (13.3±4.1 vs 14.7±5.0, p=0.001), the arterioles being shorter (447.2±103.4 vs 466.8±127.5 pixels, p=0.05) and wider (29.4±3.1 vs 28.3±3.1 pixels, p<0.001). Venular LDR was negatively associated with the risk to develop a first coronary event in DM (p=0.007) but not in non-DM (p=0.90). A similar association was also found between venular length and coronary events in DM (p=0.008) but not in non-DM (p=0.46). Venular diameter was not associated with the risk of CHD in either group and no associations were found between arteriolar LDR, diameter, or length and CHD.

Conclusion: In this treated hypertensive population diabetic people had shorter retinal vessels compared with non-diabetic individuals. Shorter venular length predicted CHD events in diabetic but not in non-diabetic individuals. These findings suggest that changes in retinal venular architecture may be useful in CHD prediction in diabetic individuals.

Changes in bone metabolism biomarkers in the ADOPT study

S.E. Kahn¹, W.H. Herman², R.R. Holman³, S.M. Haffner⁴, B. Zinman⁵, R.P. Aftiring⁶, B.G. Kravitz⁶, G. Paul⁷, N.P. Jones⁸, J.M. Lachin⁹, G.F. Viberti¹⁰, for the ADOPT Study Group

¹VA Puget Sound Health Care System, Seattle, United States, ²University of Michigan, Ann Arbor, United States, ³Diabetes Trials Unit, OCEM, Churchill Hospital, Oxford, United Kingdom, ⁴Medicine / Clinical Endocrinology, University of Texas Health Science Center, San Antonio, United States, ⁵Mount Sinai Hospital, Toronto, Canada, ⁶Metabolic Medicine Development Center, GlaxoSmithKline, King of Prussia, United States, ⁷Biomedical Data Services, GlaxoSmithKline, King of Prussia, United States, ⁸GlaxoSmithKline, Harlow, United Kingdom, ⁹The George Washington

University, Rockville, United States, ¹⁰King's College London School of Medicine, United Kingdom

Background and aims: ADOPT was a long-term randomized clinical trial comparing the effects of rosiglitazone (RSG), glibenclamide (GLIB) and metformin (MET) monotherapy on glycaemic control in patients with type 2 diabetes. Post-hoc safety data analysis revealed an increased risk for fracture in women treated with RSG compared with those treated with GLIB or MET. This analysis measured bone biomarkers in samples from the ADOPT study.

Materials and methods: Paired stored baseline and 12-month serum samples available from 1605 participants were assayed for selected bone metabolism biomarkers. Paired samples (46.6% of ADOPT participants at one year) were available from 299, 291 and 326 males and 250, 214 and 225 females in the RSG, GLIB and MET groups, respectively.

Results: More than 70% of the females were postmenopausal. Baseline characteristics (gender, menopausal status, glycaemia, blood pressure and lipids) in the subset of patients with available paired samples were similar to the overall study population.

Baseline values were similar between treatment groups for each analyte. Data were analyzed by gender and menopausal status. The pattern of change by treatment was similar for the male and female subgroups. Geometric means of the baseline 25-hydroxyvitamin D levels were low across all groups (60 nmol/l [24 ng/ml]).

Analyte	% Change from Baseline (n)		
	RSG	GLIB	MET
Aminoterminal propeptide of type I collagen (P1NP)	-10.0 (542)	-2.1 (502)*	-17.3 (547)*
C-telopeptide of collagen cross-links (CTX)	2.1 (491)	-3.9 (454)*	-8.3 (496)*
Parathyroid hormone (PTH)	-18.3 (492)	2.7(462)*	-14.5 (510)*
Estradiol	-11.5 (427)	-2.6 (426)*	-3.2(450)*
25-Hydroxyvitamin D	-4.0 (532)	-1.2 (493)	7.2 (543)*

*Statistically significant at level 0.05 compared with RSG, adjusted for multiple comparisons.

Conclusion: While the clinical relevance of these data is uncertain, the significant changes in C-telopeptide of collagen cross-links (CTX) and estradiol with RSG compared with GLIB and MET are directionally consistent with adverse effects on bone metabolism. Targeted interventions may be useful in mitigating the increased fracture risk with type 2 diabetes and thiazolidinedione (TZD) therapy; however, information on the effects of antidiabetic agents, and TZDs in particular, on bone metabolism from prospectively designed studies is required before making specific therapeutic recommendations.

The transcription factor RFX3 is critical for beta cell specification and differentiation

A. Ait-Lounis¹, C. Bonal², E. Barras¹, P. Herrera², W. Reith¹

¹Pathology and Immunology, ²Genetic Medicine and Development, University of Geneva Medical School, Switzerland

Background and aims: We have recently reported that mice lacking the transcription factor RFX3 exhibit a strong reduction in the number of cells expressing glucagon, insulin and ghrelin, whereas the number of cells expressing pancreatic polypeptide (PP) are markedly increased. This phenotype was documented mainly at stage E19.5, resulting into an absolute reduction of endocrine hormone-expressing cells.

Materials and methods: To further understand the temporal and cell-type specific role of RFX3 we have performed a detailed analysis of the pancreatic endocrine defects that arise in Rfx3^{-/-} mice during development, from the appearance of endocrine progenitor cells to their subsequent differentiation into specific cell lineages.

Results: The earliest marker of endocrine progenitor cells - the transcription factor Neurogenin3 (Ngn3) - was found to be expressed in normal numbers of cells and with a normal pattern during development. In contrast, significant reductions in the numbers of insulin and glucagon positive cells became evident by stage E15.5, during the secondary transition. The increase in PP-positive cells was observed as early as stage E13.5. We next examined the expression pattern of factors involved in early commitment to the alpha and/or beta cell lineages (mafb, arx, pax4, nkx2.2, nkx6.1) and of factors implicated in the subsequent differentiation and maturation of alpha (brn4, mafb) and beta cells (nkx6.1, pdx1, lapp). The expression of mafb, which is implicated in the initial commitment of both alpha and beta cells, was strongly reduced throughout development in Rfx3^{-/-} mice. The same was observed for all mature alpha cell markers examined, suggesting that the deficiency in RFX3 leads to an early block in alpha cell specification. In contrast, the numbers of cells expressing the beta cell marker Nkx6.1 were completely unaffected throughout development. Interestingly, the majority (70%) of these beta-lineage committed cells presented a maturation defect characterized by a marked reduction in insulin, IAPP and slc2a2 expression. Moreover, a fraction of these “immature” beta cells exhibited abnormal or “ectopic” PP expression. These results suggest that, in contrast to the early specification defect observed for alpha cells, the absence of RFX3 affects a later step in the specification or maturation of beta cells. The latter finding prompted us to explore a potential role of RFX3 in maintaining beta-cell maturity by performing siRNA knockdown experiments with the mouse insulinoma cell line MIN6. The inhibition of RFX3 expression in MIN6 cells led to a reduction in the expression of insulin and several mature beta cells marker, including pdx1, IAPP and slc2a2.

Conclusion: Taken together, the combined in vivo and in vitro results suggest that RFX3 is essential for both the terminal differentiation of beta cells and the maintenance of their mature phenotype.

TCF7L2 regulates cell proliferation and differentiation in the developing pancreatic epithelium

G. da Silva Xavier, R. An, A. McDonald, M.K. Loder, G.A. Rutter
Cell Biology, Imperial College, London, United Kingdom

Background and aims: Polymorphisms in the human TCF7L2 gene have been shown in recent whole genome studies to be associated with an increased risk of type 2 diabetes. TCF7L2, a transcription factor regulated by the Wnt/ β -catenin signaling pathway, has previously been implicated in the regulation of cell proliferation and differentiation. In this study we investigate the potential role of TCF7L2 in the regulation of embryonic pancreas development using E13.5 pancreatic epithelial explants or INSr α/β cells.

Materials and methods: siRNA against rat TCF7L2 were designed according to criteria set-out by Tuschl *et al* and synthesised using Ambion's Silencer siRNA kit (Ambion, TX). INSr α/β cells were kindly provided by Dr. Thomas

Mandrup-Poulsen and were cultured as previously described. Cells were transfected with siRNA using TransITTM-TKO (Mirus Bio Corporation, Madison), according to the manufacturer's instructions. Pancreatic epithelia were isolated from E13.5 rat embryos and were treated with 500 nM control or anti-TCF7L2 siRNA, or adenovirus encoding eGFP or hTCF7L2 (100 MOI), for ten days prior to RNA extraction. Primers for real-time PCR analysis were designed using Primer Express 3.0 (Applied Biosystems, CA) using rat mRNA sequences on the Ensembl database (<http://www.ensembl.org/>). Sequence specificity for all primers was verified using BLAST (<http://www.ncbi.nlm.nih.gov/blast/Blast.cgi>). Real time-PCR was performed on an ABI-Prism Fast 7500 device (Applied Biosystems, CA).

Results: TCF7L2 silencing in E13.5 rat epithelia led to a reduction of TCF7L2 mRNA of $44.3 \pm 2.04\%$, and complete blockade ($n = 3$ separate preparations with three pancreatic epithelia in each preparation) of development of endocrine buds and insulin-expressing cells after ten days of culture. The expression of a number of genes that are associated with differentiated endocrine cells was significantly decreased in comparison with control, namely preproinsulin ($98.8 \pm 3.58\%$), prohormone convertase 1 ($62.6 \pm 20.4\%$), and 2 ($73.6 \pm 17.2\%$), HNF-4 α ($74.9 \pm 12.5\%$), and HNF-1 β ($85.6 \pm 9.46\%$), and the cell proliferation marker, ki67 ($75.2 \pm 1.57\%$), whilst preproglucagon gene expression was enhanced ($179 \pm 7.46\%$). These phenomena were reversed by over-expression of TCF7L2 in E13.5 pancreatic epithelia that had been treated with siRNA. E13.5 epithelial cultures over-expressing TCF7L2 develop endocrine buds two days earlier than cultures treated with a control virus, and the size of the epithelial cores were 1.89 ± 0.28 -times larger than control epithelial cultures ($n = 9$). By contrast in INSr α/β cells the effect of silencing TCF7L2 on preproinsulin gene expression was minimal even though preproglucagon gene expression was increased compared to control, as observed in the E13.5 epithelial cultures.

Conclusion: TCF7L2 is expressed during pancreatic development and is required for normal β -cell development and β -cell specific gene expression from E13.5 in pancreatic epithelial explants. Thus, decreases in TCF7L2 may contribute to an elevated risk of developing diabetes by affecting the development of β -cells from pancreatic islet progenitor cells. Further studies will be required to determine whether effect of TCF7L2 silencing on endocrine cell development is due to effects on the proliferation of progenitor cells, stalling of the differentiation programme, or a combination of both.

Role of cadherin-mediated cell-cell adhesion in transdifferentiation of pancreatic acinar cells

K. Minami¹, H. Okano¹, S. Seino^{1,2}

¹Division of Cellular and Molecular Medicine, ²Division of Diabetes, Metabolism, and Endocrinology, Kobe University Graduate School of Medicine, Kobe, Japan

Background and aims: Recent studies have revealed unexpected plasticity of adult cells in their differentiation capacity. We have demonstrated that insulin-secreting cells can be generated from pancreatic acinar cells of adult mouse in vitro, using Cre/loxP-based direct cell lineage tracing. However, little is known of the mechanism of the transdifferentiation. Our aim is to clarify the mechanism of transdifferentiation of pancreatic acinar cells into insulin-secreting cells.

Materials and methods: Pancreatic acinar cells were isolated from streptozotocin-injected (200 mg/kg, i.p.) mice, and cultured in suspension with 20 ng/ml EGF in the presence or absence of signaling inhibitors (PD98059 for MEK, SB203580 for p38 MAPK, SP600125 for JNK, and LY294002 for PI3-kinase). Changes in mRNA expression of genes were quantified by real-time RT-PCR analysis. Activation of intracellular signaling was evaluated by immunoblotting of phospho-specific antibodies.

Results: Enzymatic dissociation of pancreas caused destruction of cadherin-mediated cell-cell adhesion and activation of EGF receptor in pancreatic acinar cells. The isolated acinar cells formed smooth spheroids within a few days in suspension culture. Insulin expression gradually increased during the culture. Genes characteristic of pancreatic β -cells also were induced. Insulin secretion in the newly-made cells was stimulated by KCl (30 mM), glibenclamide (100 nM), and glucose (20 mM). However, in the presence of LY294002 (10 μ M), induction of the genes characteristic of pancreatic β -cells was significantly suppressed and no insulin secretion was detected, demonstrating that PI3-kinase is essential for the transdifferentiation of pancreatic acinar cells into insulin-secreting cells. Interestingly, we found that spheroid formation

was blocked in the presence of the PI3-kinase inhibitor, suggesting that cell-cell interaction is involved in the transdifferentiation process. Indeed, when spheroid formation was inhibited by the addition of neutralizing antibody against E-cadherin, the induction of genes required for glucose-induced insulin secretion was significantly suppressed. Moreover, we found that E-cadherin and β -catenin, major components of cadherin-mediated cell-cell adhesion in isolated acinar cells, were degraded in the presence of LY294002, while removal of the inhibitor upregulates both E-cadherin and β -catenin, thereby leading to transdifferentiation into insulin-secreting cells.

Conclusion: Destruction and remodeling of cadherin-mediated cell-cell adhesion is critical in transdifferentiation of pancreatic acinar cells into insulin-secreting cells, in which the PI3-kinase pathway plays an essential role.

p27^{kip1} is a critical checkpoint for adult mouse islet regeneration during hyperglycaemia adaptation

B.R.S. Hsu, S.-H. Fu, S.-T. Chen

Internal Medicine, Chang-Gung Memorial Hospital, Taoyuan Hsien, Taiwan

Background and aims: Enhancing adult islet regeneration is a potential means of treating diabetes mellitus. However, it is not yet clear which mechanism controls adult islet cell regeneration. We intend to study the role of p27^{kip1} on adult mouse islet regeneration.

Materials and methods: We first cultured 12 weeks old male C57BL/6 mouse islets and used polyacrylamide gel electrophoresis (PAGE), western blotting and immunostaining to investigate the effect of glucose on changes of cell cycle proteins. We then used p27^{kip1} gene silencing to study the effect of p27^{kip1} on growth-related proteins and function of adult pancreatic islet cells.

Results: We used PAGE, western blotting and immunostaining to determine profiles of cell cycle proteins of adult mouse islets and found that p27^{kip1} (G1/G0 checkpoint) reduced 52% and 39% and cyclin B1 (G2/M) elevated 7-fold and 12-fold after one day (day 1) of culture in 5 mM and 20 mM glucose, respectively, when compared to that of day 0. The levels of p27^{kip1} protein of islets cultured in both 5 and 20 mM glucose elevated progressively during cultivation. The elevation slope of p27^{kip1} of islets cultured in 20 mM glucose was only 64% of that of islets cultured in 5 mM glucose. Proteins of D1 (G1/S), B1 (G2/M), and FoxM1 of islets cultured in 5 mM decreased gradually during cultivation. On the contrary, D1, B1, and FoxM1 of islets cultured in 20 mM increased progressively. We then used p27^{kip1} gene silencing to study the effect of p27^{kip1} on growth-related proteins and function of adult pancreatic islet cells. Lentivirus carrying small interfering RNA duplex (siRNA) reduced 78% (n=6) and 81% (n=6) of p27^{kip1} protein in adult male mice islets after 3 and 7 days of cultivation, respectively. Proteins of D1, B1, and FoxM1 in p27^{kip1} gene silencing islets were 3.0, 1.5, and 1.9 times and 1.0, 1.3, and 2.8 times of that of the control islets after 3 and 7 days culture, respectively. Glucose-stimulation insulin secretion tests revealed that stimulation index (SI) and insulin secretion (IS, ng/islet \times 60min) of p27^{kip1} gene silencing islets did not differ significantly from that of control islets at 3 and 7 days of culture (Day 3: gene-silencing islet: SI=2.6 \pm 0.3 (n=6), IS=0.19 \pm 0.02; control islet: SI=2.8 \pm 0.4 (n=10), IS=0.20 \pm 0.02) (Day 7: gene-silencing islet: SI=2.4 \pm 0.3 (n=6), IS=0.24 \pm 0.09; control islet: SI=2.6 \pm 0.3 (n=12), IS=0.17 \pm 0.02).

Conclusion: Suppression of p27^{kip1} rapidly up-regulates growth-related cell cycle proteins including D1, B1, and FoxM1 in adult mouse islets. Our data suggest that p27^{kip1} is a critical checkpoint for adult mouse islet regeneration during hyperglycemia adaptation.

Role of EGF-receptor signalling in physiological beta cell mass expansion

E. Hakonen¹, J. Ustinov¹, P. Ormio¹, N. De Medts², L. Bouwens², P.J. Miettinen¹, T. Otonkoski¹

¹Biomedicum Stem Cell Center, Hospital for Children and Adolescents, University of Helsinki, Finland, ²Cell Differentiation Unit, Free University of Brussels, Belgium

Background and aims: Better understanding of beta-cell regeneration mechanisms is important for the generation of new therapeutic approaches for diabetes. Beta-cell mass is known to increase in response to insulin demand and during pancreatic regeneration induced by injury. Epidermal growth factor receptor (EGF-R) signaling is required for normal pancreatic beta-cell de-

velopment and proliferation. In this study we investigated the role of EGF-R signaling in physiological situations of beta-cell mass expansion.

Materials and methods: E1-DN mice, which have a kinase negative EGF-receptor under the Pdx-1 promoter, and wild type (WT) mice were subjected to high fat diet (HF-diet) or partial pancreatic duct ligation (PDL). The mice were kept on HF-diet or standard chow for 8 weeks. BrdU was added to the drinking water (1 mg/ml) for long-term labeling of proliferating beta-cells. Intraperitoneal glucose tolerance test (IPGTT) was done on weeks 4 and 8. Morphometrical analysis of the pancreata was performed at 8 weeks. In the PDL model the pancreatic duct of 8 weeks old E1 and WT mice was partially ligated. After one week the tail and head parts of the pancreata were collected. Morphometrical analysis of the pancreata was performed. Beta-cell mass, islet size and distribution were analyzed.

Results: After 8 weeks on HF-diet E1-DN mice (n=6) were clearly diabetic in IPGTT (2h b-gluc=26 mmol/L) compared to E1-DN mice (n=5) on standard chow (2h b-gluc=15 mmol/L, p<0.01). WT mice on HF-diet (n=6) had mildly impaired glucose tolerance in IPGTT (2h b-gluc=14 mmol/L) compared to WT mice (n=6) on standard chow (2h b-gluc=10 mmol/L, p<0.01). HF-fed WT mice could increase their beta-cell surface area by 67 % (n=3, p<0.05) compared with those on standard chow, while the response in HF-fed E1-DN mice was only 19 % (n=3). WT mice had 30% more proliferating beta-cells compared to E1-DN mice (p<0.05). Surprisingly, we did not detect any significant difference in beta-cell proliferation between WT mice on standard chow vs. WT mice on HF-diet or between the two E1-DN groups. There was no difference in beta-cell apoptosis (immunohistochemistry for activated caspase 3) between the four groups. After partial duct ligation beta-cell surface area in the tail part of pancreas was increased by 300 % compared to the head part of pancreas in WT mice (n=3) and by 389% in E1-DN mice (n=3). However the total beta-cell surface area, islet number and size in the tail part remained smaller in E1-DN mice (islet size 2.6 vs. 3.7 μ m², islet number 3.7 vs. 5.9 islets/mm², n=3 in each group).

Conclusion: When fed on HF-diet, WT mice showed marked beta-cell hyperplasia, whereas the hyperplastic response of E1-DN mice was insufficient to maintain normoglycaemia. Partial duct ligation induced islet neogenesis in both WT and E1-DN mice. However, the number and size of the regenerating islets remained smaller in the E1-DN mice. These results suggests that EGF-R signaling is required for beta-cell mass expansion both in HF-diet induced insulin resistance and in pancreatic regeneration after partial duct ligation.

Attempted beta cell regeneration from replication independent sources in a rat model of type 2 diabetes

E. Manesso¹, G.M. Toffolo¹, Y. Saisho², A.E. Butler², R. Galasso², P.C. Butler², C. Cobelli¹

¹Department of Information Engineering, University of Padova, Italy,

²Department of Medicine, Larry Hillblom Islet Research Center, UCLA David Geffen School of Medicine, Los Angeles, United States

Background and aims: Type 2 diabetes (T2DM) is characterized by decreased beta cell mass, increased beta cell apoptosis and islet amyloid derived from islet amyloid polypeptide (IAPP). The human IAPP transgenic (HIP) rat reproduces this islet phenotype reaching a steady state beta cell deficit comparable to humans with T2DM at ~12 months of age. There is controversy as to whether a replication independent (RI) pathway for beta cell formation exists, and if so, if there is attempted beta cell regeneration through this mechanism to offset beta cell loss in T2DM. We addressed this by developing a model for beta cell turnover that resolves input from replication (R) and RI sources and applying it to non-diabetic wild type (WT) versus T2DM HIP rats.

Materials and methods: Beta cell mass (fractional insulin positive area \times pancreas weight), M [mg], the frequency of beta cell replication (Ki67 and insulin positive cells), R [%], and beta cell apoptosis (TUNEL and insulin positive cells), A [%], were measured in WT (n=20) and HIP (n=22) rats age 2, 5, 10 and 18 months. To establish conversion factors for both beta cell replication and apoptosis from frequency to rate, rat islet cells were cultured for 16-48 hrs and imaged by time-lapse video-associated microscopy and then immunostained for insulin and Ki67 or TUNEL. We modeled beta cell turnover by a dynamic equation supposing either the absence (M1) or the presence (M2) of a replication independent source (RI [mg/month]) of beta cell formation i.e. M1: $dM(\text{age})/d\text{age} = [\alpha_R \cdot R(\text{age}) - \alpha_A \cdot A(\text{age})] \cdot M(\text{age})$; M2:

$dM(\text{age})/d\text{age} = [\alpha_R \cdot R(\text{age}) - \alpha_A \cdot A(\text{age})] \cdot M(\text{age}) + RI(\text{Age})$, where α_R and α_A are conversion factors from frequency to rate.

Results: Changes in beta cell mass in both WT and HIP rats required beta cell formation from RI. From 2–18 months of age beta cell mass increased by 52 mg in WT, and decreased by 15 mg in HIP rats. This loss was due to a ~30 fold greater loss of beta cells through apoptosis in HIP versus WT rats (2,472 Vs 92 mg), but the extent of the loss was offset by a ~30 fold increase in new cell formation from RI in HIP versus WT rats (2,267 vs 77 mg) and a more modest contribution from R (190 vs 67 mg).

Conclusion: By use of novel model for beta cell turnover we conclude, (1) in the WT rat beta cell turnover includes comparable input from replication and replication independent sources, (2). In the HIP rat model of T2DM, increased beta cell apoptosis is partially countered by a marked increase in beta cell formation, but the contribution from replication independent sources is ten fold greater than that from replication. These data imply that in this model of T2DM in rats there is a substantial adaptive capacity for beta cell regeneration from replication independent sources that is overcome by apoptosis.

Metabolic adaptations in the early stage of insulin resistance measured *in vivo* by ^{31}P and ^1H MRS in skeletal muscle

N.M.A. van den Broek¹, H.M.M. De Feyter^{1,2}, K. Nicolay¹, J.J. Prompers¹

¹Department of Biomedical Engineering, Eindhoven University of Technology, Netherlands, ²Department of Diagnostic Radiology, Yale University, New Haven, United States

Background and aims: Current knowledge indicates that the pathology of insulin resistance involves metabolic alterations in several tissues, including skeletal muscle. Recent experiments have shown that mitochondrial oxidative phosphorylation and expression of genes involved in oxidative phosphorylation are reduced in muscle of insulin-resistant patients. Decreased muscle fat oxidation can favor the accumulation of intramyocellular lipids (IMCL), which has been associated with reduced insulin sensitivity. Therefore, impairments of mitochondrial oxidative capacity might be a major risk factor predisposing individuals to develop insulin resistance. We investigated skeletal muscle oxidative capacity and IMCL content in a rat model of early, lifestyle-induced insulin resistance using *in vivo* ^1H and ^{31}P magnetic resonance spectroscopy (MRS).

Materials and methods: Ten, 14 week old Wistar rats were put on a high fat diet (HFD, 45.7 En% fat) for 2 weeks (HF) and a control group of 10 Wistar rats received normal chow (9 En% fat) (NC). After an oral glucose tolerance test (OGTT) (1 g/kg body weight), IMCL was measured separately in both glycolytic (TA1) and oxidative (TA2) tibialis anterior muscle (TA) with *in vivo* ^1H MRS and oxidative capacity was measured in mixed TA with *in vivo* ^{31}P MRS. Data were analyzed statistically by applying two-tailed t-tests. Data are presented as means \pm SD.

Results: At 16 weeks of age (weight HF: 426 g, NC:385 g), the HF animals showed a significantly lower ratio for the area under the curve (AUC) for glucose and the AUC for insulin (figure 1a, b) during the OGTT compared to NC animals ($AUC_{\text{glucose}}/AUC_{\text{insulin}}$: 016 mM-h / pM-h vs 0.033 mM-h / pM-h respectively). This indicates that 2 weeks of HFD induces insulin resistance. IMCL levels were about 3 times higher in HF compared to NC rats for both voxels (TA1: 0.23 ± 0.05 % vs. 0.07 ± 0.03 %, $p < 0.0001$ and TA2: 0.46 ± 0.08 % vs. 0.14 ± 0.04 %, $p < 0.0001$) (figure 1c).

The phosphocreatine recovery time constant, τ_{PCr} , which is a measure for oxidative capacity, was shorter in HF compared to NC animals (70.7 ± 8.3 s and 85.7 ± 12.1 s, respectively, $p = 0.005$) (figure 1d).

Conclusion: We found that, in a rat model of early, HFD-induced insulin resistance, IMCL levels were elevated in TA. Interestingly, *in vivo* skeletal muscle oxidative capacity was higher in the rats with glucose intolerance compared to control rats. This can be explained as an adaptation to overfeeding of the mitochondria. Persistent overfeeding might have more detrimental effects in the long term. As part of a longitudinal study, we will study the same animals also during a more advanced stage of insulin resistance. In conclusion, mitochondrial dysfunction does not play a role in the early stage of insulin resistance in a validated animal model of lifestyle-induced insulin resistance.

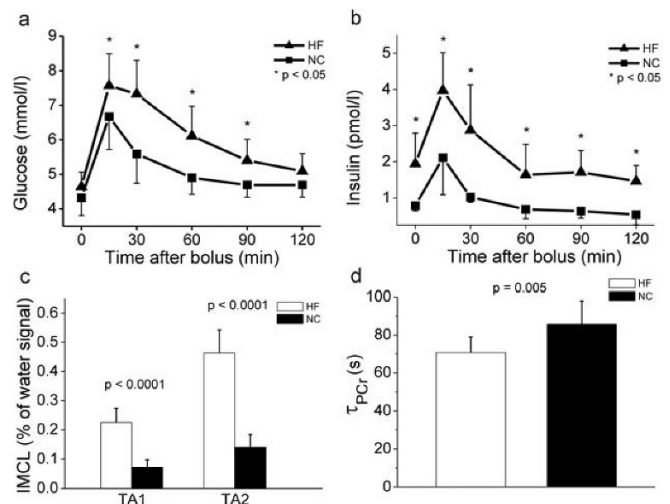

Figure 1. Glucose (a) and insulin (b) concentrations during OGTT. Mean IMCL (in glycolytic (TA1) and oxidative (TA2) TA) (c) and τ_{PCr} for HF and NC rats ion TA. Data are presented as means \pm SD

32

Regulation of fat storage in human subcutaneous adipose tissue over a 24-hour period

F. Karpe, T. Ruge, L. Hodson, B. Fielding, S.M. Humphreys, L. Dennis, J. Cheeseman, K.N. Frayn
Oxford Centre for Diabetes Endocrinology and Metabolism, University of Oxford, United Kingdom

Background and aims: Human adipose tissue stores fat from chylomicron triglycerides (TG), very low density lipoprotein (VLDL) TG and directly from non-esterified fatty acids. The contribution of these different sources for fatty acid storage in adipose tissue and how that changes in response nutritional state is not well known.

Materials and methods: Abdominal subcutaneous adipose tissue FA handling was studied over a 24h period in eight healthy men by the combination of arterio-venous blood sampling, quantification of blood flow and the use of stable isotope-labelled FA tracers in response to three nutritionally similar meals with 5h intervals.

Results: The efficiency of adipose tissue FA uptake increased with each meal, and the chylomicron-TG was the dominating source of FA. The initial fractional extraction of chylomicron-TG increased from 21 ± 4 to $47 \pm 8\%$ ($p=0.03$) between the first and the last meal. Although lipoprotein lipase rate of action increased with time (approximately 2-fold), there was an even greater increase in the efficiency of FA re-esterification (approximately 3-fold), which led to a reduced spillover fraction of chylomicron-derived FA, from 77 ± 15 to $34 \pm 7\%$ ($p=0.04$) comparing the end of the first and the third meal period, respectively. Glucose extraction by the tissue was not enhanced by meal sequence. Uptake of VLDL-derived FA was particularly noticeable in the last meal period but spillover of VLDL-derived FA was only seen in the fasting state.

Conclusion: There is a considerable induction of fat storage capacity in the healthy human adipose tissue that is not appreciated in short-term studies. Supported by: British Heart Foundation

Lipidomic characterisation of the human liver: diacylglycerols but not ceramides associate with liver fat content

A. Kotronen¹, T. Seppänen-Laakso², J. Westerbacka¹, J. Arola³, A.-L. Ruskeepää², M. Orešič², H. Yki-Järvinen¹

¹Department of Medicine, University of Helsinki, Finland, ²Technical Research Centre of Finland, Espoo, Finland, ³Department of Pathology, University of Helsinki, Finland

Background and aims: Studies in animals have shown that fat may induce insulin resistance via ceramides or diacylglycerols. Dietary interventions and tracer studies in humans suggest dietary saturated fatty acids and saturated fatty acids formed by de novo lipogenesis associate with liver fat. There are no data regarding levels of ceramides or diacylglycerols or individual triacylglycerols and their fatty acid composition in the human liver.

Materials and methods: In the present study, we approached these questions by analyzing human liver biopsies from 16 subjects, whose liver fat, as determined by histology, ranged between 1 and 90%. Increased liver fat (>10% macrovesicular steatosis, $n=8$) was due to non-alcoholic causes. In each liver biopsy, concentrations of 253 lipids were determined using ultra performance liquid chromatography coupled to mass spectrometry (UPLC/MS), and fatty acid composition using gas chromatography.

Results: The number of double bonds in triacylglycerols were negatively related to the correlation coefficients between individual triacylglycerols/total triglyceride and liver fat % ($r=-0.57$, $p<0.0001$), implying that the more saturated the triacylglycerols, the more fat the liver contains. Analyses of fatty acids revealed that liver fat content was negatively related to the concentrations of long polyunsaturated fatty acids, e.g. arachidonic (20:4n-6, $r=-0.70$, $p=0.002$) and docosahexanoic (22:6n-3, $r=-0.63$, $p=0.009$) acids, and positively to saturated and monounsaturated fatty acids, such as palmitic (16:0, $r=0.69$, $p=0.003$) and oleic (18:1n-9, $r=0.69$, $p=0.004$) acids, and to SCD1 activity (18:1/18:0, $r=0.70$, $p=0.003$) in the liver. Liver fat content was not related to total ceramide ($r=0.21$, NS) or sphingomyelin ($r=0.07$, NS) content normalized to phospholipids, but was positively related to hepatic phospholipid-normalized diacylglycerol content ($r=0.71$, $p=0.002$). The absolute amount of palmitate (16:0) was not related to ceramides ($r=0.02$, NS).

Conclusion: The results suggest that hepatic fat accumulation due to non-alcoholic causes is associated with the enrichment of saturated and monoun-

saturated fatty acids, and with depletion of polyunsaturated fatty acids. Levels of diacylglycerols but not ceramides increase with increasing liver fat content.

Changes of mitochondrial function and hepatocellular lipid content in relation to insulin sensitivity in women with a history of gestational diabetes

A. Kautzky-Willer¹, T. Prikoszovich¹, C. Winzer¹, A.I. Schmid^{2,3}, J. Szendroedi^{2,4}, M. Chmelik^{2,3}, G. Pacini⁵, M. Krssak³, E. Moser³, S. Trattig³, P. Nowotny¹, W. Waldhäusl¹, M. Roden^{2,4}

¹Department of Internal Medicine III, Division of Endocrinology and Metabolism, Medical University of Vienna, Austria, ²Karl-Landsteiner Institute of Endocrinology and Metabolism, Vienna, Austria, ³High-Field Magnetic Resonance Centre of Excellence, Medical University of Vienna, Austria, ⁴1st Medical Department, Hanusch Hospital, Vienna, Austria, ⁵Institute of Biochemical Engineering, National Research Council, Padova, Italy

Background and aims: Excessive lipid storage and reduced mitochondrial ATP-synthesis are present in type 2 diabetics with insulin resistance (T2DM) and their relatives. Women with a history of gestational diabetes (pGDM) show subtle alterations in glucose metabolism frequently with features of the metabolic syndrome and represent an important group at increased risk for development of T2DM. Here, we tested the hypothesis that changes of mitochondrial function and hepatocellular lipid content relate to glucose metabolism also in women with pGDM.

Materials and methods: We investigated 23 pGDM and 8 women with normal glucose tolerance during their pregnancies (CON) at 4-5 years after delivery. All women were glucose tolerant and comparable regarding age, BMI and physical activity. The glucose tolerance status and the insulin sensitivity were obtained by an oral (75g-oGTT; OGIS) and intravenous glucose tolerance test (IVGTT; S_i), respectively. The intramyocellular (IMCL) as well as the hepatocellular (HCL) lipid contents were determined by ¹H MR spectroscopy, myocellular fluxes through ATP synthase (fATP) and creatine kinase (fCK) by ³¹P MR spectroscopy. Insulin resistance was defined by an OGIS lower than $463 \text{ ml} \cdot \text{min}^{-1} \cdot \text{m}^{-2}$.

Results: pGDM showed a higher body fat mass (24.5 ± 1.3 vs. $18.0 \pm 1.4 \text{ kg}$; $p=0.02$), but lower HDL-cholesterol ($p=0.02$) and insulin sensitivity (447 ± 14 vs. $508 \pm 31 \text{ ml} \cdot \text{min}^{-1} \cdot \text{m}^{-2}$; $p=0.05$) versus CON. Their fATP was 13% lower compared with CON (10.5 ± 0.9 vs. $12.1 \pm 0.5 \text{ } \mu\text{mol} \cdot \text{g} \text{ muscle}^{-1} \cdot \text{min}^{-1}$; $p<0.05$), while no difference was observed in fCK. IMCL was elevated only in insulin-resistant women and 69% higher than in insulin-sensitive women (0.91 ± 0.08 vs. $0.54 \pm 0.08\%$; $p<0.003$). HCL was increased more than twofold in pGDM versus CON (3.6 ± 0.8 vs. $1.5 \pm 0.3\%$; $p<0.02$), as well as in insulin-resistant versus insulin-sensitive subjects (4.0 ± 1.1 vs. $2.0 \pm 0.5\%$; $p<0.03$). fATP correlated with plasma adiponectin ($p<0.04$; $r=0.44$) in all women and with usCRP in the insulin-resistant subgroup ($p<0.004$; $r=0.74$). HCL related to body fat mass ($p<0.01$; $r=0.50$) and insulin sensitivity (S_i , $p=0.050$; $r=-0.46$).

Conclusion: Glucose tolerant women with a history of gestational diabetes and blunted insulin sensitivity exhibit lower muscular mitochondrial function and augmented hepatic lipid accumulation suggesting the operation of similar pathogenic mechanisms as in modifications in relatives of T2DM.

35

High intramuscular triglyceride concentration and low turnover distinguish pre-diabetes from obesity in humans

L. Perreault, B.C. Bergman, M.C. Playdon, R.H. Eckel
University of Colorado Health Sciences Center, Aurora, United States

Background and aims: High intramuscular triglyceride (IMTG) concentration has been repeatedly observed in people with, or at risk for, type 2 diabetes. Whether IMTG is causative, or simply a marker, of processes underlying diabetes is controversial. Therefore, the current study examined intramuscular triglyceride (IMTG) concentration, as well as its saturation and turnover, in people with pre-diabetes before and after exercise.

Materials and methods: A pre-diabetes group (PD; $n=20$) and normal glucose tolerant control group (NGT; $n=19$) were matched for age and anthropometry. Insulin action and secretion were assessed using an intravenous glucose tolerance test (IVGTT). [¹³C]palmitate was infused for 4 hours prior and throughout 1.5 hours of treadmill walking at 50% VO₂max. IMTG

concentration was measured by GC/MS, and turnover by GC/C/IRMS, from muscle biopsies taken immediately before and after exercise. Muscle biopsies were dissected free of visible fat and lyophilized, after which lipid fractions were isolated using solid phase extraction and derivatized to fatty acid methyl esters prior to analysis.

Results: Fasting and 2-hour glucose concentrations were higher in PD vs. NGT (fasting [glucose] 106 ± 1.8 vs. 92 ± 1.2 mg/dl, 2h [glucose] 137 ± 10.3 vs. 101 ± 4.5 mg/dl, $p < 0.05$ for both), by study design, otherwise age (57 ± 1.4 vs. 58 ± 1.6 years), body mass index (32 ± 1.0 vs. 31 ± 1.0 kg/m²), body fat (35 ± 1.8 vs. 37 ± 1.8 %), and VO₂max (25 ± 1.3 vs. 22 ± 1.3 ml O₂/kg/min) were not different. Furthermore, whole-body substrate use and circulating concentrations of insulin, glucagon, free fatty acids, glycerol, lactate and catecholamines were not different between groups at rest or during exercise. Insulin action (Si) at baseline was similar between the groups, but insulin secretion (AIR & DI) was significantly lower in PD (AIR 146 ± 24 vs. 428 ± 67 μ U/ml, DI 375 ± 60 vs. 1231 ± 145 $\times 10^{-4}$ /min, PD vs. NGT, $p < 0.01$ for both). Basal IMTG concentration was higher (43.1 ± 5.2 vs. 23.5 ± 6.3 μ g/mg dry weight, $p = 0.04$) and turnover lower (0.24 ± 0.04 vs. 0.37 ± 0.5 %/hr, $p = 0.05$) in PD vs. NGT, whereas no such differences were seen for diacylglycerol (DAG) at baseline. No differences were observed in IMTG or DAG concentration or turnover during exercise, or in IMTG and DAG saturation at any time point. IMTG turnover during exercise correlated with DI, but not Si, in both groups ($R^2 = -0.438$, $p = 0.03$). Analyses were performed using repeated measures ANOVA.

Conclusion: The current study demonstrates that in groups matched for obesity, higher IMTG concentration and lower IMTG turnover, distinguish pre-diabetes from NGT. Diacylglycerol and fatty acid saturation of intramuscular lipids do not appear a major point of differentiation. Insulin secretion, rather than insulin action, was lower in pre-diabetes and correlated with IMTG turnover. How, or if, IMTG turnover influences insulin secretion, or vice versa, remains to be determined.

University of Melbourne, Australia, ⁶Department of Pharmacology and Toxicology, Radboud University Nijmegen Medical Centre, Netherlands

Background and aims: The AMP-activated protein kinase (AMPK) pathway is intact in type 2 diabetes patients and is seen as a target for the treatment of this disease. Here, for the first time, we assessed the effect of the AMPK activator 5-aminoimidazole-4-carboxamide riboside (AICAR) on both glucose and fatty acid metabolism *in vivo* in type 2 diabetes patients.

Material and methods: Stable isotope methodology with blood and muscle biopsy sampling were combined to assess glucose and fatty acid kinetics following continuous intravenous infusion of AICAR (0.75 mg.kg⁻¹.min⁻¹) and/or saline in 10 male, type 2 diabetes patients (age: 64 ± 2 y; BMI: 28 ± 1 kg/m²).

Results: Plasma glucose rate of appearance (Ra) was reduced following AICAR administration, while plasma glucose rates of disappearance (Rd) were equal in the AICAR and control test. Consequently, blood glucose disposal (Rd expressed as % of Ra) was increased following AICAR infusion ($P < 0.001$). Accordingly, a greater decline in plasma glucose concentration was observed following AICAR infusion ($P < 0.001$). Plasma FFA Ra and Rd were both significantly reduced in response to AICAR infusion, which was accompanied by a significant net decline in plasma FFA concentration. Although the phosphorylation state of AMPK in skeletal muscle was not increased, we observed a significant rise in the phosphorylation of acetyl-CoA carboxylase (ACC; $P < 0.001$).

Conclusion: We conclude that intravenous AICAR administration reduces hepatic glucose output and augments glucose disposal, thereby lowering blood glucose concentrations *in vivo* in type 2 diabetes patients. Furthermore, AICAR administration stimulates hepatic fatty acid oxidation and/or inhibits whole-body lipolysis, thereby reducing plasma FFA concentrations.

Use of a GLUT4 translocation assay strategy to identify new insulin sensitizers with efficacy *in vitro* and *in vivo*

J.C. Molero¹, N. Konstantopoulos¹, C. Hohnen-Behrens², J. Ye², D. Segal¹, G. Collier¹, K. Walder¹, D.E. James²

¹School of Exercise and Nutrition Sciences, Deakin University, Warrnambool, ²Diabetes and Obesity Program, Garvan Institute of Medical Research, Darlinghurst, Australia

Background and aims: The aim of the current study was to identify new insulin sensitising agents from a small molecule library using a GLUT4 translocation assay screening strategy.

Materials and methods: We employed a fluorescence-based HA-GLUT4 translocation assay to determine the amount of GLUT4 present at the cell surface of differentiated rat L6 myotubes. The cells were rendered insulin-resistant using 0.3 mM palmitate for 16 h (68% decrease in GLUT4 content at the cell surface compared with myotubes incubated with 100 nM insulin for 20 min in the absence of palmitate). Insulin resistant L6 myotubes were then treated with small molecules from a library of ~1500 compounds at 10 μ M for 60 min. Positive hits were selected for their ability to increase GLUT4 content at the cell surface. Hits were further tested for their ability to reverse other models of insulin resistance in cultured 3T3-L1 adipocytes: chronic insulin stimulation (10 nM for 48 h), dexamethasone (500 nM for 8 days) or glucose oxidase (100 mU for 2 h). To test the *in vivo* efficacy of the lead compound, we examined its effect on glucose tolerance in insulin resistant high fat fed (HFF) mice (60% calories from saturated fat for 6 weeks). The lead compound was administered with the food for the last 4 weeks.

Results: Using this cell-based GLUT4 translocation assay, we identified 8 compounds that reversed the inhibitory effect of palmitate on insulin stimulated GLUT4 translocation in L6 myotubes. The magnitude of the protective effect was variable between the compounds: 30 – 40% rescue, $p < 0.05$ (compounds designated as VVP086, VVP412 and VVP708); 60 – 70% rescue, $p < 0.01$ (VVP326, VVP593, VVP600 and VVP912); $>80\%$ rescue, $p < 0.005$ (VVP443). These compounds did not have a significant effect on GLUT4 translocation in the absence of insulin. We then tested the efficacy of these compounds on several models of insulin resistance in 3T3-L1 adipocytes. While several compounds were able to reverse insulin resistance induced by either chronic insulin stimulation, dexamethasone or glucose oxidase, VVP326, the berberine analog palmatine, achieved a significant effect in all models tested. We examined the effects of palmatine on glucose homeostasis in HFF mice. Palmatine (50 mg/Kg) administered with the food for 4 weeks ameliorated glucose intolerance in HFF mice (23% decrease in the area under the curve compared with control HFF mice $p < 0.05$, $n = 8$ /group). This effect was accompanied by a 55% reduction in body weight gain ($p < 0.01$).

Conclusion: The GLUT4 translocation assay successfully identified a number of new compounds with insulin sensitising properties. Palmatine showed efficacy in all cellular insulin resistant models tested and ameliorated the glucose intolerance associated with high fat feeding in mice. The GLUT4 translocation assay is a useful screen for novel insulin sensitising agents and the hit compounds identified in this study represent potential targets for the development of new diabetes therapeutics.

PPAR-sparing insulin sensitizers; path for development and clinical evaluation

J.R. Colca¹, W.G. McDonald¹, R. Malapaka², H.E. Xu², R.F. Kletzien¹

¹Metabolic Solutions Dev Co, Kalamazoo, ²Van Andel Research Institute, Grand Rapids, United States

Background and aims: We have proposed that development of insulin sensitizer therapies has been delayed because of focus on nuclear receptor activation. Further, superior pharmacological profiles, [e.g., less plasma volume expansion (and edema) as well as greater reductions in blood pressure and corrections of dyslipidemia] might be obtained by minimizing direct activation of nuclear receptors. These studies seek to establish whether a series of

insulin sensitizers could be established that limit or avoid interaction with nuclear receptors. We also aim to directly benchmark a prototype “PPAR-sparing” compound against pioglitazone in the clinic.

Materials and methods: Sixty novel analogs were generated and evaluated for PPAR γ binding activity with a fluorescence polarization assay (Invitrogen) using rosiglitazone as a positive control. Selected compounds were tested for anti-diabetic activity in KKAY mice. Compounds (10–100 mg/kg/day) were given by oral gavage for 4 days and fasting plasma glucose, insulin, and triglycerides were measured. To determine whether these compounds might interact with other PPAR transcription factors, AlphaScreen assays were set up with twelve nuclear receptor cofactor peptides for PPAR γ , PPAR α , and PPAR δ using positive controls rosiglitazone, GW7647, and GW0742, respectively. A preclinical package was developed for testing a prototype PPAR-sparing analog in human clinical trials. Phase IA (single dose) and Phase IB (seven doses) were completed in comparison to 45 mg pioglitazone in normal human volunteers.

Results: The novel analogs demonstrated a range in binding to PPAR γ as compared to rosiglitazone. Five analogs demonstrated little to no binding to PPAR γ even at 100 μ M compound. Forty percent of the novel analogs have demonstrated anti-diabetic pharmacology in vivo. The ability of the analogs in this series to lower circulating levels of glucose, insulin, and triglycerides in KKAY mice demonstrates no correlation with PPAR γ binding. The PPAR-sparing analogs with anti-diabetic activity were also tested in the AlphaScreen assays for all three PPAR subtypes. The PPAR γ sparing nature of the compounds established from initial direct binding studies was confirmed. None of the compounds interacted with PPAR δ . The interaction with PPAR α was either similar to or less than pioglitazone. A preclinical support package was created for the prototype PPAR-sparing analog that supports clinical testing at up to 50% higher exposure relative to pioglitazone (and its active metabolites) for 28 days. Phase IA and Phase IB clinical studies were completed demonstrating no safety concerns, a twelve hour half-life, steady state circulating levels of active drug after two days of dosing, and the expected increase in circulating biomarker, adiponectin.

Conclusion: We conclude that it is possible to create PPAR sparing compounds with anti-diabetic pharmacology. We are now exploring the clinical pharmacology of the prototype PPAR-sparing compound vs pioglitazone in non-diabetic and diabetic patients. We are also evaluating whether selective mitochondrial interactions might predict more optimal insulin sensitizing pharmacology.

Cycloset (Quick-Release Bromocriptine Mesylate), a novel centrally acting treatment for type 2 diabetes

A.H. Cincotta¹, J.M. Gaziano², M. Ezrokhi¹, R. Scranton¹

¹Veroscience, Tiverton, United States, ²Harvard Medical School, Boston, United States

Background and aims: Oral administration of Cycloset (quick release - bromocriptine mesylate), a dopamine D2 receptor agonist, represents a new therapeutic approach in the management of type 2 diabetes (DM). Reduced dopaminergic tone in the hypothalamus is associated with and drives the obese insulin resistant state which is restored to the lean insulin sensitive state with appropriate timed delivery of bromocriptine. In the diabetic state, morning administration of Cycloset re-establishes the daily peak of dopaminergic activity that changes neuroendocrine output to improve hepatic and muscle insulin resistance, primarily following a meal. Consequently, the Cycloset effect on gly-

cemic control may be additive to a variety of peripherally acting oral hypoglycemic agents (OHA). The aim of this study was to determine the long term effectiveness of Cycloset versus placebo in improving glycemic control among subjects with DM currently treated with various peripherally acting OHA.

Materials and methods: The Cycloset Safety Trial was a one year, 3070 subject, 2:1 randomized trial to assess the overall safety of Cycloset versus placebo among subjects with DM. Within this study design, several pre-specified efficacy analyses were conducted to assess changes in glycemic control after 24 weeks of treatment among subgroups of subjects receiving one or two oral OHAs and having an HbA1c (A1C) of $\geq 7.5\%$ and $\leq 10\%$ at baseline. Subgroups were defined as a) all subjects on one or two OHAs of any type (N: Cycloset: 261, placebo 151), b) subjects on metformin (MET) \pm another OHA (N: Cycloset: 181, placebo 101), and c) subjects on sulfonylurea (SU) \pm another OHA (N: Cycloset: 176, placebo 106). Additional post-hoc analyses included subjects on thiazolidinediones \pm OHA and subjects on metformin plus glyburide therapy. Study investigators were instructed to alter the dose or regimen of concomitant DM therapy if needed to adhere to ADA target glucose goals. Change from baseline in A1C was determined by ANCOVA. The proportion reaching an A1C of $\leq 7.0\%$ at Week 24 was compared between the two treatment groups using the Cochran-Mantel-Haenszel test.

Results: The mean A1C at baseline was 8.3, mean age was 58, 63% were male, and the mean body mass index was 33 kg/m². Among subjects on any OHA, the between-group difference in change from baseline A1C was -0.6 (P < 0.0001) in favor of Cycloset. More Cycloset subjects reached a target HbA1c of ≤ 7.0 (32% vs. 10%, respectively; p = 0.0001). Among subjects on MET \pm OHA or SU \pm OHA, A1C was significantly reduced in favor of Cycloset (-0.70, p < 0.0001; -0.6, p < 0.0001, respectively). Also more Cycloset subjects reached a goal A1C of ≤ 7.0 compared to placebo (MET subgroup: Cycloset 36%, placebo 10%; p = 0.0001 and SU subgroup: Cycloset 34%, placebo 10%; p = 0.0001). The mean between group change in A1C over this treatment period also favored Cycloset versus placebo treated subjects receiving thiazolidinediones \pm OHA (-0.91; p = 0.003) or metformin plus glyburide (-0.85; p = 0.0001). Cycloset treated subjects were less likely to intensify their concomitant diabetes therapy across all subgroups.

Conclusion: Cycloset, a centrally acting drug, represents a new oral diabetes treatment effective across a broad patient population as adjunctive therapy to a wide variety of OHAs to improve glycemic control.

Efficacy and safety of dapagliflozin in a dose-ranging monotherapy study of treatment-naïve patients with type 2 diabetes

J.F. List¹, V. Woo², E. Morales³, W. Tang¹, F.T. Fiedorek¹

¹Bristol-Myers Squibb, Princeton, United States, ²Diabetes Research & Treatment Centre, Health Sciences Centre, Winnipeg, Canada, ³Centro de Investigación Cardiometaabólica, Aguascalientes, Mexico

Background and aims: Dapagliflozin, a novel oral antidiabetic agent that selectively inhibits the renal sodium-glucose co-transporter 2, is being developed for the treatment of patients with type 2 diabetes mellitus (T2DM). Treatment-naïve T2DM patients were enrolled in a 12-wk, randomized, double-blind, parallel-group, placebo (PBO)-controlled, dose-ranging trial to evaluate the efficacy and safety of dapagliflozin.

Material and methods: After a 2-wk lead-in phase, 389 patients were randomized in equal ratios to once-daily dapagliflozin 2.5, 5, 10, 20, or 50 mg, metformin (Met) XR 750 mg titrated to 1500 mg, or PBO.

Results: Mean reductions from baseline in A1C at wk 12 were statistically significant for all dapagliflozin treatment groups compared with PBO (Table).

Table. Adjusted Mean Decreases from Baseline at Wk 12.

	Dapagliflozin dose (mg)						
	2.5 n=59	5 n=58	10 n=47	20 n=59	50 n=56	PBO n=54	Met n=56
Baseline A1C (%) (SD)	7.7 (0.8)	8 (0.9)	8 (0.8)	7.7 (0.9)	7.8 (1.0)	7.9 (0.9)	7.7 (0.8)
Change in A1C (%) at wk 12	-0.71a	-0.72a	-0.85a	-0.55a	-0.90a	-0.18	-0.73
Baseline FPG (mg/dL) (SD)	145 (34)	153 (48)	148 (38)	149 (41)	153 (42)	150 (46)	143 (33)
Change in FPG (mg/dL) at wk 12	-16.2b	-19.3c	-21.1c	-24.4d	-30.5e	-5.8	-18.0
Change in PPG mg•min/dL	-9382	-8478	-10,149	-7053	-10,093	-3182	-5891
[95% CI] at wk 12	[-11420, -7344]	[-10200, -6756]	[-12215, -8082]	[-8913, -5194]	[-12024, -8162]	[-5086, -1277]	[-7775, -4008]

^aP<0.01 for dapagliflozin vs PBO.

^bNS vs PBO, ^cP<0.01, ^dP<0.001, ^eP<0.0001 vs PBO.

Dapagliflozin also lowered fasting plasma glucose (FPG) and postprandial glucose (PPG), as measured by oral glucose tolerance testing (75 g, 3 hr), without increasing insulin concentrations. No statistical comparisons were applied to the Met arm. Laboratory monitoring revealed no clinically meaningful changes in serum sodium, potassium, or creatinine, or in serum or urinary calcium. By wk 12 dapagliflozin was associated with 0.1 to 0.2- mEq/L increases above baseline in mean serum magnesium across all doses and a 0.2-mg/dL increase above baseline in mean serum phosphate at the highest doses. Serum uric acid declined by approximately 1.0 mg/dL for all dapagliflozin doses tested. The most common adverse events in dapagliflozin-treated patients were urinary tract infection, nausea, dizziness, headache, fatigue, back pain and nasopharyngitis. The rate of reported hypoglycemic events was higher than PBO but similar to Met, but no hypoglycemic events with a documented glucose level ≤ 50 mg/dL were reported.

Conclusion: Once-daily administration of dapagliflozin improved glycemic control at all doses tested compared with PBO, without adverse short-term safety and tolerability signals.

Effect of a selective and reversible hepatic CPT1 inhibitor on HOMA index and fasting blood glucose in diabetic type 2 patients

G. Valentini, M. Bianchetti, S. Pace, P. Carminati
Medical Department, Sigma-tau, Pomezia, Italy

Background and aims: Type II diabetes is characterized by insulin resistance that can impair the adipose tissue response to insulin, with consequent great availability of free fatty acids and increase in mitochondrial β -oxidation. This results in an increased hepatic gluconeogenesis rate by activation of pyruvate carboxylase and an alteration of glucose homeostasis. In type II diabetic patients with this impaired metabolic status, increased hepatic gluconeogenesis is one of the major factors responsible for fasting hyperglycemia. The selective hepatic inhibition of CPT1, the outer mitochondrial membrane enzyme that catalyzes the transport of fatty acids into the mitochondrial matrix, can be effective in reducing hepatic gluconeogenesis and, therefore, a possible strategy in the therapy of diabetes. Teglicar is a new agent, characterized by a reversible and selective inhibitory activity on hepatic CPT1. After defining its safety and pharmacokinetic (PK) profiles in several studies in healthy volunteers, a study in diabetic type II patients was conducted, having as primary objective safety and tolerability and as secondary, PK and pharmacodynamics (PD).

Materials and methods: Double-blind, randomized, placebo-controlled, multiple-dose study for 15 days in 40 male and female type II diabetic subjects. ANOVA was applied to $AUC_{(0-t_{1/2})}$ on day 1, AUC_{ss} on days 14 and 15 and peak concentration (C_{max}) after dose correction and logarithmic pretransformation; PD and safety parameters were evaluated descriptively.

Results: Despite the study being dimensioned for safety and tolerability and not for efficacy, evidence of efficacy was obtained at dose of 450 mg/day. In particular, HOMA index was calculated after an overnight fast at baseline (day 1) and after the last day of treatment (day 16), demonstrating significant improvement ($p < 0.04$) in tissue insulin resistance in subjects treated with 450 mg/day of Teglicar (decrease from 4.1 ± 3.1 on day 1 to 3.0 ± 1.9 on day 16) compared to placebo (increase from 4.9 ± 2.6 on day 1 to 5.7 ± 2.9 on day 16). Subjects treated with 450 mg/day of ST1326 showed a mean decrease in fasting blood glucose from day 1 to day 16 of 16 mg/dl, compared to 4 mg/dl of subjects in placebo group. The pharmacokinetics of Teglicar, defined here and in previous studies carried out in healthy volunteers, were characterized by slow absorption and a slow elimination process ($t_{1/2}$ ranging between 18 and 35 h), which led to accumulation in plasma as consequence of daily dosing. Based on an average $t_{1/2}$ of 25 h, according to standard rules, steady-state conditions may be assumed by day 5. AUC after 24 h increased about two to three times from first administration to steady-state condition. Teglicar was well tolerated, with no clinically relevant changes in vital signs, clinical laboratory results, or ECG findings in any of the studies so far conducted.

Conclusion: Glucose homeostasis is regulated by complex mechanisms, thus administration of Teglicar is expected to induce only very slight modifications after such short-term administration. Nevertheless, the statistically significant results obtained on reduction of tissue insulin resistance and a clear tendency to reduce fasting blood glucose make Teglicar a promising tool in the control of fasting blood glucose in those patients where other glucose-lowering drugs fail to control nocturnal hepatic glucose production.

42

A novel glucokinase activator RO4389620 improved fasting and postprandial plasma glucose in type 2 diabetic patients

J. Zhi¹, S. Zhai¹, M.-E. Mulligan¹, J. Grimsby¹, C. Arbet-Engels¹, M. Boldrin¹, R. Balena¹

¹Hoffmann-La Roche Inc., Nutley, United States, ²Pharma Development, F. Hoffmann-La Roche Ltd., Basel, Switzerland

Background and aims: RO4389620 is a nonessential, mixed-type activator of glucokinase (GK). It binds to an allosteric site on GK, which leads to an increase in the catalytic effectiveness of GK to metabolize glucose, and increases the glucose phosphorylation capacity of pancreatic beta-cells and hepatocytes. Thus, RO4389620 is proposed as a novel treatment of type 2 diabetes. In a completed single-ascending dose study in healthy volunteers, RO4389620 effectively lowered fasting plasma glucose in a dose-related fashion. The aim of the present study was to assess the safety, tolerability, pharmacokinetics (PK), and pharmacodynamics (PD) following multiple-ascending doses (MAD) of RO4389620. Food effect on RO4389620 PK/PD was also examined.

Material and methods: This was a double-blind, randomized, placebo-controlled, MAD study. Fifty-nine T2D patients, either treatment naïve (on diet and exercise) or previously treated with oral antidiabetic drugs, were recruited. They were given RO4389620 or placebo as a single dose on day 1 and multiple doses from day 3 to day 8, at doses from 10, 25, 50, 100, and, 200 mg BID for 5½ days and 200 mg QD for 6 days, with a parallel dose-escalation design. Blood and urine samples were collected for PK analysis. PD assessments (fasting and postprandial 24-h AUC) included plasma glucose, insulin, C-peptide, glucagon, and GLP-1 on pretreatment day (baseline) and post-dose up to day 8. Non-compartmental methods were applied to compute the PK and PD parameters.

Results: The plasma exposure of RO4389620 was dose-proportional over the range tested with no appreciable drug accumulation or food-effect. The 24-h postprandial glucose AUCs at steady-state yielded dose-dependent reductions from baseline, up to 35.5% at the highest dose. There was also a dose-dependent decrease of fasting plasma glucose with a reduction (from baseline) up to 32.5% after 5½ days of treatment. A relative increase in insulin secretion was observed at high doses. RO4389620 was well tolerated. The most common adverse event was headache, with no clear dose-related pattern. No clinically significant laboratory, vital sign, or ECG abnormalities were reported. Mild or moderate hypoglycemia with rapid recovery after sugar-containing drinks or scheduled meals was the only dose-limiting adverse event.

Conclusion: Multiple doses of RO4389620 in T2D patients consistently showed a rapid, dose-dependent glucose reduction over 24 hours resulting from fasting and postprandial plasma glucose decreases, demonstrating its potential utility in the treatment of type 2 diabetes. Other than mild or moderate hypoglycemia, RO4389620 was safe and well tolerated.

OP 08 Nephropathy: development and treatment

43

Progression of diabetic nephropathy is predicted by increased oxidative stress and decreased deglycation

P.J. Beisswenger¹, S.K. Howell¹, B.S. Szewgold¹, S.S. Rich², G.B. Russell³, Y.-K. Kim⁴, M. Mauer⁴

¹Medicine, Dartmouth Medical School, Hanover, ²Public Health Sciences, University of Virginia, Charlottesville, ³Public Health Sciences, Wake Forest University, Winston-Salem, ⁴Pediatric Nephrology, University of Minnesota, Minneapolis, United States

Background and aims: Oxidative stress (OS) has been proposed as a key initiator of diabetic complications, primarily by inactivating Glyceraldehyde-3-Phosphate Dehydrogenase (GAPDH) and increasing vascular damage, while the enzyme Fructosamine-3-Kinase (FN3K) can reverse damaging non-enzymatic glycation. Since OS has not been shown to predict progression of biopsy proven diabetic nephropathy (DN), and FN3K has not been explored in this clinical setting, we studied OS and FN3K in cultured skin fibroblasts (SF) from subjects with Type 1 Diabetes (T1D), discordant for progression or non-progression of DN.

Materials and methods: From 125 subjects, 25 fast progressors (P), 25 non-progressors (NP) (from the highest and lowest quintiles of mesangial expansion scores and degree of albuminuria) and 25 controls (CON) were studied. Cells were cultured in physiologic (5mM) and high (25mM) glucose. OS was measured by fluorescence (FU) of 2',7'-dichlorodihydrofluorescein diacetate, and GAPDH activity was measured by an arsenolysis reaction. GAPDH and FN3K mRNA was measured by RT-PCR, while Poly (ADP-ribose) polymerase (PARP) activity was measured by a P32 NAD assay. A repeated measures ANOVA was used with covariates to determine independent effects of group (P, NP, CON) and glucose condition on the above parameters.

Results: OS was significantly ($P=0.025$) greater in P relative to CON in 5 and in 25 mM glucose (750 ± 166 FU vs 623 ± 148 FU, and 679 ± 154 FU vs 580 ± 140 FU), while CON and NP were not significantly different (714 ± 191 and 654 ± 152 FU) under these conditions. Increasing glucose to 25 mM resulted in a significant ($P < 0.001$) decrease in OS (698 ± 176 vs 640 ± 153 FU). GAPDH activity was significantly ($P=0.01$) lower in P (986.8 ± 173.5) than in CON (1145.3 ± 273.1) in 5 and 25 mM glucose, but did not differ ($P=0.15$) between NP (1056.2 ± 188.8) and CON, while 25mM glucose significantly decreased overall GAPDH activity ($p=0.006$). There were no significant differences between DN groups and CON in GAPDH mRNA ($P=0.30$), which was increased by 25 mM glucose. FN3K mRNA levels were significantly ($P=0.04$) lower in P (0.42 ± 0.21) than in CON (0.52 ± 0.25) in 5mM glucose, while NP (0.50 ± 0.16) did not differ from CON or P. Increasing glucose to 25 mM decreased overall FN3K mRNA ($P=0.0001$) in the combined DN groups and CON, while it increased PARP. PARP increase was greater in P (18.9 and 19.1) compared with NP or CON (14–16); but did not achieve statistical significance.

Conclusion: Cells from nephropathy progressors show increased oxidative stress, decreased GAPDH activity, and increased PARP relative to controls, in contrast with non-progressors. GAPDH mRNA increased, suggesting that post-translational change led to decreased enzyme activity. Levels of FN3K mRNA were lower in P than in NP or CON, suggesting impaired deglycation in P. High glucose suppressed GAPDH activity, increased PARP, and decreased FN3K, but led to a previously unobserved decrease in OS in SF. These results directly link OS, decreased GAPDH activity, and impaired deglycation, to DN in human diabetic patients. Since these differences did not require high glucose in vitro, they could be secondary to inherent genetic traits or metabolic memory.

Can diabetic kidney disease develop in the absence of a history of elevated urinary albumin excretion?

J. Karalliedde, R. Ghosal, G. Viberti

Diabetes, King's College London, United Kingdom

Background and aims: Elevated urinary albumin excretion rate (AER) accompanies the development of nephropathy in diabetes. However the validity

of AER as a predictor and marker of kidney disease in diabetes has been questioned by reports of renal impairment, as measured by estimated glomerular filtration rate or histology, in the absence of a history of elevated AER. Aims: To establish whether diabetic kidney disease (DKD) with significant renal functional impairment can develop in the absence of a history of elevated AER.

Materials and methods: We performed a comprehensive retrospective analysis and audit of electronic patient records and patient notes of all type 1 and type 2 diabetic patients attending a specialist diabetes renal unit at Guy's and St Thomas' Hospital foundation trust between January 2005 and January 2007. DKD impaired renal function was defined at two different serum creatinine levels of $>150\mu\text{mol/l}$ or $>300\mu\text{mol/l}$ and as current history of renal replacement therapy [RRT] such as regular dialysis or transplantation. Elevated AER was defined as: albumin:creatinine ratio $\geq 2.5\text{mg}/\text{mmol}$ in men and $\geq 3.5\text{mg}/\text{mmol}$ in women and / or AER $\geq 20\text{mcg}/\text{min}$ on timed overnight urine collections and /or positive urine protein dipstick. All electronic and medical case notes were verified and double checked independently by two investigators.

Results: Six hundred and twelve diabetic patients had a serum creatinine $>150\mu\text{mol/l}$ or were receiving RRT ($n=62$). Ninety six (52M 47F) patients had type 1 diabetes (T1DM) and 516 (272M 108F) patients had type 2 diabetes (T2DM). Of these patients, 55 (RRT =22) with T1DM and 154 (RRT=40) patients with T2DM had serum creatinine value $>300\mu\text{mol/l}$ or were receiving RRT. At time of diagnosis of confirmed elevated AER in T1DM, mean (SD), age was 47.4 (12.4) years and duration of diabetes was 24.6(11.8) years. In the T1DM cohort 5 patients had clinical and histological evidence of non-diabetic renal disease. All patients who had developed DKD had a history of albuminuria prior to developing renal impairment whether a cut-off of serum creatinine $>150\mu\text{mol/l}$ or $>300\mu\text{mol/l}$ was used. In T2DM at diagnosis of elevated AER, mean (SD), age was 65.4(10) years, with duration of diabetes of 9.9 (8.3) years. In the T2DM cohort of 516 patients, 88 had clinical/histological evidence of non-diabetic renal disease. Of the remaining 428 patients, 14 had incomplete clinical records and had to be excluded from the analysis. Only 2 patients of the remaining 414 had no recorded evidence of raised AER preceding the development of renal impairment. When a serum creatinine threshold of $>300\mu\text{mol/l}$ was used to define renal failure all patients with evidence of DKD had a documented history of preceding raised AER.

Conclusion: In a large clinic based cohort of diabetic patients with overt diabetic kidney disease a history of elevated AER almost invariably precedes the development of significant renal impairment. AER therefore remains a critical diagnostic tool to identify diabetic patients at risk of renal failure.

45

The combination of aliskiren, a direct renin inhibitor, and losartan in patients with type 2 diabetes and nephropathy

H.-H. Parving^{1,2}, F. Persson³, J.B. Lewis⁴, E.J. Lewis⁵, N.K. Hollenberg⁶

¹Department of Medical Endocrinology, Rigshospitalet, Copenhagen, Denmark, ²Faculty of Health Science, Aarhus University, Denmark, ³Steno Diabetes Center, Gentofte, Denmark, ⁴School of Medicine, Vanderbilt University, Nashville, United States, ⁵Medical Center, Rush University, Chicago, United States, ⁶Brigham and Women's Hospital, Harvard Medical School, Boston, United States

Background and aims: We evaluated the renoprotective effects of dual blockade of the renin-angiotensin system by adding aliskiren, a novel oral direct renin inhibitor to treatment with maximal recommended dose of losartan (100 mg daily) and optimal antihypertensive therapy in hypertensive type 2 diabetic patients with nephropathy.

Materials and methods: 599 patients were enrolled in this multi-national, randomized, double blind study. After a 3-month open-label run-in period on losartan 100 mg daily, patients were randomized to receive 6 months treatment with placebo or aliskiren (150 mg daily for 3 months followed by forced titration to 300 mg daily for another 3 months). The primary outcome was reduction in early morning urinary albumin creatinine ratio at 6 months.

Results: The baseline characteristics in the two groups were similar. Aliskiren 300 mg daily reduced the mean urinary albumin creatinine ratio by 20% (95% confidence interval 9–30) ($P<0.001$) compared to placebo. The number of patients with $\geq 50\%$ reduction in urinary albumin creatinine ratio at the end of the study was 24.7% versus 12.5% for aliskiren and placebo respectively ($P<0.001$). A small difference in blood pressure of 2/1 mmHg occurred during aliskiren treatment ($P=0.08$). The decline in kidney function tended to be smaller with aliskiren ($P=0.07$). The total number of adverse and serious adverse events was similar between groups.

Conclusion: Aliskiren is renoprotective independent of its blood-pressure-lowering effect in hypertensive type 2 diabetic patients with nephropathy receiving recommended renoprotective treatment, and has a safety profile comparable to placebo.

Urinary liver-type fatty acid-binding protein increases with levels of albuminuria in type 1 diabetic patients, and is reduced with ACE inhibition

S. Nielsen¹, T. Sugaya², L. Tarnow¹, K.J. Schjoedt¹, A.S. Astrup¹, T. Babs³, H.-H. Parving⁴, P. Rossing¹

¹Steno Diabetes Center, Gentofte, Denmark, ²St. Marianna University School of Medicine, Kanagawa, Japan, ³Internal Medicine 3, Fukushima Medical University, Japan, ⁴Department of Medical Endocrinology, Rigshospitalet, University Hospital of Copenhagen, Denmark

Background and aims: Urinary liver-type fatty acid-binding protein (u-LFABP) is a marker of tubulointerstitial inflammation, and has been suggested to be a marker for chronic renal disease. We studied the level of u-LFABP in type 1 diabetic patients with different albuminuria level. Subsequently we evaluated the effect of renoprotective treatment with ACE inhibition on u-LFABP in patients with diabetic nephropathy.

Materials and methods: Three groups of Caucasians with type 1 diabetes (T1D) from Steno Diabetes Center: 58 with normoalbuminuria (N)(u-albumin<30mg/24h), 45 with persistent microalbuminuria (MA)(30-300 mg/24h) and 45 with persistent macroalbuminuria (DMN)(≥300 mg/24h). Control group consisted of 55 healthy individuals (C). Groups were matched by gender and duration of diabetes (> 30 years). In 56 T1D patients with DMN a randomized crossover trial consisting of three treatment periods was performed, 7 patients did not complete all visits. After 2 months wash-out period (baseline), patients were treated in random order with lisinopril 20, 40, and 60 mg once daily, each dose for 2 months and furosemide in fixed doses. **Results:** In the cross sectional study median levels (IQR) of u-LFABP (μg/g creatinine) in spot urine samples were significantly higher in N vs. C (2.6 (1.3-4.1) vs. 1.9 (0.8-3.0), p=0.02) and were increasing with increasing levels of albuminuria: MA, 4.2 (1.8-8.3); DMN: 71.2 (8.1-123.4), p<0.05 for all comparisons. U-LFABP is correlated with urinary albumin/creatinine ratio (UACR) (r=0.58, p<0.001), eGFR (r=-0.58 p<0.001) in patients with DMN and with UACR in MA (r=0.44, p=0.002). No correlations between u-LFABP and age or HbA1c and no difference between sexes.

In the intervention study baseline urinary albumin excretion rate (UAER) were [geometric mean (95% CI)] 362 (240 to 545) mg/24 hours. All doses of lisinopril significantly reduced UAER, u-LFABP from baseline. Reductions (95%CI) in UAER from baseline were 63% (55 to 69), 71 (66 to 76), and 70 (64 to 75) with increasing doses of lisinopril (p< 0.001 vs baseline, p<0.05 for 40 and 60 vs 20 mg). At baseline u-LFABP was 12.69 (3.88 - 49.82) μg/24h. Reductions in u-LFABP was 43% (15-62), 46 (19-64) and 40 (11-60) with increasing doses of lisinopril (ns between doses). This reduction in u-LFABP was associated with the changes in BP and UAER.

Conclusion: Early and progressive rise in tubulointerstitial damage as reflected by u-LFABP occurs in type 1 diabetic patients associated with albuminuria. ACE inhibition has a beneficial effect both on glomerular and tubulointerstitial markers of damage.

47

New onset diabetes mellitus in white coat, masked and sustained hypertension

P. Gamba, F. Paleari, M. Bombelli, F. Ganz, A. De Matteis, F. Quarti-Trevano, D. Fodri, L. Primitz, M. Volpe, L. Magni, R. Facchetti, R. Seta, G. Grassi, G. Mancia
Università Milano-Bicocca, Ospedale San Gerardo, Monza, Milan, Italy

Background and aims: In the general population, the increase of “office” and “out of office” blood pressure (BP) is accompanied by an increase of metabolic variables, included blood glucose. Aim of the present study is to investigate the long term risk of white coat (WCH), masked (MH) and sustained hypertension (SH) of developing impaired fasting glucose (IFG) and diabetes mellitus (DM).

Materials and methods: In a sample of 1400 subjects of the PAMELA Study, randomly selected from the general population of Monza (Milan, Italy), strat-

ified for gender and decades of age (25 to 74 years), we measured 1) office BP (mercury sphygmomanometric technique), 2) 24 hour BP mean by ambulatory blood pressure (Spacelabs 90207, automatic oscillometric measurements every 20 min during the 24-hours), 3) plasma glucose (radioenzymatic method). The condition of WCH was identified when “office” BP was ≥ 140 mmHg systolic or 90 mmHg diastolic and 24 hour BP mean was < 125 mmHg systolic or 79 mmHg diastolic. MH was identified when “office” BP was < 140 mmHg systolic or 90 mmHg diastolic and 24 hour BP mean was ≥ 125 mmHg systolic or 79 mmHg diastolic. SH was identified when both “office” and 24 hour BP mean were over the threshold values, derived from previous analysis of the BP distribution curves in the general PAMELA population. The subjects were re-analyzed 10 years later, to identify the new cases of IFG and DM, defined when fasting blood glucose was ≥ 110 mg/dL and ≥ 126 mg/dL (or use of antidiabetic drugs) respectively, being < 110 mg/dL and < 126 mg/dL respectively at the first examination.

Results: WCH, MH and SH were identified respectively in 225 (16.1%), 124 (8.9%) and 293 (20.9%) subjects of the original sample. At the second examination we found 101 and 53 new cases of respectively IFG and DM. As compared to subjects with both “office” and 24 hour mean BP normal (normotensives), WCH, MH and SH have higher age and gender-adjusted risk of developing a new IFG (HR 3.715, 2.852 and 2.96 respectively, p<0.005). Statistical significance remains also after a further adjustment for antihypertensive treatment and baseline glycemia. The age and gender adjusted risk of developing a new DM was also significantly higher in WCH, MH and SH as compared to normotensives (HR 2.876, 2.71, 2.228 respectively, p<0.05). Statistical significance disappeared after further adjustment for antihypertensive treatment and baseline glycemia. Independent contributors in the development of DM were: antihypertensive treatment, baseline blood glucose, cholesterol, tryglicerides and body mass index.

Conclusion: The abnormality of either “office” or 24 hour mean BP is associated with an enhanced risk of developing IFG and DM. This may contribute to the increased cardiovascular hazard characterizing not only SH but also WCH and MH.

48

Cardiovascular risk is associated with night-time rather than daytime blood pressure in normoalbuminuric type 2 diabetic patients

H. Haller¹, A. Januszewicz², S. Ito³, J.L. Izzo Jr⁴, S. Katayama⁵, A. Mimran⁶, A.J. Rabelink⁷, E. Ritz⁸, L.M. Ruilope⁹, L.C. Rump¹⁰, G.C. Viberti¹¹

¹Abteilung Nephrologie, Medizinische Hochschule Hannover, Germany, ²Department of Hypertension, Institute of Cardiology, Warsaw, Poland, ³Department of Clinical Medicine, Division of Nephrology, Endocrinology, and Vascular Medicine, Tohoku University, Sendai, Japan, ⁴Department of Medicine, Erie County Medical Center, Buffalo, United States, ⁵The Fourth Department of Medicine, Saitama Medical School, Japan, ⁶Medicine Interne, Hospital Lapeyronie, Montpellier, France, ⁷Department of Nephrology and Hypertension, Leiden University, Netherlands, ⁸Department of Nephrology, University of Heidelberg, Germany, ⁹Division of Hypertension, Hospital 12 de Octubre, Madrid, Spain, ¹⁰Medical Clinic, Marienhospital Herne, University Clinic Ruhr-University-Bochum, Germany, ¹¹Division of Medicine, KCL Guy's Hospital, London, United Kingdom

Background and aims: Whether night-time blood pressure (BP) values outperform daytime BP values in cardiovascular risk prediction is controversial.

Materials and methods: We monitored 24hr ambulatory BP (ABPM) in 1137 (46%M) Type 2 diabetic patients (T2DM), a random subgroup of the 4449 T2DM with normoalbuminuria and at least one additional cardiovascular risk factor enrolled in the Randomised Olmesartan And Diabetes Micro-Albuminuria Prevention (ROADMAP) study. Mean 24 hour, daytime and nighttime systolic BP (SBP) and diastolic BP (DBP) and the night-to-day BP ratios were evaluated in relation to cardiovascular risk factors at baseline.

Results: Mean (SD) age in this population was 57.9 (8.9) yrs, duration of diabetes 6.0 (6.0) yrs and 93% of patients had office BP≥130/80mmHg or were receiving anti-hypertensive treatment. Both mean daytime and night-time SBP and DBP levels correlated significantly (p<0.01 for all) with history of cardiovascular disease; presence of metabolic syndrome; albumin to creatinine ratio (ACR); fasting plasma glucose (PG) concentration. Moreover daytime and night-time SBP also correlated significantly (p<0.01 for all) with 10yr risk of CHD, duration of diabetes, and HbA1c levels. After adjusting daytime for night-time BP values, daytime SBP correlated significantly only with presence of metabolic syndrome ($r_{s,partial} = 0.07$, p<0.01 by mean of partial Spearman rank correlation) and PG concentrations ($r_{s,partial} = 0.06$,

$p < 0.01$). By contrast after adjusting night-time for daytime BP values, night-time SBP was significantly associated with 10yr risk of CHD ($r_{s, \text{partial}} = 0.10$, $p < 0.001$), history of cardiovascular disease ($r_{s, \text{partial}} = 0.11$, $p < 0.0001$), ACR ($r_{s, \text{partial}} = 0.13$, $p < 0.0001$), presence of metabolic syndrome ($r_{s, \text{partial}} = 0.09$, $p < 0.01$) and duration of diabetes ($r_{s, \text{partial}} = 0.07$, $p < 0.01$).

Conclusion: In this group of T2DM with normoalbuminuria night-time BP adjusted for daytime values correlated significantly with a greater number of cardiovascular risk factors than daytime BP adjusted for night-time values. These results suggest that night-time BP may be a better predictor of cardiovascular risk than daytime BP and require confirmation from prospective studies.

OP 09 Prediction of diabetes

49

Perinatal factors and immunological markers at birth are associated to type 1 diabetes risk - a population-based study

S. Eising^{1,2}, B. Carstensen¹, K. Skogstrand^{2,3}, D.M. Hougaard², B. Norgaard Pedersen², J. Nerup^{1,4}, F. Pociot^{1,4}

¹Steno Diabetes Center, Gentofte, Denmark, ²Department of Clinical Biochemistry, Statens Serum Institut, Copenhagen, Denmark, ³Department of Epidemiology and Social Medicine, NANE, Aarhus, Denmark, ⁴Department of Clinical Sciences, Lund University/ CRC, Malmö, Sweden

Background: Reliable prediction is a prerequisite for developing and testing prevention strategies for type 1 diabetes (T1D). Epidemiological studies found perinatal factors (birth weight BW, maternal age) being associated to increased T1D risk. These findings could not be confirmed in previous Danish data.

Aims: To test the impact of perinatal and other demographic data on T1D risk in a large population-based case-control study, and to test for interaction with immunological markers.

Materials and methods: 2265 T1D cases from the birth cohort 1981 - 2002 diagnosed before 2004/05/01 were identified via National Patient Registry. Cases were validated against independent registry and hospital records. Cases and two controls per case (together $n=6795$) were matched by place and date of birth. Birth data, gender, parental age at birth, and information on parental diabetes, for cases and controls were collected from Danish registers (Patient Registry, Birth Register). Measurements of cytokines and MBL, CrP, TREM-1, adiponectin, leptin were available from 6143 samples, measured by use of flowmetric Luminex xMAP technology. We used conditional logistic regression for matched sets to analyse the case-control outcome (SAS 9.1 proc phreg).

Results: Maternal diabetes (HR 5.00, $p < 0.0001$, 95per cent CI 3.02-8.28), paternal diabetes (HR 6.96, $p < 0.0001$, CI 4.76-10.19), BW (HR 1.11 per kg, $p < 0.0174$, CI 1.02-1.20), birth length (HR 1.02 per cm, $p < 0.05$, CI 1.00-1.04), and maternal age at delivery (HR 1.13 per 10 years, $p < 0.036$, CI 1.01-1.26), were significantly associated to an increased T1D risk. In the randomly selected subsets from cytokine measurements, only parental diabetes (HR mother 5.13, CI 3.231-8.128; father 6.40, CI 4.49-9.11, $p < 0.0001$) and maternal age (HR 1.15 per 10 years; $p < 0.0278$; CI 1.02-1.31) remained significant. Maternal age under 25 years was associated to an increased T1D risk (HR 1.34, $p < 0.0001$, CI 1.18-1.51), while paternal age under 25 years was associated to a reduced T1D risk (HR 0.76, $p < 0.0024$, CI 0.63-0.91). By classification of the dataset into two groups by age at T1D onset (below and above 10 years of age), a significant association of BW (HR 1.31 per kg, $p < 0.0162$, 1.05-1.62) to T1D risk was only detected in the young onset group. In small newborns, every 10 fold increase in CrP (ug/ml) and in adiponectin (ug/ml) were associated to a decreased T1D risk (HR 0.72, $p < 0.0052$, CI 0.57-0.91 and HR 0.54, $p < 0.0160$, CI 0.33-0.89, respectively). A similar effect was seen for CrP (HR 0.62, $p < 0.0005$, CI 0.48-0.81) in premature babies. Every 10 fold increase in IL-10 (pg/ml) was in small babies associated to an increased T1D risk (HR 1.37, $p < 0.0031$, CI 1.11-1.69), corresponding to IL-10 effects in the whole dataset as previously described by our group.

Conclusion: We confirm for the Danish population that perinatal factors like BW and maternal age are associated to T1D risk. Effects are small and can only be detected in large datasets, or in subsets such as children with T1D onset below the age of 10. Significant interactions were detected for CrP, adiponectin, and IL-10 with low birth weight and for CrP with gestational age.

Immunological changes in subjects positive for diabetes-associated autoantibodies at preclinical and clinical stages of type 1 diabetes mellitus

V. Popova, K. Zak, B. Mankovsky

Diabetes, Institute of Endocrinology, Kiev, Ukraine

Background and aims: The presence of diabetes-associated autoantibodies (DAAb) provides the opportunity to predict type 1 diabetes mellitus in

healthy persons. However, immunological changes occurring during the progression of disease from preclinical to clinical stages are not fully understood. Therefore, the aim of this study was to monitor the immunological changes in subjects positive for DAAb at preclinical and clinical stages of type 1 diabetes mellitus compared to subjects negative for DAAb.

Materials and methods: We prospectively studied 294 children aged 12.34 ± 0.82 years for the period over 10 years. All of those subjects were normoglycemic at the baseline. There was the family history of type 1 diabetes mellitus in the first degree relatives in 226 children and 70 children without such a history were examined as the control group. The measurements of DAAb titers (IAA, GADA and IA-2A) were carried out by radioimmunoassay at least twice at baseline and then in the course of progression from preclinical to clinical stages of type 1 diabetes mellitus. We performed the repeated measurements of leucocytic composition, immunophenotype of lymphocytes (CD3+, CD4+, CD8+, CD20+ and CD56+ cells) by FACS-analysis. The concentration of circulating cytokines (IL-1 α , IL-1 β , IL-4, IL-6, IL-8, IL-16, FNO α and IFN γ) was measured by immunoenzymic method (ELISA).

Results: An elevated titer of autoantibodies to GADA and IA-2A was found in 94 children (42%). The overt type 1 diabetes mellitus was diagnosed in 47 children positive for DAAb at the different terms of follow-up after primary examination (from 6 months until 9 years - the mean time was 30.9 ± 3.2 months since the first examination). In the group of children negative for DAAb only one child developed diabetes. We found the significant decrease of absolute numbers of CD3+, CD4+ and CD56+ cells and IL-4 concentration along with elevated levels of IL-6, IL-8, FNO α and IFN- γ in the group of children positive for DAAb at preclinical stage of diabetes compared to DAAb negative ones. The number of CD3+ cells was $0.79 \pm 0.05 \cdot 10^9/l$, $1.02 \pm 0.06 \cdot 10^9/l$, $1.39 \pm 0.09 \cdot 10^9/l$; CD4+ cells - $0.52 \pm 0.03 \cdot 10^9/l$, $0.67 \pm 0.04 \cdot 10^9/l$, $0.98 \pm 0.04 \cdot 10^9/l$, and CD56+ cells - $0.18 \pm 0.02 \cdot 10^9/l$, $0.24 \pm 0.03 \cdot 10^9/l$, $0.29 \pm 0.02 \cdot 10^9/l$, in those children positive and negative for DAAb and control group, respectively, $p < 0.05$ for all comparisons between children positive for DAAb and those negative for DAAb and controls. These changes of immunological indices between those groups became less pronounced after the onset of the clinically overt diabetes. It was an association between immunological changes and the progression to clinical stage of diabetes - the more decreased the number of CD3+, CD4+ CD56+ cells and plasma IL-4 levels the faster the progression of type 1 diabetes was registered.

Conclusion: The measurement of the numbers of CD3+, CD4+ and CD56+ cells and IL-4 plasma concentration could be used as the test to predict the progression of type 1 diabetes from subclinical to clinical stages in children positive for DAAb.

51

Dysregulation of lipid and amino acid metabolism precedes islet autoimmunity in children who later progress to type 1 diabetes

M. Oresic¹, S. Simell², M. Sysi-Aho¹, K. Nantö-Salonen², T. Seppänen-Laakso¹, V. Parikka², A. Hekkälä³, I. Mattila⁴, M. Katajamaa¹, P. Keskinen⁴, T. Simell², R. Veijola⁵, J. Ilonen⁵, M. Knip⁶, O. Simell²

¹VTT Technical Research Centre of Finland, Espoo, ²Department of Pediatrics, University of Turku, ³Department of Pediatrics, University of Oulu, ⁴Department of Pediatrics, University of Tampere, ⁵Department of Clinical Microbiology, University of Kuopio, ⁶Hospital for Children and Adolescents, University of Helsinki, Finland

Background and aims: To explore etiopathogenesis and prevention possibilities of type 1 diabetes (T1D), over 8000 children carrying HLA-conferred genetic risk for T1D have been followed since birth at 3- to 12-month intervals for development of T1D-related autoantibodies (ICA, IAA, GADA and IA-2A) and overt T1D in Type 1 Diabetes Prediction and Prevention Study (DIPP), launched in Finland in 1994. As changes in the concentrations of metabolites reflect responses in biological systems to the interaction between genes and the environment, we hypothesized that extended serum metabolite patterns might differ between children remaining autoantibody negative (nonprogressors) and children who later develop autoantibodies and progress to T1D (progressors), and that the changes might reflect etiopathogenetic events that precede development of autoimmunity.

Materials and methods: Serum metabolite profiles were compared between 56 children who progressed to T1D and 73 nonprogressors, who remained permanently healthy and autoantibody negative and were matched with the progressors for time and site of birth, gender, and HLA risk group. The 129 children contributed 1196 samples. Additionally, the cord blood samples of 39 children, 15 of whom progressed to diabetes before the age of 12 years were investigated. Lipidome was analyzed using ultra performance liquid

chromatography coupled to mass spectrometry (UPLC/MS). 53 lipids were measured in each of the 1196 samples, and 249 lipids were identified in each of the 39 cord blood samples. Serum samples were also analyzed by two dimensional gas chromatography coupled to time of flight mass spectrometry (GCxGC-TOF/MS). The metabolomic analysis was performed on a subset of DIPP study samples from 13 progressors and 26 matched nonprogressors. The final metabolomics dataset consisted of 75 identified metabolites measured in each of the 419 samples.

Results: The individuals who developed disease have reduced serum levels of succinate ($P=0.042$), citrate ($P=0.018$) and phosphatidylcholine ($P=0.0041$) at birth, significantly reduced levels of multiple antioxidant ether phospholipids throughout follow-up and increased levels of proinflammatory lysophosphatidylcholines several months prior to seroconversion to autoantibody positivity ($P=0.034$). Ketoleucine was decreased 20-fold within the period of 9-18 months prior to seroconversion to IAA ($P=0.0093$) and 2.5-fold within the succeeding 9-month period ($P=0.015$). Elevation of glutamate was associated with the subsequent appearance of autoantibodies to glutamic acid decarboxylase (GADA) and to IAA. The metabolic profile was partially normalized following the seroconversion.

Conclusion: Dysregulation of metabolism precedes β cell autoimmunity and overt T1D. Our findings imply that metabolic interventions during the preautoimmune period may be used as a potential strategy for T1D prevention.

Low levels of insulin-like growth factor binding protein-1 is associated with development of type 2 diabetes: a prospective observational study

U. Petersson¹, C. Östgren¹, L. Brudin¹, K. Brismar², P.M. Nilsson³

¹Medical and Health Sciences, Department of Medical and Health Sciences, Linköping University, Sweden, ²Department of Molecular Medicine and Surgery, Department of Medical and Health Sciences, Linköping University, Solna, Sweden, ³Department of Clinical Sciences Medicine, Lund University Hospital, Malmö, Sweden

Background and aims: To explore the association between IGFBP-1 at baseline and the development of impaired glucose tolerance (IGT), and type 2 diabetes in a defined middle-aged population.

Materials and methods: A cross-sectional population-based screening study was conducted in 1989-1990 including baseline data on 664 non-diabetic subjects aged 40-59. Anthropometric data were collected and blood samples were analyzed for blood glucose, serum lipids and serum insulin. Blood specimens were frozen at baseline and analyzed for IGF-I, IGFBP-1 and C-reactive protein (CRP). At the follow-up in 2006, through primary care medical records, the incidence of type 2 diabetes and IGT, was registered.

Results: During the 17-year observation period 42 subjects (6.3%) developed type 2 diabetes/IGT. Subjects in the lowest quintile of IGFBP-1 ($< 24 \mu g/l$) at baseline had an incidence of diabetes of 12.1%, while in the highest quintile of IGFBP-1 ($\geq 59 \mu g/l$) the incidence was 1.4%. Cox proportional hazard model regression analyses were used for incidence of type 2 diabetes, corrected for age and gender with regard to IGFBP-1, CRP and waist circumference. Subjects in the lowest IGFBP-1 quintile showed an independent increased risk of developing type 2 diabetes or IGT, hazard ratio (HR) 3.09; CI 95% (1.09-9.10, $p < 0.041$). For CRP and waist circumference the corresponding figures were HR 6.39; CI 95% (2.41-17.0, $p < 0.001$) and HR 3.37; CI 95% (1.48-7.7, $p < 0.001$), respectively.

Conclusion: Low levels of IGFBP-1 predicted the development of type 2 diabetes or IGT in a defined middle-aged population. The association was independent of CRP and abdominal obesity.

Interactions between genes and birth size for development of type 2 diabetes

N. Pulizzi¹, V. Lyssenko², A. Jonsson², C. Osmond², E. Kajantie², D. Barker², L.C. Groop², J.G. Eriksson²

¹Clinical sciences-Diabetes and endocrinology, Lund Universitet, Malmö, Sweden, ²Clinical sciences-Diabetes and endocrinology, Lund Universitet, Malmö, Sweden

Background and aims: A small body size at birth is a well-recognized risk factor for type 2 diabetes (T2D). Previous studies have shown that there is an interaction between early environmental factors and genes in the development of T2D. Recently several whole genome-wide association studies for T2D have identified a number of novel loci (TCF7L2, IGF2BP2, HHEX, CDKN2A/2B, CDKAL1 and JAZF1) increasing susceptibility to the disease. Our study aimed to investigate the potential influence of these genetic variants on birth weight and the possible interaction between genes and birth size on development of T2D.

Materials and methods: 2003 subjects, (M/F: 928/1075), 56-70 yrs old, from the Helsinki Birth Cohort Study (HBCS), were genotyped by Taq Man allelic discrimination assay, and common variants detected by ABI PRISM 7900. Logistic regression analysis was used to test the effect of genetic variants on risk of T2D adjusted for age, gender and BMI.

Results: 311 (15.6%) subjects had developed T2D. Subjects with low birth weight had an increased risk of developing T2D (OR 1.43 [1.11-2.0], $p=0.008$). Only the HHEX gene influenced birth weight (AA: 3495 \pm 452 g; AG: 3426 \pm 460 g; GG: 3422 \pm 466 g, $p<0.05$). Common variants in the TCF7L2, HHEX and JAZF1 genes predicted T2D in subjects born in the lowest tertile of birth weight (OR 1.71 [1.2-2.45], $p=0.003$; 2.22 [1.17-4.18], $p=0.014$; 1.64 [1.007-2.67], $p=0.04$, respectively), whereas variants in the IGF2BP2 gene predicted independently of birth weight future T2D (OR 1.71 [1.15-2.56], $p=0.008$). High-risk genotype (>7 alleles) carriers, whose insulin secretion was reduced compared to the low-risk (<4 alleles) (corrected insulin response, 3.54 ± 1.2 vs. 3.76 ± 1.07 , $p=0.019$; disposition index, 1.36 ± 1.22 vs. 1.57 ± 1.1 , $p=0.02$), had also a 2-fold increase of T2D risk (1.98 [1.33-2.92], $p=0.0006$), and this risk was highest in individuals from the lowest tertile of birth weight (OR 3.87 [1.96-7.65], $p=0.00009$) demonstrating a strong interaction between genetic variants and birth weight for prediction of future T2D ($p_{\text{inter}}=0.0002$). Neither insulin secretion nor insulin resistance were clearly shown to influence this interaction in our cohort.

Conclusion: Common variants in T2D susceptibility genes interact with birth weight to increase future risk of T2D; this interaction cannot be fully explained by their effects on insulin secretion and action.

Development of multimarker algorithms for the prediction of type 2 diabetes from a 5 yr prospective study of 6,784 Danish people (Inter99)

J.A. Kolberg¹, R. Gerwien¹, E.J. Moler¹, M.W. Rowe¹, M. Urdea¹, M.P. McKenna¹, T. Hansen², O. Pedersen², K. Borch-Johnsen², T. Jorgensen³
¹Tethys Bioscience, Emeryville, United States, ²Steno Diabetes Center, Copenhagen, Denmark, ³Research Centre for Prevention and Health, Glostrup University Hospital, Copenhagen, Denmark

Background and aims: Improved identification of subjects at high risk for development of Type 2 diabetes (T2D) would allow more aggressive preventive interventions to be targeted towards those individuals who would benefit most. The aim of the study was to develop a multivariate serum biomarker algorithm to predict 5 year risk of T2D. Subjects were selected from the Inter99 cohort, a population-based primary prevention study of cardiovascular disease and T2D in middle-aged Danes.

Materials and methods: Among subjects with BMI ≥ 25 kg/m² and age ≥ 39 yrs at baseline, all 160 individuals who progressed to T2D (converters: age 51 ± 6 yrs; BMI 31 ± 4 kg/m²) during 5 yrs were compared with 472 randomly selected non-converters (age 48 ± 6 yrs; BMI 29 ± 4 kg/m²). 92 protein biomarkers were measured in each subject's baseline fasting serum sample using an ultrasensitive Molecular Counting Technology (MCT). MCT protein assays had dynamic ranges of 10^2 to 10^3 , intra-plate CVs of $\leq 5\%$, and sensitivities ranging from sub-pg/mL to ng/mL using ~ 1 μ L of serum per assay. Additional laboratory measures included fasting plasma glucose, serum insulin, cholesterol (total, HDL, LDL) and triglycerides.

Results: Data from one half of the 632 subjects were used for marker selection and development of the algorithms (training set). Univariate and multivariate statistical analyses were conducted employing protein biomarker concentrations and clinical annotations. Markers were prioritized on the basis of performance in univariate and small (≤ 6) multivariate logistic models, and on frequency of selection under bootstrap resampling using heuristic model building methods (e.g., forward selection). The bootstrap estimates of Area Under the Receiver Operator Characteristic Curve (AUC) for nested 9-, 7- and 5-marker models using the best predictors were ~ 0.76 for 5 year risk of developing diabetes. When the same algorithms were applied to the second half of the data (testing set) to validate the models, similar performance (AUC = 0.75) was achieved. An algorithm developed using all 632 subjects and utilizing < 15 serum biomarkers had an AUC of 0.78. The performance of this algorithm was significantly better than fasting plasma glucose, HbA1c, fasting insulin, BMI and gender-adjusted waist and was similar in performance to 2 hr glucose.

Conclusion: These results suggest that algorithms using panels of serum biomarkers can predict the risk of developing type 2 diabetes in a general population and provide additional information beyond current clinical methods.

OP 10 High glucose, oxidative stress and cellular signalling

The relation of diabetes-associated membrane fusion processes to impaired brain function: effect of gabapentin treatment

T. Kuchmerovska¹, V. Gumenyuk², A. Klimenko¹, I. Triakash²¹Coenzymes, A.V. Palladin Institute of Biochemistry, ²Neurochemistry, A.V. Palladin Institute of Biochemistry, Kiev, Ukraine

Background and aims: Alterations in neurotransmission may directly or indirectly contribute to diabetes-associated pathophysiology. Regulated exocytosis forms the basis for many intracellular signaling processes e.g. neurotransmitter release. Ca²⁺-triggered fusion of synaptic vesicles (SVs) with the presynaptic plasma membranes (PM) is regarded as a final step of exocytosis. Calcium-dependent SVs fusion's disturbances may be a pathophysiological mechanism in diabetes. It is known that effect of gabapentin (GP) can be realized via regulation of GABA and others neurotransmission. The study was aimed to investigate the diabetes-induced alterations and GP effect in the Ca²⁺-triggered fusion of SVs with target membranes.

Materials and methods: STZ-induced (60 mg/kg of body weight, i.p.) diabetic rats were treated with GP (50 mg/kg, i.p.) for 1 mo following 4 wks of untreated diabetes. SVs and PM were isolated from rat brain synaptosomes. SVs size was monitored by dynamic light scattering using the Zetasizer Nano system (Malvern 4700, UK). Fusion studies were performed in cell-free model system using fluorescent dye octadecylrhodamine B (R18) incorporated into SVs membranes at self-quenching concentration. The fusion of SVs, containing marker R18, with target membranes was detected by dequenching of the probe fluorescence. The Ca²⁺-dependent SVs fusion was carried out on heterotypic and homotypic membrane systems in synaptosomal cytosolic proteins media. PM were overloaded with cholesterol by methyl- β -cyclodextrin (MCD).

Results: We identified that suspension of SVs from control and diabetic brains were abundant in the fractions of the particles with the average size about 50 and 80 nm respectively. It was found that in diabetic rats the rate of SVs fusion with PM (heterotypic) in the presence of Ca²⁺ and synaptosomal cytosolic proteins was decreased as it is evident from lowering of fluorescence from 23% in control to 14.5% in diabetes, $p < 0.05$. Diabetes-induced reduction in fusion is likely to be associated with alteration of PM cholesterol that can play a critical role in this process. To verify this idea we overloaded the PM by cholesterol using MCD:cholesterol mixture. PM cholesterol level in control was 0.67 ± 0.06 $\mu\text{M}/\text{mg}$ of protein as compared with 0.75 ± 0.07 in diabetes ($p < 0.05$). After overloading PM by cholesterol its level in control was 0.88 ± 0.07 $\mu\text{M}/\text{mg}$ of protein, $p < 0.05$. The fusion ability of cholesterol-saturated PM as well as PM of diabetic rats was reduced to the same extent. The opposite effect has been shown in the rate of SVs fusion with each other (homotypic): in diabetes the fluorescence signal was achieved up to 30% vs 25% in control, $p < 0.05$. Following GP treatment the rate of SVs fusion with target membranes was partially normalized.

Conclusion: The findings suggest that diabetes may cause failures in realization of the last step of exocytosis - membrane fusion. These alterations may be associated with increased cholesterol content of synaptosomal PM that modifies the structure and function of membrane-bounded proteins and affects membrane fluidity and fusibility. Our data imply that GP is involved in the exocytosis more likely acting on proteins that provide SVs fusion. Thus, presynaptic fusion machinery may be considered as a viable therapeutic target for development of new drugs for the treatment of diabetes-related CNS abnormalities.

56

Association of impaired brain protein ADP-ribosylation with mitochondrial dysfunction in diabetes: evidence for the beneficial role of acetyl-L-carnitine supplementation

I. Shymanskyi, O. Zolocheska, G. Donchenko, A. Klimenko, T. Kuchmerovska

Coenzymes, O.V. Palladin Institute of Biochemistry, Kiev, Ukraine

Background and aims: An excessive and sustained increase in reactive oxygen species (ROS) formation and oxidative stress have been implicated in the pathogenesis of diabetic complications. ROS-mediated enhancement of

ADP-ribosylation of nuclear and extra-nuclear proteins has been also shown to underlie several neuropathological aspects of diabetes mellitus. Since mitochondrial dysfunction might be associated with enhanced generation of free radicals, the present study was designed to investigate whether mitochondrial ROS overproduction is involved in the activation of protein mono- and poly-ADP-ribosylation in diabetic brain. To this end, the effects of acetyl-L-carnitine (ALC), mitochondria-specific neuroprotective nutrient, were assessed.

Materials and methods: All studies were carried out after 4 weeks of STZ-induced diabetes (60 mg/kg of body weight, i.p.) in rats treated for 14 days with or without ALC (150 mg/kg, i.p.). The mitochondrial membrane potential ($\Delta\psi_m$) was assayed spectrofluorimetrically with rhodamine123 (Rh123). ADP-ribosylation was measured by incorporation of labelled ADP-ribose from [¹⁴C]NAD⁺ to proteins. Mitochondrial ROS production was analysed using 2',7'-dichlorodihydrofluorescein diacetate which is converted to the fluorescent 2',7'-dichlorofluorescein (DCF) upon oxidation.

Results: The major diabetes-related changes that occur to brain mitochondria comprise decreased $\Delta\psi_m$ ($21.7 \pm 0.19\%$ elevation of Rh123 fluorescence, $p < 0.01$) with concomitant $25.4 \pm 0.21\%$ decline in brain ATP content without pronounced alterations in the total sum of ATP and ADP as compared to control ($p < 0.05$). Brain mitochondria isolated from diabetic rats generated more reactive oxygen species as DCF fluorescence level was approximately 30% higher than in control. Administration of ALC to diabetic rats diminished the development of cellular respiration defects strongly attenuating the loss of $\Delta\psi_m$ with corresponding restoration of ATP content. It also reversed the diabetes-associated DCF-sensitive mitochondrial ROS production (by 23%), thus indicating that the efficiency of mitochondrial electron transport had improved after the treatment. The ability of ALC to counteract energy imbalances and ROS generation in mitochondria may account for the decrease in elevated protein ADP-ribosylation found in diabetes (56.4 ± 3.9 , 98.3 ± 7.2 , 240.3 ± 20.4 vs. 67.4 ± 5.1 , 115.8 ± 9.1 , 293.5 ± 22.4 and 48.3 ± 3.2 , 89.0 ± 7.0 , 234.8 ± 19.8 pmol [¹⁴C]ADP-ribose/mg of protein respectively in brain synaptosomes, mitochondria and nuclei of ALC-treated vs. diabetic and control rats, $p < 0.05$). Probably due to increased consumption of NAD⁺ in ADP-ribosylation of proteins, diabetes exhibited accelerated NAD⁺ catabolism in brain (29.5% reduction, $p < 0.05$). ALC treatment of diabetic rats did not affect hyperglycaemia or brain polyol pathway activity as reflected by sorbitol levels but did increase NAD⁺ levels.

Conclusion: Thus, mitochondria may be an important therapeutic target for ameliorating diabetes-related brain failures when energy depletion is accompanied by oxidative stress and ROS-induced activation of general ADP-ribosylation. Because ALC is unlikely to be a potent radical scavenger or a direct inhibitor of ADP-ribosylating enzymes, these data suggest that ALC protects against excessive ADP-ribosylation through mitochondria-mediated mechanisms.

57

The impact of oscillating glucose and the metabolic memory effect on oxidative stress in human endothelial cells

C.R. Radford, B. Schisano, P.G. McTernan, A. Ceriello

Diabetes and Metabolism, CSRI University of Warwick, Coventry, United Kingdom

Background and aims: The 'cellular memory' phenomenon, which occurs after hyperglycaemic stress, has been suggested as a mechanism for the long term complications of diabetic stress. Our previous studies have shown that human endothelial cells which have been exposed to high glucose, followed by a phase of normal glucose, maintain a cellular stress response referred to as the 'cellular memory' effect. Cellular stress can be mediated through activating transcriptional factors such as NRF2 which modulates anti-oxidant defenses in cells and has been shown to be activated by high glucose. NRF2 can also activate NQO1 which also has an anti-oxidant role. Therefore the aim of this study was to (1) determine in the effect of oscillating glucose on oxidative glucose stress compared with chronic high glucose in human endothelial cells (HUVECs) and (2) to identify whether the cells retain the cellular memory effect following oscillating glucose which is subsequently normalized.

Materials and methods: HUVECs were cultured in either normal glucose (5 mmol/L), high glucose (30 mmol/L), oscillating glucose (12 h high glucose, 12 h normal glucose) for 21 d, or 14 d oscillating glucose (12 h high glucose, 12 h normal glucose) followed by 7 d normal glucose. Protein was extracted using a standard protocol and samples were analysed by Western blotting.

Results: Exposure of endothelial cells to three weeks oscillating glucose levels resulted in considerable upregulation of both NRF2 and NQO1, as compared to exposure to either continuous normal or high glucose conditions. Further-

more, there was a three fold elevation of these anti-oxidative proteins even after glucose levels had been normalised for one week following oscillating conditions ($p>0.05$). This suggests oscillating glucose conditions imparts a cellular memory, resulting in sustained elevation of these proteins. General markers of high glucose stress, such as Bax, were also found to be elevated to a higher degree in oscillating glucose compared to constant high glucose. TIGAR, a protein which protects against oxidative stress was elevated two fold in oscillating glucose compared to constant high glucose. This effect was maintained after normalisation, supporting the cellular memory phenomenon seen with anti-oxidative proteins.

Conclusion: In summary, exposure to oscillating glucose induces extensive levels of oxidative stress mediated through NRF2, NQO1, BAX and TIGAR compared with chronic, high glucose treated HUVEC cells; and this stress results in a cellular memory effect. Furthermore, in addition to continuous hyperglycaemia, type 2 diabetic individuals are often exposed to postprandial oscillations in glucose levels. Our current findings support the theory that daily oscillations in blood glucose levels may be a contributing factor for the long-term complications associated with type 2 diabetes.

58

High glucose acutely impairs the nitric oxide/ cyclic GMP/ PKG/ VASP pathway in arterial vascular smooth muscle cells: a putative mechanism of vascular damage induced by glycaemic spikes

I. Russo, M. Viretto, P. Del Mese, G. Doronzo, C. Giordanino, L. Mattiello, G. Anfossi, M. Trovati

Diabetes Unit, Department of Clinical and Biological Sciences, University of Turin, San Luigi Gonzaga Hospital, Orbassano - Torino, Italy

Background and aims: In type 2 diabetes, blood glucose excursions are considered a risk factor for cardiovascular events and are correlated with intima-media thickness. Oxidative stress has been claimed to play a role in the relationships between blood glucose excursions and vascular damage. Previous studies evaluated the effects of glucose spikes on vascular endothelium: less attention has been given to their influence on vascular smooth muscle cells (VSMC), which play a pivotal role in vascular tone and remodelling. VSMC are targets of nitric oxide (NO), which induces relaxation and inhibits proliferation. NO downstream molecules are cyclic GMP (cGMP), cGMP-dependent protein kinase (PKG) and Vasodilator Stimulated Phosphoprotein (VASP), which is phosphorylated by PKG at Ser-239. Aim of this study is to evaluate in VSMC whether high glucose acutely affects the NO/cGMP/PKG/VASP pathway, and whether oxidative stress is involved in this phenomenon.

Materials and methods: In rat aortic VSMC obtained as primary culture in our laboratory and pre-incubated for 120 min with 5, 15 and 25 mM glucose, we measured by western blot the expression of total VASP and the extent of VASP phosphorylation at Ser-239 in response to a 60-min incubation with 100 μ M of the NO donor Sodium Nitroprusside (SNP) or with 500 μ M of the permeable cGMP analogue 8-Br-cGMP. Experiments ($n=6$) have been repeated in the presence of a 30-min pre-incubation with the antioxidant mixture Superoxide Dismutase (SOD)(300 U/ml) and Catalase (250 U/ml) ($n=6$). Data are expressed as mean \pm SEM.

Results: High glucose did not modify total VASP expression, but significantly impaired VASP phosphorylation at Ser-239 in response to SNP and 8-Br-cGMP. In particular, in the presence of glucose 5, 15 and 25 mM, VASP phosphorylation -expressed as fold increase vs baseline- was i) in response to SNP: 682.3 ± 40.2 , 308.8 ± 31.1 and 184.1 ± 24.3 , respectively (ANOVA, $p=0.0001$); ii) in response to 8-Br-cGMP: 978.5 ± 38.8 , 325.5 ± 33.3 and 201.0 ± 51.6 , respectively (ANOVA, $p=0.0001$). Incubation with SOD/Catalase prevented the inhibiting effect exerted by high glucose on VASP phosphorylation in response to SNP and 8-Br-cGMP, supporting the role of oxidative stress: in particular, in VSMC incubated with SOD/Catalase, VASP phosphorylation in the presence of 15 mM glucose (fold increase vs baseline) was 665.7 ± 26.31 in response to SNP and 824.0 ± 31.01 in response to 8-Br-cGMP ($p=0.0001$ for both vs values in the absence of SOD/Catalase).

Conclusion: A short-term VSMC exposure to high glucose impairs via oxidative stress the NO/cGMP/PKG/VASP pathway, as indicated by the reduced phosphorylation at Ser-239 of VASP, a protein deeply involved in vascular relaxation and in inhibition of VSMC proliferation. Since exposure to antioxidants prevents the impairment of VASP phosphorylation in response to both SNP and 8-Br-cGMP induced by high glucose, we can state that PKG activity is negatively affected by oxidative stress. In conclusion, our study provides a further link between rapid increases of glucose concentrations, oxidative stress and mechanisms involved in vascular damage, inducing to suppose

that glucose spikes reduce not only NO availability by influencing endothelial function, but also NO action on arterial VSMC.

Postmeal hyperglycaemia induced oxidative stress is associated with cardio-vascular dysfunction in patients with type 2 diabetes - assessed by tissue Doppler and Wave-Intensity

H. von Bibra¹, A. Ceriello², T. Siegmund¹, P.-M. Schumm-Draeger¹

¹Endocrinology, Academic Hospital Bogenhausen, München, Germany,

²Diabetology, Warwick Medical School, Coventry, United Kingdom

Background and aims: Given the high prevalence and prognostic relevance of diastolic myocardial dysfunction in people with type 2 diabetes, we tested the hypothesis that postmeal hyperglycemia induced generation of oxidative stress is associated with cardio-vascular dysfunction by using tissue Doppler and the new Wave-Intensity technique.

Materials and methods: In 46 healthy controls (C) (mean age 60 ± 10 years) and 31 individuals with type 2 diabetes (D) (mean age 58 ± 5 years) without hypertension and overt cardiovascular disease, the effects of a carbohydrate breakfast (48 g) on oxidative stress and cardiac and vascular function were assessed in the fasting state and 2 hours after the meal. At both time-points, serum glucose, insulin and lipids were determined in addition to nitrotyrosine as marker of oxidative stress. Global left ventricular function was assessed by tissue Doppler as systolic (Vs) and diastolic (Ve) myocardial velocities averaged from 6 basal segments. Traditional parameters of carotid arterial stiffness and the early systolic peak (W1) of Wave-Intensity, a measure of blood wave energy transfer into the systemic circulation, were recorded by a combined echo-tracking Doppler-system (ALOKA SSD-5500, Tokyo).

Results: In D (HbA1c $7.0\pm1.2\%$, HOMA-IR 9.6 ± 9.0), the postmeal increase of glucose ($p<0.016$), insulin ($p<0.03$) and nitrotyrosine (0.33 ± 0.37 vs 0.26 ± 0.42 nM, $p<0.001$) was significantly higher than in C. Postmeal lipid levels were unchanged so that triglycerides remained higher and HDL lower in D than in C ($p<0.04$). Ve was lower in D than in C (7.9 ± 1.5 vs 9.9 ± 1.4 cm/s, $p<0.001$) and Vs was similar in both groups. Coincidentally, the rate pressure product (9009 ± 2647 vs 7853 ± 1438 mmHg/min, $p<0.007$) and stiffness parameters ($p<0.04$) were higher in D. W1 was higher as well (11842 ± 8466 vs 7949 ± 3911 mmHg/m/s³, $p<0.02$) and had a significant correlation with the rate pressure product ($r=0.669$, $p<0.001$), taking the latter as indicator of myocardial oxygen requirement and W1 as a measure of energy transfer into the stiffened arterial system. In multivariate regression models, independent predictors of fasting Ve were age, HOMA-IR and the postmeal changes of nitrotyrosine (R^2 0.474), for postmeal Ve the postmeal changes of nitrotyrosine alone (R^2 0.354) and for W1 the rate pressure product and HOMA-IR (R^2 0.534).

Conclusion: In people with type 2 diabetes, postmeal hyperglycemia induced oxidative stress is associated with diastolic dysfunction and increased myocardial oxygen requirements and energy transfer into the stiffened vascular bed already at rest. Given the known impairments of perfusion and intramitochondrial energy production in the diabetic heart, this myocardial mismatch of energy demand and supply bears the prodromic risk of myocardial energy exhaustion, as indicated by diastolic dysfunction. In order to avoid this risk, respective therapeutic strategies should be developed.

60

The relationship between plasma osteoprotegerin levels, coronary artery calcification score and arterial stiffness in asymptomatic type 2 diabetes

C. Jung¹, W. Lee², Y. Bae², S. Kim², S. Jo³, E. Lee³, J. Mok¹, K. Oh³, C. Kim¹, S. Park³, S. Kim³

¹Endocrinology and Metabolism, Soonchunhyang University College of Medicine, Bucheon, ²Endocrinology and Metabolism, Kangbuk Samsung Hospital, Seoul, ³Endocrinology and Metabolism, Kangbuk Samsung, Seoul, Republic of Korea

Background and aims: Contemporary studies have shown similarities between vascular and skeletal calcification suggesting a regulatory role for osteogenic and calcitropic factors in the development of cardiovascular disease. Elevated OPG levels are associated with the progression of vascular calcification and the presence and severity of CAD. Coronary calcium is a good marker for atherosclerosis and correlates with the total extent of prevalent atherosclerosis. Coronary calcium score (CACS) has been shown to predict

CHD events in non-diabetic group. In addition, pulse wave velocity (PWV) is a well-known indicator of arteriosclerosis, and it may predict cardiovascular risk. Because type 2 diabetes increases the risk of coronary atherosclerosis and CAD, the aim of this study was to evaluate the relationship between plasma OPG levels, the extent of coronary artery calcification and PWV.

Materials and methods: One hundred three patients (male; 60, female; 43) who were treated with type 2 diabetes in Kangbuk Samsung Hospital, Sungkyunkwan University, Seoul, South Korea were enrolled in this study. The subjects underwent both CACS by MDCT (Philips Brilliance 40) and brachial-ankle PWV from November 2006 to December 2007. Plasma OPG levels were measured by enzyme-linked immunosorbent assay. The concentrations of HbA_{1c}, lipid profile, hsCRP and other basic laboratory parameters were determined in serum.

Results: The mean age was 57.8±11.4 years, BMI was 25.1±3.6 kg/m² and DM duration 6.6±5.8 years. The mean OPG levels were 685.3±278.8 pg/ml. The mean CACS was 96.4±261.9 and PWV was 1,516±371 cm/sec. The CACS showed significant correlation with OPG levels, PWV ($r=0.353$, $p=0.004$, $r=0.305$, $p=0.006$) in all subjects. Also, OPG levels showed significant correlation with PWV ($r=0.304$, $p=0.023$). The CACS, OPG and other CHD risk factors such as lipid profiles, hsCRP, DM duration, HbA_{1c}, smoking, blood pressure didn't show significant correlation in all subjects. Also, when the subjects were analyzed according to the severity of CACS (CAC score > 400 or ≤400), only OPG levels and PWV showed different levels significantly between groups ($p=0.046$, $p=0.005$). Plasma OPG levels were significantly higher in severe CACS group. Of the 6 patients who showed severe CACS, 4 showed abnormal myocardial perfusion and positive treadmill test.

Conclusion: This study showed CACS and plasma OPG had significant correlation. Therefore, CACS measured by MDCT might be helpful assessing of coronary atherosclerosis and measurement of OPG merits further investigation as a simple test for identifying asymptomatic type 2 diabetic patients.

Novel type 2 diabetes susceptibility loci and measures of glycaemic control in a population based study of healthy children

C. Langenberg¹, R.J.F. Loos¹, S. Brage¹, L.B. Sardinha², L.B. Andersen³, U. Ekelund¹, N.J. Wareham¹

¹Institute of Metabolic Sciences, MRC Epidemiology Unit, Cambridge, United Kingdom, ²Faculty of Human Movement, Technical University, Lisbon, Portugal, ³Department of Sports Medicine, Norwegian School of Sport Sciences, Oslo, Norway

Background and aims: Genome-wide association studies have recently associated previously unsuspected common genetic variants with type 2 diabetes (T2D), and several of these have since been shown to affect β -cell function in studies of adults. Associations with measures of glucose homeostasis in childhood or adolescence have not been investigated, but may show whether genetic susceptibility to T2D is already apparent early in life. Our objective was to examine associations of novel T2D loci with fasting glucose and insulin, and the homeostasis model of assessment for β -cell function (HOMA-B) and insulin resistance (HOMA-IR) in European children.

Materials and methods: Variants linked to CDKN2A/B, CDKAL1, IGF2BP2, SLC30A8, chromosome 11p12, and HHEX were genotyped in Danish and Estonian Caucasian children of the European Youth Heart Study, a population-based study of 2,027 girls and boys aged between 9–10 and 15–16 years. Multivariate linear regression was used to investigate associations of genetic variants with fasting plasma glucose and insulin, and HOMA-B and HOMA-IR, adjusting for age, sex, country and laboratory.

Results: Variants in CDKAL1 (G-minor allele of rs7756992, C-minor allele of rs10946398) were each significantly associated with lower levels of HOMA-B, with differences between minor and common homozygotes of 10.0% ($p=0.011$) and 8.3% ($p=0.019$), respectively. The G-minor allele of rs7756992 was also weakly associated with higher levels of insulin ($p=0.055$). These findings support previous studies of adults linking these variants in CDKAL1 to altered β -cell function and insulin secretion. In addition, we found that the C-major allele of rs13266634 in SLC30A8 was associated with higher fasting glucose ($p=0.016$), in line with recent case-control studies showing increased odds of T2D in adult carriers of the C-major allele. None of these associations differed significantly by sex, country or age group. Other candidates from recent GWA studies did not show any such relationships.

Conclusion: This is the first study to show that CDKAL1 and SLC30A8 may influence susceptibility to T2D from an early age. Future studies with detailed measures of insulin processing and secretion in children and adults will help to understand how and when in life these genes operate to influence the risk of T2D.

62

Metabolic effects of novel type 2 diabetes genes in a population aged 18–75 years

A. Jonsson¹, B. Isomaa², T. Tuomi³, V. Lyssenko¹, L. Groop^{1,3}

¹Clinical Sciences, Diabetes & Endocrinology, Lund University, Malmö, Sweden, ²Folkhälsan Research Center, Biomedicum, Folkhälsan Genetic Institute, Helsinki, Finland, ³Department of Medicine, University Hospital, University of Helsinki, Finland

Background and aims: Recently, several whole genome association scans (WGAS) for type 2 diabetes (T2D) have identified a number of novel T2D loci. Although many of them have been suggested to influence β -cell function, the quantitative effects of these variants on 1) BMI, 2) insulin secretion, 3) insulin action, and 4) FFA in a representative population is not known and formed the basis for the study carried out as part of population-based PPP-Botnia Study (Prevalence, Prediction and Prevention of Diabetes), including 8–10% of the population aged 18–75 years.

Materials and methods: 3,500 individuals from the PPP-Botnia Study (age 49.3±16.0, BMI 26.4±4.4; 2,903 with normal glucose tolerance (NGT), 395 with impaired fasting glucose and/or impaired glucose tolerance (IFG/IGT) and 202 with T2D) were genotyped for common variations in IGF2BP2 (rs4402960 and rs1470579), CDKAL1 (rs9460545), CDKN2A/2B (rs10811661), HHEX (rs1111875), FTO (rs9939609), SLC30A8 (rs11558471), TCF2 (rs4430796), TCF7L2 (rs7903146), KCNJ11 (rs5219) and PPARG (rs1801282). Insulin sensitivity was assessed with Matsuda Insulin sensitivity

index (ISI). Insulin secretion was measured with corrected insulin response (CIR) and beta-cell function as disposition index (DI), i.e. insulin secretion adjusted for the degree of insulin sensitivity. Linear regression analysis was used to test genotype-phenotype correlations.

Results: In all non-diabetic individuals, variants in *CDKAL1* (C-allele, CIR $p=5.97 \times 10^{-5}$ and DI $p=3.49 \times 10^{-5}$), *HHEX* (G-allele, CIR $p=1.33 \times 10^{-2}$ and DI $p=7.60 \times 10^{-3}$), *KCNJ11* (T-allele, CIR $p=3.73 \times 10^{-3}$), and *TCF2* (A-allele, CIR $p=2.60 \times 10^{-2}$) were associated with reduced insulin secretion. In NGT, risk genotype carriers in *CDKAL1* (CIR, $p=1.86 \times 10^{-4}$ and DI $p=5.24 \times 10^{-4}$), *HHEX* (CIR, $p=2.56 \times 10^{-2}$ and DI, $p=7.92 \times 10^{-3}$) and *CDKN2A/2B* (A-allele, CIR $p=2.95 \times 10^{-2}$ and DI, $p=3.06 \times 10^{-2}$) had reduced β -cell function. *PPARG* CC-carriers had lower insulin sensitivity ($p=1.89 \times 10^{-2}$) compared to G-allele carriers. In the whole cohort, the *FTO* AA-genotype carriers had 1.07 kg/m² higher BMI than TT-carriers ($p=6.52 \times 10^{-5}$) which resulted in an extra 1.9 kg weight increase per A-allele. Furthermore, *CDKAL1* and *IGF2BP2* risk carriers showed impaired postprandial suppression of FFA levels ($p<0.05$). Carriers of more than 7 risk alleles from genes previously shown to influence insulin secretion (*CDKAL1*, *HHEX*, *CDKN2A/2B*, *KCNJ11*, *TCF2*, *TCF7L2* and *IGF2BP2*) had lower insulin secretion (CIR -22.7% $p=2.38 \times 10^{-4}$ and DI -22.0% $p=3.63 \times 10^{-4}$) than carriers of less than 5 risk-alleles.

Conclusion: Most novel common variants increase susceptibility to T2D by influencing β -cell function, possibly mediated through alterations in FFA stimulated mechanisms. The exceptions are *FTO* and *PPARG*, which confer risk of T2D by influencing BMI and insulin sensitivity.

⁵Research Centre for Prevention and Health, Glostrup University Hospital, Denmark, ⁶Epidemiology, Steno Diabetes Center, Copenhagen, Denmark,

⁷Faculty of Health Sciences, University of Aarhus, Denmark

Background and aims: We evaluated the impact on diabetes-related intermediary traits of common novel type 2 diabetes-associated gene variants in the *JAZF1*, *CDC123/CAMK1D*, *TSPAN8*, *THADA*, *ADAMTS9*, and *NOTCH2* loci which were recently identified by meta-analysis of genome-wide association data.

Materials and methods: We genotyped the *JAZF1* (rs864745), *CDC123/CAMK1D* (rs12779790), *TSPAN8* (rs7961581), *THADA* (rs7578597), *ADAMTS9* (rs4607103), and *NOTCH2* (rs10923931) variants in 6,083 middle-aged subjects with available DNA from the population-based Inter99 cohort who had all been subjected to an oral glucose tolerance test (OGTT).

Results: In 4,516 glucose-tolerant individuals, homozygous carriers of the minor diabetes-associated G-allele of the *CDC123/CAMK1D* rs12779790 variant showed an 18% decreased insulinogenic index (10–27%; $P=4 \times 10^{-5}$), an 18% decreased corrected insulin response (8.1–29%; $P=5 \times 10^{-4}$), and a 13% decreased ratio of area under the serum-insulin and plasma-glucose curves during an OGTT (AUC-insulin/AUC-glucose) (5.8–20%; $P=4 \times 10^{-4}$). Carriers of the diabetes-protective C-allele of *JAZF1* rs864745 had an allele-dependent 3% increase in BIGTT-AIR (0.9–4.3%; $P=0.003$). Furthermore, the diabetes-associated C-allele of *TSPAN8* associated with decreased levels of corrected insulin response (4.5% [0.5–8.4]; $P=0.03$), of AUC-insulin/AUC-glucose ratio (3.9% [1.2–6.7]; $P=0.005$), and of insulinogenic index (5.2% [1.9–8.6%]; $P=0.002$). Associations were confirmed when taking the effect of insulin sensitivity into account by constructing an OGTT-based disposition index or when performing multivariate analysis of insulin release and insulin sensitivity. Similar associations were found when including all 5,964 treatment-naïve individuals from the Inter99 cohort.

Conclusion: If replicated our data suggest that type 2 diabetes at-risk alleles in the *JAZF1*, *CDC123/CAMK1D*, and *TSPAN8* loci associate with various OGTT-based surrogate measures of insulin release emphasising the contribution of abnormal pancreatic β -cell function in the pathogenesis of type 2 diabetes.

64

Large-scale type 2 diabetes association analysis of low-frequency nonsynonymous coding variants in the *HNF4A* gene including up to 17,600 individuals

B. Jafar Mohammadi¹, C.J. Groves¹, B. Herrera^{1,2}, T.M. Frayling³, A.T. Hattersley³, A.L. Gloyn¹, M.I. McCarthy^{1,2}

¹Oxford Centre for Diabetes, Endocrinology and Metabolism, University of Oxford, ²Wellcome Trust Centre for Human Genetics, University of Oxford,

³Institute of Biomedical and Clinical Science, Peninsula Medical School, Exeter, United Kingdom

Background and aims: Despite the tremendous increase in our understanding of genetics of Type 2 Diabetes (T2DM) over the past 18 months, the familial aggregation seen in T2DM remains poorly explained. Low frequency variants, which crucially are likely to have been missed by both genome-wide association and linkage scans, may explain this “heritability gap”. Genes already implicated in diabetes risk are logical candidates within which to start the search for low frequency, incompletely-penetrant variants that may make substantial contributions to diabetes predisposition. This study focused on *HNF4A* and two rare non-synonymous variants, T130I (rs1800961) and V255M (minor allele frequencies [MAF], 0.05 and 0.001 respectively), for which previous small-scale studies had provided suggestive, but not genome-wide significant, evidence for association. This study aims to establish, through large-scale, well-powered association analysis, the true contribution of these variants to diabetes risk.

Materials and methods: The *HNF4A* T130I and V255M variants were genotyped on the ABI 7900HT platform. Genotyping was carried out in between 15,546 (T130I: 6,079 cases, 9,467 controls) and 17,628 individuals (V255M: 5,011 cases, 12,617 controls) of UK British/Irish ancestry. We conducted association testing using an exact implementation of the Cochran-Armitage (CA) trend test (StatXact 6).

Results: Genotyping success rates were 98.7% for the T130I variant and 97.9% for the V255M variant with no genotyping error revealed by discordance testing. Neither variant showed any evidence of association with diabetes in these analyses. For T130I, using the common homozygote as reference, an OR_{het} of 0.93 (95%CI 0.81–1.06) and an OR_{hom} of 0.86 (95% CI 0.65–1.13) was observed (case AF: 3.32%; control AF: 3.14%, $p=0.30$). For V255M an OR_{het} of 1.68 (95% CI 0.62–5.35) was obtained and no rare homozygotes were detected (case AF: 0.06%; control AF: 0.09%, $p=0.33$).

Conclusion: Although both these non-synonymous coding variants in a gene implicated in diabetes pathogenesis, have been previously reported to be associated with T2DM susceptibility, the large-scale, well-powered association analyses performed here indicate that these findings are not robust. This study once again emphasises the importance of using adequately powered studies when investigating associations, especially where the frequency of the susceptibility allele is low.

65

Is there a unifying genetic factor predisposing to the metabolic syndrome?

M. Sjögren¹, M. Orho-Melander¹, A. Jonsson¹, M. Svensson¹, G. Berglund², P. Nilsson², L. Groop^{1,3}, V. Lyssenko¹

¹Clinical Sciences, Diabetes & Endocrinology, Lund University, Malmö, Sweden, ²Clinical Sciences, Medicine, Lund University, Malmö, Sweden,

³Program of Molecular Medicine, University of Helsinki, Finland

Background and aims: The metabolic syndrome (MetS) is defined as cluster of factors contributing to increased risk of cardiovascular disease and type 2 diabetes. Heritability of MetS is relatively high, indicating a genetic component but environmental factors, such as physical inactivity and westernized high fat diet are also important. No unifying mechanism for MetS has to date been identified. One approach could be to search for common genetic susceptibility loci. Our aim was therefore to study whether common variations in 20 genes previously associated with either T2D or insulin resistance/obesity also would increase risk for MetS.

Materials and methods: Association between 21 SNPs (*TCF7L2* rs7903146, *PPARG* rs1801282, *KCNJ11* rs5219, *HHEX* rs111875, *IGF2BP2* rs4402960, *CDKAL1* rs7754840, *FTO* rs9939609, *CDKN2A* rs10811661, *SLC30A8* rs13266634, *WSF1* rs10010131, *CAPN10* rs3792267 and rs2975760, *UCP2* rs659366, *IRS1* rs1801278, *PPARGC1A* rs8192678, *BIAR* rs1801253, *B2AR* rs1042714, *B3AR* rs4994, *PTPN1* rs3787348, *ENPP1* rs1044498 and *GCKR* rs1260326) and risk of developing MetS was investigated in 16064 non-dia-

betic individuals from the Malmoe preventive project (MPP) followed prospectively for a mean time of 23 ± 4 years. The definition of MetS in our study includes at least three of the following features: obesity ($\text{BMI} \geq 30 \text{ kg/m}^2$), dyslipidemia (triglycerides $\geq 1.7 \text{ mmol/l}$ or lipid lowering treatment), hypertension (blood pressure $\geq 140/90 \text{ mmHg}$ or anti-hypertensive medication) and hyperglycemia (fasting plasma glucose $\geq 5.6 \text{ mmol/l}$ or overt diabetes). The risk of developing MetS was calculated by logistic regression adjusted for age and gender, when appropriate.

Results: Polymorphisms in *TCF7L2* rs7903146 ($\text{OR} = 1.11 [1.04-1.17]$, $p = 0.001$), *FTO* rs9939609 ($\text{OR} = 1.08 [1.02-1.14]$, $p = 0.006$), *IGF2BP2* rs4402960 ($\text{OR} = 1.07 [1.01-1.13]$, $p = 0.023$) and *WSF1* rs10010131 ($\text{OR} = 1.07 [1.02-1.13]$, $p = 0.010$) increased the risk of developing MetS in individuals unaffected at baseline. The *FTO* rs9939609 ($\text{OR} = 1.09 [1.03-1.16]$, $p = 0.004$) was associated with development of obesity, *GCKR* rs1260326 ($\text{OR} = 1.15 [1.09-1.22]$, $p = 1.43 \times 10^{-6}$) with development of dyslipidemia and *TCF7L2* rs7903146 ($\text{OR} = 1.17 [1.09-1.25]$, $p = 9.15 \times 10^{-6}$), *IGF2BP2* rs4402960 ($\text{OR} = 1.10 [1.03-1.18]$, $p = 0.004$), *CDKAL1* rs7754840 ($\text{OR} = 1.12 [1.04-1.20]$, $p = 0.002$) and *SLC30A8* rs13266634 ($\text{OR} = 1.12 [1.05-1.19]$, $p = 0.001$) with increased risk of developing hyperglycemia. None of the studied polymorphisms was associated with all sub-components of MetS.

Conclusion: A number of common studied variants predispose to MetS by influencing specific sub-components but do not identify a unifying pathophysiological etiology.

66

The fasting plasma glucose-associated *G6PC2/ABCB11* rs560887 variant influences pancreatic beta cell function in studies of 10,317 Danes

T. Nielsen¹, C.S. Rose¹, N. Grarup¹, N.T. Krarup¹, A. Albrechtsen², K. Borch-Johnsen^{3,4}, T. Jørgensen⁴, T. Lauritzen⁵, A. Sandbæk⁵, T. Hansen¹, O. Pedersen^{1,6}

¹Genetics, Steno Diabetes Center, Gentofte, Denmark, ²Department of Biostatistics, University of Copenhagen, Denmark, ³Epidemiology, Steno Diabetes Center, Gentofte, Denmark, ⁴Research Centre for Prevention and Health, Glostrup University Hospital, Denmark, ⁵Department of General Practice, University of Aarhus, Denmark, ⁶Department of Health Science, University of Aarhus, Denmark

Background and aims: An association between fasting plasma glucose (FPG) and variants in a locus containing the *G6PC2* (glucose-6-phosphatase, catalytic subunit 2) and *ABCB11* (ATP-binding cassette, subfamily B, member 11) genes has been reported. Since *G6PC2* is expressed predominantly in the pancreatic β -cells, variants in *G6PC2* may also contribute to susceptibility to type 2 diabetes and insulin release. Thus, the aim of the present study was to extensively characterise diabetes-related metabolic traits in carriers of the *G6PC2* rs560887 variant and to assess association with type 2 diabetes.

Materials and methods: The rs560887 polymorphism was genotyped in 5,924 middle-aged Danes from the population-based Inter99 study, 369 young, healthy subjects, and additionally in 3,514 type 2 diabetic patients and 510 glucose-tolerant subjects from the Danish ADDITION study and Steno Diabetes Center.

Results: Besides decreased FPG the A-allele of rs560887 variant showed association with lower levels of serum insulin ($p=0.0003$) and serum C-peptide ($p=1 \times 10^{-5}$) after 30 minutes during an oral glucose tolerance test in 5,808 treatment-naïve subjects from the Inter99 study. Furthermore, the A-allele of the rs560887 variant was associated with a decreased glucose-stimulated insulin release as assessed by the insulinogenic index ($p=4 \times 10^{-5}$). In a study of 369 young, healthy subjects we replicated the association with FPG ($p=0.01$), and found a borderline association with lowered acute insulin response during an intravenous glucose tolerance test ($p=0.06$). Yet, in a statistically well-powered case-control study of 3,856 type 2 diabetic cases and 4,918 glucose-tolerant control subjects, we observed no association with type 2 diabetes.

Conclusion: The *G6PC2* rs560887 variant influences FPG and decreases glucose-stimulated insulin release implying an impaired pancreatic β -cell function in carriers of the minor A-allele.

67

Modulation of TACE activity by high fat diet and metabolic stimuli

L. Fiorentino, M. Cavallera, F. Tornei, R. Amoroso, R. Menghini, R. Lauro, M. Federici

Internal Medicine, University of Rome, Italy

Background and aims: Obesity progressively leads to an increase of white adipose mass and to the recruitment of macrophages to the visceral adipose tissue, thus establishing a low grade, systemic inflammatory status that arises from deregulated production and release of inflammatory cytokines and free fatty acids. The mechanisms underlying obesity-driven inflammation are not fully understood, but it has been shown that nutritional fatty acids activate Toll-like receptor 4 and trigger low grade inflammation and mild endotoxemia in experimental models that recapitulate some effects of high fat diet on insulin sensitivity. TNF- α is the most potent pro-inflammatory cytokine produced by adipose tissue, and initiate the low-grade inflammatory response characteristic of obesity. It is regulated at a post-translational level by TACE (TNF- α Converting Enzyme), a transmembrane sheddase that releases soluble TNF- α from the membrane-bound form. Recent studies have suggested that the activity of TACE, and of its inhibitor Timp3, may be altered in patients affected by chronic metabolic and inflammatory diseases as levels of soluble forms of many TACE substrates like TNF- α , TNFR-1, and IL6R resulted increased in these patients. Thus, we sought evidence *in vivo* and *in vitro* for an increased activation of TACE in the inflammatory status characteristic of high fat diet-induced obesity.

Materials and methods: To gain insight into TACE activation in an animal model of obesity, we compared wild-type mice fed a standard or a high fat diet for different periods of time, and measured TACE activity using a fluorogenic TACE substrate encompassing TNF- α cleaving site. For *in vitro* studies, we treated murine hepatocytes and pre-hepatocytes with different metabolic stimuli, and then proceed to TACE activity measurement.

Results: To test the hypothesis that excessive fat intake results in increased TACE activity we fed wild type mice with standard chow or high fat diet for 20 weeks. We analyzed TACE and Timp3 expression in liver, muscle and white adipose tissue (WAT), by Real-Time PCR and Western blot, and showed that TACE levels were significantly increased in HFD-fed mice, while Timp3 levels resulted significantly reduced ($p < 0.05$ for all). This prompted us to analyze the shedding activity of TACE in the same tissues, using a fluorimetric assay. TACE activity was significantly higher in liver, muscle and fat of HFD-fed animals compared to the control ones ($p < 0.01$ for all). Next, we analyze more in details the metabolic stimuli that are able to activate TACE; to this aim, we used *in vitro* cultured pre-hepatocytes and hepatocytes, and treated them with palmitic acid (PA), endotoxin (LPS) and, as a positive control, TPA, a known activator of TACE. The shedding activity of TACE was significantly increased in both cell lines, mostly by LPS and, to a lesser extent, by PA treatment.

Conclusion: Our studies demonstrated that modulation of TACE activity occurs in an *in vivo* model of obesity, partially explaining the increased production of TNF- α and other pro-inflammatory cytokines, and consequently the low grade inflammatory status characteristic of obesity. Moreover, other metabolic stimuli, such as free fatty acids and endotoxin, which are released from the expanding WAT, are also able to activate TACE shedding activity. Our results suggested that modulation of TACE activity is a new pathway to be investigated for development of agents acting against obesity.

68

TIMP3 controls diet-induced inflammation and metabolic disorders in mice

M. Federici¹, R. Menghini¹, R. Amoroso¹, V. Marzano¹, S. Menini², L. Fiorentino¹, F. Tornei¹, A. Urbani¹, G. Pugliese¹, R. Lauro¹

¹Dept. of Internal Medicine, University of Tor Vergata, Rome, ²Dept. of Clinical Sciences, University of Rome La Sapienza, Italy

Background and aims: Obesity is associated with low-grade inflammatory state which prompts to diabetes and atherosclerosis. We found that activity and expression of Tissue inhibitor of Metalloproteinase 3 (TIMP3) are

decreased in humans and mice affected by obesity. TIMP3 is an inhibitor of metalloproteinases such as MMP9 and TNF- α converting enzyme (TACE), of VEGFR and EGFR activation. Alteration of TIMP3 activity may impact on processes such as inflammation, angiogenesis, cell proliferation and fibrosis, all potentially relevant in obesity and its metabolic and vascular complications. Because obesity is associated with increased macrophage accumulation in different tissues, we used a transgenic approach under control of CD68 promoter to reconstitute TIMP3 levels in vivo and we analyzed its effects on metabolic homeostasis.

Materials and methods: Transgenic (Tg) mice were identified by RT-PCR and confirmed by Southern blot. In Tg mice, TIMP3 overexpression was confirmed by RT-PCR, Western blot and Reverse Zymography in spleen, liver, peripheral blood monocytes and bone marrow derived macrophages, treated or not with LPS. WT and Tg mice fed standard chow or a high fat diet (HFD, 60% cal from fat) were subjected to metabolic and molecular phenotypization.

Results: After 20 weeks of High Fat Diet (HFD), we observed that Tg mice compared with WT littermates showed a significant improved glucose tolerance and insulin sensitivity, measured by IPGTT and IPITT ($p < 0.01$ for all, $n = 8$ per group). Insulin, leptin, AST and ALT were lower and adiponectin increased in Tg mice compared with WT littermates ($p < 0.01$ for all, $n = 8$ per group). Histology of white adipose tissue (WAT), liver, kidney and aorta showed accumulation of lipids, intense fibrosis and increased inflammatory markers in WT compared with Tg mice. Expression profiling for metabolic and inflammatory genes revealed that Tg compared with WT have significant lower levels for MCP1, CXCL16, IL6, SOCS3 and SCD1 in WAT, and for SCD1, FAS, Srebp and G6Pase in liver ($p < 0.01$ for all, $n = 5$). Tg mice showed also lower levels of pJNK, and pIKK and pEGFR and higher levels of pAMPK in liver. To further elucidate the mechanisms involved in Timp3 rescue of hepatic steatosis we analyzed liver homogenates by shotgun proteomics (ESI-LC-qTOF-MS/MS) identifying 62 differentially expressed proteins in WT compared with Tg mice, including acyl-CoA synthetase long-chain family member 1 or ACSL1 (5-fold higher in WT vs Tg, $p < 0.001$), Fatty Acid Binding Protein-1 or FABP1 (2.2 higher in WT vs Tg, $p < 0.01$) and Retinaldehyde Dehydrogenase 1 or RALDH1 (1.9 higher in WT vs Tg, $p < 0.01$), all confirmed by western blot. Analysis of results by IPA software revealed that WT significantly differed from Tg mice for pathways including 1.Fatty acid Metabolism, 2.Glycolysis/Gluconeogenesis and 3.Fatty Acids elongation in mitochondria.

Conclusion: Our data indicate that macrophage specific overexpression of TIMP3 protects from HFD induced inflammation and metabolic disorders. Since TIMP3 related pathways play a role in linking inflammation to disruption of metabolic homeostasis, we suggest that TIMP3 should be investigated by a therapeutic point of view in obesity and its metabolic and vascular complications.

P-selectin glycoprotein ligand-1 (PSGL-1) deficient mice are protective for insulin resistance induced by high-fat diet

D. Hirota, K. Shikata, C. Sato, M. Sasaki, S. Nishishita, S. Miyamoto, R. Kodera, N. Kajitani, H. Makino
Department of Medicine and Clinical Science, Okayama University Graduate School of Medicine Dentistry and Pharmaceutical Sciences, Okayama, Japan

Background and aims: There have been accumulating evidences that inflammation in adipose tissue are involved in the mechanism of insulin resistance in obesity. Macrophages and proinflammatory cytokines are increased in visceral adipose tissues of obese people and animal models. However, the recruitment pathway of monocyte/macrophage into visceral adipose tissues has not been clarified. We have recently screened the gene expression profiles of adhesion molecules in adipose tissues of obese mice using DNA microarray and found that P-selectin glycoprotein ligand-1 (PSGL-1) is up-regulated in both db/db mice and C57/BL6 mice fed a high-fat diet (HFD). We also found that CD68, MCP-1 and P-selectin are concomitantly increased in adipose tissues. PSGL-1 is known to express on both leukocytes and endothelial cells and has binding capacity to P-, L- and E-selectin. We found PSGL-1 is expressed on both endothelial cells and macrophages in adipose tissues. These data suggest that PSGL-1-selectin pathway may mediate the recruitment of macrophages into adipose tissues. The aim of this study is to clarify the role of PSGL-1 in macrophage infiltration and insulin resistance in obesity using PSGL-1 deficient (KO) mice.

Materials and methods: Seven week-old male PSGL-1 KO mice ($n = 8$) and C57/BL6 mice (wild type mice, $n = 7$) were fed a HFD. Metabolic data were measured, and an intraperitoneal insulin tolerance test (ITT) and an intraperitoneal glucose tolerance test (IPGTT) were performed at 10 weeks after start of HFD. We measured HbA1c, serum lipids, insulin, leptin, adiponectin. We examined the expression of proinflammatory cytokines, chemokines and adhesion molecules and infiltration of macrophages in epididymal white adipose tissues (WAT). We also measured the size of adipocytes. PSGL-1 KO mice and wild type mice with normal fat diet were used for controls.

Results: There was no significant difference in body weight (BW) (Mean values of PSGL-1-KO and wild type mice fed a HFD; 39.2 vs 36.9 g), weight of epididymal WAT per BW (4.5 vs 4.8 %), fasting blood glucose (247.0 vs 260.4 mg/dl) and HbA1c (3.0 vs 3.1 %) between PSGL-1 KO and wild type mice fed a HFD. Significant reductions were observed in total cholesterol (134.8 vs 189.1 mg/dl), LDL cholesterol (15.4 vs 34.1 mg/dl), triglyceride (40.5 vs 62.5 mg/dl), free fatty acid (672.8 vs 1070.5 μ Eq/l), fasting insulin (1.05 vs 1.45 ng/ml) and leptin (6.4 vs 11.9 ng/ml) in PSGL-1 KO mice as compared with wild type mice fed a HFD. The size of adipocytes in epididymal WAT was also significantly decreased in PSGL-1 KO mice as compared with wild type mice fed a HFD. Glucose tolerance was significantly improved in PSGL-1 KO mice in ITT and in IPGTT. The expression of MCP-1, F4/80, leptin and NOS2 (iNOS) were decreased in PSGL-1 KO mice as compared with wild type mice fed a HFD. Serum adiponectin level was increased in PSGL-1 KO mice but there was no statistical significance.

Conclusion: PSGL-1 deficient mice revealed decreased macrophage infiltration into adipose tissues, improved adipocyte hypertrophy and improved insulin resistance induced by high fat diet. These results suggest that the PSGL-1-selectin pathway promotes the recruitment of macrophages into adipose tissue. PSGL-1 might be a novel target for the prevention of diabetes in obese people.

Changes in gut microbiota control intestinal permeability-induced inflammation in obese and diabetic mice through unexpected dependent mechanisms

P.D. Cani¹, O. Rottier¹, Y. Guiot², A. Neyrinck¹, L. Geurts¹, N. Delzenne¹

¹Unit PMNT, ²Unit of Pathology, Université catholique de Louvain, Brussels, Belgium

Background and aims: Recently, we and others have proposed that gut microbiota would favor the occurrence of the metabolic diseases associated with obesity. In the light of the role of gut microbiota for the development of metabolic diseases, we reported that high fat feeding was associated with metabolic endotoxaemia, and a lower *Bifidobacterium* spp caecal content in mice. Moreover, we found that selective increases of *Bifidobacterium* spp in gut microbiota improve high fat diet induced diabetes in mice through a mechanism associated with endotoxaemia. We and other have demonstrated that obese and diabetic mice (*ob/ob* and HF-fed) display enhanced intestinal permeability, and are characterised by a metabolic endotoxaemia and a low grade inflammation. Hence, we tested the hypothesis that specific and selective changes in gut microbiota control the intestinal permeability and the occurrence of inflammation and obesity-associated metabolic diseases.

Materials and methods: Since bifidobacteria have been reported to reduce plasma endotoxin and improve gut barrier function by an unknown mechanism, we specifically changes gut microbiota of *ob/ob* mice by the mean of prebiotics (oligofructose, Ob-OFS) for 5 weeks.

Results: Ob-OFS fed mice exhibit a significantly lower intestinal permeability as measured by an oral Dx-FITC challenge. We found a strong improved intestinal mucosal integrity as shown by the epithelial intestinal tight-junction (TJ) proteins ZO1 and Occludin (mRNA and immunohistochemistry analysis) compared with normal chow-fed *ob/ob* mice (Ob-CT). This phenomenon was associated with a dramatic decreased inflammatory tone (lower plasma endotoxin levels, plasma and liver cytokines concentrations, liver macrophages infiltration and oxidative stress) as compared to Ob-CT mice. Interestingly, OFS feeding significantly increased jejunum and colon proglucagon mRNA concentrations, and was positively correlated with a higher portal plasma GLP-1 and GLP-2 levels. To identify whether the gut microbiota induced proglucagon mRNA expression was involved in the improved intestinal permeability of Ob-OFS mice, we performed multiple correlations analysis between TJ proteins and intestinal proglucagon mRNA. We found that proglucagon mRNA were significantly and positively correlated with TJ

mRNA, and were negatively correlated with *in vivo* intestinal permeability. All these results were independent of the OFS-induced lower food intake, since all the parameters measured in the energy pair fed group were equivalent to the Ob-CT fed mice.

Conclusion: Together, these findings suggest that gut microbiota participate to the inflammatory phenotype of *ob/ob* mice. In addition, these data demonstrate that a selective modulation in gut microbiota improves intestinal permeability, inflammatory markers, obesity and diabetes, via several unexpected mechanisms. We propose that the gut microbiota controls and increases endogenous production of the intestinotrophic proglucagon derived peptides GLP-2, and consequently improves gut barrier functions. These new findings demonstrate that it would be useful to develop specific therapeutic strategies using GLP-2 or by modifying gut microbiota to control intestinal permeability and obesity related metabolic disorders.

71

Transgenic expression of human C-reactive protein suppresses adiponectin and induces insulin resistance in spontaneously hypertensive rats

O. Oliyarnyk¹, H. Malinska¹, M. Maxova¹, L. Kazdova¹, M. Pravenec²

¹Department of Metabolism and Diabetes, Institute for Clinical and Experimental Medicine, ²Institute of Physiology, Academy of Sciences, Prague, Czech Republic

Background and aims: C-reactive protein (CRP), a marker and mediator of inflammation, is now recognized as central to the development of cardiovascular disease. Growing evidence indicates that CRP may also participate in the development of metabolic syndrome-related disease, but the mechanism of CRP implication in insulin resistance is not well understood. We tested the hypothesis that increased expression of human CRP in adipose tissue affects age-related changes in glucose tolerance, adiponectin levels, and insulin resistance of peripheral tissues in one year old transgenic spontaneously hypertensive rats (SHR), a well established animal model of genetic hypertension, dyslipidemia, and insulin resistance. Keeping in mind that chronic inflammation can contribute to increased oxidative stress, we measured liver antioxidant enzymes activity, reduced glutathione (GSH), and lipid peroxidation products (LPO) levels.

Materials and methods: One year old male SHR expressing the human CRP gene (SHR Tg) under control of the fat-specific aP2 promoter were used. Control group comprised age-matched genetically identical rats with absence of the transgene (SHR). Tissue sensitivity to insulin action was measured *in vitro* without or with insulin (250 µU/ml) according to basal and insulin-stimulated ¹⁴C-U-glucose incorporation into muscle glycogen or adipose tissue lipids. Adiponectin was determined by EIA kit (B-Bridge Inc, USA). Triacylglycerols (TAG) and glucose concentration were determined by kits of Pliva Lachema, Czech Republic. NEFA level was measured using kit of Roche Diagnostics, Germany. Antioxidant enzymes activities, GSH and LPO products concentrations were determined by kits of Cayman Chemical, USA and Randox Laboratories, UK.

Results: There were no significant differences in body weight, weight of epididymal fat pads, serum NEFA, fasting blood glucose levels or adipose tissue insulin sensitivity between rats with and without the CRP transgene. The transgenic expression of CRP was associated with a significant increase in serum TAG (0.84±0.05 vs 0.64±0.037 mmol/l, *p*<0.05), serum insulin levels after glucose load (insulinemia in 30 min.: 9.1±0.4 vs 6.0±0.1 mmol/l, *p*<0.05; in 60 min.: 10.3±1.6 vs 6.2±0.18 mmol/l, *p*<0.02), liver TAG accumulation (4.30±0.56 vs 6.89±0.56 mmol/g, *p*<0.05) and markedly decreased insulin stimulated glycogenesis in muscle (174±8 vs 278±35 nmol/g/2h, *p*<0.05). The SHR Tg had markedly decreased levels of serum adiponectin (2.37±0.31 vs 4.32±0.59 µg/ml, *p*<0.05), reduced liver glutathione peroxidase activity (388±29 vs 546±27 µmol GSH/min/mg protein, *p*<0.01) and GSH concentration (15.9±1.0 vs 21.8±0.9 µmol/mg protein, *p*<0.01). Liver LPO products levels were elevated in SHR Tg rats in comparison to control SHR: conjugated dienes 26.5±1.3 vs 22.4±1.1 nmol/mg protein, *p*<0.05; thiobarbituric acid reactive substances 1.17±0.09 vs 0.81±0.07 nmol/mg protein, *p*<0.01.

Conclusion: It can be concluded that fat-specific overexpression of human CRP promotes skeletal muscle insulin resistance, liver triglyceride accumulation and lipoperoxidation in the one year old SHR rats. Our data support the hypothesis that this effect of transgenic CRP expression could be related to lower adiponectin secretion under these conditions.

Pioglitazone treatment in subjects with impaired glucose tolerance: inhibition of cytokine gene and protein expression from mononuclear cells and cross-talk with adipocytes

P.D. Reaven, W. Zhang, E. Schwartz, P. Permana

Endocrinology, Phoenix VA Health System, Phoenix, United States

Background and aims: Infiltration by monocytes and lymphocytes in the artery wall and their production of a variety of inflammatory factors contribute to the development of atherosclerosis. Previous studies have demonstrated that therapy with thiazolidinediones (TZDs) might play a protective role not only by improving metabolic disorders but also by inhibiting inflammation. However, the specific *in vivo* effects of TZDs on individual mononuclear cell types is unclear, as is whether these circulating cells from TZD treated individuals are less able to induce inflammation in other tissues.

Materials and methods: To address these questions, we first confirmed that inflammation, as assessed by IL-6 gene and protein expression, was increased in monocytes and lymphocytes isolated (using sequential percoll and histopaque gradient centrifugations) from subjects with IGT (*n*=13) compared to age and BMI matched individuals with normal glucose tolerance (*n*=13). We then randomized 67 IGT subjects to 5 months of placebo or pioglitazone (PIO) therapy (45mg/d) and assessed effects on mononuclear cell gene expression. Inflammatory effects of conditioned media from both monocytes and lymphocytes were also tested on human adipocytes.

Results: Plasma IL-6 levels were increased and gene expression and protein secretion in the conditioned media of IL-6 was increased nearly 3-fold (*p*<0.05) in both monocytes and lymphocytes from IGT subjects, confirming enhanced inflammatory activity in this group. After 5-months of therapy, subjects receiving PIO had lower (*p*<0.05) triglycerides and higher HDL cholesterol than subjects receiving placebo (*p*<0.05). While IL-1b, IL-6 and IL-8 gene expression from freshly isolated monocytes was similar in both groups at baseline, gene and protein expression levels of these factors after PIO therapy were significantly lower (*p*<0.05 for all). Conditioned media from monocytes from PIO (but not placebo) treated subjects still contained significantly less secreted protein even when stimulated for 16 hrs with LPS. Similarly, gene expression, and protein secretion into conditioned media, of IL-2, IL-6 and IL-8 were lower in lymphocytes isolated from PIO treated subjects. Interestingly, for all subjects, cytokine secretion was strongly and inversely related to plasma HDL levels at follow-up (*r*=0.3–0.8, *P*<0.05). As we have previously demonstrated that factors secreted from macrophages can greatly enhance adipocyte inflammation, we compared the effects of conditioned media from monocytes and lymphocytes on human adipocyte inflammation. Gene expression of IL-6, IL-8 and MCP-1 were all increased (8–38-fold) in human adipocytes conditioned with media from monocytes or lymphocytes from placebo treated subjects, while these were reduced by nearly 50% when exposed to conditioned media from monocytes or lymphocytes from PIO subjects.

Conclusion: These results demonstrate 1) that both peripheral monocytes and lymphocytes demonstrate greater inflammation in IGT subjects (even when matched with subjects of equal weight); 2) that PIO therapy can reduce gene and protein expression from both these inflammatory cell types; and 3) that treatment with PIO can potentially reduce the inflammatory cross-talk between inflammatory cells and adipose tissue which may in turn contribute to metabolic improvements resulting from PIO therapy.

Two-year treatment with sitagliptin and initial combination therapy of sitagliptin and metformin provides substantial and durable glycaemic control in patients with type 2 diabetes

D.S. Qi¹, R. Teng², M. Jiang¹, M.J. Davies³, K.D. Kaufman¹, J.M. Amatruda¹, D. Williams-Herman¹¹Clinical Research, Merck Research Laboratories, Rahway, ²BARDS, Merck Research Laboratories, Rahway, ³Medical Communications, Merck Research Laboratories, Rahway, United States

Background and aims: Long-term efficacy and safety of sitagliptin and initial combination therapy with sitagliptin and metformin were assessed in patients (pts) with type 2 diabetes (T2DM) and inadequate glycemic control (A1C 7.5% to 11%) on diet and exercise.

Materials and methods: After completing the initial, double-blind, 54-wk phase of the study, consenting pts continued in a double-blind, 50-wk extension. Pts initially randomized to active treatments remained on these treatments during the extension: sitagliptin 100 mg/metformin 2000 mg (S100/M2000), sitagliptin 100 mg/metformin 1000 mg (S100/M1000), metformin 2000 mg (M2000), metformin 1000 mg (M1000) [all as divided doses], and sitagliptin 100 mg q.d. (S100); pts initially randomized to placebo were switched to M2000 at Wk 24. This report presents 104-wk results for pts who were randomized to active treatment and who entered the extension. The primary efficacy analyses of this population required at least one measurement in the extension (all-patients-treated [APT] cohort), imputed missing data using LOCF, and excluded data from pts after they initiated glycemic rescue therapy.

Results: Of the original 1091 randomized pts, 915 received active treatment, 587 of these entered the extension and 402 were included in the APT analysis. In the APT cohort, mean baseline A1C was 8.6% (range 8.5% to 8.7%). Mean A1C changes from baseline (%) at Wk 104 were -1.7 (S100/M2000, n=105), -1.4 (S100/M1000, n=96), -1.3 (M2000, n=87), -1.1 (M1000, n=64), and -1.2 (S100, n=50). The proportions of patients with an A1C <7% at Wk 104 were 60% (S100/M2000), 45% (S100/M1000), 45% (M2000), 28% (M1000), and 32% (S100). For FPG and 2-hr postmeal glucose, respectively, mean changes from baseline (mmol/L) at Wk 104 were -3.2 and -6.1 in the S100/M2000 group, -2.8 and -5.3 in the S100/M1000 group, -2.4 and -4.8 in the M2000 group, -2.3 and -4.0 in the M1000 group, and -1.5 and -4.1 in the S100 group. For pts who completed treatment through Wk 104, mean HbA_{1c} changes from baseline (%) were -1.7 (S100/M2000, n=77), -1.5 (S100/M1000, n=64), -1.7 (M2000, n=53), -1.4 (M1000, n=26), and -1.4 (S100, n=22). Glycemic response was generally durable over time across treatments. All treatments were generally well tolerated.

Conclusion: Over 2 yrs, sitagliptin and the initial combination of sitagliptin and metformin provided substantial and durable glycemic improvements and were well tolerated in pts with T2DM.

Supported by: Merck & Co., Inc.

Vildagliptin is safe and well tolerated in patients with mild or moderate renal impairment

T. Thuren¹, S. Byiers², P. Mohideen³, M. Goodman³¹CVM-TA, Global CD&MA, Novartis Pharmaceuticals Corporation, East Hanover, United States, ²Biostatistics, Global CD&MA, Novartis Pharma AG, Basel, Switzerland, ³CVM-TA, Global CD & MA, Novartis Pharmaceuticals Corporation, East Hanover, United States

Background and aims: Vildagliptin is a potent and selective DPP-4 inhibitor that has been shown to enhance the physiological effects of incretin hormones thereby increasing islet alpha- and beta-cell responsiveness to glucose.

	Vilda50 mg QD	Vilda50 mg BID	Met ≤ 2 g/d	Rosi8 mg/d	Pio30 mg/d	PBO
Normal renal function (GFR ≥ 90 mL/min/1.73 m ²)						
n (%)	223 (54.5)	630 (45.9)	67 (26.6)	151 (56.6)	137 (63.4)	160 (46.1)
Any AE %	54.3	60.3	74.6	64.9	50.4	63.8
Mild renal insufficiency (GFR 60 - <90 mL/min/1.73 m ²)						
n (%)	163 (39.9)	662 (48.2)	165 (65.5)	104 (39.0)	75 (34.7)	162 (46.7)
Any AE %	55.2	65.3	76.4	61.5	48.0	57.4
Moderate renal insufficiency (GFR 30 - <60 mL/min/1.73 m ²)						
n (%)	23 (5.6)	79 (5.8)	20 (7.9)	12 (4.5)	4 (1.9)	25 (7.2)
Any AE	82.6	68.4	70.0	75.0	75.0	44.0

At marketed doses of 50mg once or twice-daily vildagliptin effectively reduces HbA_{1c} and is well tolerated. Although vildagliptin is not predominantly renally excreted, it is not approved in Europe for moderate and severe renal impairment due to insufficient clinical experience at this time.

The purpose of this abstract is to report on the prevalence of renal impairment in the vildagliptin global development program and to compare the safety and efficacy profiles of the marketed doses of vildagliptin in patients with renal impairment compared to those with normal renal function.

Materials and methods: Safety data from pooled vildagliptin monotherapy studies were used and glomerular filtration rate (GFR) was estimated using the MDRD method. Renal impairment was defined by categories of 60 to <90 mL/min/1.73 m² (mild) and 30 to <60 mL/min/1.73 m² (moderate). The number of patients with severe renal impairment (<30 mL/min/1.73 m²) were too small to allow an assessment of safety in this population.

Results: 927 patients receiving the marketed doses of vildagliptin as monotherapy had mild (n = 825) or moderate (n = 102) renal impairment, compared to 853 vildagliptin-treated patients with normal renal function. In patients with normal renal function or mild renal impairment, incidence of any adverse event (AE) was similar among patients receiving vildagliptin 50mg either once or twice-daily, rosiglitazone, pioglitazone or placebo, but lower than those who received metformin. In patients with moderate renal impairment, the incidence of any AE was similar among all active treatment groups, but higher than in the placebo group.

As expected, patients with normal renal function tended to have somewhat lower incidences of serious AEs and discontinuations due to adverse events, compared to patients with impaired renal function. Importantly, the incidences of these events in patients with renal impairment, were similar across the treatment groups (vildagliptin vs comparators). Additionally, there were no adverse changes in renal function over time following long term vildagliptin treatment. The HbA_{1c} lowering of vildagliptin 50 mg twice-daily was similar in patients with mild renal impairment ($\Delta = -1.06 \pm 0.10$) compared with those with normal renal function ($\Delta = -0.89 \pm 0.09$).

Conclusion: Half of all patients in the global development program exposed to the marketed doses of vildagliptin as monotherapy had either mild or moderate renal impairment at study baseline. Vildagliptin was effective and well tolerated in this population.

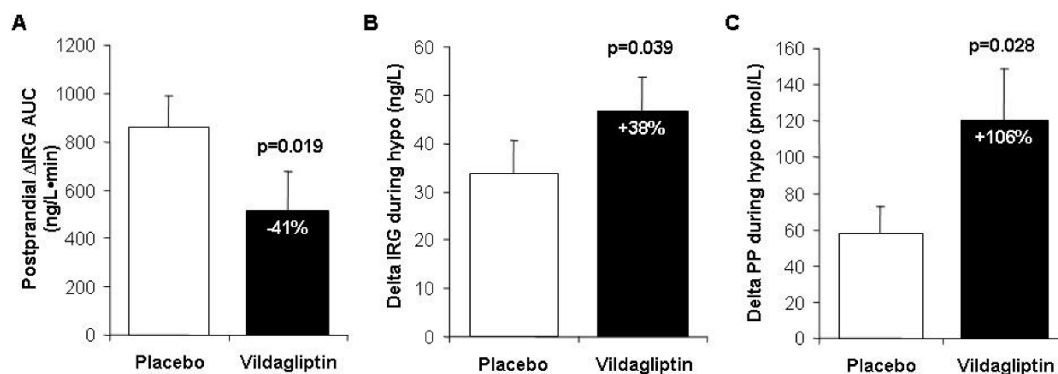

75

Vildagliptin improves alpha cell glucose sensing in patients with type 2 diabetes

B. Åhrén¹, A. Schweizer², S. Dejager³, B.E. Dunning⁴, M. Persson⁵, J.E. Foley⁶¹Clinical Sciences, Lund University, Sweden, ²Methodology & Innovation, Novartis Pharma AG, Basel, Switzerland, ³Clinical Research, Novartis Pharmaceuticals, Rueil Malmaison, France, ⁴Diabetes & Metabolism, PharmaWrite, Princeton, United States, ⁵Clinical Sciences, Malmö, Lund University, Malmö, Sweden, ⁶Clinical Research, Novartis Pharmaceuticals, E Hanover, United States

Background and aims: Vildagliptin is a potent and selective DPP-4 inhibitor that improves glycemic control in patients with type 2 diabetes (T2DM) by increasing islet responsiveness to glucose. A previous study demonstrated that vildagliptin improved glycemic control when added to high dose insulin monotherapy in patients with T2DM and reduced the frequency and severity of hypoglycemia. Hence we hypothesized that vildagliptin would increase the glucagon response to hypoglycemia while suppressing the glucagon response to hyperglycemia.

Materials and methods: This single-center, double-blind, randomized, placebo (PBO)-controlled crossover study assessed the glucagon response to hyper- and hypoglycemic stimuli. Thirty patients (24M, 6F) with T2DM (baseline BMI, A1C and FPG = 28.0 kg/m², 6.3% and 7.4 mM, respectively)

received vildagliptin 100 mg qd or PBO for 4 wks in random order with a 4-wk washout between treatment periods. On Day 28 of treatment, patients underwent standard meal tests followed by hyperinsulinemic, stepped glucose clamps (7.5, 5.0 and 2.5 mM glucose). During the hypoglycemic step, plasma levels of epinephrine, norepinephrine and cortisol were measured to assess sympathoadrenal activation, and pancreatic polypeptide (PP) was assessed as an index of parasympathetic activation.

Results: Plasma glucose levels were lower with vildagliptin than with PBO throughout the meal test and during the hyperglycemic clamp, but were superimposable during the euglycemic and hypoglycemic clamps. As shown below, vildagliptin significantly reduced inappropriate glucagon secretion (by 41%) during standard meal tests (Panel A), confirming previous results, and plasma glucagon levels were significantly lower during the hyperglycemic and euglycemic clamps with vildagliptin vs. PBO (data not shown). In contrast, during hypoglycemia, the increase in plasma glucagon levels (Panel B) and PP levels (Panel C) were significantly greater with vildagliptin than with PBO (+38% for glucagon, +106% for PP). The increases in plasma epinephrine, norepinephrine and cortisol during hypoglycemia were essentially identical during the two treatment periods, demonstrating that the degree of stress induced by (the identical degrees of) hypoglycemia did not differ between treatments.

Conclusion: Vildagliptin enhances α -cell sensitivity to both the suppressive effects of hyperglycemia and the stimulatory effects of hypoglycemia. The increase in PP seen during hypoglycemia in the vildagliptin treatment period suggests that vagal mechanisms contribute to the glucagon response to hypoglycemia.

76

Efficacy and safety of alogliptin and glyburide combination therapy in patients with type 2 diabetes

P. Fleck¹, Q. Mekki¹, M. Kipnes², C. Wilson³, R. Pratley⁴

¹Clinical Research, Takeda Global Research & Development Center Inc., Deerfield, ²Medicine, Christus Santa Rosa Medical Center, San Antonio, ³Biometrics Statistics, Takeda Global Research and Development Center Inc., Deerfield, ⁴Medicine, University of Vermont, Burlington, United States

Background and aims: Alogliptin (ALO) is a potent and highly selective DPP-4 inhibitor being developed for the treatment of type 2 diabetes mellitus (T2DM). Sulfonylureas, a class of antidiabetic agents, act by increasing insulin release from β -cells in a glucose-independent fashion but are associated with decreased efficacy over time. Therefore, the addition of alogliptin to an ongoing sulfonylurea regimen may result in improved glycemic control. This randomized, double-blind, placebo (PBO)-controlled study was designed to assess the efficacy and safety of ALO in combination with glyburide (GLY) in patients with T2DM inadequately controlled on sulfonylurea monotherapy. **Material and methods:** Patients (N=500; mean age=57 years; 71% White; 48% men; mean baseline HbA_{1c}=8.1%; mean duration of T2DM=8 years) were randomized to receive ALO 12.5 mg (n=203), ALO 25 mg (n=198), or PBO (n=99) once daily in combination with their ongoing GLY regimen (mean dose=12 mg/day) for 26 weeks after participating in a 4-week single-blind PBO run-in/stabilization period. The primary endpoint was change from baseline in HbA_{1c} at week 26 (or last observation) in the intent-to-treat population.

Results: A total of 363 patients completed the study (ALO 12.5 mg, 75.4%; ALO 25 mg 74.7%; PBO, 62.6%). At week 26, least-squares (LS) mean changes from baseline in HbA_{1c} were significantly ($P<.001$) greater for ALO 12.5 mg (-0.38%) and ALO 25 mg (-0.52%) vs PBO (+0.01%) (Figure). The

changes from baseline in HbA_{1c} were similar regardless of age (<65 or ≥ 65 years), BMI (<30 or ≥ 30 kg/m²), or ethnicity (Hispanic or non-Hispanic) and were greater in patients with higher baseline HbA_{1c}. A significantly ($P<.001$) greater proportion of patients achieved a $\geq 1\%$ reduction in HbA_{1c} for ALO 12.5 mg (28.6%) and ALO 25 mg (30.0%) vs PBO (8.7%). LS mean changes from baseline in fasting plasma glucose were greater for both ALO 12.5 mg (-0.26 mmol/L; $P=.241$) and ALO 25 mg (-0.46 mmol/L; $P=.072$) vs PBO (+0.12 mmol/L) at week 26. LS mean changes from baseline in weight and lipids at week 26 were not clinically meaningful. The proportions of patients who experienced ≥ 1 adverse event (ALO 12.5 mg, 63.5%; ALO 25 mg, 63.1%; PBO, 53.5%) or who discontinued the study due to an adverse event (ALO 12.5 mg, 2.5%; ALO 25 mg, 2.0%; PBO, 2.0%) were similar across groups. The proportion of subjects who experienced ≥ 1 serious adverse event was low across groups (ALO 12.5 mg, 5.4%; ALO 25 mg, 5.6%; PBO, 2.0%). Hypoglycemia was reported in 11.1% of patients for PBO, 15.8% for ALO 12.5 mg, and 9.6% for ALO 25 mg.

Conclusion: ALO added to ongoing GLY monotherapy significantly improved glycemic control in patients with T2DM without a clinically meaningful increase in weight gain or the incidence of hypoglycemia.

Addition of alogliptin to insulin therapy reduces HbA_{1c} without increasing weight gain or hypoglycaemia in patients with type 2 diabetes

M. Rendell¹, J. Rosenstock², J. Gross³, P. Fleck⁴, C. Wilson⁴, Q. Mekki⁴

¹Creighton Diabetes Center, Creighton University, Omaha, United States, ²University of Texas Southwestern Medical Center at Dallas, United States, ³Hospital de Clinicas de Porto Alegre, Brazil, ⁴Takeda Global Research & Development Center Inc., Deerfield, United States

Background and aims: Alogliptin (ALO) is a potent and highly selective DPP-4 inhibitor being developed for the treatment of type 2 diabetes (T2DM). Insulin therapy is most effective at achieving and maintaining glycemic control when used in combination with oral antidiabetic agents in patients with T2DM. This randomized, double-blind, placebo (PBO)-controlled study as-

sessed the efficacy and safety of ALO added to conventional insulin therapy (INS) in patients with T2DM inadequately controlled on INS alone or on INS with metformin (MET).

Materials and methods: Patients (N=390; mean age=55 years; 65% White; 41% men; mean baseline HbA_{1c}=9.3%; mean duration of T2DM=13 years; mean insulin dose=57 IU/day) were randomized to receive ALO 12.5 mg (n=131), ALO 25 mg (n=129), or PBO (n=130) once daily as an add-on to INS for 26 weeks after a 4-week single-blind PBO run-in/stabilization period. Patients already taking MET (59%; mean dose=1733 mg/day) continued this therapy unchanged. The primary endpoint was change from baseline in HbA_{1c} at week 26 (or last observation) in the intent-to-treat population.

Results: A total of 215 patients completed the study (ALO 12.5 mg, 63%; ALO 25 mg 60%; PBO, 42%). At week 26, least-squares (LS) mean changes from baseline in HbA_{1c} were significantly greater ($P<.001$) for ALO 12.5 mg (-0.63%) and ALO 25 mg (-0.71%) vs PBO (-0.13%) (Figure). The changes from baseline in HbA_{1c} were similar regardless of age (<65 or ≥65 years), BMI (<30 or ≥30 kg/m²; mean=32.4 kg/m²), ethnicity (Hispanic or non-Hispanic), or background therapy (MET or none). LS mean changes from baseline in fasting plasma glucose were +0.13 mmol/L for ALO 12.5 mg ($P=.662$) and -0.65 mmol/L for ALO 25 mg ($P=.030$) vs +0.32 mmol/L for PBO. At week 26, no significant differences from PBO in LS mean changes from baseline in weight or lipids were observed for either ALO dose. The proportions of patients who experienced ≥1 adverse event (ALO 12.5 mg, 67.9%; ALO 25 mg, 66.7%; PBO, 73.6%) or ≥1 serious adverse event (ALO 12.5 mg, 6.1%; ALO 25 mg, 5.4%; PBO, 4.7%) were similar across groups. The proportion of patients who discontinued the study due to an adverse event was small (ALO 12.5 mg, 0.8%; ALO 25 mg, 4.7%; PBO, 3.1%). Incidence of severe hypoglycemia was very low [ALO 12.5 mg (0%), ALO 25 mg (0.8%), PBO (1.6%)], and mean daily insulin dose was unchanged from baseline across groups.

Conclusion: ALO added to ongoing INS therapy (with or without MET) significantly improved glycemic control in patients with T2DM inadequately controlled on INS without increasing weight gain or hypoglycemia.

Initial combination therapy with saxagliptin and metformin improves glycaemic control compared with either monotherapy alone in drug-naïve patients with type 2 diabetes

R. Chen¹, A. Pfützner², M. Jadzinsky³, E. Paz-Pacheco⁴, Z. Xu¹, E. Allen¹

¹Bristol-Myers Squibb, Princeton, United States, ²Institute for Clinical Research and Development, Mainz, Germany, ³Department of Nutrition, Durand Hospital, Buenos Aires, Argentina, ⁴Department of Medicine, The Medical City, Pasig City, Philippines

Background and aims: Saxagliptin is a potent modulator of key hormones that regulate glucose homeostasis, specifically designed to provide selective, durable inhibition of the dipeptidyl peptidase-4 (DPP-4) enzyme. In this study, the efficacy and safety of the initial combination of saxagliptin plus immediate-release metformin (MET) were compared with saxagliptin or MET monotherapy in drug-naïve patients with type 2 diabetes (T2D) and inadequate glycemic control.

Materials and methods: This 24-wk, double-blind, active-controlled trial (CV181-039) randomized 1306 patients with T2D, HbA_{1c} 8%-12% and age 18-77 y. Patients were randomized to 1 of 4 treatment arms: saxagliptin 5 mg + MET 500 mg (S5/MET), saxagliptin 10 mg + MET 500 mg (S10/MET), saxagliptin 10 mg + placebo (S10), or MET 500 mg + placebo (MET). Saxagliptin was dosed once daily. From wk 1-5, in the S5/MET, S10/MET, and MET treatment arms, metformin was up-titrated based on fasting plasma glucose (FPG) levels in 500-mg/d increments as tolerated to a maximum of 2000 mg/d. The primary end point was the HbA_{1c} change from baseline at wk 24. Changes in FPG, PPG, and HOMA-2β were also evaluated. Efficacy analyses for continuous variables were performed using an ANCOVA model with last observation carried forward (LOCF) methodology.

Results: Treatment groups were well balanced for baseline demographics and diabetes characteristics: 49% male, mean age 52 y, mean duration of T2D 1.7 y, mean HbA_{1c} 9.5%, mean FPG 200.6 mg/dL. Final mean metformin total daily doses in the S5/MET, S10/MET, and MET arms were 1790 mg, 1776 mg, and 1817 mg, respectively. At 24 wks, patients randomized to S5/MET and S10/MET demonstrated significant reductions in HbA_{1c}, FPG, and PPG, and increases in HOMA-2β (a measure of β-cell function) from baseline compared with either monotherapy (Table).

	S5/MET	S10/MET	S10	MET
HbA _{1c} * (%)	-2.53a,b	-2.49a,b	-1.69	-1.99
FPG* (mg/dL)	-59.8a,c	-62.2a,b	-30.9	-47.3
PPG* 120 min post-OGTT (mg/dL)	-137.9f,b	-137.3d,b	-106.3	-96.8
HOMA-2β* (%)	33.0a,e	38.0a,b	18.2	22.6
Patients who achieved HbA _{1c} <7.0% (%)	60.3a,b	59.7a,b	32.2	41.1

*Adjusted mean change from baseline.

aP<.0001 vs S10.

bP<.0001 vs MET.

cP=.0002 vs MET.

dP=.0002 vs S10.

eP=.0004 vs MET.

fP=.0001 vs S10.

A numerically greater decrease in HbA_{1c} was seen in patients with a baseline HbA_{1c} ≥10% (adjusted mean change from baseline -3.33%, -3.25%, -2.52%, and -2.73% for S5/MET, S10/MET, S10, and MET, respectively). Overall, the occurrence of adverse events was similar across all treatment groups: S5/MET 55.3%, S10/MET 57.3%, S10 53.4%, and MET 58.5%. Occurrences of hypoglycemic events were few (S5/MET 3.4%, S10/MET 5.0%, S10 1.5%, and MET 4.0%).

Conclusion: In drug-naïve patients with T2D, initial combination therapy of saxagliptin and metformin produced statistically significant and clinically meaningful improvements in glycemic parameters compared with either saxagliptin or metformin alone, and was well tolerated.

Leptin is released from human skeletal muscle *in vivo*

E. Wolsk-Jackson¹, H. Mygind¹, T. Hansen², B.K. Pedersen¹, G. van Hall²¹Centre of Inflammation and Metabolism, ²Department of Biomedical Sciences, Rigshospitalet, Copenhagen, Denmark

Background and aims: Leptin has been characterized as an adipokine released from adipose tissue. Furthermore human *in vivo* leptin concentrations seem to be correlated with total body fat mass. Recent reports indicate that leptin may also be produced by skeletal muscle, however a characterization of the leptin release from adipose tissue versus skeletal muscle has never been investigated. Our aim was to;

- Characterise and quantify the release of leptin from leg skeletal muscle and from anterior abdominal wall adipose tissue.
- Quantify the possible contribution of leptin from skeletal muscle to systemic circulation compared to the concomitant contribution from subcutaneous adipose tissue.

Materials and methods: Eight healthy male volunteers were recruited in this observational study. After an overnight fast, subjects reported to the lab where they remained fasting, supine and sedentary during the entire study. The femoral artery and vein, as well as the superficial epigastric vein were cannulated allowing arterio-venous blood sampling over the lower extremity and abdominal subcutaneous tissue bed. The femoral venous catheter was placed retrograde, bypassing the saphenous vein, thus minimizing subcutaneous blood contamination. Blood flow was measured using 133-Xenon washout, and Doppler ultrasound in the abdomen and groin, respectively. This allowed quantification of leptin flux across the aforementioned tissue beds according to Fick's principle. Blood was collected every 30 min. for three hours, followed by hourly sampling for the remaining three hours. All data listed are pooled geometric means \pm SD.

Results: Leptin concentrations were 1067 \pm 105 pg ml⁻¹, 1391 \pm 136 pg ml⁻¹, and 1783 \pm 244 pg ml⁻¹, for artery, leg vein, and abdominal vein, respectively. There was a significant difference between arterio-venous samples from both leg ($p=0.02$) and adipose tissue ($p<0.0001$), indicating that both organs released leptin to the systemic circulation throughout the trial. There was not any significant change over time within groups. Leptin flux across the adipose tissue and leg averaged 1250 \pm 308 pg min⁻¹100 g⁻¹ and 89796 \pm 25020 pg min⁻¹, respectively.

Conclusion: In agreement with our aims, we showed that leptin not only was released into the systemic arterial circulation from adipose tissue, but also from the lower extremity. Although our femoral catheter placement minimizes subcutaneous adipose tissue contribution to the leptin flux observed, it cannot be ruled out as a contributor. Calculations were performed using a "worst-case" scenario that the leg flux observed was due to leg adipose tissue. Assuming that leptin release pr. mass unit from adipose tissue in leg and abdomen is equal, approximations using tissue composition obtained through DXA scans reveal that adipose contribution to the flux observed maximally could account for (31569 \pm 7794 pg min⁻¹) 35% of the leptin release. This would leave the remaining 65% to be accounted for by skeletal muscle, equaling a release of 834 pg min⁻¹100 g⁻¹ tissue. Conclusively, it seems plausible that skeletal muscle is a major contributor to human leptin production.

A common MC4R variant is associated with higher intakes of total energy and dietary fat, long-term weight change, and obesity risk in women

L. Qi, P. Kraft, D. Hunter, F. Hu

Nutrition and Epidemiology, Harvard School of Public Health, Boston, United States

Background and aims: Melanocortin-4 receptor (MC4R) regulates energy balance. The common variants near to MC4R gene were recently associated with obesity risk (Loos et al. Nature Genet. 2008). We examined the associations of the MC4R gene variants with energy intakes, adiposity and the longitudinal changes of anthropometrical measures.

Materials and methods: The associations of MC4R SNPs rs17782313 (T>C) and rs17700633 (G>A) with dietary intakes (total energy, fat, and carbohydrates) and longitudinal measures of adiposity (1976 to 2004) were analyzed in 5,724 women (1,533 with type 2 diabetes) from the Nurses' Health Study.

Results: Women with CC genotype of rs17782313 had 84 kcal/d, 4.6 g/d, and 1.8 g/d higher intakes in total energy ($P=0.028$), total fat ($P=0.008$), and saturated fat ($P=0.007$) compared with those carrying TT genotype, adjusting for age, BMI, and diabetes status. Per allele-C of SNP rs17782313 was significantly associated with 0.34 kg/m² higher BMI ($P=0.002$), 0.73 cm higher waist circumference ($P=0.01$), and 12% (1%–26%) greater obesity risk (measured in 1986). Adjustment for dietary factors (total energy and fat) did not appreciably change the SNP-adiposity associations. Carrying allele-C was also associated with moderate but statistically significant difference (0.2 kg/m²) in ten-year (1976–1986) changes of BMI ($P=0.028$). Age-specific analyses indicated that the genetic difference in BMI was significant across all the age groups and was most evident in women aged 50–54.9 years (Figure; * $P<0.05$). In addition, body size (height) significantly modified the associations between rs17782313 and BMI (P for interaction=0.03). The allelic difference in BMI was 0.9, 0.6, and 0.2 kg/m² respectively in women with height of greater than 165 cm, 160–164.9 cm, and less than 160 cm. Analyses restricting to non-diabetic women generated similar results.

Conclusion: The common SNP rs17782313 in MC4R gene was significantly associated with higher intakes of total energy and dietary fat (total and saturated), long-term weight change, and obesity risk. Body size may modify the genetic effects.

Development of leptin resistance during long-term substitutive therapy on children with congenital lipodystrophy

J. Beltrand^{1,2}, N. Lahlou³, N. Tubiana Rufi⁴, M. Polak⁵, M. De Kerdanet⁶, F. Huet⁷, D. Lacombe⁸, D. Chevenne¹, C. Lévy Marchal¹¹U690, Inserm, Paris, France, ²Hopital Robert Debré, Paris, France,³UF Hormonologie pédiatrique, Hopital Saint Vincent de Paul, Paris,France, ⁴Endocrinologie pédiatrique, Hopital Robert Debré, Paris, France,⁵Endocrinologie pédiatrique, Hopital Necker, Paris, France, ⁶Endocrinologiepédiatrique, Hopital Sud, Rennes, France, ⁷Pédiatrie, Hopital d'enfants,Dijon, France, ⁸Génétique médicale, Hopital Pellegrin, Bordeaux, France

Background and aims: It has been proposed that leptin could be used as a treatment against metabolic complications in patients with congenital lipodystrophy (CLD). The benefit of short-term replacement therapy on dyslipidemia, steatosis and insulin resistance has been previously reported in children with CLD but the persistence of such an effect on a long-term basis is unknown.

Materials and methods: The efficacy of long-term leptin replacement therapy (24 months) has been evaluated in children with CLD. R-metHU leptin was initially given (subcutaneous injections) at a daily "physiological" dose (0.06 mg/kg/d) and increased up to 0.12 mg/kg/d if necessary. Patients were evaluated every 4 months. Criteria for a positive response to treatment were defined as a reduction in liver volume by 30% or more (CT scan) and/or an improvement in insulin sensitivity (M) measured during a euglycemic hyper-

insulinemic clamp by at least 30% and/or a reduction in fasting triglyceride (TG) levels by 40% or more in comparison to baseline values. Antibodies against leptin were measured with a specific home-made radio-binding assay.

Results: Eight non-diabetic children (6 boys, 2 girls, 6–16 years old) were included in the study. In 3 patients, improvement of TG levels was sustained for up to 24 months (TG: M0 2.23 \pm 0.9 to M24: 1.43 \pm 0.8) associated with an increase in insulin sensitivity (M: M0 4.6 mg/kg FFM/mn to 7.3 mg/kg FFM/mn) and a marked decrease in hepatic volume (M0 5087 \pm 618 mm³ to M24: 3153 \pm 392 mm³). In 2 patients, leptin dosage needed to be increased in order to maintain these effects. In 2 other patients, the increase in the leptin dosage failed to maintain the benefit on insulin sensitivity whereas the effect on liver volume was still observed after 24 months of therapy (6752 mm³ 4713 mm³ and 5714 to 2759 mm³). In 3 patients, no benefit at all was observed and one patient developed overt diabetes despite leptin concentration above the physiological range (133 \pm 90 ng/ml). In all children antibodies against leptin were detectable after 4 month with levels parallel to the increase in leptin dosage.

Conclusion: The benefit of leptin replacement therapy on metabolic complications of CLD was fully maintained in 3 patients whereas a partial or a null response was observed in 5 patients despite a 150 to 200% increase in the leptin dosage. This resistance to leptin therapy in patients with CLD has never been previously reported and the present observation argues for the contribution, at least in part, of an immunological reaction. Further investigations are crucial since leptin replacement remains the only therapeutical hope in this disease with a life-threatening prognosis.

Responsiveness to leptin restored by amylin in diet-induced obese (DIO) rats: magnitude and mechanisms of synergy

J. Roth, J. Koda, B. Roland, R. Cole, T. Coffey, C. Cronister, C. Weyer, A. Baron, D. Parkes

Research, Amylin Pharmaceuticals, Inc., San Diego, United States

Background and aims: Previously, we reported that single dose combination therapy with rat amylin (100 μ g/kg/d) and murine leptin (500 μ g/kg/d) elicited greater body weight (BW) loss in leptin resistant DIO rats than predicted by the sum of monotherapy-induced BW loss, a finding consistent with amylin restoration of responsiveness to leptin.

Materials and methods: Here, we used a 3 \times 4 factorial design to define the interaction of a lower range of doses of amylin (0, 10, 50 μ g/kg/d) and leptin (0, 5, 25, 125 μ g/kg/d) for BW loss following 4 w of subcutaneous (SC) osmotic infusion in DIO rats. This design enabled a Response Surface Methodology (RSM) analysis and statistical testing for synergy.

Results: At 4 w, the RSM revealed a synergistic effect of the amylin+leptin combination ($P < 0.03$), at doses lower than previously reported. The highest dose combination (amylin 50+leptin 125) induced a maximal mean BW loss of $-14.8 \pm 3.2\%$ (vehicle corrected). Leptin resistance in DIO rodents has been attributed to impaired hypothalamic leptin signaling, chiefly within the arcuate nucleus (Arc). We hypothesized that amylin modulates hypothalamic sensitivity to leptin. Hypothalamic pSTAT-3 immunoreactive (IR) cells stimulated by leptin (15 mg/kg, IP) were quantified in DIO rats pre-treated with either vehicle, amylin (100 μ g/kg/d, SC) or food restriction by pair-feeding (PF) to amylin rats for 7d, and in lean rats maintained on low fat diet. Compared to lean controls, vehicle-treated DIO rats had reduced pSTAT-3 IR in both the Arc (-46% , $p < 0.0001$) and the ventromedial hypothalamus (VMH; -45% , $p < 0.0001$). Amylin pre-treatment for 7 d increased leptin-induced pSTAT-3 IR in the VMH relative to vehicle (by 40%; $p = 0.015$) and PF controls (by 50%, $p = 0.004$), but not in the Arc.

Conclusion: These findings formally confirm BW loss synergy between amylin and leptin in DIO rodents and reveal a novel neural correlate for synergy, whereby amylin, via hindbrain signaling, upregulates leptin VMH signaling. Unexpectedly, restoration of pSTAT-3 signaling in Arc does not appear to be necessary for expression of this effect.

83

Enhanced weight loss following pramlintide/metreleptin combination treatment in obese subjects: clinical evidence for restoration of leptin responsiveness by amylin agonism

J. Koda¹, C. Weyer¹, S. Smith², E. Ravussin², J. Mitchell¹, N. Kesty¹, K. Shan¹, A. Baron¹

¹Amylin Pharmaceuticals, Inc., San Diego, United States, ²Biomedical Research, Louisiana State University, Baton Rouge, United States

Background and aims: Numerous clinical trials have failed to demonstrate significant weight loss with human recombinant leptin (metreleptin) monotherapy. In diet-induced obese rats, prior or concomitant amylin agonism restores responsiveness to leptin, yielding marked synergistic weight loss.

Materials and methods: We conducted a 24-wk, randomised, active-drug-controlled, double-blind clinical study in 177 obese or overweight subjects (Enrolled; 63% female; 39 ± 8 y; 32.0 ± 2.1 kg/m²; 93.3 ± 13.2 kg; mean \pm SD). During a 4-wk lead-in period, subjects were treated with the amylin agonist pramlintide (180 μ g BID for 2 wks; then 360 μ g BID) and diet (40% calorie deficit). Subjects (N=139) completing the lead-in and achieving 2–8% weight loss by Wk 4 were randomised 2:2:1 to pramlintide (360 μ g BID) + metreleptin (5 mg BID), pramlintide+placebo or metreleptin+placebo for 20 wks.

Results: Following the 4-wk lead-in, 9% of the subjects did not achieve 2% weight loss. By Wk 20 (Evaluable N=93), pramlintide+metreleptin elicited significant reductions in weight from enrollment ($12.7 \pm 0.9\%$; LS mean \pm SE) compared to pramlintide ($8.4 \pm 0.9\%$; $P < 0.001$) or metreleptin following the pramlintide lead-in ($8.2 \pm 1.3\%$; $P < 0.01$). From Wk 12–20, weight loss had stabilised with pramlintide or metreleptin (rate of weight change -0.05 kg/wk or -0.02 kg/wk; both $P > 0.05$), but not with pramlintide+metreleptin (rate of weight change -0.20 kg/wk; $P < 0.001$). The proportion of subjects achieving $\geq 10\%$ weight loss was greater with pramlintide+metreleptin (56%) than with pramlintide (35%) or metreleptin (21%). The most common side effects with pramlintide+metreleptin were injection site adverse events and nausea, which were mostly mild to moderate.

Conclusion: This is the first demonstration of a significant and robust weight loss effect of leptin in subjects with general obesity and is consistent with pre-clinical studies showing amylin+leptin synergy. Further clinical development of pramlintide+metreleptin combination treatment is warranted as part of a novel, integrated neurohormonal approach to obesity pharmacotherapy.

84

Anti-obesity effect of highly purified eicosapentaenoic acid in mice with high-fat/high-sucrose diet-induced obesity: possible role of hepatic lipogenesis

A. Sato¹, M. Itoh², M. Nakakuki¹, M. Ohta¹, H. Kawano¹, K. Mizuguchi¹, T. Suganami², Y. Ogawa²

¹Pharmaceutical Research Center, Mochida Pharmaceutical Co., Ltd., Shizuoka, Japan, ²Department of Molecular Medicine and Metabolism, Medical Research Institute, Tokyo Medical and Dental University, Tokyo, Japan

Background and aims: Obesity is a major risk factor of coronary heart disease (CHD). A large-scale, prospective, randomized clinical trial has recently revealed that the addition of highly purified eicosapentaenoic acid (EPA), one of the major *n-3* polyunsaturated fatty acids in fish oil, to statin therapy significantly reduces the incidence of CHD. Here we investigated the anti-obesity effect of highly purified EPA in mice with diet-induced obesity.

Material and methods: 10-week-old male C57BL/6 mice were fed standard diet (N), high-fat/high-sucrose diet (HF/HS), high-fat diet (HF), or HF/HS or HF containing 5% EPA (HF/HS+EPA or HF+EPA). Body weight, tissue weight, expression of mRNAs for enzymes related to β -oxidation, glycolysis, and lipogenesis in white adipose tissue (WAT), liver, and skeletal muscle, hepatic triglyceride (TG) secretion, and O₂ consumption were measured.

Results: After 20-week feeding, body weight was significantly higher in both HF/HS and HF groups than N group. Both HF/HS and HF groups also showed increased hepatic weight and TG content ($P < 0.01$ vs. N group). The HF/HS+EPA group showed significant reduction in body weight relative to HF/HS group ($P < 0.01$), which was accompanied by the reduction in visceral (epididymal, mesenteric, and retroperitoneal) and subcutaneous (inguinal) fat weights ($P < 0.01$). The HF/HS+EPA group was protected from HF/HS-induced increase in liver weight ($P < 0.01$). By contrast, there was no such reduction of body and liver weight in HF+EPA group relative to HF group. Increased O₂ consumption and respiratory exchange ratio were observed in

HF/HS+EPA group relative to HF/HS group after 6 weeks of feeding ($P < 0.01$). In this study, HF/HS+EPA group did not show appreciable increases in mRNA expression of enzymes related to β -oxidation in WAT, liver, and skeletal muscle, those related to glycolysis in liver and skeletal muscle, and lipogenic enzymes in WAT, relative to HF/HS group. On the other hand, expression of mRNAs for hepatic lipogenic enzymes such as ACC-1, FAS, and SCD-1 was markedly increased in HF/HS group relative to N group, which was significantly suppressed by treatment with EPA ($P < 0.01$). In this study, there was no significant increase in mRNA expression of hepatic lipogenic enzymes in HF group relative to N group. The hepatic TG secretion rate in HF/HS+EPA group was significantly lower than that in HF/HS group ($P < 0.05$). Analysis of fatty acid composition in very low density lipoprotein (VLDL) obtained from HF/HS+EPA group revealed significant decrease in palmitic (16:0), palmitoleic (16:1) and oleic (18:1) acids, but increase in stearic (18:0), linoleic (18:2) acids, and EPA relative to HF/HS group ($P < 0.05$).

Conclusion: This study demonstrates that treatment with EPA attenuates HF/HS-induced obesity and hepatic steatosis in parallel with the reduction of hepatic lipogenesis. Given that EPA does not affect HF-induced obesity with no marked increase in hepatic lipogenesis, the data of this study suggest that anti-obesity effect of EPA is related to reduced amount and altered composition of fatty acids delivered from the liver to the adipose tissue via VLDL.

OP 15 Molecular mechanisms in insulin signalling

Subcellular localisation determines protein kinase zeta function in 3T3-L1 adipocytes

C. Blouin¹, K.K. Takane², A. Garcia-Ocana², I. Dugail¹, E. Hajdouch¹

¹Centre de Recherches des Cordeliers, INSERM U872, Paris, France,

²Division of Endocrinology, University of Pittsburgh, United States

Background and aims: Atypical Protein kinase Cs (aPKCs) are involved in a wide variety of biological processes and data suggest an important role in insulin signalling and stimulation of glucose uptake in adipocytes and skeletal muscle. However, under certain circumstances, particularly in the presence of the sphingomyelin lipid derivative ceramide, aPKCs are also able to negatively regulate important proteins for insulin signalling, like protein kinase B (PKB), a key component of the signalling cascade that induces an increase in glucose uptake. The exact mechanism of this inhibition begins to be understood and is the result of a lipid-induced association between the aPKC zeta (PKC ζ) and PKB, leading to the sequestration of the latter kinase in a repressed state within specific plasma membrane domains called caveolae. The aim of this study is to figure out how PKC ζ can act positively or negatively on the insulin signalling pathway, depending of the stimulus by using different PKC ζ mutants in 3T3-L1 adipocytes.

Materials and methods: We used adenovirus vectors containing either wild-type PKC ζ (WT-PKC ζ), kinase-dead PKC ζ (KD-PKC ζ) or membrane associated myristoylated PKC ζ (myr-PKC ζ) mutants to infect 3T3-L1 adipocytes. Subcellular localization of these mutants were carried out and we have evaluated the impact of insulin and ceramide on PKB activity.

Results: With the help of these mutants, we wanted to evaluate the importance of PKC ζ subcellular localization in the differential effects of insulin and ceramide on the insulin signalling pathway. Although both WT- and KD-PKC ζ mutants were preferentially present in the cytosol, all membranes fractions, including detergent resistant membranes (DRM) containing caveolae were enriched with the myr-PKC ζ mutant. Insulin, which induced the recruitment and phosphorylation of PKC ζ to the plasma membrane, did not alter the partitioning between caveolar enriched membranes and other membrane fractions. Ceramide prevented insulin-induced PKB activation in WT- and myr-PKC ζ expressing cells and induced the phosphorylation of both PKC ζ mutants on their Thr⁴¹⁰ residue in DRM. However, in KD-PKC ζ mutant expressing cells, PKC ζ did not distribute in DRM, and PKB activation by insulin was near to normal in the presence of ceramide. Importantly, in myr-PKC ζ expressing cells, the constitutive presence of PKC ζ in caveolar enriched fraction did not mimic the negative effect of ceramide on insulin-induced PKB activation, indicating the importance of the lipid to activate PKC ζ for the transduction of its signal.

Conclusion: All together, these findings indicate that activation of PKC ζ in response of insulin or ceramide occurs in different subcellular membrane domains, leading the kinase to different actions on the insulin signalling pathway.

Nelfinavir-induced adipocyte insulin resistance is caused by impairment in PKB/Akt sensing of PI_{3,4,5}P₃

A. Maissel¹, I. Kachko¹, L. Mazor¹, R. Ben-Romano¹, R. Watson², J. Pessin², N. Bashan¹, A. Rudich¹

¹Department of Clinical Biochemistry, Ben-Gurion University, Beer Sheva,

Israel, ²Department of Pharmacological Sciences, Stony Brook University, Stony Brook, United States

Background and aims: HIV protease inhibitors frequently cause insulin resistance and loss of adipose tissue, but the mechanisms remain largely unknown. In response to nelfinavir, adipocytes manifest insulin resistance characterized by normal signaling to PI 3-kinase (as detected *in-vitro*), but impaired activation of PKB/Akt and stimulation of glucose uptake. In this study we aimed to dissect out the signaling defect at the level of PKB/Akt phosphorylation, caused by nelfinavir.

Materials and methods: A single-cell assay was used, based on 3T3-L1 adipocytes electroporated with a 3Xmyc-GLUT4-GFP reporter along with

constitutively active PI 3-kinase or PKB/Akt, assessed by laser confocal microscopy. This was complemented by cell population analyses using Western blotting.

Results: Utilizing a single cell assay, we observed that nelfinavir treatment impaired the insulin-stimulated translocation and membrane-fusion of the myc-GLUT4-GFP tagged reporter. Signaling downstream of PKB/Akt (to GSK3, and to other PKB/Akt substrates, including AS160) was decreased, confirming that defective PKB/Akt activation is rate-limiting for signal propagation, and that PKB/Akt function is required for insulin-stimulated GLUT4 translocation. However, insulin-induced generation of phosphatidylinositol (PI)-3,4,5-trisphosphate (PIP3) was comparable between nelfinavir-treated and control cells. Consistent with a nelfinavir induced inhibition of PKB/Akt activation, expression of a membrane-targeted catalytic subunit of PI 3-kinase induced phosphorylation of PKB/Akt and of GSK3, and myc-GLUT4-GFP translocation in the absence of insulin in control, but not in nelfinavir-treated cells. Conversely, a membrane targeted and constitutively active PKB/Akt mutant was normally phosphorylated on S473 and T308 (confirming intact PKB/Akt kinases activity), and induced myc-GLUT4-GFP translocation even in nelfinavir-treated cells. Finally, nelfinavir treatment results in elevated expression of endogenous TRB3 (nearly 2.5 fold, $p=0.001$), a putative PKB/Akt inhibitor protein.

Conclusion: A constitutively active PKB/Akt, but not PI 3-kinase normally induces GLUT4 translocation in adipocytes, suggesting that nelfinavir induces insulin resistance by directly interfering with PIP3-dependent activation of PKB/Akt.

Downregulation of Sam68 inhibits insulin action by decreasing insulin receptor signalling

S. Najib, C. Gonzalez-Yanes, M. Martinez de Ubago, V. Sánchez-Margalet
Medical Biochemistry and Molecular Biology, Virgen Macarena University Hospital, Seville, Spain

Background and aims: Sam68, is an RNA binding protein with a proposed role as an adaptor protein in signal transduction based on the modular structure containing different domains for protein-protein interaction. We have previously found that Sam68 is tyrosine phosphorylated by the insulin receptor and recruited to signaling complexes in the PI3K and Ras pathways via interaction with SH2 and SH3 domain containing proteins. In the present study we have investigated the possible contribution of Sam68 in insulin receptor signaling by decreasing Sam68 expression.

Materials and methods: We have studied the role of Sam68 on insulin action and insulin receptor signaling pathways by decreasing Sam68 expression using an antisense oligonucleotide in CHO cells overexpressing insulin receptor (CHO-IR). A sense oligonucleotide was used as a control. We have investigated DNA synthesis by thymidine incorporation assay, and we have investigated insulin receptor signalling studying the phosphorylation of MEK, Erk-1-2, Akt and GSK-3.

Results: Downregulation of Sam68 expression decreased insulin stimulated DNA synthesis and insulin receptor signaling pathways in CHO-IR. Insulin stimulated thymidine incorporation was inhibited by 50%, and this effect was correlated with a decrease in insulin receptor signalling. More precisely, both the insulin-stimulated PI3K and MAPK activation were decreased in CHO-IR. Thus, the insulin-stimulated phosphorylation of MEK, MAPK, PKB, and GSK-3 were decreased by inhibiting the expression of Sam68 in CHO-IR cells.

Conclusion: These results provide evidence for a role of Sam68 in insulin action and signalling, and confirm the participation of Sam68 in the signal transduction pathways of the insulin receptor.

Synergy of SIRT1 with insulin signalling

L. Pirola, S. Fröjdö, C. Durand, H. Vidal
Medical Faculty BP12, INSERM U870, Oullins Cedex, France

Background and aims: Sir2 and its mammalian homolog SIRT1, that are proteins deacetylases belonging to the sirtuin family, underlie the control of genetic programs determining longevity in eukaryotes by acting as a stress resistance factor. Under caloric-restriction (CR) conditions, in which energy

supply is limited - yet not to the stage of inducing starvation, Sir2/SIRT1 is considered to be the major genetic target. CR is, at present, the only experimental intervention known to prolong lifespan in eukaryotes. As CR is associated to enhanced peripheral insulin sensitivity, lower insulinaemia and improved glycaemic control, we sought to determine whether SIRT1 plays a direct role in the modulation of the insulin signalling cascade in muscle cells, that constitute the principal glucose-disposing tissue of the body.

Materials and methods: Adenoviruses expressing myc-SIRT1, IRS1 and myc-IRS2 have been constructed using the pVAdcDNA3 system. Delivery of small interfering RNA in 293 cells was achieved by calcium phosphate transfection. The insulin-induced activation of PKB was monitored by measuring the PKB phosphorylation at Serine 473, with anti-phospho-specific antibodies.

Results: 293 cells transiently co-overexpressing myc-SIRT1 and myc-PKB displayed increased endogenous PKB and overexpressed myc-PKB Serine 473 phosphorylation when stimulated with 1000 nM insulin. To reproduce this observation in physiologically relevant insulin-responsive cells, we constructed a SIRT1-expressing adenovirus allowing SIRT-1 overexpression in L6 muscle cells and human primary myotubes. Upon adenoviral-mediated overexpression of SIRT1, both in human primary myotubes and L6 cells, insulin-induced PKB phosphorylation was increased. Reciprocally, RNA interference of SIRT1 in 293 cells substantially decreased insulin-induced PKB Serine 473 phosphorylation after 10 nM insulin stimulation. To test at which level of the insulin signalling cascade SIRT1 may act upon, we performed co-immunoprecipitation experiments and showed that SIRT1 interacts with IRS-1 and IRS-2 in an insulin dependent manner. Whether IRS proteins functionality and tyrosine phosphorylation status is enhanced through this interaction is being currently investigated.

Conclusion: SIRT1 have been proposed to improve glucose disposal and exert its metabolic-promoting effects through several pathways, including i) positive modulation of PGC 1-alpha via deacetylation and ii) transcriptional suppression of the protein tyrosine phosphatase PTP1B. Here, we show that SIRT1 also directly participate in the positive modulation of insulin signalling, in 293 and muscle cell lines, possibly by modulating the function of IRS-1 and IRS-2 via a physical association induced by insulin.

A novel role for Synaptotagmins in insulin-regulated glucose uptake in the 3T3-L1 adipocyte

S.C.M. Miller^{1,2}, J.M.C. Connell¹, G.W. Gould²

¹Faculty of Medicine, University of Glasgow, ²Faculty of Biomedical and Life Sciences, University of Glasgow, Scotland, United Kingdom

Background and aims: When insulin binds to its receptor at the surface of an adipocyte, myocyte or cardiomyocyte, the ensuing cascade of protein-protein and protein-lipid interactions leads to the translocation of a GLUT4-containing vesicle (GSV) to the plasmalemma (PM) where it docks, binds and fuses. In this way GLUT4 is delivered to its intended site of action, and glucose can enter the cell. The exact molecular machinery which governs GSV-PM fusion is incompletely characterised, but it is known that cognate interaction between the v-SNARE VAMP2, and t-SNAREs Syntaxin4 (Stx4) and SNAP23 is required for effective GLUT4 delivery. GSV-PM fusion is known to be disrupted in adipocytes from individuals with Type-2 diabetes, and this disruption is proposed to contribute to insulin resistance.

SNARE-mediated fusion events are best understood in neurons and neuroendocrine cells, where an isoform of the Synaptotagmin (SYT) family, is known to bind to the assembled SNARE complex, and both target and vesicle membranes. Thereafter the opposing thermodynamic forces between adjacent lipid bilayers are overcome and membrane fusion can occur. We hypothesised that in a similar way a SYT isoform may bind the VAMP2/Stx4/SNAP23 SNARE complex, and thus influence GSV-PM fusion. We therefore investigated the role of SYT isoforms in insulin-dependent glucose uptake in the adipocyte.

Materials and methods, and results: Using RTPCR, the expression of SYTs was confirmed in cultured 3T3-L1 adipocytes. SYT7 and SYT11 were shown to be the predominant isoforms, and SYT11 expression is upregulated as cells differentiate and acquire insulin-sensitivity. Both SYT7 and SYT11 proteins were observed in intracellular membrane fractions alongside GLUT4, and SYT7 was observed at the PM. siRNA-mediated knockdown of SYT7 was seen to potentiate glucose uptake, whereas SYT11 knockdown led to abrogated insulin-stimulated glucose uptake and reduced intracellular GLUT4.

Finally SYT7 can be seen to bind VAMP2 and Stx4/SNAP23 *in vitro* whereas SYT11 does not.

Conclusion: These findings are consistent with a novel role for SYTs in the adipocyte, and we propose that SYT7 may influence the GSV-PM fusion machinery, and SYT11 may regulate intracellular GLUT4 trafficking and availability.

Role of AMPK in IL-6 release from isolated mouse skeletal muscle

S. Glund¹, J.T. Treebak², Y.C. Long¹, R. Barres¹, B. Viollet³, J.F. Wojtaszewski², J.R. Zierath¹

¹Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden,

²Department of Exercise and Sports Sciences, University of Copenhagen, Denmark,

³Institute Cochin, Université Paris Descartes, Paris, France

Background and aims: Interleukin-6 (IL-6) is released from skeletal muscle during exercise, and has consequently been implicated to mediate beneficial effects on whole body metabolism. Using 5-aminoimidazole-4-carboxamide-1- β -D-ribofuranoside (AICAR), a pharmacological activator of AMPK, we tested the hypothesis that AMPK modulates IL-6 release from isolated skeletal muscle. We also tested whether AICAR suppresses IL-6 release via an AMPK-dependent pathway in animal models with impaired AMPK signaling.

Materials and methods: Skeletal muscle from AMPK α 2 kinase dead (KD) transgenic, AMPK α 1 knockout (KO) and AMPK γ 3 KO mice and respective wild-type littermates was incubated *in vitro*, in the absence or presence of 2 mM AICAR. Skeletal muscle from wild-type mice was also incubated with the AMPK activator A-769662.

Results: Incubation of mouse extensor digitorum longus (EDL) and soleus muscles for 2 h was associated with a profound, ionomycin-independent IL-6 mRNA production and protein release, which was suppressed by AICAR ($P < 0.001$). Basal IL-6 release from soleus was increased between AMPK α 2 KD and AMPK α 1 KO and their respective wild-type littermates ($P < 0.05$), suggesting AMPK participates in the regulation of basal IL-6 release from oxidative muscle. The effect of AICAR on muscle IL-6 release was similar between AMPK α 2 KD, AMPK α 1 KO and AMPK γ 3 KO mice and their respective wild-type littermates ($P < 0.001$), indicating AICAR-mediated suppression of IL-6 release is independent of AMPK function. IL-6 release from soleus, but not EDL muscle, was reduced 40% by A-769662 stimulation, further supporting the finding that the AICAR effects on muscle IL-6 release are for the most part unspecific.

Conclusion: Using transgenic and knockout mouse models to perturb AMPK, we provide evidence that AMPK-dependent pathways regulate IL-6 release from isolated oxidative skeletal muscle. We show *in vitro* AICAR-stimulation blunts IL-6 mRNA expression and protein release independent of functional AMPK-signaling in mouse skeletal muscle. Our results provide evidence for a role of AMPK in the regulation of IL-6 release from oxidative skeletal muscle.

Department of Medicine and Clinical Science, Okayama University

Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Japan

Background and aims: We have recently reported that blockade of inflammatory axis of ICAM-1 activation to macrophage infiltration ameliorates diabetic nephropathy in ICAM-1 deficient (KO) mice, indicating that inflammatory mechanism is involved in the pathogenesis of diabetic nephropathy. DNA microarray analyses demonstrated that cholecystokinin (CCK) is up-regulated in the kidney of diabetic wild type mice but not increased in diabetic ICAM-1 KO mice. These data suggest the involvement of CCK in development of nephropathy. CCK is a peptide with various functions including gastrointestinal homeostasis and neurotransmission, however, little is known about renal effects of CCK. Two types of CCK receptors, types A and B, have been identified in kidney tissues and cultured macrophages. We have also reported that deficiency of both CCK-A and B receptors accelerates renal injuries in 5/6 nephrectomized model, and that CCK-peptide suppressed the expression of proinflammatory cytokines in cultured macrophages. The aim of this study is to clarify the role of CCK in the pathogenesis of diabetic nephropathy using CCK receptor deficient mice.

Materials and methods: We induced diabetes by streptozotocin (STZ) in CCK-A receptor deficient, CCK-B receptor deficient (B-DM) and CCK-A and B receptor double deficient mice (AB-DM) and wild type mice (WT-DM). Non diabetic control mice were injected with citrate buffer. Renal functions and renal pathology were evaluated over a period of 3 months. We examined the expression of ICAM-1, CD-68 and type-IV collagen in kidney tissues by quantitative real-time RT-PCR and immunostaining. Gene expression profile were evaluated using DNA microarray.

Results: In non-diabetic mice, there was no difference of HbA1c, blood pressure (BP) and albuminuria in all 4 strains. In diabetic mice, there was no significant difference of HbA1c in 4 strains. AB-DM showed markedly increased albuminuria as compared with WT-DM (Mean value; 474 vs. 154 mg/gCr, $P < 0.001$). There was no significant difference of BP between AB-DM and WT-DM (108 vs. 106 mmHg). Mesangial matrix index was significantly greater in AB-DM than in WT-DM (17.5 vs. 10.3 %, $p < 0.01$). The intensity of type-IV collagen in glomeruli was higher in AB-DM as compared with WT-DM. Gene expression of ICAM-1 and CD-68 were significantly increased in AB-DM as compared with WT-DM ($p < 0.001$ and $p < 0.05$, respectively). Gene expression of CCK was increased in diabetic group, whereas there was no difference between AB-DM and WT-DM. DNA microarray analysis indicated that various kinds of proinflammatory genes including cytokines, chemokines and adhesion molecules were up-regulated in AB-DM as compared with WT-DM.

Conclusion: Our results have shown that deficiency of both CCK-A and B receptors enhances inflammatory reactions and tissue injuries in the kidney after induction of diabetes. These findings suggest that anti-inflammatory effects of CCK in the development of diabetic nephropathy were largely abrogated in CCK-A and B receptor double deficient mice. In conclusion, CCK is increased in diabetic kidney tissues and may play protective roles against progression of diabetic nephropathy through anti-inflammatory effects. CCK might be beneficial for the treatment of diabetic nephropathy.

Exendin-4 ameliorates diabetic nephropathy via anti-inflammatory and anti-ischæmic effects without change of blood glucose level in type 1 diabetic rats

R. Kodera, H. Kataoka, K. Shikata, C. Sato, M. Sasaki, S. Nishishita, S. Miyamoto, D. Hirota, N. Kajitani, H. Makino

Department of Medicine and Clinical Science, Okayama University

Graduate School of Medicine Dentistry and Pharmaceutical Sciences, Japan

Background and aims: Glucagon like peptide-1 (GLP-1) is known to have various extrapancreatic effects in addition to enhancement of insulin secretion. GLP-1 receptor has been shown to express in the kidney suggesting that GLP-1 may directly act on kidney via GLP-1 receptor. Exendin-4 is a DPP-IV-resistant long-acting GLP-1 analog and synthetic exendin-4 is used for the therapy of type 2 diabetes. The aim of this study is to investigate the renoprotective effects of exendin-4 independent of blood glucose lowering actions using streptozotocin induced diabetic rats.

Materials and methods: Five-week old male Sprague-Dawley rats were divided into four groups: non-diabetic: ND, non-diabetic rats treated with exendin-4: ND+EX, diabetic rats without treatment: DM, diabetic rats treated with exendin-4: DM+EX. Rats were administered intraperitoneally with exendin-4 (10µg/kg/day, ND+EX and DM+EX) or vehicle (ND and DM) every day for 8 weeks. To evaluate the effects of exendin-4, we measured urinary albumin excretion and creatinine clearance and examined the expression of GLP-1 receptor, TGF-β1, ICAM-1, MCP-1, CD68, hypoxia-inducible factor (HIF) in kidney tissues by quantitative real-time RT-PCR and immunostaining.

Results: GLP-1 receptor was expressed in glomeruli, tubular epithelium and arterioles. Exendin-4 significantly reduced urinary albumin excretion (Mean values; ND 254µg/day, ND+EX 157µg/day, DM 2,215µg/day, DM+EX 713µg/day, DM vs DM+EX: $P<0.05$) without change of blood glucose levels (HbA1c; ND 3.7%, ND+EX 3.8%, DM 10.4%, DM+EX 9.9%, DM vs DM+EX: n.s.) and blood pressure (systolic blood pressure; ND 115mmHg, ND+EX 114mmHg, DM 120mmHg, DM+EX 123mmHg: n.s.). Hyperfiltration in diabetic rats were improved by treatment with exendin-4. Exendin-4 significantly attenuated mesangial matrix expansion (mesangial matrix index; DM 9.2% vs DM+EX 5.4%: $P<0.05$) and also significantly reduced mRNA expression of TGF-β1 (Ratio to ND; ND 100%, ND+EX 103%, DM 262%, DM+EX 143%, DM vs DM+EX: $P<0.05$), ICAM-1 (ND 100%, ND+EX 120%, DM 283%, DM+EX 142%, DM vs DM+EX: $P<0.05$) and HIF (ND 100%, ND+EX 104%, DM 160%, DM+EX 106%, DM vs DM+EX: $P<0.05$) in kidney tissues. Expression of CD68 and MCP-1 were reduced by exendin-4, however, there was no statistical significance. Immunohistochemical analysis revealed that macrophage infiltration into kidney tissues in diabetic rats was suppressed by treatment with exendin-4.

Conclusion: Exendin-4 ameliorated albuminuria and renal tissue injuries without change of blood glucose level and blood pressure in type 1 diabetic rats. Exendin-4 decreased the expressions of ICAM-1 and HIF suggesting that exendin-4 ameliorated diabetic nephropathy through anti-inflammatory and anti-ischemic effects. Exendin-4 may exert novel extrapancreatic effects of reno-protection beyond blood glucose lowering effect.

Deletion of the receptor for advanced glycation end products, RAGE, protects from diabetic nephropathy and atherosclerosis

K.A.M. Jandeleit-Dahm¹, J. Yong¹, L. Jiaze¹, D. Barit¹, A. Soro-Paavonen¹, S. Giunti¹, A. Watson¹, A. Bierhaus², T. Allen¹, M. Cooper¹

¹Albert Einstein JDRF Centre for Diabetes Complications, Diabetes & Metabolism Division, The Baker Heart Research Institute, Melbourne, Australia,

²Medicine and Clinical Chemistry, University of Heidelberg, Germany

Diabetic nephropathy remains the leading cause of end-stage renal disease in the Western World and diabetes associated macrovascular disease accounts for the increased morbidity and mortality in diabetes. There is increasing evidence that the multiligand receptor RAGE, plays a pivotal role in development and progression of diabetic nephropathy and macrovascular disease. We have previously shown that inhibition of AGE accumulation in the kidney and aorta can attenuate renal injury and atherosclerosis in diabetic apoE KO mouse. In this study we investigated if RAGE deletion protects from diabetic nephropathy and atherosclerosis.

ApoE KO and RAGE/apoE double KO mice were rendered diabetic by streptozotocin (55 mg/kg in 5 daily injections ip) and followed for 20 weeks. At the end of the study, blood pressure was measured by tail cuff method and blood and urine were collected for analysis of glycated hemoglobin (GHb, HPLC) and plasma lipids as well as albuminuria. The aorta was assessed for plaque area after Sudan IV staining. The kidneys were analysed for structural renal injury including assessment of glomerulosclerosis index, mesangial area and tubulointerstitial injury. Extracellular matrix expression (collagen IV and fibronectin) as well as expression of pro-inflammatory and profibrotic growth factors, cytokines and chemokines were investigated by RT-PCR.

The results are presented in the Table below. Data are presented as mean ± SEM * $p<0.05$ vs control apoE KO, # $p<0.05$ vs diabetic apoE KO, ‡ $p<0.05$ vs control RAGE/apoE KO.

	Control apoEKO	Control RAGE/apoE KO	Diabetic apoE KO	Diabetic RAGE/apoE KO
Plaque area %	4.3 ± 0.4	2.3 ± 0.4	14.9 ± 1.7*	4.9 ± 0.4
Mesangial area %	0.34 ± 0.02	0.41 ± 0.01*	0.50 ± 0.01*	0.45 ± 0.01#
Collagen IV (fold expression)	1.0 ± 0.1	0.5 ± 0.1	1.6 ± 0.3*	0.9 ± 0.1#
Fibronectin (fold expression)	1.4 ± 0.1	0.8 ± 0.1	2.9 ± 0.3*	1.1 ± 0.2#
MCP-1 (fold expression)	1.0 ± 0.1	0.4 ± 0.1*	3.5 ± 0.4*	1.5 ± 0.2#
NFκB subunit p65 (fold expression)	1.0 ± 0.1	0.7 ± 0.1	2.9 ± 0.7*	0.9 ± 0.2
Albuminuria microgram/24 hours	49 ± 6	73 ± 11	188 ± 20*	212 ± 20

RAGE deletion attenuates renal structural injury and atherosclerosis in the diabetic apoE KO mouse, a model of diabetes accelerated atherosclerosis and renal disease. These changes were associated with reduced expression of pro-inflammatory and profibrotic growth factors in the kidney and aorta, including MCP-1 and the p65 subunit of NF kappaB. By contrast, albuminuria was not significantly attenuated by RAGE deletion.

Functional expression of TRPV4 in human collecting duct (HCD) cells: a role in diabetic nephropathy

P.E. Squires¹, C.E. Hills², P.M. Ronco³, R. Bland¹

¹Biological Science, University of Warwick, Coventry, United Kingdom,

²Infection, Immunity and Inflammation, University of Leicester, United Kingdom,

³Unite INSERM 489, Université Paris, France

Background and aims: According to the World Health Organisation (WHO Fact sheet 312, Sept 2006) diabetes is among the leading causes of kidney failure with a 10–20% mortality. When hyperglycaemia spills over into the urine (glucosuria), loss of glucose causes osmotic drag and diuresis and exposes the kidney to various physical and nutrient stresses. In collecting duct epithelium, sodium absorption is linked to cell volume regulation and depends upon detection of these mechanical stimuli. Prolonged exposure of renal epithelial to osmotic changes and increased fluid flow has led to a number of suggestions concerning the mechanisms involved in stimulus-response coupling. One mechanism involves the calcium permeable transient receptor potential-vanilloid-4 (TRPV4) channel. Gated by changes in osmolarity or membrane stretch, these mechano-sensitive channels reputedly regulate cell volume via a Ca^{2+} dependent mechanism. In the present study, mechanical stimulation was employed as a surrogate form of osmotic stress to elucidate a role for TRPV4 in cell volume regulation in a novel model system of the human collecting duct.

Materials and methods: RT-PCR and western blot analysis were used to determine mRNA and protein expression for TRPV4 in a human collecting duct (HCD) cell line. Fura-2-microfluorimetry was used to assess generation of touch evoked calcium transients. Knockdown of TRPV4 expression was achieved using a TRPV4 specific siRNA and the siLentGene U6 Cassette RNA Interference System different siRNA protocols.

Results: Bands corresponding to TRPV4 were identified from HCD mRNA and protein. Mechanical stimulation of a single HCD cell evoked a transient increase in cytosolic calcium ($[Ca^{2+}]_i$) that propagated between neighbouring cells within a cluster (5 separate experiments). Touch evoked changes in $[Ca^{2+}]_i$ were still observed under Ca^{2+} -free conditions, however the basal to peak amplitude of the response was only 35% of that obtained in the presence of extracellular calcium ($P<0.05$ n=6). Pre-incubation with the Ca^{2+} -ATPase inhibitor thapsigargin (1µM) was used to assess contribution of intracellular Ca^{2+} -stores on touch-evoked changes in $[Ca^{2+}]_i$. Whilst removal of extracellular calcium alone, failed to negate the generation of touch evoked Ca^{2+} transients, the chelation of extracellular calcium in conjunction with the depletion of Ca^{2+} -stores completely prevented touch-evoked changes in $[Ca^{2+}]_i$.

($P<0.05$; $n=6$). Confirmation of a role for TRPV4 in the generation of touch evoked Ca^{2+} -transients was assessed by siRNA knockdown. Transient transfection of HCD cells with TRPV4 siRNA reduced TRPV4 protein expression by approximately 40% ($n=4$; $P<0.01$ compared to control), whilst mechanical stimulation of individual RFP-tagged anti-TRPV4 cells failed to significantly elevate $[\text{Ca}^{2+}]_i$, compared to control cells observed in the same field of view under identical culture conditions.

Conclusion: These data confirm a functional role for TRPV4 in generation of touch evoked Ca^{2+} -signals between coupled cells of the human collecting duct and suggest that knockdown of TRPV4 expression inhibit the cells ability to both detect and respond to osmotic signals via a Ca^{2+} -dependent mechanism. These data have implications for altered fluid and electrolyte handling in the diabetic kidney.

PARP inhibition counteracts multiple manifestations of nephropathy associated with type 1 diabetes

I.G. Obrosova¹, W. Xu², B. Slusher², J. Zhang², U. Julius³, V.R. Drel¹

¹Pennington Biomedical Research Center, Louisiana State University, Baton Rouge, United States, ²Pharmacology, Eisai Inc., Baltimore, United States, ³Medical Clinic III, University Hospital, Dresden, Germany

Background and aims: Evidence for the important role of poly(ADP-ribose) polymerase (PARP) activation in the pathogenesis of diabetes mellitus and diabetic complications is emerging. PARP activation manifest by increased poly(ADP-ribose) immunoreactivity and poly(ADP-ribosyl)ated protein expression is clearly manifest in the renal cortex of Type 1 diabetic rodents. The purpose of this work was to evaluate the role for PARP in early diabetic nephropathy using rat STZ-diabetic model.

Materials and methods: The experiments have been performed in rats with 12-wk duration of STZ-diabetes treated with or without two structurally diverse PARP inhibitors, 1,5-isoquinolinediol (ISO) and 10-(4-methyl-piperazin-1-ylmethyl)-2H-7-oxa-1,2-diaza-benzo[de] anthracen-3-one (GPI-15427, Eisai Inc.), at the doses of 3 mg $\text{kg}^{-1}\text{d}^{-1}$ i.p. and 30 mg $\text{kg}^{-1}\text{d}^{-1}$ p.o., respectively, for 10 weeks after first 2 weeks without treatment. PARP activity in the renal cortex was assessed by immunohistochemistry and Western blot analysis of poly(ADP-ribosyl) ated proteins. Urinary albumin excretion, and renal concentrations of vascular endothelial growth factor, endothelin-1, transforming growth factor- β 1, tumor necrosis factor- α , and monocyte chemotactic protein-1 were evaluated by ELISA. Renal podocyte loss, PAS-positive substances, and collagen- α 1 (IY) were assessed by immunohistochemistry, and endothelin (B) receptor and advanced glycation end product expression by Western blot analyses.

Results: Final body weights were similarly reduced and blood glucose concentrations similarly increased in untreated and ISO- or GPI-15427-treated STZ-diabetic rats compared with controls. Urinary albumin excretion was increased ~4-fold in diabetic rats vs controls and this increase was essentially prevented by both ISO and GPI-15427. Both ISO and GPI-15427 alleviated diabetes-associated PARP activation in glomerular and tubular compartments of rat renal cortex. Kidney concentrations of vascular endothelial growth factor and endothelin-1, two important players in diabetic nephropathy, were increased in diabetic rats vs controls and this increase

was completely (endothelin-1) or essentially (VEGF) prevented by PARP inhibition. ISO and GPI-15427 prevented diabetes-induced upregulation of renal endothelin (B) receptor. Both PARP inhibitors reduced diabetes-associated podocyte loss, and accumulation of transforming growth factor- β 1, collagen- α 1 (IY), PAS-positive substances, and methylglyoxal-, but not glycol-derived advanced glycation end-products in the renal cortex. Elevation of renal concentrations of two inflammatory markers, tumor necrosis factor- α and monocyte chemotactic protein-1, was reduced although not completely prevented.

Conclusion: PARP activation is an important factor in early kidney disease associated with Type 1 diabetes. Assessment of the effects of PARP inhibition on chronic diabetic nephropathy is in progress.

Deficiency in the angiotensin II type 1a receptor subtype decreases renal injury in diabetic mice

A. Koitka, A. Somasegar, P. Sivakumaran, A. Mibus, A. Watson, P. Koh, M.C. Thomas, M.E. Cooper, T.J. Allen
Diabetes & Metabolism, Baker Heart Research Institute, Melbourne, Australia

Background and aims: Angiotensin II (AII) plays a key pathophysiological role in the progression of diabetic renal disease. Agents that block the binding of AII to the AT1 receptor are an important therapeutic strategy to prevent renal damage in patients with diabetes. However, the specific role of AT1 receptors in diabetic renal disease remains to be defined. Two subtypes of the AT1 receptor, AT1a and AT1b, have been identified in the kidney. Because pharmacological AT1 receptor antagonists block both AT1a and AT1b receptors, it has been difficult to separate their distinct functions.

Materials and methods: We used genetically modified mice deficient in AT1a receptor (AT1a KO) or AT1b receptor (AT1b KO) to address the mechanism of RAS blockade-induced renoprotection in a diabetic model. Diabetes was induced by injection of streptozotocin (60 mg. $\text{kg}^{-1}\text{day}^{-1}$, 5 daily intraperitoneal injections) in 6-week old male AT1a KO, AT1b KO and appropriate wild-type (WT) mice. In addition, control and streptozotocin-induced diabetic WT mice were randomised to the AT1 receptor antagonist, candesartan cilexetil (10 mg. $\text{kg}^{-1}\text{day}^{-1}$ in drinking water) or no treatment for 20 weeks. Renal fibrosis was assessed by standard histological methods. Kidney function included measurement of urinary albumin excretion.

Results: Twenty weeks of diabetes in WT mice was associated with renal hypertrophy and an increase in glomerulosclerosis, tubulointerstitial fibrosis and albuminuria. The progression of diabetic kidney disease was attenuated in diabetic AT1a KO mice but not in diabetic AT1b KO mice. Deficiency in the AT1a receptor subtype conferred similar renoprotection to that seen with candesartan in the diabetic WT mice (Table 1) as assessed by a similar reduction in albuminuria and glomerular and tubulointerstitial injury.

Conclusion: Our results provide direct evidence that the renoprotective effects of candesartan in diabetic mice are predominantly mediated by blockade of the AT1a receptor. Given the clear benefits observed in AT1a KO mice and the negative effect of AT1b gene deletion on renal function, the potential utility of selective AT1a blockade deserves to be further explored.

	Control WT	Diabetic WT	Diabetic WT + Candesartan	Diabetic AT1a KO	Diabetic AT1b KO
Metabolic parameters

OP 17 Dynamics of beta cell exocytosis

97

Both the first and second phases of glucose-induced insulin secretion involve insulin granules newly recruited to the plasma membrane

H. Takahashi¹, T. Shibasaki¹, S. Seino^{1,2}

¹Division of Cellular and Molecular Medicine, ²Division of Diabetes, Metabolism and Endocrinology, Kobe University Graduate School of Medicine, Kobe, Japan

Background and aims: Insulin granule exocytosis includes several steps such as recruitment, docking, and fusion to the plasma membrane. Using a total internal reflection fluorescence microscopy (TIRFM) system, we have shown that fusion of insulin granules to the plasma membrane occurs in three modes, based on the dynamics of the granules. These modes are 1) *old face*: predocked granules are fused to the plasma membrane by stimulation. 2) *restless newcomer*: granules are newly recruited by stimulation and immediately fused to the plasma membrane without docking. 3) *resting newcomer*: granules are newly recruited by stimulation, docked, and then fused to the plasma membrane. In this study, we investigated granule dynamics in the first and second phases of glucose-induced insulin secretion.

Materials and methods: To monitor insulin granule dynamics, insulin fused to fluorescent protein Venus (insulin-Venus) was constructed. Insulin-Venus was introduced to isolated mouse pancreatic β -cells by adenovirus infection. Insulin granule dynamics in the infected cells was examined by sequential treatment of 16.7 mM glucose and 60 mM K^+ stimulation. In condition A, cells were stimulated with 16.7 mM glucose for 20 min.; after a 10 min interval of incubation in 2.8 mM glucose, the cells were stimulated with 60 mM K^+ for 5 min. In condition B, cells were stimulated with 60 mM K^+ for 5 min.; after a 10 min interval of incubation in 2.8 mM glucose, the cells were stimulated with 16.7 mM glucose for 20 min. Insulin granule dynamics was monitored by TIRFM and analyzed.

Results: In cells stimulated with high glucose, fusion events occurred in a biphasic manner, most of them *restless newcomer* in both the first and the second phases. In contrast, in cells stimulated with K^+ , fusion events occurred immediately and transiently, more than 60% of them *old face*. In β -cells stimulated with 16.7 mM glucose after K^+ stimulation, *restless newcomer* fusion events still occurred in a biphasic manner, similar to β -cells stimulated with glucose without initial K^+ stimulation. On the other hand, in β -cells stimulated with 60 mM K^+ after glucose stimulation, fusion events also occurred transiently and were mainly *old face*. In addition, the fusion sites in the β -cell induced by K^+ stimulation differed from those induced by glucose stimulation.

Conclusion: Our data indicate that the mode of insulin granule dynamics involved in the first phase of glucose-induced exocytosis differs from that involved in K^+ -triggered exocytosis, suggesting that K^+ stimulation and glucose stimulation induce fusion of granules from distinct pools. The data also demonstrate that the readily releasable pool (RRP) involved in the first phase of glucose-induced insulin secretion does not necessarily comprise predocked granules, indicating that some granules in pancreatic β -cells a distance away from the plasma membrane are readily releasable.

98

The role of depolarisation in the initiation of insulin secretion

M. Willenborg, K. Hatlapatka, I. Rustenbeck

Institute of Pharmacology and Toxicology, Technical University of Braunschweig, Germany

Background and aims: The relevance of plasma membrane depolarization and the resulting Ca^{2+} influx for the initiation of insulin secretion was explored

Materials and methods: NMRI mouse islets and beta cells were used to measure insulin secretion by perfusion and ELISA, membrane potential by patch clamping (perforated patch) and cytosolic free calcium concentration ($[Ca^{2+}]_c$) by microfluorimetry of Fura 2PE-loaded islets.

Results: The depolarization by KCl followed closely the theoretical values as calculated by the Goldman equation. In contrast to the K_{ATP} channel-blocking sulfonylurea, tolbutamide, KCl depolarization did not induce a visible action potential spiking. The depolarization by 15 mmol/l KCl (21 mV) correspond-

ed to the plateau depolarization by 500 μ M tolbutamide, that by 40 mmol/l KCl (41 mV) corresponded to the peak values of tolbutamide-induced action potentials. Nifedipine abolished tolbutamide-induced action potentials but had only a minimal effect on the depolarization by 40 mmol/l KCl. Action potential spiking was also abolished by diazoxide, even before the onset of repolarization. Apparently, the influx of Ca^{2+} during KCl depolarization is not reflected by action potential spiking because of a compensatory charge efflux through the open K^+ channels. Thus, depolarization by 15 mmol/l, but not by 40 mmol/l KCl is equivalent to the depolarizing effect of K_{ATP} channel closure. In contrast to 40 mmol/l KCl, which induced a massive secretory response in the presence of 5 mmol/l glucose, 15 mmol/l KCl was only minimally effective under this condition, even though an increase in $[Ca^{2+}]_c$ could be clearly shown. The $[Ca^{2+}]_c$ measurements suggest the participation of intracellular Ca^{2+} stores as a reason for the different insulinotropic characteristics of the two KCl concentrations.

Conclusion: The influx of Ca^{2+} caused by a moderate depolarization, as is typically produced by a physiological or pharmacological K_{ATP} channel closure, is only weakly effective to initiate insulin secretion. K_{ATP} channel-independent signalling may play a major role for the full expression of the first phase.

99

Glucose can increase insulin secretion by controlling Ca^{2+} influx and oscillations of cytosolic Ca^{2+} in beta cells independently of K_{ATP} channels

M.A. Ravier¹, M. Nenquin¹, T. Miki², S. Seino², J.-C. Henquin¹

¹Endocrinology and Metabolism, University of Louvain, Brussels, Belgium, ²Cellular and Molecular Medicine, University of Kobe, Japan

Background and aims: Glucose-induced insulin secretion is classically attributed to the cooperation of two major mechanisms in β -cells. The indispensable triggering signal, a rise in cytosolic $[Ca^{2+}]_c$, results from a K_{ATP} channel-dependent depolarization that leads to acceleration of Ca^{2+} influx through voltage-dependent Ca^{2+} channels. Amplifying signals, which do not directly involve K_{ATP} channels, then augment the secretory response without further increasing Ca^{2+} . In β -cells, K_{ATP} channels are composed of a pore (Kir6.2) and a regulatory subunit (SUR1). In this study we have evaluated the ability of glucose to control insulin secretion in islets lacking K_{ATP} channels because of a deletion of Kir6.2.

Materials and methods: Islets were isolated from 1-year and 2-week old control and Kir6.2 knockout (KO) mice, and studied 2h after isolation (fresh) or after 18h of culture in 5 or 10 mmol/l glucose. Insulin secretion and $[Ca^{2+}]_c$ were measured in parallel, in perfused islets usually obtained from the same animals.

Results: Kir6.2KO islets were insensitive to diazoxide and tolbutamide, which indicates that they really lack functional K_{ATP} channels. During perfusion with 1 mmol/l glucose, fresh adult Kir6.2KO islets showed only marginally elevated basal $[Ca^{2+}]_c$ and insulin secretion compared with controls. Upon stimulation with 15 mmol/l glucose, $[Ca^{2+}]_c$ only transiently increased, so that insulin secretion was only doubled (as compared to > 20-fold increase in controls), in spite of a well functioning amplifying pathway (evidenced in the presence of 30 mmol/l KCl). Culture in 10 mmol/l glucose increased basal insulin secretion and markedly improved acute glucose-induced insulin secretion in Kir6.2KO islets (200% of controls whose response was unchanged by culture). These changes in Kir6.2KO islets were unexpectedly due to an increase in average $[Ca^{2+}]_c$ which entirely depended on extracellular Ca^{2+} . Culture in 5 mmol/l glucose did not influence basal $[Ca^{2+}]_c$, but unmasked biphasic $[Ca^{2+}]_c$ and insulin acute responses to high glucose. Oscillations of $[Ca^{2+}]_c$ were present in Kir6.2KO islets perfused with 1 mmol/l glucose (never in control islets) and were accelerated but shortened by 15 mmol/l glucose. Similar results were obtained with 2-week old Kir6.2KO islets tested in the presence of forskolin. Particularly striking were the biphasic increases in $[Ca^{2+}]_c$ and insulin secretion produced by high glucose in islets studied freshly and after culture in 5 mmol/l glucose. They were unambiguously caused by a K_{ATP} channel-independent stimulation of Ca^{2+} influx through voltage-dependent Ca^{2+} channels.

Conclusion: Kir6.2KO β -cells down-regulate insulin secretion by maintaining low $[Ca^{2+}]_c$ but overnight culture unmasks their intrinsic glucose-responsive phenotype mainly by increasing $[Ca^{2+}]_c$. The results support models implicating a K_{ATP} channel-independent amplifying pathway in glucose-induced insulin secretion, and show that K_{ATP} channels are not the only possible transducers of metabolic effects on the triggering Ca^{2+} signal.

Mitochondrial reactive oxygen species are obligatory signals for glucose-induced insulin secretion

C. Leloup

Metabolism, Plasticity and Mitochondria, UMR CNRS 5241, Toulouse, France

Background and aims: insulin secretion involves a complex cascade of events in which the mitochondria plays a pivotal role in the generation of signals coupling glucose detection to insulin secretion. Studies on the mitochondrial generation of reactive oxygen species (ROS) generally focus on chronic nutrient exposure and consequent deleterious effects of ROS. Here, we investigate whether an early moderate and transient mitochondrial ROS production linked to glucose-induced increased respiration might act as a signal to monitor insulin secretion.

Materials and methods: all investigations were carried out on freshly isolated static or perfused islets. Basal glucose was 5.5 mM and stimulated concentration 16.7 mM. All pharmacological products had been tested for their toxic effects. ROS production was measured using H₂DCFDA probe; ATP, NADH, lipid peroxidation with classical biochemical kit, insulin secretion using ELISA. Ca²⁺ imaging was performed using the Fura-2probe.

Results: Transient glucose increase from 5.5 to 16.7 mM stimulated ROS generation that was reversed by antioxidants. Strikingly, insulin secretion was dose-dependently blunted by antioxidants and highly correlated with ROS level. The β -cells incapacity to secrete insulin in response to glucose with antioxidants induced inhibition was associated with the maintenance of high levels of ATP and NADH. Then, we investigated the mitochondrial origin of ROS (mROS) as the triggering signal. Insulin release was mimicked by the mitochondrial complex blockers antimycin and rotenone that generate mROS. Both adding antioxidants to mitochondrial blockers or to glucose in order to lower mROS reversed insulin secretion. Imaging Ca²⁺ in perfused islets with glucose or with the complex blocker I rotenone showed in both cases a Ca²⁺ mobilization which exhibited different profiles. It occurred in the first 3 min with the glucose 16.7 mM and after 10 min with the mitochondrial blocker, after a first slight decrease. Although this might be due to a different kinetic of mROS production, insulin secretion exhibited a similar profile whatever the stimulus, glucose or rotenone. These data suggest that part of the mROS signaling might operate downstream Ca²⁺ mobilization, at least in the 10 first min. In both cases, the mROS scavenger trolox was showed to inhibit Ca²⁺ mobilization. Whatever, any toxic effects were present as showed by lipid peroxidation evaluations and re-secretion tests using these pharmacological approaches.

Conclusion: Altogether these complementary and cohesive results demonstrate that mROS production is an obligatory stimulus for glucose induced insulin secretion.

Single nucleotide polymorphism rs13266634 modifies the zinc transport activity of SLC30A8/ZnT-8 in clonal pancreatic beta cellsF. Chimienti¹, M.B. Wheeler², T.J. Nicholson³, E.A. Bellomo³, N. Wijesekara², A.I. Tarasov³, T. Taneja³, R. Sladek⁴, S.A. Baldwin⁵, J. Baldwin⁵, G.A. Rutter³

¹Mellitech, CEA Grenoble, France, ²Dept of Physiology, University of Toronto, Canada, ³Dept of Cell Biology, Imperial College, London, United Kingdom, ⁴Dept of Human Genetics, McGill University, Montreal, Canada, ⁵Institute of Membrane and Systems Biology, University of Leeds, United Kingdom

Background and aims: A recent genome-wide association study identified rs13266634 single nucleotide polymorphism (SNP) in the SLC30A8 gene as associated with type 2 diabetes. This SNP induces a non synonymous transition from arginine to tryptophan at position 325 of the secretory granule zinc transporter ZnT-8, expressed largely in pancreatic β - and α -cells. Correspondingly, the C “at risk” genotype is linked to impaired β -cell function *in vivo*. Here, we investigated whether the SNP affects Zn²⁺ and Ca²⁺ ion homeostasis in pancreatic β -cells *ex vivo*.

Materials and methods: We used plasmid or adenovirus-mediated delivery systems to overexpress either form of the human protein in clonal MIN6 β -cells. Subcellular localization was studied by confocal immunofluorescence, and steady-state levels of free Zn²⁺ ions were measured with Zn²⁺-specific fluorescent probes. Free cytosolic Ca²⁺ concentrations were measured using

Fura-red. Plasma membrane potential (Vm) and whole-cell KATP channel conductance (GKATP) were recorded in patch-clamps

Results: Homology modeling indicated that R325 lies in the loop connecting the second β -strand and the second α -helix of the predicted cytosolic domain. It thus sits at the dimer interface, close to the binuclear Zn²⁺ clusters identified in the cytosolic domain of the bacterial homologue, YjiP. Over-expressed in clonal β -cells, the R325 variant displayed unaltered subcellular localization, being confined largely to secretory granules with a minor component on the plasma membrane. However, R325 ZnT8-expressing cells displayed elevated cytosolic Zn²⁺ uptake rates, assessed using FluoZin3 or RhodZin, but decreased Zn²⁺ accumulation into secretory granules (Zinquin). R-variant expressing cells displayed elevated cytosolic free Ca²⁺ concentrations in response to glucose or KCl. Finally, ZnT8 silencing decreased Zn²⁺ influx into the cytosol. No differences were noticeable in glucose-mediated closure of KATP channels or membrane depolarization between cells over-expressing R- or W-325 ZnT8

Conclusion: These data suggest that the R325W SNP affects the zinc transport efficiency of ZnT8, and may result in altered β cell intracellular Zn²⁺, and possibly Ca²⁺, homeostasis. Moreover, by using differentially-localised Zn²⁺ probes, we show that the R form catalyses Zn²⁺ uptake into granules less efficiently than the W-form. This may result either from lower intrinsic transporter activity of R325-ZnT8, or from a relatively weakened interaction with an associated protein. Importantly, we now provide direct evidence for a role for endogenous ZnT8 in Zn²⁺ uptake across the plasma membrane. We speculate that Zn²⁺ influx are both enhanced by the R vs W form but that inhibitory effects of Zn²⁺ on exocytosis may lead to defective insulin secretion. At the same time, decreased uptake of Zn²⁺ into granules likely causes the less efficient processing of proinsulin described in carriers of the at-risk C-allele. Finally, alterations of Zn²⁺ transport into insulin granules may also have implications for the paracrine regulation of glucagon secretion.

Beta cell heterogeneity *in vivo*: functional characterisation and involvement in pancreatic islet plasticityM. Karaca¹, J. Castel¹, C. Tourrel-Cuzin¹, A. Geant², M. Brun², M. Rodriguez², B. Lockhart², A. Ktorza², C. Magnan¹, C. Kargar²

¹Université Paris7 Denis Diderot, CNRS UMR 7059, ²IdRS, Maladies Métaboliques, Paris, France

Background and aims: Using PSA-NCAM as a marker for sorting B-cell sub-populations in non diabetic Wistar rats, we previously identified 2 B-cell sub-populations: a population highly expressing PSA-NCAM (B⁺-cells) and highly responsive to glucose (60% of total B-cells) and a population poorly expressing PSA-NCAM (B⁻-cells) and poorly responsive to glucose (40% of total B-cells). The aim of the present work was to explore the functional and the gene expression profiles of the 2 sub-populations. In order to evaluate the physiological relevance of these populations we also measured the B⁺/B⁻ cell ratio in a model of type 2 diabetes with reduced B-cell mass and function, the ZDF rat and in a model of increased insulin demand, the non diabetic Wistar rat infused with glucose during 48 h (HG/HI).

Materials and methods: Islet cell suspensions from adult rats were sorted by flow cytometry according to their PSA-NCAM surface labelling. Insulin release was measured by perfusion in a system allowing concomitant recording of intracytoplasmic Ca²⁺ influx ([Ca²⁺]_i) by microfluorimetry. cAMP content and/or insulin release in response to glucose (5.5 or 16.7mM) and/or 10nM GLP-1, 10mM leucine, were studied using batch-incubated cells. The gene expression profile was analyzed by quantitative real-time RT-PCR.

Results: In B⁺-cells, insulin release in response to 16.7mM glucose was 8-fold higher than in B⁻-cells and was correlated with a high [Ca²⁺]_i, contrarily to B⁻-cells. In batch-incubated B⁺-cells, insulin secretion in response to 16.7mM glucose was strongly potentiated by GLP-1, in parallel with a huge increase in cAMP content, whereas in B⁻-cells insulin release and cAMP content remained very low under all conditions. Moreover, leucine elicited a sustained insulin response in B⁺-cells but not in B⁻-cells. The analysis of gene expression profile of the 2 B-cell populations showed that many genes related to B-cell maturation (PDX1, Nkx6.1, NeuroD, Insulin), metabolic activity (Glut2, GK), pumps/ion channels (Sur-1, Kir6.2, SERCA2b and 3, Cav1.2, Znt8), signaling (PC1/3 and 2, PKA) and adhesion/exocytosis machinery (Connexin36, Integrin β 1, SNAP25, VAMP2, Rab3A) were upregulated in B⁺-cells compared to B⁻-cells, while genes such as NGN3, TCF7L2, involved in early B-cell differentiation were expressed at higher levels in B⁻-cells. Glucose infusion in Wistar rats resulted in increased B-cell mass and gain of function which was

correlated with an excess of B⁺-cells compared to B⁻-cells (80% versus 20%). In 12 week-old ZDF fa/fa rats the B⁻-cells were largely predominant (70% of total B-cells) in high contrast with ZDF lean control non diabetic rats of the same age in which they represented only 40% of the total B-cells.

Conclusion: We have identified and characterized 2 B-cell sub-populations with quite different functional and gene expression profiles. The data suggest that B⁻-cells did not achieve functional maturity and that the proportion of B⁺ / B⁻-cells varies according to the prevailing insulin demand but in opposite ways in non diabetic and diabetic rats. This suggests that pancreatic islet plasticity may involve changes not only in the B-cell mass but also in the distribution between the 2 B-cell sub-populations and that the inability to increase the B⁺-cell sub-population may be part of the inadequate insulin response to insulin resistance in diabetics.

How does the parental age-at-onset of type 1 diabetes (T1D) affect the risk of T1D in the offspring? A comparison of two large cohorts (age-at-onset 0-17 years and 15-39 years) in Finland

V. Harjutsalo¹, N. Lammi¹, M. Karvonen¹, J. Tuomilehto^{1,2}

¹Department of Health Promotion and Chronic Disease Prevention, Diabetes Unit, National Public Health Institute, ²Department of Public Health, University of Helsinki, Finland

Background and aims: Number of studies have detected sex-specific transmission of type 1 diabetes (T1D) from one generation to the next. Age at onset of T1D in the proband has been known to strongly influence the recurrence risk of T1D in the first-degree relatives. There are few data available on the recurrence risk of T1D among the offspring of probands with young adult-onset T1D and no reports comparing the risk of T1D between the offspring of parents with early-onset T1D and those of parents with young adult-onset T1D. The aim of this study was to examine the wide range effect of the parental age at onset of T1D on the recurrence risk of T1D in offspring stratifying the offspring data by the sex of the T1D parents.

Materials and methods: The offspring (n=9,158) of a population-based cohort of probands with early-onset T1D (0-17 years) (n=5,144) and a population-based cohort of T1D among 15-39 years old (young adult-onset T1D, n=3,389) were studied for recurrence of T1D. Offspring with both parents affected were excluded. Life table method was used to estimate the cumulative incidence of T1D. The analyses were carried out stratifying the data by the age at diagnosis of T1D in the parent in 5-year age groups (0-4, 5-9, 10-14, 15-19 and 20-39). Based on the preliminary analysis ages 20-39 were pooled together. Analyses were carried out separately in the offspring of fathers and mothers with T1D.

Results: During 127,174 follow-up years, 92 offspring of parents with young adult-onset T1D and 299 offspring of early-onset T1D were affected with T1D by the end of the year 2006. In all offspring with one diabetic parent, the overall cumulative incidence to develop T1D by the age of 15 years was 4.9% (95% CI 4.4-5.4) and by the age of 20 years 5.8% (95% CI 5.2-6.4). A young age at onset of T1D in diabetic mothers did not increase the risk of T1D in the offspring. The overall cumulative risk by age 15 years was 4.1% (95% CI 3.4-4.8) in all offspring of diabetic mothers irrespective of maternal age at onset of diabetes. On the contrary, each 5-year increase in the age at onset of T1D in the fathers until 25 years decreased the risk of T1D in their offspring. The cumulative risk by age 15 years in the offspring of the fathers with T1D was 12.9% (95% CI 8.0-17.4), 8.7% (95% CI 6.5-10.8), 6.0% (95% CI 4.7-7.3), 4.7% (95% CI 3.1-6.2) and 3.1% (95% CI 1.9-4.4) for age at onset groups 0-4, 5-9, 10-14, 15-19 and 20-39 years, respectively.

Conclusion: Maternal age at onset of diabetes did not have an impact on the recurrence risk of T1D in their offspring. On the contrary, the risk of T1D in

Cumulative incidence of T1D in the offspring of patients with T1D according to age at onset of T1D

the offspring of the fathers with T1D decreased progressively with increasing age at onset of fathers. The decrease, however, levelled off around 25 years of age at onset.

104

Incidence trends for childhood type 1 diabetes in Europe during 1989–2003 and projection of numbers to 2025

C.C. Patterson¹, G. Dahlquist², E. Gyürüs³, G. Soltész³ on behalf of the EURODIAB Study Group

¹Department of Epidemiology & Public Health, Queen's University Belfast, United Kingdom, ²Department of Clinical Sciences Paediatrics, Umeå University, Sweden, ³Department of Paediatrics, Pécs University, Hungary

Background and aims: To describe fifteen-year trends in incidence of childhood type 1 diabetes in European centres and to use these data to predict future burden of childhood diabetes in European countries.

Materials and methods: Twenty population-based EURODIAB registers in 17 countries registered 29,311 new cases of type 1 diabetes diagnosed before the age of 15 years during a fifteen year period 1989–2003. Each centre validated completeness of ascertainment. Age-specific log linear rates of increase were estimated in five geographic regions of relatively homogeneous incidence rates, and these trends were used in conjunction with published incidence rates and population projections to make predictions of the numbers of new cases throughout Europe in the years 2010, 2015, 2020 and 2025.

Results: Ascertainment rates were better than 90% in most registers throughout the period. All but two registers showed significant increases in incidence, and in the six registers where there were significant differences in the rate of increase between age groups it was lowest in relative terms in 10–14 year olds. When centres were amalgamated into five regions the rates of increase were largest among 0–4 year olds in central and eastern Europe. The number of new cases in Europe in 2005 is estimated as 14,700, and this total is divided between the 0–4 yr, 5–9 yr and 10–14 yr age groups in the ratio 23%, 35% and 42%, respectively. By the year 2025 the predictions show almost a doubling in the yearly numbers of new cases to 29,000 but this change is not shared evenly between the age-groups and the percentage distribution across the three age groups is predicted to become rather more uniform at 31%, 37% and 32%, respectively.

Conclusion: A near doubling in absolute numbers of new cases of type 1 diabetes in European children is to be anticipated in the next 20 years if current trends continue. A disproportionate change over time with more new cases in the youngest age groups is predicted and the differences in different part of Europe are indicated to be less pronounced. Resources to meet this changing pattern must be made available.

105

Childhood BMI trajectories and the risk for type 1 and type 2 diabetes diagnosed in young adulthood

N.M. Lammi¹, E.V. Moltchanova¹, P.A. Blomstedt¹, J.G. Eriksson^{1,2}, J. Tuomilehto^{1,3}, M. Karvonen¹

¹Department of Health Promotion and Chronic Disease Prevention, National Public Health Institute, Helsinki, ²Department of General Practise and Primary Health Care, University of Helsinki, ³Department of Public Health, University of Helsinki, Finland

Background and aims: The rate of growth during infancy and childhood can influence the risk for type 1 diabetes (T1DM) and type 2 diabetes (T2DM). Subjects with childhood-onset T1DM are heavier and taller during infancy, and they also seem to grow faster during infancy than their healthy peers. Conversely, patients with T2DM are smaller up to two years of age and they have accelerated growth after infancy compared with children who remain non-diabetic. The aim of this case-control study was to examine the childhood growth trajectories in individuals diagnosed with T1DM and T2DM between ages 15–39 years.

Materials and methods: Patients with diabetes, aged 15–39 years at diagnosis, were identified from the Finnish national healthcare registers, and classified as T1DM or T2DM utilizing the register information as well as their medical statements when necessary. Two non-diabetic, sex- and age-matched control subjects were obtained for each case from the National Population Registry. The original childhood welfare records including anthropometric measurements were collected for the cases and controls from the healthcare archives nationwide. Only the case-control pairs with sufficient growth data

recorded were included in the analysis. A quadratic curve was estimated (in accordance with the widely accepted ICP-growth model).

Results: The results of the analysis including 224 case-control pairs of T1DM (161 with 1 control and 63 with 2 controls) indicated that the maximum BMI between ages 0–2 and the minimum BMI between ages 3–11 were similar in cases with T1DM and control subjects. The age of the minimum BMI between ages 3–11 was lower in individuals with T1DM but the result was not statistically significant (Figure 1a). The analysis of young adult-onset T2DM was based on data from 69 case-control pairs (54 with 1 control and 15 with 2 controls). (Figure 1b) The maximum BMI between ages 0–2 years was similar between cases and controls. The risk for T2DM was strongly affected by the minimum BMI between ages 3–11 years: 1 kg/m² rise in the BMI increased the risk of T2DM by 59% ($p < 0.05$). The excess weight gain in individuals who later developed young adult-onset T2DM began already at childhood after the age of the minimum BMI (Figure 1b).

Conclusion: Childhood growth does not affect the risk for young adult-onset T1DM contrary to the previous findings in childhood-onset T1DM. The etiology of young adult-onset T1DM may therefore be different from childhood-onset T1DM. The profound effect of the childhood growth on the risk for T2DM was confirmed, and it seems that the pattern of childhood growth may be even more important than birth size in predicting the future risk for T2DM.

Modern-day clinical course of type 1 diabetes mellitus. The DCCT/EDIC experience 1983–2008

D.M. Nathan¹, B. Zinman², P.A. Cleary³, J.-Y.C. Backlund³, R. Miller⁴, T. Orchard⁴

¹Diabetes Unit, Massachusetts General Hospital, Boston, United States,

²Centre for Diabetes, Mount Sinai Hospital, Toronto, Canada, ³The Biostatistics Center, The George Washington University, Rockville, United States, ⁴Epidemiology, University of Pittsburgh, United States

Background and aims: The DCCT/EDIC has collected clinical data, including treatments and outcomes, for twenty-five years and provides the opportunity to describe the clinical course of type 1 diabetes mellitus (T1DM) in the latter part of the 20th and early 21st century. We describe the clinical care, metabolic results and the long-term complications and outcomes that can be expected with current diabetes therapy, comparing and contrasting the DCCT/EDIC conventional (CONV) and intensive (INT) therapy groups. In addition, data collected in the Epidemiology of Diabetes Complications (EDC) study, a population-based observational study, provide the results of conventional therapy in an unselected population with T1DM.

Materials and methods: Although not population-based, the DCCT/EDIC cohort has the advantage of being current, distributed in the US and Canada, and complete in its followup, with 92% of the baseline cohort (96% of survivors) followed for a mean of 19.5 years. DCCT CONV treatment (n=730) was designed to represent the standard of clinical care at the time. At the end of the DCCT in 1993, all CONV subjects were offered intensive therapy. While the DCCT CONV treatment group and the EDC cohort (n=161, selected to have similar baseline age, diabetes duration, and complications to the DCCT), reflect contemporaneous clinical care and outcomes, the clinical care and outcomes in the INT group (N=711) represent what we can expect of diabetes care going forward. The long-term complications presented here include proliferative retinopathy (PDR), albumin excretion rate (AER) > 300 mg/24h, and cardiovascular disease (CVD: fatal and non-fatal myocardial infarction or stroke, death secondary to CVD, subclinical myocardial infarction, confirmed angina, or cardiac revascularization).

Results: The frequencies of serious complications in the DCCT CONV treatment group by diabetes duration are shown in the figure. The cumulative incidences of PDR, AER > 300 mg/24 h, and CVD are 49.7%, 25.1%, and 14%, respectively, after 30 years diabetes duration. In the population based EDC, the corresponding values are very similar at 47%, 17%, and 14%. The cumulative incidences with intensive therapy are substantially lower with 21.1% with PDR, 8.6% with AER > 300 mg/24 h, and 8.5% with CVD after 30 years duration.

Conclusion: This more current data provides a more accurate assessment of the long-term outcomes of T1DM with current care and should be used in models evaluating health outcomes of and quality of life for T1DM. The long-term outlook for patients with T1DM is projected to improve further as intensive therapy is applied throughout their diabetes duration.

Validating a coronary heart disease prediction model for type 1 diabetes

J.C. Zgibor¹, K. Ruppert¹, S. Soedamah-Muthu², T.J. Orchard¹, M.S. Roberts³

¹Epidemiology, University of Pittsburgh, United States, ²Epidemiology, Julius Center for Health Sciences and Primary Care, Utrecht, Netherlands,

³Medicine, University of Pittsburgh, United States

Background and aims: Previous analyses demonstrated that existing coronary heart disease (CHD) risk prediction models do not predict events well in type 1 diabetes (T1D). Therefore, our objective was to create CHD risk prediction models specific to T1D and to validate the models in a separate cohort of people with type 1 diabetes.

Materials and methods: Development of the CHD prediction model used data from the Pittsburgh Epidemiology of Diabetes Complications Study (EDC). EDC subjects had T1D diagnosed between 1950–1980 and received their first study exam between 1986–1988, and have been followed biennially since. The final cohort for model development consisted of 603 subjects and 46 incident events. Hard CHD was defined as CHD death, fatal or non-fatal MI or Q-waves. Baseline CHD risk factors were tested bivariate and introduced into a Weibull model. The model was externally validated using the EURODIAB Prospective Complications Study (PCS) population. The EURODIAB PCS is a hospital based multi-center study designed to examine risk factors for micro and macrovascular complications in type 1 diabetes subjects in 31 centers from 16 countries across Europe. Baseline exams took place in 1989–91 on 3250 subjects diagnosed with type 1 diabetes before age 36 who were on continuous insulin treatment within one year of diagnosis. Follow-up exams were conducted on 2328 participants 6–8 years later. Of these participants, 53 had incident hard CHD events at follow-up.

Results: The following risk equations were developed.

Males: $X = 1.8738 - 0.9452 (\log \text{ white blood cell count}) - 1.0625 (\text{presence of microalbuminuria}) + 1.4808 (\log \text{ HDLc}) - 0.2286 (\text{sqrt diabetes duration at baseline})$
Females: $X = 21.62 - 4.4331 (\text{waist/hip ratio}) - 1.594 (\log \text{ nonHDLc}) - 0.023 (\text{systolic blood pressure}) - 0.498 (\text{use of blood pressure medication}) - 0.705 (\text{sqrt diabetes duration at baseline})$. Following this calculation, the probability of not having an event was calculated using

$S_i(t) = \exp\{-[t e^{\beta X_i}]^{1/\sigma}\}$ where $\sigma=0.6417$ for males and $\sigma=0.6215$ for females. $1 - S_i(10) = \text{probability of an event in 8 years}$. Results of external validation included comparison between expected and actual events applying the newly developed type 1 diabetes CHD prediction model to data from the EURODIAB Study. The outcome of interest was the same although fatal cases were based solely on death certificate information. In males, the model performed well with a c statistic of 0.77. Events were slightly overpredicted in the tenth decile. The female model also performed well with a c statistic was 0.78, however the model overpredicted events in the tenth decile.

Conclusion: This is the first clinically practical model developed to predict CHD events for type 1 diabetes that was externally validated in an independent type 1 diabetes population. This model can be used as a tool to enhance both patient and provider knowledge about CHD risk.

Future burden of diabetes in Denmark; the National Diabetes Register

B. Carstensen¹, P. Ottosen²

¹Epidemiology, Steno Diabetes Center, Gentofte, ²Medical statistics, National Board of Health, Copenhagen, Denmark

Background and aims: For planning purposes it is of paramount interest to predict the likely number of future diabetes cases in the Danish population. Therefore we want to estimate incidence and mortality rates in order to predict future diabetes prevalence and life time risk in the Danish population.

Materials and methods: The National Diabetes Register covers the period 1995–2006 inclusive, and holds all cases of diabetes in Denmark alive in this period. Based on this we derived age-specific incidence rates and mortality rates for diabetes patients, and based on population data from statistics Denmark we derived mortality rates for non-diabetic persons. These were used to estimate future prevalences and lifetime risk of diabetes in the Danish population.

Results: There were 359,000 cases in the register, 233,000 included after 1995. We saw an annual increase in incidence rates of 5% until 2003 and after

that an annual decrease of 5%. Mortality rates decreased 3.6% per year. The lifetime risk of diabetes was found to be 28% for women and 31% for men, assuming the current rates prevail at the 2003 in the future. The peak prevalence in the population will be 22% for both sexes, attained at age 75 for men and age 85 for women.

Conclusion: We have observed a significant decrease in incidence rates. Even though the anticipated lifetime risk for currently born is around 30%, this is likely to decrease if the incidence rates continue to decrease. This is however difficult to assess with the rather short time span observed.

OP 19 Cardiomyopathy and dysfunction of the heart

109

Microarray expression analysis in delayed cardioprotection: the effect of exercise, AICAR or metformin and the possible role of AMP-activated protein kinase (AMPK)

L. Solskov¹, N.E. Magnusson¹, S.B. Kristiansen², H.E. Bøtker², T.T. Nielsen², O. Schmitz^{3,1}, S. Lund³

¹Department of Pharmacology, Aarhus University, ²Department of Cardiology, Aarhus University Hospital, Skejby Sygehus, ³Medical Research Laboratory and Medical Department M (Endocrinology and Diabetes), Aarhus University Hospital, Denmark

Background and aims: AMP-activated protein kinase (AMPK) is an enzyme which acts as an energy sensor in various cell types and has been indicated to play an important protective role in the ischaemic heart. It has previously been demonstrated that exercise, 5-aminoimidazole-4-carboxamide-1- β -D-ribofuranoside (AICAR) and metformin, all known activators of AMPK, induce delayed preconditioning which protects the heart against ischaemia-reperfusion injury. The aim was to determine the effect of exercise, AICAR and metformin on rat left ventricular gene expression profile and to demonstrate possible interactions in different pathways.

Materials and methods: Rats were divided into the following groups: 1) an exercise group trained on a treadmill for one hour, 2) an AICAR group given a single injection of AICAR, 3) a metformin group given a single oral dose of metformin. Sedentary rats were used as controls. 24 hours later hearts were removed and gene expression profiles were analysed in tissue from the left ventricle using affymetrix gene chip probe arrays. Ingenuity Pathway Analysis software was used to analyse regulated genes and regulatory pathways. To reduce low intensity genes in the analysis a cut-off limit was chosen at a fold change ≥ 2.0 and signal ≥ 100 .

Results: Each gene chip identified 30,000 different probesets of which Ingenuity identified approximately 12,000 genes. The total numbers of up- and down-regulated genes in the three groups are shown in table 1. Ingenuity identified 17 pathways all regulated by exercise, AICAR and metformin. 5 of these are summarized in table 1 including top genes involved. Among these genes *HIF1A* (hypoxia inducible factor 1 alpha), *NR2C2* (nuclear receptor subfamily 2) and *EIF2S3* (eukaryotic translation initiation factor 2) have all previously been indicated to play a role in the protection against myocardial ischaemia-reperfusion injury.

Conclusion: This study demonstrates that exercise, AICAR and metformin, all known activators of AMPK, regulate several identical pathways in the rat myocardium with the most overlapping genes observed in the exercise and AICAR group. These results may provide insight into the molecular mechanisms of delayed cardioprotection.

Table 1: Regulated genes (presented by gene names) representing relevant pathways

	Exercise	AICAR	Metformin
Total up-regulated genes	84	131	248
Total down-regulated genes	19	39	141
Pathways	–	–	–
PPAR α /RXR α Activation	GHR \uparrow	GHR \uparrow	NR2C2 \uparrow
VEGF Signaling	HIF1A \uparrow	HIF1A \uparrow	EIF2S3 \downarrow
Axonal Guidance Signaling	CFL2 \uparrow	CFL2 \uparrow	PRKD1 \uparrow
Leukocyte Extravasation Signaling	ROCK1 \uparrow	ROCK1 \uparrow	ACTN1 \downarrow
Cardiac β -adrenergic Signaling	PPP1CB \uparrow	PPP1CB \uparrow	PKIB \uparrow

110

HMGB1- a new prognostic marker in the development of diabetic cardiomyopathy?

M. Andrassy¹, C. Volz¹, Z. Kaya¹, A. Bierhaus², H. Katus¹

¹Department of Cardiology, Department of Medicine III, ²Endocrinology and Clinical Chemistry, Department of Medicine I, Heidelberg, Germany

Background and aims: Diabetes is one of the most important comorbid factors in patients with acute myocardial infarction (MI). The association of dia-

betes with higher incidence, severity and complexity of cardiac diseases compared to euglycemic patients is poorly understood. We studied the impact of High-mobility group box 1 (HMGB1), a newly recognized innate danger signal for the initiation of host defense and tissue repair, and the receptor for advanced glycation endproducts (RAGE) on the pathogenesis of early and late phase complications of diabetic cardiomyopathy.

Materials and methods: Immunohistochemical expression analyses of HMGB1 was analyzed in reperused left ventricles in an animal model of type 1 diabetes mellitus followed by studies on the influence of the HMGB1-RAGE axis on the development of cardiac inflammation, fibrosis and apoptosis next to its influence on compensatory hypertrophy of the viable myocardium at the early and late phase of diabetic cardiomyopathy. The influence of HMGB1-RAGE axis on cardiac function was assessed in 2-dimensional echocardiography.

Results: Diabetes (DM) induced an enhanced HMGB1 expression in the myocardium of mice in comparison to healthy control mice. Furthermore, diabetic mice subjected to I/R injury (IR) displayed significantly pronounced cardiac remodelling compared to healthy mice with I/R or diabetes in the absence of I/R. Treatment with the functional HMGB1 antagonist HMGB1 box A significantly reduced cardiac remodeling in diabetic mice with I/R injury. Survival rates during the study period of 10 weeks were significantly lower in the group with diabetes alone versus control mice, while the DM+ I/R group displayed the highest mortality rate. Treatment of the DM + I/R group with the functional HMGB1 antagonist box A significantly enhanced the survival rate compared to the non-treated DM + I/R group pointing to an essential role of HMGB1 in the development of diabetic cardiomyopathy. Echocardiography revealed significant reduction of the fractional shortening (FS) of the left ventricles of diabetic mice despite unchanged left ventricular diameter compared to sham operated control mice. The DM+ I/R group demonstrated significantly enhanced remodelling with reduced FS and LV dilation compared to untreated I/R group or the DM group without I/R. Treatment with the HMGB1 antagonist box A showed a drastic improved recovery of cardiac function in the DM+ I/R group compared with the untreated DM+I/R group.

Conclusion: We propose that HMGB1/RAGE-interaction is a key component initiating and sustaining an inflammatory response following ischemic stress eventually leading to the development of diabetic cardiomyopathy.

111

Cardiomyopathy, glycogen accumulation and low AMP-activated protein kinase γ 2 expression in the heart of transgenic mice with activated polyamine catabolism

E. Pirinen^{1,2}, M. Merentie¹, M.-M. Ryhänen¹, M. Hedman^{1,2}, S. Heinonen¹, P. Korpiälä¹, A. Virkamäki³, J. Kuusisto⁴, J. Jänne¹, S. Ylä-Herttuala¹, M. Laakso²

¹Department of Biotechnology and Molecular Medicine, University of Kuopio, ²Department of Medicine, University of Kuopio, ³Minerva Foundation Institute for Medical Research, University of Helsinki, ⁴Cardiology Unit, Kuopio University Hospital, Kuopio, Finland

Background and aims: Mutations in the γ 2 subunit of AMP-activated protein kinase (AMPK) produce glycogen storage hypertrophic cardiomyopathy with Wolff-Parkinson-White syndrome in man, often evolving systolic dysfunction resembling dilated cardiomyopathy (DCM). We have previously shown that transgenic mice overexpressing spermidine/spermine N¹-acetyltransferase (SSAT), the key enzyme in the catabolism of polyamines, have severely reduced fat mass, increased insulin sensitivity and improved glucose tolerance. In this study, we investigated the mechanisms of cardiac dysfunction in these mice.

Materials and methods: Echocardiographic measurements were accomplished in female SSAT (tg) and wild-type (wt) mice using a high-frequency ultrasound imaging system (Vevo 770). Blood pressure was measured in female SSAT and wt mice with a tail-cuff system (CODA 2TM system). Renal perfusion of female SSAT and wt mice was analyzed with Acuson sequoia 512 ultrasound device using Doppler mode with administration of ultrasound contrast agent. Gene expression levels in the hearts were analyzed using quantitative RT-PCR. Glycogen content was analyzed microfluorometrically after KOH hydrolysis.

Results: Echocardiography revealed that SSAT mice have dyskinetic wall motions of the left ventricles and impaired pump function since ejection fraction (tg: 57.9±4.0 vs. wt: 71.7±4.3 %, p<0.001) and fractional shortening (tg: 30.2±2.8 vs. wt: 40.3±3.7 %, p<0.01) were significantly reduced. In addition, left ventricle mass (tg: 5.9±0.7 vs. wt: 5.1±0.1 mg/g, p<0.05), left ventricle di-

astolic volume (tg: 74.4±10.7 vs. wt: 55.5±2.5 μ l, p<0.01), left ventricle systolic volume (tg: 31.1±3.2 vs. wt: 15.7±2.0 μ l, p<0.001), left ventricle diastolic internal diameter (tg: 4.1±0.3 vs. wt: 3.6±0.1 mm, p<0.01) and left ventricle systolic internal diameter (tg: 2.9±0.1 vs. wt: 2.2±0.1 mm, p<0.001) were significantly increased. In contrast, systolic (tg: 94±16 vs. wt: 128±6 mmHg, p<0.01) and diastolic (tg: 58±12 vs. wt: 89±6 mmHg, p<0.01) arterial blood pressure and renal cortex perfusion (tg: 0.82±0.05 vs. wt: 0.95±0.03 cortex/artery ratio, p<0.01) were significantly reduced. Glycogen content in the hearts of SSAT mice was significantly increased in the fed state (tg: 66±21 vs. wt: 35±14 mmol/g prot, p<0.001). Message RNA level of AMPK γ 2 subunit (tg: 0.72±0.02 fold to wt, p<0.001) was significantly decreased in the hearts of SSAT mice compared to wt mice.

Conclusion: Activated polyamine catabolism leads to DCM. The underlying mechanisms seem to be related to the accumulation of glycogen in the heart and altered cardiac energy metabolism, especially downregulation of AMPK γ 2 subunit in heart muscle, mimicking human glycogen-storage cardiomyopathy.

Impaired glucose tolerance exacerbates the abnormal myocardial metabolic response to pacing in subjects with dilated cardiomyopathy

A. Natali¹, S. Baldi¹, A. Gastaldelli², D. Ciociano², S. Frascerra¹, A. De Caterina², P. Marraccini², E. Ferrannini¹, F. Recchia², D. Neglia²

¹Department of Internal Medicine, University of Pisa, ²Institute of Clinical Physiology, C.N.R., Pisa, Italy

Background and aims: Studies in animal models and in man have shown that dilated cardiomyopathy (DCM) under resting conditions is characterized by a shift of myocardial substrate metabolism towards carbohydrates at the expense of fatty substrates. During a metabolic stress (pacing), it has been documented that DCM patients fail to increase myocardial glucose uptake. Since an abnormal glucose homeostasis is rather common in patients with DCM, we hypothesised that it could be responsible for some of the observed myocardial metabolic defects.

Materials and methods: In 10 patients with DCM (ejection fraction<50%), 5 with normal (NGT) and 5 with impaired glucose tolerance (IGT), we measured coronary blood flow (by intravascular ultrasonometry) and transmyocardial arterio-venous differences of oxygen and metabolites at rest, during pacing (up to 130 b/min) and during 30 min of recovery. Lactate exchange (by ¹³C-lactate) and oleate oxidation (from ³H-oleate/ ³H₂O conversion) were also measured. Metabolic fluxes are normalized per gram of myocardial tissue (LV mass was measured by echography). Glucose, lactate and FFA were converted in ATP equivalents assuming 36, 18 and 131 mol per mol, respectively.

Results: Atrial pacing induced a similar rate-pressure product plateau in IGT (11,410 mmHg*b/min) and NGT (12,089) and a similar increment in coronary blood flow (+0.26 and +0.25 ml/min/g). In response to pacing, myocardial glucose and lactate uptake did not change in either NGT or IGT patients. During recovery, the uptake of these substrates increased in NGT (from 5.6±1.2 to 11.6±2.8 μ mol of ATP/g/min, p<0.05) but decreased in IGT (from 10.5±1.7 to 6.5±0.8 μ mol of ATP/g/min, p<0.05). Furthermore, in the latter group a significant increase in lactate release occurred during the pacing (from 62 to 142 pmol/g/min, p<0.05). While the myocardium of the IGT patients sustained the pacing work by increasing free fatty acids oxidation (from 61±16 to 124±2 nmol/g/min, p<0.05), in the NGT patients there was a rapid and prolonged increase in β -OH-butyrate uptake (from 131±55 to 211±95 nmol/g/min). The enhanced reliance on lipid oxidation during pacing and recovery of the IGT patients was confirmed by the gas exchange measurements, which gave estimates of ATP derived from lipids (from 11.2±5.6 to 18.3±4.5 μ mol of ATP/g/min) similar to the estimates obtained from the conversion of ³H-oleate to ³H₂O (from 8.0±2.1 to 16.3±0.3 μ mol of ATP/g/min).

Conclusion: Patients with DCM and IGT show a more severe impairment in the ability to use carbohydrate for an acute increase in myocardial work and are heavily dependent on fatty substrate utilisation. The presence of IGT in DCM exacerbates a (presumably) primary myocardial metabolic defect in substrate handling.

113

Myocardial steatosis is an independent predictor of diastolic dysfunction in type 2 diabetes mellitusR.W. van der Meer¹, L.J. Rijzewijk², M. Diamant², J.J. Bax³, J.A. Romijn⁴, J.W.A. Smit⁴, A. de Roos¹, H.J. Lamb¹¹Radiology, Leiden University Medical Center, ²Endocrinology, VU university Medical Center, Amsterdam, ³Cardiology, Leiden University Medical Center, ⁴Endocrinology, Leiden University Medical Center, Netherlands

Background and aims: Type 2 diabetes mellitus (T2DM) is a major risk factor for cardiovascular disease. Increasing evidence is emerging indicating that lipid oversupply to cardiomyocytes plays a role in the development of diabetic cardiomyopathy, by causing lipotoxic injury and myocardial steatosis. Therefore, the aim of this study was to compare myocardial triglyceride content and myocardial function in patients with uncomplicated T2DM and age- and body mass index (BMI) matched healthy subjects and to study the associations between myocardial triglyceride content and heart function.

Materials and methods: Myocardial triglyceride content and myocardial function were measured in 41 T2DM patients (mean \pm SE age: 57 ± 1 years, BMI: 28.1 ± 0.6 , and HbA_{1c} 7.2 ± 0.2 , free of cardiac ischaemia (verified by dobutamine stress echocardiography) and 30 healthy age- and BMI matched volunteers by proton magnetic resonance (MR) spectroscopy (fig 1) and MR imaging, respectively.

Results: Myocardial triglyceride content was significantly higher in T2DM patients compared to healthy volunteers (0.96 ± 0.07 vs. $0.65 \pm 0.05\%$, $p < 0.05$). Systolic function did not significantly differ between both groups. Indices of diastolic function, including left ventricular E/A ratio and E peak deceleration, were significantly impaired in T2DM compared to healthy subjects (1.24 ± 0.06 vs. 1.08 ± 0.04 and 4.4 ± 0.3 vs. 3.6 ± 0.2 ml/s² $\times 10^{-3}$ respectively, $p < 0.05$). Multivariable analysis indicated that myocardial triglyceride content was associated with E/A and E peak deceleration, independently of diabetic state, age, BMI, heart rate, visceral fat and diastolic blood pressure.

Conclusion: Myocardial triglyceride content is increased in uncomplicated T2DM and associated with impaired left ventricular diastolic function, independently of age, BMI, heart rate, visceral fat, and diastolic blood pressure.

Fig. 1. Proton Magnetic Resonance Spectroscopy. Spectroscopic volume localization in the interventricular septum on 4-chamber (A) and short-axis (B) views. Panel C shows a typical water suppressed ¹H spectrum of myocardial tissue located in the interventricular septum. Peak heights are in arbitrary units

114

Effect of pioglitazone versus metformin on myocardial function, metabolism and triglyceride content in men with well-controlled type 2 diabetes and verified absence of cardiac ischaemiaL.J. Rijzewijk¹, R.W. van der Meer², H.J. Lamb², H.W.A. Jong³, M. Lubberink³, J.A. Romijn⁴, J.J. Bax⁵, A. de Roos², O. Kamp⁶, W.J. Paulus⁷, A.A. Lammertsma³, J.W.A. Smit⁴, M. Diamant¹¹Diabetescenter, VU medical center, Amsterdam, ²Radiology, Leiden University Medical Center, ³Nuclear Medicine & PET Research, VU medical center, Amsterdam, ⁴Endocrinology, Leiden University Medical Center, ⁵Cardiology, Leiden University Medical Center, ⁶Cardiology, VU medical center, Amsterdam, Netherlands, ⁷Physiology, VU medical center, Amsterdam, Netherlands

Background and aims: Cardiac disease is the leading cause of mortality in type 2 diabetes mellitus (T2DM). Pioglitazone (PIO) therapy is associated with potential benefits but also with an elevated risk of heart failure. In the PIRAMID study (Pioglitazone Influence on rTriglyceride Accumulation in the Myocardium In Diabetes) we determined the effects of PIO, versus metformin (MET), on myocardial function, perfusion, glucose and fatty acid metabolism in T2DM patients. In addition, myocardial and liver triglyceride content were determined.

Materials and methods: Seventy-eight T2DM patients (mean \pm SE: age 56.6 ± 0.6 y; HbA_{1c} 7.1 ± 0.1 %; BMI 28.7 ± 0.4 kg/m²), without cardiac ischaemia, as verified by dobutamine-stress echocardiography, were randomly assigned to PIO (30 mg daily) or MET (2000 mg daily) and matching placebo during 24 weeks. The primary endpoint was change from baseline in cardiac function, relative to myocardial metabolic and perfusion changes, measured by magnetic resonance imaging, proton MR spectroscopy and positron-emission tomography using [¹⁵O]-H₂O, [¹¹C]-palmitate in the fasting state and [¹⁸F]-fluoro-2-deoxy-glucose under euglycaemic hyperinsulinaemic conditions.

Results: Seventy-one patients completed the study. No patient developed congestive heart failure. Both therapies similarly improved glycaemic control and systolic blood pressure. PIO increased body weight ($p = 0.001$) and end-diastolic volume ($p < 0.001$) without changing cardiac index or left ventricular mass. Only PIO improved diastolic function ($p = 0.034$), in association with improved whole-body insulin sensitivity ($p < 0.02$), changes in myocardial fatty-acid uptake ($p < 0.02$) and oxidation ($p < 0.03$). However, these functional changes were unrelated to increased myocardial glucose uptake. MET also improved insulin sensitivity ($p = 0.033$) but reduced myocardial glucose uptake ($p = 0.005$) and fatty acid oxidation ($p = 0.024$), without affecting myocardial function. MET increased, whereas PIO decreased, plasma lactate ($p = 0.001$, between groups). Neither treatment affected myocardial triglyceride content or perfusion. However, PIO but not MET decreased liver triglyceride content ($p = 0.001$, between groups).

Conclusion: In the absence of cardiac ischaemia, PIO therapy may have beneficial cardiac effects in T2DM patients, both by directly affecting cardiac metabolism and by inducing systemic metabolic changes related to improvement in insulin sensitivity.

A mouse model of neonatal diabetes caused by the K_{ATP} channel mutation Kir6.2-V59M

C.A. Girard¹, T.F. Wunderlich², K. Shimomura¹, S. Collins³, S. Kaizik¹, P. Proks¹, F. Abdulkader^{3,4}, A. Clark³, L. Bentley⁵, J. Galvanovskis³, R. Cox⁵, P. Rorsman³, J.C. Bruning², F.M. Ashcroft¹

¹Department of Physiology, Anatomy and Genetics, University of Oxford, United Kingdom, ²Department of Mouse Genetics and Metabolism, University of Cologne, Germany, ³The Oxford Center for Diabetes, Endocrinology and Metabolism, Churchill Hospital, Oxford, United Kingdom, ⁴Department of Physiology and Biophysics, Institute of Biomedical Sciences, Sao Paulo, Brazil, ⁵MRC Harwell, Medical Research Council, Harwell, United Kingdom

Background and aims: Gain-of-function mutations in Kir6.2, the pore-forming subunit of ATP-sensitive potassium channels (K_{ATP} channels) are a common cause of human neonatal diabetes. Around 20% of patients also exhibit muscle weakness and developmental delay, a condition known as intermediate DEND syndrome, usually due to mutation of valine 59 to methionine (V59M). Using Cre-loxP technology, we generated a mouse expressing the Kir6.2-V59M mutation specifically in pancreatic beta-cells (V59M mice) in order to determine its contribution to the development of neonatal diabetes observed in humans.

Materials and methods: Five week old mice (Wild-Type, V59M, RIP-Cre, ROSA) were used in this study. Hormone concentrations were determined after overnight fasting. Insulin secretion and intracellular calcium measurements were assessed on isolated islets stimulated with either high glucose concentration or sulphonylurea drugs. Morphometric analyses were performed on wax-embedded pancreases. Glucose and ATP sensitivity of mutant K_{ATP} channels were determined by electrophysiology on isolated beta-cells.

Results: V59M mice developed severe diabetes soon after birth: plasma glucose was >30mM and insulin was undetectable. Isolated islets failed to secrete insulin in response to glucose, due to a reduced sensitivity of K_{ATP} currents in V59M beta-cells to inhibition by glucose and ATP (IC_{50} 270 μ M, vs. 25 μ M for wild-type beta-cells). However, the sulphonylurea tolbutamide closed V59M K_{ATP} channels and stimulated insulin release. Unexpectedly, morphometric analysis revealed that V59M islets also displayed an abnormal morphology, reduced beta-cell number (~20% less), and lower insulin content.

Conclusion: Our findings demonstrate that expression of the V59M mutation in beta-cells alone is sufficient to recapitulate the neonatal diabetes observed in humans, and explain why human patients with this mutation can be successfully transferred from insulin injections to sulphonylurea therapy.

The use of prophylactic dose of alfacalcidol maintains remission regardless of children's age in new onset type 1 diabetes - 2 years observation

R. Piekarski, Y. Azab, A. Bury, L. Szewczyk

Pediatric Endocrinology and Neurology, Medical University in Lublin, Lublin, Poland

Background and aims: In recent years studies focused on prevention of type 1 diabetes mellitus (DM) and possibility of beta-cell protection at the clinical diagnosis of DM. Some recent studies have demonstrated beneficial role of vit. D3 analogue in human beta-cell activity maintenance at the early stages of DM. In this study have been continued the observations concerning the role of vit. D3 analogue with the aim of beta cells functional state evaluation.

Materials and methods: The study was performed in 54 children and adolescents aged 4-18 years (21 children < 7 year old and 33 \geq 7 year old) who received insulin and vit D3 analogue (alfacalcidol - α -OH-vitamin D3) in daily dose 0.25 μ g. 37 peers with type 1 DM who received only insulin therapy without vit. D3 administration were the control group. After two years therapy we compared the level of HbA1c, body mass, daily insulin dose in both groups.

Results: There are no differences in mean body mass and in metabolic control of diabetes reported by mean HbA1c level at the onset of the DM and after two years observation of these patients among studied groups. How-

ever, daily insulin dose in 60% of patients who received vit. D3 therapy after two years observation were below 0.5 u/kg. There are no differences in insulin requirement regardless the children's age. On the contrary, insulin requirement in the group of patients without vit. D3 treatment significantly increased ($p < 0.01$) after two years observation (from 0.37 u/kg to 0.78 u/kg). In this group remission rate (<0.5 u/kg) in only 6% was found. There are disturbances in calcium homeostasis in the group of children treated with alfacalcidol not observed.

Conclusion: 1. In 60% of children treated alfacalcidol insulin requirement after two years therapy with vit. D3 analogue was below 0.5 u/kg. 2. There are no differences in insulin requirement in the group of children treated with alfacalcidol related to the age. 3. Children without vit. D3 administration had twofold increase of insulin requirement after two years observation from clinical diagnosis. 4. Our observations suggest, that alfacalcidol could play a role in prevention of further beta-cells destruction.

¹Institute of Biometrics and Epidemiology, German Diabetes Centre, Düsseldorf, Germany, ²Paediatric Clinic, University Hospital München, Germany, ³Children's Hospital, Hospital Bremen North, Germany, ⁴Institute of Epidemiology, Ulm University, Germany, ⁵Children's Hospital, University Hospital Innsbruck, Austria, ⁶Children's Hospital, University Hospital München, Germany, ⁷Children's Hospital, Hospital Nürnberg South, Germany

Background and aims: During the past decade considerable efforts have been undertaken in diabetes care to intensify insulin therapy and to improve patient education. The issue, whether treatment results have contemporaneously improved, has great public health importance. HbA1c is the most important parameter to assess long-term metabolic control and quality of diabetes care. Evaluation of metabolic control is complicated by methodical problems (laboratory specific normal ranges for HbA1c) and the great number of correlating predictors.

Materials and methods: Within the framework of the quality assurance project DPV German and Austrian diabetes centres document relevant parameters of diabetes care using the DPV software. Twice a year anonymous data are transmitted for central plausibility checks and analysis to provide centres with benchmarking reports. Further, this anonymous data base is available for epidemiologic-scientific research. This analysis is based on data of 27360 patients from 268 diabetes centres documented during 1995-2007. HbA1c values were converted to the international DCCT standard using the multiple-of-the-mean method. For each patient, the median of all HbA1c measurements during the most recent treatment year was evaluated. Data were analysed by descriptive statistics and generalized linear mixed regression models including various relevant factors (year and month of treatment, age, sex, diabetes duration, foreign ethnicity, treatment modality, size and kind of centre) as fixed and treatment centre as random effect to account for variation between diabetes centres.

Results: Crude median HbA1c decreased from 8.0% (interquartile range: 2.0%) in 1995 to 7.6% (interquartile range: 1.7%) in 2007. Multivariate regression analysis showed treatment year, age, sex, diabetes duration, foreign ethnicity, month of HbA1c measurement, and mode of insulin treatment to be significant predictors of metabolic control ($p < 0.001$), adjusting for variation between diabetes centres. Size and kind of diabetes centre (< 100 vs. \geq 100 children treated or regular vs. rehab hospital, respectively) had no significant effect ($p > 0.5$). Trend analysis indicated that mean HbA1c decreased significantly by 0.7% per year on average in relative terms, corresponding to an absolute average decrease by 0.06%.

Conclusion: Applying a complex statistical model this study showed a slight improvement in metabolic control in diabetic children and adolescents during the past decade. This improvement was not fully explained by changes in the mode of insulin treatment. Possibly, improved patient education during the last decade may account for this trend, at least in part. Using observational data the study can not prove observed associations to reflect causal effects on the metabolic control.

Intensive care admissions for acute diabetic complications of children and adolescents in England and WalesJ. Bodansky¹, R.C. Parslow², R.G. Feltbower³, P.A. McKinney³¹General medicine, The Diabetes Centre, ²Paediatric Epidemiology Unit, Centre for Epidemiology and Biostatistics, ³Paediatric Epidemiology Group, Centre for Epidemiology and Biostatistics, Leeds, United Kingdom

Background and aims: The incidence of type 1 diabetes in young people is increasing and places a growing burden on healthcare providers. The treatment of severely ill children and adolescents in intensive care is very expensive. There is evidence of self-harm or neglect of their condition in teenage patients, especially males, some of whom may require intensive care. Nationally available data on children admitted to paediatric intensive care (PICU) with acute diabetic complications are now available for the UK. The aim of this study was to examine patient demographics and outcomes of these children and adolescents in England and Wales, using a high quality national dataset.

Materials and methods: The Paediatric Intensive Care Audit Network (PICANet) collects data on all admissions to paediatric intensive care in England and Wales. Admissions between April 2003 and March 2007 whose primary diagnosis was related to diabetes were identified by expert clinical review of coded data. Demographic information included age at admission, sex, ethnic group (south Asian or not, determined by two name classification algorithms) and socioeconomic status. Crude and risk-adjusted mortality (using the Paediatric Index of Mortality (PIM)) and length of stay (LOS) were used as outcome measures. Descriptive statistics and logistic regression were used to analyse the data.

Results: 330 diabetic children and adolescents were admitted to a PICU in the 4 year period, with 341 admissions overall representing 0.6% of all PICU admissions. There was an excess of female admissions (56% vs. 44%) with a M: F ratio of 0.78:1 in this cohort of patients compared with 1.33:1 in the PICU population overall (chi square 24.39, 1df, $p < 0.001$). 89% of admissions were diagnosed with diabetic ketoacidosis (DKA) (57% female, 43% male). 40% of admissions were aged 11–15 years. The proportion of admissions increased with lower socioeconomic status following a similar pattern to all PICU admissions. There were significantly fewer admissions of South Asians (7% vs. 11%, chi-square 4.44, 1df, $p = 0.035$). Five deaths (1.47% of admissions) occurred in this period, all female, four with DKA, and one with hypoglycaemia. PIM predicted 27 deaths based on presenting physiology. The risk-adjusted odds of mortality for admission with a diabetes-related condition was 0.22, $p = 0.002$, 95% CI, 0.09–0.56. Median length of stay was 2 days (IQR 2–3) compared with 3 days (IQR 2–6) in the rest of the PICU population.

Conclusion: Admission to PICU for diabetes related conditions is proportionately higher in females despite higher incidence of type 1 diabetes in males nationally (M: F ratio 1.2:1) and in PICU admissions generally. Despite high PICU survival overall, there is an unexpected sex bias in mortality. The apparently low risk-adjusted mortality may relate to using base excess as a predictive component of the model, which is usually corrected rapidly in this group of patients. Avoiding acute diabetic complications would reduce the admission rate to costly intensive care beds, which are usually in short supply.

High prevalence of cardiovascular risk factors in youths with type 2 diabetes: the search for diabetes in a youth case-control studyD. Dabelea¹, N.A. West¹, E.J. Mayer-Davis², R.B. D'Agostino Jr.³, S. Marcovina⁴, A.D. Liese⁵, P.S. Zeitler⁶, S.R. Daniels⁶, R.F. Hamman¹¹Preventive Medicine and Biometrics, University of Colorado Denver, ²Nutrition, University of North Carolina at Chapel Hill, ³Public Health Sciences, Wake Forest University, Winston-Salem, ⁴Northwest Lipid Research Laboratories, University of Washington, Seattle, ⁵Epidemiology, Arnold School of Public Health, Columbia, ⁶Pediatrics, University of Colorado, Denver, CO, United States

While the increased risk of cardiovascular disease (CVD) in adults with Type 2 Diabetes (T2D) compared to the general population has been well documented, data on CVD risk factor profile in youth with T2D remain rela-

tively sparse. We evaluated case/control differences in CVD risk factor profile among 331 multi-ethnic participants (38% African American, 16% Hispanic, 46% non-Hispanic white), age 10–22 years, in the SEARCH for Diabetes in Youth Case-Control Study. T2D ($n=116$) and control ($n=215$) youth were recruited in Colorado and South Carolina. Compared with controls, youth with T2D had higher age- and race/ethnicity-adjusted prevalence of hypertension (blood pressure $\geq 95^{\text{th}}$ percentile or medication: 27% vs 5%, $p < .0001$), obesity (body mass index-BMI $\geq 95^{\text{th}}$ percentile: 86% vs 26%, $p < .0001$), large waist circumference ($\geq 90^{\text{th}}$ percentile: 82% vs 22%, $p < .0001$), low HDLc (≤ 35 mg/dl: 25% vs 5%, $p < .0001$), high triglycerides (TG ≥ 150 mg/dl: 27% vs 6%, $p < .0001$), and high urinary albumin:creatinine ratio (ACR ≥ 30 $\mu\text{g}/\text{mg}$: 17% vs 7%, $p = .02$). There was little difference among youth with and without T2D in the prevalence of high LDLc (14% vs 10%, $p = .29$). The distribution of the total number of CVD risk factors (0, 1, 2, 3, or 4+) in youth was also significantly different ($p < .0001$), with a less favorable CVD risk profile for T2D youth (figure). T2D youth also had a less favorable profile of non-traditional CVD risk factors. This included higher apolipoprotein B (79 vs. 61 mg/dl) and lower LDL particle density (0.27 vs 0.28 Rf), even after adjusting for differences in BMI ($p < 0.0001$ for each), as well as higher fibrinogen (404 vs 319 mg/dl, $p < 0.0001$) and IL6 levels (13 vs 6 pg/ml, $p = 0.02$), even after adjustment for both BMI and HbA1c. In conclusion, when compared with healthy adolescents, youth with T2D have a higher prevalence of many CVD risk factors. Obesity is an important contributor to a less favorable CVD risk profile; however, additional mechanisms, such as hyperglycemia and inflammation, may also play a role. These data highlight the need for early prevention and treatment strategies aimed at reducing the prevalence of CVD risk factors in youth with T2D.

Ethnic differences in cardiovascular risk profile in an overweight/obese multiethnic paediatric cohortI. von Rosenstiel¹, M. van Vliet¹, R.K. Schindhelm², D.P.M. Brandjes³, J.H. Beijnen⁴, M. Diamant⁵¹Paediatrics, Slotervaart Hospital, Amsterdam, ²Clinical Chemistry, Isala Clinics, Zwolle, ³Internal Medicine, Slotervaart Hospital, Amsterdam, ⁴Pharmacy & Pharmacology, Slotervaart Hospital, Amsterdam, ⁵Diabetes Centre, VU University Medical Centre, Amsterdam, Netherlands

Background and aims: Among children, the global prevalence of obesity and all components of the metabolic syndrome (MetS), including glucose intolerance, insulin resistance, dyslipidaemia and hypertension is increasing at an alarming rate. However, differences in prevalence of these cardiovascular risk factors between different ethnic groups are unknown. In the present study, we determined the variation in cardiovascular risk profile and the association of insulin resistance with cardiometabolic risk factors according to ethnicity in a cohort of overweight/obese children.

Materials and methods: An oral glucose tolerance test was performed in 516 consecutive overweight/obese Dutch children of multiethnic origin, from an obesity out-patient clinic of a community hospital (mean age 11 ± 3 yrs; $n=285$ boys). Anthropometric parameters and fasting blood samples were collected.

The prevalence of (components of) MetS (according to a previously defined paediatric definition) and insulin resistance (defined by the Homeostasis Model Assessment for Insulin Resistance [HOMA-IR] ≥ 3.5) were determined. Data were analysed after stratification for ethnic group.

Results: Major ethnic groups were Dutch native (18.4%), Turkish (28.1%), Moroccan (25.8%), Hindu (4.3%) and a group with other or mixed origins (23.4%, i.e. with parents of different origins). MetS was established in 18.6%, impaired glucose tolerance in 3.2%, low HDL-cholesterol in 31.2%, high triglycerides in 17.4% and hypertension in 22.9%. Of all children, 4.3% did not meet the obesity criterion of MetS. Turkish children had the highest mean waist circumference ($P < 0.05$) and prevalences of MetS (26.9%), low HDL-cholesterol (37.9%), hypertension (29.7%) and insulin resistance (54.9%), whereas in Moroccan children, insulin resistance was least frequently present (37.4%), as compared to other ethnic groups (all $P < 0.05$). Although the prevalences of the various MetS-components in Moroccan children did not significantly differ from other ethnic groups, mean plasma HDL-cholesterol was higher, while triglycerides and systolic blood pressure were lower in these children ($P < 0.01$, $P < 0.001$ and $P < 0.05$, respectively) as compared to other ethnic groups. In addition, apart from obesity, 60.6% of Moroccan children ($P < 0.01$), relative to 40.0% of Turkish children ($P < 0.01$) were free of MetS-components, compared to 48.7% of their peers of other origins. HOMA-IR was associated with MetS and its separate components, after adjustment for ethnicity and BMI. When observing these relations in Dutch native, Turkish and Moroccan children separately (after adjustment for BMI), HOMA-IR was associated with at least two MetS-components (apart from obesity).

Conclusion: In a Dutch cohort of overweight/obese children, Turkish children showed a higher prevalence of cardiovascular risk factors relative to their peers of other ethnicities. In contrast, children of Moroccan background had a relatively favourable cardiovascular risk profile. Long-term studies are needed to establish whether our findings are compatible with actual risk of future cardiometabolic disease in the different ethnic populations.

OP 21 Incretins: action and secretion

The effects of jugular vs. portal GLP-1 during hyperglycaemic clamps in rats

M. Perabo^{1,2}, B.A. Aulinger¹, E.E. Elfers¹, J. Heyl¹, K. Ellis¹, R.J. Seeley³, D.A. D'Alessio¹

¹Medicine - Division of Endocrinology, University of Cincinnati, Cincinnati, United States, ²Medizinische Klinik und Poliklinik 2, Ludwig-Maximilians-Universität, München, Germany, ³Psychiatry, University of Cincinnati, United States

Background and aims: Glucagon-like-peptide 1 (GLP-1) is secreted by intestinal L-cells after nutrient ingestion and augments insulin secretion from pancreatic beta-cells in a glucose-dependent manner, thus contributing to the incretin effect. Its very low circulating levels, the moderate relative increment over fasting levels and the rapid degradation by ubiquitous dipeptidyl-peptidase-IV have opened discussion as to whether GLP-1 acts through an endocrine mechanism or rather mediates its effect by activation of a neuroendocrine pathway. Previous studies have shown the presence of the GLP-1 receptor (GLP-1r) in the portal vein (PV) and suggested that those receptors are necessary for mediation of glucose tolerance by GLP-1. We sought to determine whether insulin secretion differs after GLP-1 administration into the PV vs. a systemic infusion into the jugular vein (JV) during fixed and constant glycemia.

Materials and methods: Catheters were implanted into the JV, PV and carotid artery of Long-Evans rats weighing 300–320g. After 7–10 days of recovery with animals returning to their pre-surgical BW, the vascular catheters were connected to infusion pumps allowing administration of test substances, and blood draws under conscious and freely moving conditions. All rats had a glucose target of 210 mg/dl that was maintained by a variable infusion of 20% dextrose for 120 min. Blood samples for determination of glucose and insulin were taken at fixed intervals. After reaching steady-state glycemia a GLP-1 infusion of 7.5 pmol/kg BW/min was started at 60 min and was raised to 12.5 and 25 pmol/kg/min at 80 and 100 min, respectively.

Results: Before GLP-1 was started (50–60 min) glucose and insulin were not different between the JV and PV group (214 ± 4 vs. 216 ± 4 mg/dl; 318 ± 29 vs. 283 ± 33 pM). There was no increase of insulin secretion above the hyperglycemic baseline during infusion of the lowest GLP-1 dose in either group. However, the two higher doses of GLP-1 resulted in a significant increase of arterial insulin concentrations with both JV and PV infusion. The insulin response was significantly greater in animals receiving JV vs. PV GLP-1 (679 ± 112 and 1178 ± 235 pM vs. 396 ± 47 and 577 ± 71 pM; $p < 0.05$). Consistent with this, the glucose infusion needed to maintain the glucose clamp was significantly higher in JV vs. PV during the last 20 min of the clamp (5.1 ± 0.4 vs. 3.3 ± 0.4 , $p < 0.005$).

Conclusion: These data suggest that the GLP-1r previously described in the wall of the PV does not mediate the effects of GLP-1 on insulin secretion. However the significant difference in the GLP-1:insulin dose-response between JV and PV administration indicates a differential fate of GLP-1 in the systemic and portal circulation. Specifically these data support a central role of the liver in inactivation of endogenous GLP-1 such that a lesser amount is available for interaction with target organs through the arterial circulation. Since supraphysiologic amounts of GLP-1 were infused in this study our results raise questions as to the amount of endogenously secreted GLP-1 is available to the general circulation after meals. We conclude that an alternative mechanism, beyond PV or endocrine signalling, is required to explain how GLP-1 physiologically mediates its incretin effect.

The effect of delayed incretin clearance on fasting and postprandial glucose turnover in subjects with impaired fasting glucose

A. Vella¹, C. Dalla Man², G. Bockl¹, R. Basu¹, P.D. Giesler¹, J.M. Laugen¹, G. Toffolo², C. Cobelli², R.A. Rizza¹

¹Endocrinology, Mayo Clinic, Rochester, United States, ²Informatics, University of Padua, Italy

Background and aims: Abnormal concentrations of the incretin hormone Glucagon-like Peptide-1 (GLP-1) have been associated with type 2 diabetes and impaired fasting glucose (IFG) in some, but not all, studies. It is uncer-

Data are shown as mean + SEM

Area above basal	Endogenous Glucose Production (mol/kg per 6 h)		Glucose Disappearance (mol/kg per 6 h)		Meal Ra (mol/kg per 6 h)	
	Placebo	Sitagliptin	Placebo	Sitagliptin	Placebo	Sitagliptin
Baseline	-2.66 ± 0.12	-3.24 ± 0.20	2.66 ± 0.36	2.61 ± 0.44	5.86 ± 0.42	6.64 ± 0.38
At 6 weeks	-2.45 ± 0.30	-3.29 ± 0.17	2.41 ± 0.67	2.68 ± 0.28	5.74 ± 0.63	6.58 ± 0.32
P	0.41	0.86	0.5	0.81	0.14	0.85

tain if these abnormalities contribute directly to the pathogenesis of IFG and impaired glucose tolerance (IGT). GLP-1 stimulates insulin secretion in the presence of hyperglycemia; however, it is unknown if this effect is extant at the concentrations observed in IFG. Dipeptidyl peptidase-4 (DPP-4) inhibitors provide an opportunity to modulate fasting and postprandial incretin hormone concentrations and examine their effects on glucose turnover in non-diabetic humans.

Materials and methods: We studied 20 subjects with IFG using a double blind, placebo-controlled parallel group design. At the time of study enrollment, subjects ate a standardized, labeled mixed meal consisting of 50g of bacon, 2 scrambled eggs and 75g of Jell-O labeled with [^{13}C]-glucose. [$^{6,3}\text{H}$] glucose was infused intravenously to measure the systemic rate of meal appearance (Meal Ra). Infused [$^{6,3}\text{H}$] glucose enabled measurement of endogenous glucose production (EGP) and glucose disappearance (Rd). Subsequently, subjects were randomized to daily treatment with 100mg of sitagliptin or placebo. After a 6-week treatment period, the mixed meal test was repeated.

Results: Subjects with IFG who received placebo did not experience any change in fasting (5.92 ± 0.08 vs. 5.87 ± 0.12 Mmol/L, $P = 0.69$) and postprandial glucose concentrations (0.375 ± 0.0062 vs. 0.337 ± 0.0074 mol per 6h, $P = 0.25$). Glucose fluxes did not change over the study period. Treatment with sitagliptin did not alter fasting (5.79 ± 0.15 vs. 5.81 ± 0.11 Mmol/L, $P = 0.91$) or significantly decrease postprandial glucose concentrations (0.54 ± 0.0132 vs. 0.42 ± 0.0091 mol per 6h, $P = 0.09$). Sitagliptin was associated with a decrease in fasting glucagon concentrations (60.5 ± 5.9 vs. 58.2 ± 5.9 ng/L, $P < 0.01$). EGP, Rd and MRa were unchanged from baseline values.

Conclusion: The use of a DPP-4 inhibitor to raise endogenous incretin hormone concentrations was not associated with significant effect on glucose metabolism in subjects with IFG. Therefore, in contrast to their effects in type 2 diabetes, DPP-4 inhibitors do not significantly lower glucose concentrations. Whether this effect is proportional to the degree of hyperglycemia during treatment remains to be determined.

Obestatin, a peptide derived from preproghrelin, stimulates insulin secretion without affecting glucagon or somatostatin output

E.M. Egido, R.A. Silvestre, R. Hernández, J. Marco

Hospital Puerta de Hierro and Department of Physiology, Universidad Autónoma de Madrid, Spain

Background and aims: Obestatin is a 23-amino acid peptide derived from preproghrelin, purified from stomach extracts and detected in peripheral plasma. In contrast to ghrelin, obestatin has been reported to inhibit appetite and gastric motility, but these effects remain controversial. Obestatin is mainly produced in the A cells of the oxyntic mucosa and is also present in the pancreas, where it colocalizes with ghrelin in the peripheral region of pancreatic islets, a distribution distinct for alpha and beta cells. We have previously observed that obestatin dose-dependently potentiated the insulin response to glucose. In the present study, we have investigated the effect of obestatin on insulin, glucagon and somatostatin secretion, both under basal and stimulated conditions, in the isolated perfused rat pancreas.

Materials and methods: Rat obestatin (Bachem, Switzerland) was infused at 1 nM, a concentration that, in our perfused pancreas system, has been shown to potentiate glucose-induced insulin release. Insulin secretion was stimulated by increasing the perfusate glucose concentration (from 5.5 to 9 mM or from 9 mM to 13 mM) and by infusing arginine (5 mM), Na-tolbutamide (100mg/l) or carbachol (5 μM). The effect of obestatin on glucose-induced insulin release was also tested in the presence of diazoxide (300 μM). Insulin, glucagon and somatostatin were measured by RIA.

Results: 1 nM obestatin potentiated by 50% ($p < 0.05$) the insulin response to glucose (an increase from 5.5 to 9 mM) and to tolbutamide, both of which are known to stimulate beta cell output by inducing the blockade of ATP-

dependent K⁺ channels. Furthermore, the insulinotropic effect of obestatin on glucose-induced insulin secretion was not observed in the presence of diazoxide, an agent known to open these K⁺ channels. These results suggest that beta cell ATP-dependent K⁺ channels might be sensitive to obestatin. Obestatin did not affect the insulin response induced by increasing the glucose concentration from 9 to 13 mM (260 ± 23 vs. 280 ± 41 ng/15 min; $p = 0.66$), thus indicating that, at high glucose concentrations, the beta cells are less responsive to obestatin than at normal glucose levels. Basal insulin secretion was unaffected either at 5.5 mM or at 9 mM glucose. Obestatin did not modify the insulin response to carbachol, thus indicating that this peptide is not a general inhibitor of insulin output, acting at a crucial step in the insulin secretion-coupling mechanism. Finally, obestatin potentiated the insulin response to arginine, while it did not modify glucagon or somatostatin responses to this amino acid, thus suggesting that the insulinotropic effect of obestatin represents a direct effect on the beta cell, not mediated by an alpha- or delta-cell paracrine effect.

Conclusion: Our results allow us to speculate about a role of obestatin in the control of beta cell secretion. As an insulinotropic agent, its potential antidiabetic effect may be worthy of investigation.

124

Peripheral N-acetylated cholecystokinin-8 administration has more potent effect in reducing short term food intake than peptide YY in mice

F.P.M. O'Harte, P.A. Frizelle, P.R. Flatt

School of Biomedical Sciences, University of Ulster, Coleraine, Northern Ireland, United Kingdom

Background and aims: The neuropeptide hormone cholecystokinin octapeptide (CCK-8), along with the gut hormone peptide YY (PYY) are peripheral hormones which help regulate short-term feeding and satiety. Both peptides have short circulating biological half-lives due to the actions of peptidase enzymes. Here we examined the effects of CCK-8 and a stable N-terminally modified analogue N-acetylated-CCK-8 (N-Ac-CCK(26-33)amide) on food intake in mice and compared their actions with those of the C-terminally truncated peptide N-Ac-CCK(26-31), as well as PYY(1-36) and PYY(3-36).

Materials and methods: Food intake was examined using 12-14 week-old male Swiss TO mice, which were gradually habituated over 3-weeks to 3 h (10.00-13.00 h) of voluntary food intake per day. Mice had access to water *ad libitum*. The dose-dependent effects on food intake of native CCK-8, N-Ac-CCK-8, the C-terminally truncated peptide N-Ac-CCK(26-31), PYY(1-36) and PYY(3-36) were examined in this model. Groups of eight 21 h fasted mice (body weight 29.5 ± 0.1 g mean \pm sem) were injected intraperitoneally (10.00 h) with peptide (1, 5, 10, 25, 50 and 100 nmol/kg) or saline control (10 ml/kg) and immediately allowed access to food. Cumulative food intake was measured at times 30, 60, 90, 120, 150 and 180 min.

Results: Food intake studies showed that saline-treated control Swiss TO mice ($n = 8$) consumed (mean \pm sem) between 1.5 ± 0.1 g and 3.3 ± 0.2 g per mouse at 30-180 min. CCK-8 dose-dependently reduced food intake by 23-97% over the range of concentrations (5-100 nmol/kg) compared to saline controls ($P < 0.05$ to $P < 0.001$, Student's t-test). N-Ac-CCK-8 (5-100 nmol/kg) was more effective than native CCK-8 at reducing food intake by 52-99% up to 180 post injection and had a more protracted action at the later time points. At all concentrations tested the C-terminally truncated CCK peptide analogue N-Ac-CCK(26-31) failed to reduce food intake at any time point (30-180 min) compared to the saline treated controls, indicating the importance of an intact C-terminal region for retention of biological activity. Both PYY(1-36) and PYY(3-36) dose-dependently reduced food intake from 10-100 nmol/kg (but not at 1 and 5 nmol/kg) by 34-48% ($P < 0.05$ to $P < 0.01$) and 48-54% ($P < 0.05$ to $P < 0.001$), respectively. The N-terminally truncated PYY(3-36) was only slightly more effective than the intact PYY(1-36) but both peptides were significantly less potent than equivalent concentrations of either native sulphated CCK-8 or N-Ac-CCK-8. These data indicate that

N-terminal acetylation of CCK-8 leads to a significantly enhanced and prolonged satiety activity compared to native CCK-8. This improved activity is most likely due to enhanced resistance to aminopeptidases, which helps to prolong the circulating half-life. In contrast, results with N-Ac-CCK(26-31) demonstrate that removal of two C-terminal amino acids from CCK-8 results in a total loss of activity.

Conclusion: The CCK-8 analogue N-Ac-CCK(26-33)amide is significantly more effective than equivalent doses of PYY at suppressing food intake, indicating the potential of stable N-terminally modified CCK analogues as future agents for treatment of obesity and related metabolic disorders.

Oleylethanolamide stimulates glucagon-like peptide-1 secretion from intestinal L cells in a GPR119 receptor-dependant manner

L.M. Lauffer¹, R. Jakubov¹, P.L. Brubaker^{1,2}

¹Physiology, University of Toronto, Canada, ²Medicine, University of Toronto, Canada

Background and aims: Intestinal L cells secrete glucagon-like peptide-1 (GLP-1) in response to nutrients, especially long-chain fatty acids, e. g. oleic acid (OA); GLP-1 then increases both insulin secretion and satiety. We have previously shown that the endogenously-produced long-chain fatty acid derivative, oleylethanolamide (OEA), increases GLP-1 secretion from the mouse intestinal L cell line (GLUTag). Additionally, OEA regulates food intake and body weight by an unknown mechanism. Excitingly, OEA has been identified as a ligand of the recently de-orphanized G protein-coupled receptor GPR119, acting through the cAMP/PKA pathway. We detected GPR119 mRNA in mouse (GLUTag) and human (NCI-H716) L cell lines, as well as rat intestinal cells, mouse ileum and human colon. We therefore hypothesized that OEA-stimulated GLP-1 release is GPR119-dependent.

Materials and methods: GLUTag and NCI-H716 L cell lines were used for cAMP and GLP-1 RIA-based secretion bioassays. For in vivo studies, fasted male Wistar rats (180–250 g) were anesthetized and injected with the dipeptidylpeptidase-4 inhibitor sitagliptin (5mg/kg i.v.), to prevent GLP-1 degradation. The abdominal cavity was then opened and OEA (10µM) or vehicle was infused into a 10 cm distal ileal pouch. Blood samples were collected over 1 hour. Bioactive GLP-1, insulin and glucose plasma levels were detected by ECL-based microassay, ELISA and glucose analyzer, respectively.

Results: Treatment of GLUTag cells with OEA (5–15 µM) increased cAMP levels, by up to 13±5% (p<0.05 vs. control; n=13–19), and induced a dose-dependent increase in GLP-1 secretion, by up to 106±19% (p<0.001 vs. control; n=6–9). OEA treatment (10–15 µM) also increased GLP-1 secretion from NCI-H716 cells, by up to 302±62% (p<0.01 vs. control; n=4). OEA is known to be rapidly degraded to OA by a naturally occurring fatty acid amide hydrolase (FAAH), and we have previously shown that OA stimulates GLP-1 secretion through PKCζeta. Therefore, GLUTag cells were pre-treated with the FAAH inhibitor URB597, causing an increase in the OEA-induced cAMP response, by 28±2% (p<0.01 vs. control; n=4) and the GLP-1 response, by 119±38% (p<0.01 vs. OEA treatment alone; n=6), suggesting that OEA degradation to OA decreases its effects on GLP-1 secretion. To isolate the role of GPR119 in OEA signaling, GLUTag cells were pretreated with siRNAs to induce specific GPR119 knockdown. OEA failed to increase cAMP levels in siRNA-treated GLUTag cells (n=5), in parallel with a 32% reduction in GLP-1 secretion (n=3), suggesting a major contribution of GPR119 to OEA-induced GLP-1 secretion. Finally, to determine the effects of OEA on the L cell in vivo, OEA or vehicle were administered directly into the rat ileum. Basal plasma bioactive GLP-1 levels were 5±1 pg/ml (n=5–6) and did not differ between groups. OEA (10 µM) induced a robust increase in GLP-1 secretion, by up to 160±22% at 60 min (p<0.05 vs. basal; p<0.01 vs. vehicle). Basal plasma insulin and glucose levels (62±11 pg/ml and 126±12 mg/dl, respectively) were not different between the groups and did not change during the course of the treatment.

Conclusion: In summary, these findings demonstrate that OEA mediates GLP-1 secretion through the novel G protein-coupled receptor, GPR119, in mouse and human L cell lines and in vivo. These studies provide support for the use of OEA as a nutraceutical approach to enhance GLP-1 secretion in type 2 diabetic patients.

The Rho GTPase, Cdc42, regulates glucagon-like peptide-1 secretion from the enteroendocrine L cell

G.E. Lim¹, P.L. Brubaker^{1,2}

¹Physiology, University of Toronto, ²Medicine, University of Toronto, Canada

Background and aims: Glucagon-like peptide-1 (GLP-1) is secreted from intestinal endocrine L cells, whereupon its main role is to enhance glucose-dependent insulin release. We have recently demonstrated that, like the beta cell, depolymerization of the actin cytoskeleton enhances secretagogue-stimulated GLP-1 release from the L cell. Moreover, secretagogue-induced secretion was also accompanied by a transient depolymerization of the actin cytoskeleton. Cdc42 has been found to regulate actin dynamics and hormone release from the beta cell; therefore, we hypothesized that Cdc42 similarly controls GLP-1 secretion, in addition to regulating actin dynamics, in the L cell.

Materials and methods: GLUTag cells, which are immortalized murine L cells, were used in all experiments. RT-PCR was performed to determine mRNA expression of various Rho GTPases. Following treatment with 10⁻⁸M insulin (INS) for 5–60 min, GLUTag cells were immediately lysed, and lysates were incubated with GST-tagged PAK-PBD proteins, which bind to activated Rho GTPases. Immunoblot analysis was used to quantify the amount of activated protein. Cells were also transfected with two targeting siRNAs against Cdc42 (100nM final concentration), and western blotting was used to confirm decreased protein expression as well as to examine ERK1/2 phosphorylation. Finally, normal or transfected cells were treated with INS for up to 2 hr, and GLP-1 secretion was measured by radioimmunoassay. Statistical analysis was performed by one- or two-way ANOVA, following by appropriate post-hoc tests, and significance was achieved when p<0.05.

Results: RT-PCR confirmed the expression of mRNA transcripts for the Rho GTPases, Cdc42 and Rac1 in GLUTag cells. Following stimulation with INS, a 1.8-fold increase (p<0.05) in Cdc42 activation was detected at t = 15 min. In contrast, Rac1 activation was not detected at any time point. We have previously demonstrated that treatment of GLUTag cells with INS activates the actin-severing enzyme cofilin as early as 5 min following treatment, in addition to inducing actin depolymerization (as detected by an increase in the ratio of G:F actin) by t = 15 min. In light of this temporal pattern of events, we examined the secretion kinetics of GLP-1. After treatment with INS for 15, 30, 60, and 120 min, a 1.4-fold increase (p<0.05) in insulin-induced GLP-1 release was observed after 60 min. To determine the role of Cdc42 in insulin-induced GLP-1 release, GLUTag cells were transfected with siRNAs against Cdc42, which resulted in a 31% decrease (p<0.01) in Cdc42 protein expression, and a complete abrogation of insulin-induced GLP-1 secretion. Finally, we examined the activation of ERK1/2 in Cdc42-knockdown cells, as we have previously demonstrated a requirement for the MEK-ERK1/2 pathway in INS-induced GLP-1 secretion. Interestingly, a 2.5-fold (p<0.05) increase in basal ERK1/2 phosphorylation was detected, and this was accompanied by a 1.8-fold (p<0.05) increase in basal GLP-1 release.

Conclusion: In summary, we demonstrate for the first time, a role for the Rho GTPase, Cdc42, in regulating basal and insulin-induced GLP-1 secretion from the intestinal L cell. These studies also indicate that Cdc42 acts in concert with changes in the actin cytoskeleton, and may also interact with the MEK-ERK1/2 pathway.

Glucose homeostasis is altered in transgenic mice with brain specific knockout of the mitochondrial enzyme glutamate dehydrogenase

F. Frigerio¹, S. Carobbio¹, V. Mlynarik², R. Gruetter², P. Maechler¹¹Department of Cell Physiology and Metabolism, University of Geneva,²Biomedical Imaging Center, EPFL, Lausanne, Switzerland

Background and aims: Glutamate dehydrogenase (GDH) is a mitochondrial enzyme that catalyzes the reversible transformation of glutamate into alpha-ketoglutarate. GDH represents a key link between catabolic and biosynthetic pathways in several tissues and in particular in the central nervous system (CNS). Astrocytes take up the neurotransmitter glutamate from the intersynaptic space and GDH converts glutamate into alpha-ketoglutarate, thereby providing energy to the cells. The aim of the present study was to investigate the importance of GDH in the brain and potential connections with systemic metabolic homeostasis.

Materials and methods: Taking advantage of our *Glud1 lox/lox* mice, we generated CNS specific GDH knockout mice, crossing GDH-exon 7 floxed mice with Nestin-Cre expressing mice. Then, we characterized the knockout mice in comparison to wild types, measuring metabolic parameters and hormone levels.

Results: Brain specific knockout mice are viable and fertile, but show a significant reduction in body weights compared to wild types (-20% at 6 months, $p < 0.001$). We could exclude intrauterine growth retardation, pointing to post-natal growth impairment. Respiration from brain mitochondria was impaired upon GDH dependent glutamate stimulation, while preserved when induced by succinate. Calorimetric recording did not reveal differences in energy intake and expenditure between the two groups. Epididymal fat was about 30% larger in knockout mice, while lean mass was lower. DEXA scan measurements confirmed the elevated body fat mass (+23%) in knockout mice. Interestingly, glucose tolerance test (ipGTT) showed elevated glucose excursions in brain GDH null mice; although they exhibited higher insulin sensitivity. We also compared glucagon and leptin plasma levels in fed and starved animals. Knockout mice had higher leptin levels in both starved (+212%) and fed state (+69%) but normal glucagon levels. This complex phenotype indicated energy imbalance possibly driven by modification in brain metabolism. In particular, the absence of GDH could impair the energy balance between neurons and glial cells. To test this, we performed preliminary NMR studies measuring metabolite levels directly in the brain of living animals. Glutamate and glutamine concentrations were higher in knockout mice, indicating impaired catabolism of these metabolites. As an alternative energy source, the brain could increase glucose consumption. Accordingly, brain glucose levels were lower in knockouts.

Conclusion: The absence of GDH in the brain altered whole body energy balance and storage resulting in glucose intolerance. We hypothesize that impaired CNS glutamate metabolism affected energetic fluxes in the brain, with outcomes on whole body energy metabolism modifying glucose homeostasis.

Intrahypothalamic circuitry regulating hypothalamic fuel sensing to induce insulin sensitivity or insulin resistance

S. Luo, M. Ezrokhi, Y. Trubitsyna, A.H. Cincotta

Research and Development, VeroScience, Tiverton, United States

Background and aims: The hypothalamic arcuate nuclei are capable of sensing and responding to free fatty acid (FFA) levels during feeding times of day in rodents. Depending if the FFA are re-esterified and stored or oxidized in the arcuate, these nuclei initiate signaling to the liver that stimulates insulin suppression of glucose output or not, respectively. However, little is known of what endogenous hypothalamic factors govern the arcuate response to the FFA molecule to elicit either its subsequent action or inaction. We have previously demonstrated that increased noradrenergic tone at the ventromedial hypothalamus (VMH) can elicit a marked peripheral insulin resistance and obesity and is characteristic of these states. Here we investigate the possible effects of increased VMH noradrenergic tone on the peripheral glucose

response to intracerebroventricular FFA administration during the feeding time of day in rats.

Materials and methods: Female Sprague-Dawley rats were implanted with dual cannulas directed to the third ventricle and the VMH. Animals were divided into three groups and assigned treatment to either chronic VMH vehicle and subsequent acute icv oleic acid (OA) infusion, chronic VMH NE and acute icv OA infusion, or chronic VMH vehicle and acute icv vehicle infusion. Animals were infused continuously for 6 weeks with either norepinephrine (NE) (25 nmol/hour) ($N = 6$), or vehicle ($N = 12$) to the VMH. At 2 weeks after the initiation of VMH infusion, animals were infused icv with oleic acid (30 nM) or vehicle during the feeding time of day and blood samples were taken at 2-4 hours afterwards. After 6 weeks of VMH infusion, such groups of animals were subjected to an insulin suppression test (insulin, somatostatin and glucose infusion rates 1 mU/kg*min, 3 µg/kg*min, and 10 mg/kg*min respectively) and steady state plasma insulin (SSPI) and plasma glucose levels (SSPG) were determined. In a similarly designed separate study, animals from these three groups were subjected to an euglycemic-hyperinsulinemic clamp.

Results: After 2 weeks of VMH infusion, The VMH vehicle/ icv vehicle infused rats exhibited plasma glucose and insulin levels of 120 ± 5 mg/dL and 1.0 ng/ml, respectively at 3 hours after the icv vehicle infusion. The VMH vehicle/icv OA infused rats by contrast exhibited plasma glucose and insulin levels of 100 ± 3 mg/dL and 1.1 ng/ml ($P = 0.013$). The VMH NE infusion completely blocked the effect of icv OA on plasma glucose without altering the plasma insulin level (123 ± 8 mg/dL and 1.0 ng/ml, respectively, $P = 0.007$). Such VMH NE infusion for 6 weeks again completely blocked the effect of acute icv OA infusion on SSPG (VMH vehicle/icv vehicle SSPG: 175 ± 15 mg/dL; VMH vehicle/icv OA SSPG: 124 ± 14 mg/dL; VMH NE/icv OA SSPG 234 ± 38 mg/dL; $P = 0.007$) without altering SSPI (0.95, 0.91, and 1.28, respectively) during an insulin suppression test. Finally, in such animals subjected to an euglycemic-hyperinsulinemic clamp, VMH NE / icv OA infusion, relative to the VMH Vehicle / icv OA infusion reduced clamp glucose infusion rate needed to maintain euglycemia by 29%; $p = 0.018$.

Conclusion: Central lipid sensing mechanisms that regulate peripheral insulin sensitivity and hepatic glucose output are strictly controlled by VMH NE tone. Increases in VMH NE tone can completely abrogate the normal central lipid sensing response to OA during feeding and have important implications for understanding the neuroendocrine regulation of peripheral fuel metabolism and insulin resistance syndrome.

Restored hypothalamic leptin signalling to Koletsy rats increases hepatic insulin sensitivity

G.J. Morton¹, J. German¹, F. Kim¹, C.J. Rhodes², M.W. Schwartz¹¹Medicine, University of Washington, Seattle, ²Medicine, University of Chicago, United States

Background and aims: We recently reported that using adenoviral gene therapy to selectively restore leptin receptors to the hypothalamic arcuate nucleus (ARC) of leptin receptor-deficient Koletsy (*fa^{fa}*) rats improves whole-body insulin sensitivity. To better understand the mechanism mediating this effect, we used the glucose clamp technique to determine whether hypothalamic leptin action regulates hepatic glucose production (HGP), glucose utilization (GU), or both.

Materials and methods: To accomplish this, obese Koletsy rats received a bilateral microinjection of adenovirus (Ad) expressing either the signaling form of the leptin receptor, *lepr^b* (Ad-LEPR-B) or the reporter gene, GFP (Ad-GFP), directed to the hypothalamic arcuate nucleus (ARC). Six days later, at a time when there were no differences in mean daily food intake or body weight between groups, animals were subjected to an euglycemic-hyperinsulinemic clamp.

Results: Confirming our previous findings that hypothalamic leptin signaling increases peripheral insulin sensitivity, the rate of glucose infusion required to maintain euglycemia was significantly increased in animals that received Ad-LEPR-B compared to Ad-GFP (5.30 ± 0.31 vs. 4.25 ± 0.42 mg/kg/min; $p < 0.05$). Using tracer dilution techniques to measure rates of glucose appearance (Ra) and disappearance (Rd), we found that while there was no effect on Rd (8.95 ± 0.45 vs. 9.43 ± 0.43 mg/kg/min; $p = ns$), insulin-induced suppression of HGP during the clamp was increased in Ad-LEPR-B-treated animals compared to Ad-GFP-treated controls ($44.7 \pm 0.5\%$ vs. $34.4 \pm 4.4\%$; $p < 0.05$). Enhanced insulin-mediated suppression of HGP was accompanied by reduced hepatic expression of two key gluconeogenic genes, *G6Pase* and *Pepck*, by 80% and 51%, respectively ($p < 0.05$ for each). Similarly, in separate

groups of animals, peripheral administration of glucose suppressed *G6Pase* and *Pepck* mRNA levels to a greater extent (by 15% and 25%, respectively; $p < 0.05$ for each) in animals treated with Ad-LEPR-B than Ad-GFP. In a parallel study, we also found that restoring leptin receptors to the ARC of Koletsky rats increased insulin-induced tyrosine phosphorylation of IRS-1 and serine phosphorylation of AKT (markers of IRS-PI3K-AKT activation) in the liver by 51% and 49% respectively, compared to Ad-GFP animals ($p < 0.05$ for each), whereas insulin receptor signal transduction was not altered in skeletal muscle.

Conclusion: Taken together, these findings demonstrate that hypothalamic leptin signaling increases peripheral insulin sensitivity via enhanced insulin-mediated suppression of HGP. Our data suggest that the mechanism mediating this effect involves increased hepatic insulin signal transduction via the IRS-PI3K pathway, which in turn inhibits gluconeogenic gene expression. *Supported by: the Diabetes Endocrinology Research Center, University of Washington and the Naomi Berrie Investigator in Diabetes Research Award*

Increased insulin sensitivity in mice lacking inhibitory leptin receptor signals

M. Björnholm¹, R.Z. Tom¹, S. Glund¹, E. Vieira¹, M.G. Myers Jr², M. Gilbert¹

¹Dept of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden, ²Dept of Medicine, University of Michigan, Ann Arbor, United States

Background and aims: Leptin regulates food intake and neuroendocrine function by activating the long form of the leptin receptor (LRb) in the brain. Furthermore, leptin regulates lipid and glucose metabolism to improve whole body insulin sensitivity. In addition to stimulating positive signals via Jak2 and STAT3, activation of LRb promotes the phosphorylation of LRb Tyr985, which mediates both positive and inhibitory signals. In order to understand the contribution of LRb Tyr985-mediated signals to leptin action *in vivo*, we have mutated LRb Tyr985 in mice (*l/l* mice). These *l/l* mice display decreased body weight and adiposity and consequently low leptin levels. The aim of this study is to investigate the mechanisms of enhanced insulin sensitivity in these leptin receptor mutated *l/l* mice.

Materials and methods: We have performed glucose tolerance test and euglycemic-hyperinsulinemic clamp in female *+/+* and *l/l* mice. Insulin-stimulated glucose transport and insulin signaling have been assessed in isolated soleus and extensor digitorum longus muscle. Liver, adipose tissue and skeletal muscle have been collected for further analysis of expression profiles and insulin signal transduction.

Results: Female *l/l* mice have normal blood glucose levels under fed and fasted conditions. The glucose profile under a glucose tolerance test is also normal in the *l/l* mice. Conversely, insulin concentration in the blood is decreased 30–35% at baseline and 15 minutes post a glucose injection indicating increased insulin sensitivity in the *l/l* mice. Euglycemic-hyperinsulinemic clamps on conscious mice show increased hepatic insulin sensitivity and increased peripheral glucose utilization in *l/l* mice. We further examined whether the insulin sensitivity in the *l/l* mice is due to improved insulin signaling and glucose transport in skeletal muscle. The *l/l* mice have normal insulin-stimulated glucose transport in isolated soleus and extensor digitorum longus muscle. Moreover, insulin-stimulated phosphorylation of Akt Ser473, a key component in the pathway to insulin-stimulated glucose uptake, is also unchanged.

Conclusion: In conclusion, the *l/l* mice display increased whole body insulin sensitivity with an increased suppression of hepatic glucose production and peripheral glucose utilization under a euglycemic-hyperinsulinemic clamp. Further studies to identify the mechanisms of improved insulin sensitivity in LRb Tyr985 mutated mice are required.

A two-week central leptin infusion is not sufficient to induce hypothalamic leptin- or insulin-resistance but is able to induce hypothalamic PTP-1B expression

F. Berthou¹, C. Rouch², A. Gertler³, J. Djiane¹, K. Gerozissis², M. Taouis¹

¹Laboratoire de Neuroendocrinologie Moléculaire de la Prise Alimentaire, INRA / Université Paris Sud XI, Orsay, France, ²Laboratoire de Physiopathologie de la Nutrition, Université Paris VII, Paris, France,

³The Institute of Biochemistry, Food Science and Nutrition, The Hebrew University of Jerusalem, Rehovot, Israel

Background and aims: To regulate energy and glucose homeostasis, leptin and insulin act through their respective receptors on hypothalamic nuclei. Obesity is generally associated to a leptin-resistance state characterized by hyperleptinemia with a loss of leptin-dependent food intake (FI) control. We have recently demonstrated in human neuroblastoma cell line that overexposure to leptin induced both leptin- and insulin-resistance. Here, we hypothesized that a central leptin resistance induced by provoked hyperleptinemia may lead to reduced insulin sensitivity at the hypothalamic level. This may suggest a plausible link between leptin resistance and insulin resistance, and latest may contribute to the onset of type 2 diabetes. To assess the role of leptin on insulin hypothalamic sensitivity, leptin-dependent signaling pathways were either activated by leptin infusion or blocked by leptin antagonist infusion.

Materials and methods: Adult male Wistar rats received chronic central leptin (0.25 µg/ml) or leptin antagonist (1 µg/µl) infusion in the third ventricle for 14 days, via osmotic pumps. Body weight (BW) and FI were daily measured. After sacrifice, blood sample, hypothalamus and liver were collected and glycemia, insulinemia and leptinemia determined. Protein lysates from hypothalamus and liver were subjected to a western-blotting analysis.

Results: BW gain and FI were significantly increased in animals treated with leptin antagonist as compared to controls. As expected, central leptin infusion led to a significant reduction of FI and BW. Leptin also caused an important decrease of glycemia, insulinemia and leptinemia whereas leptin antagonist increased leptinemia. Furthermore, central leptin infusion led to a significant increase of hypothalamic STAT-3 (signal transducer and activator of transcription 3) phosphorylation. This is in good agreement with the reduction in BW and FI, but indicates that 2 weeks of central leptin infusion are not sufficient to induce hypothalamic leptin resistance. In contrast, leptin antagonist did not affect STAT-3 phosphorylation. We have also clearly shown that this treatment does not affect neither hypothalamic nor hepatic IR protein expression. Interestingly, we report a significant increase in PTP-1B (phosphotyrosine phosphatase) expression subsequent to leptin treatment. This may indicate a progressive installation of leptin resistance and most likely insulin resistance since it has been reported that this phosphatase negatively affects both leptin and insulin signaling pathways.

Conclusion: We show that a two-week leptin central infusion is not sufficient to induce leptin resistance and to affect hypothalamic or hepatic IR expression. However, this treatment was able to induce PTP-1B expression at the protein level which may constitute an early sign of the progressive onset of leptin and/or insulin resistance.

Mitochondrial reactive oxygen species and brain glucose sensing: dysregulation in the insulin resistant obese Zucker rat

A.-L. Colombani¹, L. Carneiro¹, C. Magnan², A. Galinier¹, A. Benani¹, L. Casteilla¹, L. Pénicaud¹, C. Leloup¹

¹Métabolisme Plasticité Mitochondrie, UMR 5241 CNRS-UPS, Toulouse,

²Physiopathologie de la nutrition, UMR 7059 CNRS-UDD, Paris, France

Background and aims: It is now well established that the brain has a critical role for both monitoring and regulating the energy needs of the body. In conditions of obesity and non-insulin-dependent diabetes mellitus (NIDDM), the brain's ability to respond to alterations in glucose metabolism becomes aberrant. We aimed at understanding the abnormalities in cerebral glucose sensing in insulin resistant, hyperinsulinic state. The link between substrates, mitochondrial reactive oxygen species (mROS) production and their deleterious effects has been already highlighted. Emerging data now demonstrate also a physiological role for mROS. Therefore, we have developed the hypothesis that hypothalamic glucose sensing involves mROS signalling pathway and we recently demonstrated their implication *in vivo*. In the Zucker rat model, hypothalamic glucose sensing *in vivo* is altered, showing a hypersen-

sitivity to a lower dose of glucose than in lean rats (3mg/kg vs 9mg/kg). We questioned in this study whether the mROS signalling as well as the redox status might be involved in this abnormal response.

Materials and methods: In vivo model of brain glucose sensing consists of a glucose load (9 mg/kg or 3mk/kg for testing hypersensitivity) towards the brain via the carotid. This induces an increased hypothalamic electrical activity and a peak of insulin 1 min later. Multiunit recordings were made in arcuate nucleus. mROS were quantified with the H2DCFDA probe and redox status by evaluating the oxidized glutathione (HPLC). Complex IV and aconitase activities were determined on whole tissue. Insulin was measured by ELISA. Mitochondrial respiration was evaluated by oxygraphy on permeabilized tissue. Each group consists of 6–9 rats.

Results: Hypothalamic mitochondrial oxidative potential (complex IV activity) is significantly higher in this obese model and the aconitase activity, a mitochondrial negatively ROS-sensitive enzyme, is significantly (40%) down-regulated compared to lean rats. Glutathione is although more oxidized in obese, insulino-resistant rat compared to the lean rat. Finally, the hypersensitivity to 3 mg/kg which is only observed in obese group is clearly linked to an exacerbated production of hypothalamic mROS: restoration of the redox status (monoester ethyl glutathione in the third ventricle) in obese Zucker rats completely reverses the abnormalities observed, i.e., hypersensitivity to glucose in terms of insulin secretion is lost and mROS signalling is normalized.

Conclusion: In the obese insulino-resistant Zucker rat, abnormal hypothalamic glucose sensing may be due to mROS signalling, leading to an increase in the overall electrical activity of the hypothalamus and then the insulin secretion. Normalization of the redox state with glutathione supplementation in the hypothalamus of insulino-resistant rats restores the physiological responses identical to that of lean rats. Oxygraphic measures on hypothalamic tissues point out a major role of insulin in these abnormal responses, suggesting that hyperinsulinism *in vivo* accelerates the mitochondrial activity.

Free fatty acid-induced endoplasmic reticulum stress signalling and apoptosis in human pancreatic islets

L.C.L. Ladrière¹, M. Igoillo-Esteve¹, D.A. Cunha¹, J.-P. Brion², R. Lupi³, P. Marchetti³, D.L. Eizirik¹, M. Cnop^{1,4}

¹Laboratory of Experimental Medicine, Université Libre de Bruxelles, Belgium, ²Laboratory of Histology and Neuropathology, Université Libre de Bruxelles, Belgium, ³Department of Endocrinology and Metabolism, Metabolic Unit, University of Pisa, Italy, ⁴Division of Endocrinology, Erasmus Hospital, Brussels, Belgium

Background and aims: Free fatty acids (FFA) cause pancreatic beta cell apoptosis and may contribute to beta cell loss in type 2 diabetes via the induction of endoplasmic reticulum (ER) stress. We have previously shown that oleate and palmitate trigger an ER stress response in rat beta cells. Both FFA activate the ATF6 branch, but palmitate induces more apoptosis and activates the IRE1 and PERK pathways more potently. Salubrisal (sal), a selective inhibitor of eIF2α dephosphorylation, has been used to protect other cell types against ER stress-mediated apoptosis. In INS-1E cells and primary rat beta cells, however, sal markedly potentiates the deleterious effects of oleate and palmitate. The aim of this study was to examine whether FFA induce ER stress in human islets and whether enhanced PERK-eIF2α signaling by sal protects or exacerbates FFA effects in human β cells.

Materials and methods: Human pancreatic islets were cultured in the presence of oleate or palmitate (0.5 mM, 1% BSA), with or without sal (75 μM). Islet viability and β cell morphology were assessed by Hoechst 33342/propidium iodide staining and electron microscopy. Gene expression was analyzed by real time RT-PCR and corrected for β-actin expression levels.

Results: The saturated FFA palmitate caused human islet cell death (19±4% vs control 9±2%, 72h treatment, n=8, p<0.05 vs control), while the unsaturated oleate did not. Sal alone was no toxic but it potentiated FFA toxicity (oleate+sal 17±2% cell death, palmitate+sal 26±6%, p<0.05). FFA induced cytoplasmic accumulation of triglycerides and dilation of the ER in INS-1E and human islet cells (electron microscopy after 48h exposure). The combination of FFA and sal lead to mitochondrial morphological changes and signs of apoptotic cell death. The PERK-dependent ER stress markers ATF3 and CHOP were induced by palmitate (ATF3: 2.7- and 2.6-fold increase compared to control after 24 and 48h; CHOP: 1.8- and 2.9-fold; n=4–5, p<0.05). Sal alone did not induce these markers but markedly potentiated oleate and palmitate effects (ATF3: oleate+sal 1.9- and 1.8-fold increase after 24–48h, p<0.05, palmitate+sal 7.9-fold increase, 48h, p<0.01; CHOP: oleate+sal 4-fold increase, 48h, p<0.05, palmitate+sal 3.7- and 9.5-fold increase after 24–48h, p<0.05). Palmitate also induced the ER chaperone BiP (1.7- and 2.2-fold after 24 and 48h, p<0.05), and this was potentiated by sal (4.8-fold, 48h, p<0.01). Activation of XBP1 by its alternative splicing by IRE1 was not observed with FFA, and the combination of FFA+sal decreased splicing (p<0.05).

Conclusion: Palmitate, but not oleate, triggers ER stress (characterized by PERK and ATF6 signaling) and apoptosis in human islets. The activation of the PERK-eIF2α pathway by the chemical sal sensitizes islets to oleate, suggesting that this pathway plays an important role in FFA-induced ER stress and human islet demise. Intervention strategies to prevent lipotoxic β-cell loss should avoid prolonged eIF2α phosphorylation.

134

Endoplasmic reticulum stress signalling contributes to palmitate- but not to cytokine-induced beta cell death

M. Åkerfeldt, J. Chan, T. Biden, R. Laybutt

Diabetes and Obesity, Garvan Institute of Medical Research, Sydney, Australia

Background and aims: Increased pancreatic β-cell death is implicated in the reduced β-cell mass of both type 1 and type 2 diabetes. Cytokines [interleukin-1β (IL-1β) and γ-interferon (IFN-γ)] and fatty acids are likely mediators of β-cell death in type 1 and type 2 diabetes, respectively. However, the mechanisms by which β-cells are destroyed remain to be clarified. In this study, we tested whether endoplasmic reticulum (ER) stress and the unfolded protein response (UPR) were necessary for the increased cell death in INS-1 cells following exposure to cytokines (IL-1β and IFN-γ) or the saturated fatty acid, palmitate. Furthermore, we investigated whether the UPR was activated in β-cells of the non-obese diabetic (NOD) mouse model of type 1 diabetes.

Materials and methods: INS-1 cells were treated with the chemical chaperones phenyl butyric acid (PBA, 2.5 mM) or trimethylamine *N*-oxide (TMAO, 100 mM) and thereafter exposed to IL-1 β (50 U/ml) + IFN- γ (100 U/ml) or palmitate (0.4 mM coupled to 0.92% BSA) for 6 or 24 h. Rat pancreatic islets were treated with PBA followed by exposure to cytokines. The role of the proapoptotic transcription factor CHOP in cytokine- and palmitate-induced apoptosis was investigated in INS-1 cells in which CHOP protein levels were reduced using siRNA. Apoptosis was measured using an apoptosis ELISA. Expression of UPR genes was evaluated using Western blotting and real-time PCR. Islets were isolated from C57BL/6J (control) and NOD mice (before and after the onset of diabetes), and mRNA levels assessed by real-time PCR. XBP-1 splicing was also assessed.

Results: Cytokines and palmitate triggered ER stress in INS-1 β -cells as evidenced by increased phosphorylation of PERK and EIF2 α as well as increased expression of ATF4 and CHOP. Both cytokines and palmitate increased JNK phosphorylation, but only palmitate increased XBP-1 splicing in INS-1 cells. PBA and TMAO act as chemical chaperones to reduce the load of unfolded proteins in the ER by improving folding capacity and trafficking of mutant proteins. PBA attenuated cytokine- and palmitate-induced ER stress as indicated by reduced PERK and EIF2 α phosphorylation as well as reduced mRNA and protein levels of ATF4 and CHOP. Additionally, PBA reduced JNK phosphorylation in response to palmitate, but not in response to cytokines. Strikingly, this was associated with a complete block of palmitate-induced cell death ($p < 0.05$) but did not affect cytokine-induced cell death. Similar results were found with TMAO. Moreover, siRNA-mediated reduction of CHOP protected against palmitate-, but not against cytokine-induced cell death. In cultured rat islets, PBA-mediated reduction in UPR gene activation had no effect on cytokine-induced cell death. Importantly, in islets from NOD mice, both before and after the onset of diabetes, ER stress was absent as indicated by reduced (BiP, GRP94, ATF4, Edem1, Erp72, p58, XBP-1 splicing; all $p < 0.05$) and unchanged (CHOP) mRNA levels of UPR genes.

Conclusion: We conclude that although both cytokines and palmitate induce ER stress in cultured β -cells, UPR activation is selectively necessary for lipotoxicity and not for cytokine-induced cell death. These data suggest that ER stress is responsible for β -cell death in type 2 diabetes and that inhibition of CHOP protects against lipotoxicity. Different mechanisms operate in type 1 diabetes, with β -cell death possibly mediated via ER stress-independent activation of JNK.

Molecular mechanism of diet effect on pancreatic beta cell preservation in diabetic *db/db* mice: evidence for anti-oxidative stress mechanism

Y. Kanda, M. Shimoda, K. Tawaramoto, F. Kawasaki, M. Hashiramoto, K. Nakashima, M. Matsuki, K. Kaku
Diabetes and Endocrine Division, Kawasaki Medical School, Kurashiki-shi, Japan

Background and aims: It is well known that diet therapy is important at all levels of diabetes prevention. The aim of this study is to assess the molecular mechanism for preventive effect of diet on beta cell damage in obese diabetic animal model *db/db* mice.

Materials and methods: Male BKS.Cg- $+ Lepr^{db}/+ Lepr^{db}/Jcl$ (*db/db*) mice were divided into 2 groups with or without diet therapy (DT) ($n=5$). Daily food intake of DT(+) mice was restricted to that of the control BKS.Cg- $+ Lepr^{db}/Jcl$ (*db/m*) mice previously estimated. DT was implemented for 6 weeks from 6 weeks of age. Body weight (BW), fasted blood glucose (FBG), insulin (FIRI), TG and FFA were measured at 6, 8 and 12 weeks of age, and intraperitoneal insulin tolerance test (ipITT: 1 IU/kg BW) was performed at 12 weeks. The beta-cell mass and cell proliferation/apoptosis were assessed by histological analysis including proliferating cell number antigen (PCNA) and 4-hydroxynonenal modified protein (4-HNE) immunostaining of the islet tissue. Gene expressions specific for the core area of pancreatic islet were analyzed by Laser Capture Microdissection method and real time RT-PCR. Primer pairs encoding genes associated with pancreatic hormones, cell proliferation, apoptosis, cell cycle, and oxidative stress were prepared, and real-time RT-PCR with Sybr Green was applied. Each gene expression was relatively quantified by the comparative Ct method with each result in the 18 S rRNA as a control.

Results: Food intake in *db/m* mice was 50% in *db/db* mice. BW, FBG and FIRI in DT(+) group were significantly lower than those in DT(-) group of mice, but were significantly greater than in *db/m* mice at 12 weeks of age (BW: 34.0 ± 0.07 , 49.4 ± 0.45 , 27.3 ± 0.38 g, $p < 0.0001$, FBG: 106.5 ± 10.1 , 200.7 ± 29.9 ,

66.6 ± 4.8 mg/dl, $p < 0.05$, FIRI: 12.9 ± 1.0 , 17.5 ± 2.3 , 0.46 ± 0.01 ng/ml, $p < 0.05$, respectively). TG and FFA level in DT(+) *db/db* mice were significantly lower than those in DT(-) mice, but no difference was observed between DT(+) and control *db/m* mice. The ipITT at 30 min was $77.6 \pm 3.4\%$ in DT(+) mice, $107 \pm 7.3\%$ in DT(-) mice, $60.4 \pm 1.6\%$ in *db/m* mice ($p < 0.05$, respectively). The pancreatic beta cell mass was greater in DT(+) mice than that in DT(-) mice (7.8 ± 1.7 vs. 4.4 ± 1.0 mg, $p < 0.05$). Beta cell gene expression for insulin was decreased in DT(+) *db/db* mice. Cyclin E and ERK1 genes related with cell proliferation and CAD gene related with promotion of apoptosis were significantly up-regulated at 8 week, but Cyclin E and ERK1 genes were down-regulated at 12 weeks of age in DT(-) *db/db* mice. On the other hand, DT significantly increased Cyclin E gene expression, and down-regulated CAD gene expression at 12 weeks. Anti-apoptotic bcl-2 gene expression was significantly increased by DT. NADPH oxidase gene and TNF gene related with oxidative stress and inflammatory process were markedly down-regulated in DT(+) mice. Morphometric results for PCNA and 4-HNE observed corresponded to the data of gene expression analysis.

Conclusion: DT increases insulin sensitivity and preserves pancreatic beta cell function in diabetic *db/db* mice. Our results strongly suggest that DT prevents beta cell loss by suppressing cell apoptosis probably through anti-oxidative stress mechanism.

Mononuclear cell infiltration of intra-pancreatic fat and decreased islet beta cell area in human type 2 diabetes

M. Galli, S. Torri, M. Bugliani, M. Masini, N. Funel, R. Lupi, S. Del Guerra, V. D'Aleo, U. Boggi, F. Filippini, D. Campani, L. Marselli, F. Dotta, P. Marchetti
Endocrinology and Metabolism, Metabolic Unit, Pisa, Italy

Background and aims: Increased accumulation of visceral fat (AVF) is associated with type 2 diabetes (T2D), but the factors linking AVF and the pathophysiological mechanisms leading to T2D are still unclear. We assessed the relationships between intra-pancreatic fat (IPF, quantified by light microscopy) and several features of beta-cells in human T2D.

Materials and methods: Pancreata were obtained from 26 non-diabetic (ND) and 17 T2D organ donors, matched for age and body mass index. Immunohistochemistry studies were performed on pancreatic samples. Islets were isolated by enzymatic digestion and gradient purification. Glucose-stimulated (3.3 and 16.7 mmol/l) insulin secretion was assessed ex-vivo by the batch incubation technique. Beta-cell apoptosis was quantified by electron microscopy. MessengerRNA expression of selected genes was performed by quantitative RT-PCR.

Results: IPF accumulation was higher in T2D ($11.7 \pm 11.3\%$) than ND ($5.8 \pm 7.4\%$, $p < 0.05$) samples, and beta-cell area was lower in T2D ($59.7 \pm 20.4\%$) than in ND ($81.9 \pm 9.8\%$, $p < 0.05$). However, no significant correlation was found between IPF amount and beta-cell area. The number of macrophages and mast cells (immunostaining by anti-CD68 and anti-CD117 antibodies, respectively) was significantly ($p = 0.01$) higher in IPF of T2D than ND ($n = 7$ each group, 23.7 ± 9.6 vs $14.0 \pm 6.5/100$ adipocytes nuclei). The number of infiltrating mononuclear cells (MC) was correlated with beta-cell depletion in T2D ($p < 0.001$), but it did not affect ex-vivo insulin secretion. When islets from ND were exposed for 1 week to cytokines of MC origin (IL-6, 5 pg/ml; TNF α , 5 pg/ml; or a combination of both), decreased glucose-stimulated insulin secretion ($65 \pm 22\%$ of control ND cells, $p < 0.05$), increased apoptosis (7.0 ± 1.0 vs $1.1 \pm 0.6\%$, $p < 0.05$) and reduced PDX-1 expression ($79 \pm 20\%$ of control ND, $p < 0.05$) were observed with IL-6 plus TNF α .

Conclusion: 1) IPF amount was higher in T2D than ND, but it did not correlate with beta-cell area or ex-vivo islets function; 2) mononuclear cell infiltration of IPF was higher in T2D pancreata and was associated with reduced beta-cell area; 3) cytokines of MC origin impaired isolated islets function and survival. Therefore, the presence of an "inflamed" intrapancreatic fat tissue might affect the beta-cell in human T2D, representing a possible link between AVF and beta-cell defects.

137

Gene expression regulated by pioglitazone and exenatide in normal and diabetic human islets exposed to lipotoxicity

H. Ghanaat-pour, Å. Sjöholm

Karolinska Institutet, Stockholm South Hospital, Department of Internal Medicine, Stockholm, Sweden

Background and aims: Chronically elevated free fatty acids (FFAs) are believed to have a detrimental effect on glucose-stimulated insulin secretion (GSIS), insulin resistance, β -cell failure, and β -cell apoptosis in type 2 diabetes. Whether FFAs alter beta-cell function and apoptosis in synergy with glucose or separately, remains controversial. It is still unclear whether β -cell failure is induced by increased FFAs alone or together with genetic factors, since most of the previous studies have been performed in animal models with a genetic predisposition to diabetes/obesity. The objective of the present study was to investigate the global alterations in gene expression induced by long term exposure to palmitate, pioglitazone (a TZD), and/or exenatide (an incretin mimetic) in human diabetic and non-diabetic pancreatic islets (at physiological glucose concentration). Also, to investigate the possible protective effect of these drugs against the β -cell lipotoxicity, which is still debated.

Materials and methods: Gene expression analysis using Affymetrix microarray measurements of mRNA from human diabetic and non-diabetic pancreatic islets were performed after 48 hrs of culture in 6 mM glucose, 0.125 mM palmitate, 10 mM pioglitazone and/or 1 nM exenatide.

The differentially regulated transcripts were annotated and then clustered according to functional annotation. Cluster analyses were performed as described in GeneSpring 7.3, NetAffx and other databases.

Results: Gene expression profiling revealed alterations in several functional categories, such as epigenetic regulation of gene expression, cell proliferation and differentiation, metabolism, response to stimulus, transport, and signal transduction. Palmitate, pioglitazone and/or exenatide appear to have a substantial influence on epigenetic processes, e.g. stable alterations in gene expression potential that arise during development and cell proliferation. Pancreatic polypeptide (PPY), Epidermal growth factor receptor (EGFR), Thioredoxin interacting protein (TXNIP), Carboxyl ester lipase (CEL), Growth arrest and DNA-damage-inducible, beta (GADD45B), Glyceraldehyde-3-phosphate dehydrogenase (GAPDH), Defender against cell death 1 (DAD1), Regenerating islet-derived 3 alpha (REG3A), Transcription factor 7-like 2 (TCF7L2)(TCF4), Aryl hydrocarbon receptor nuclear translocator (ARNT), LIM homeobox 4 (LHX4), ISL1 transcription factor, LIM/homeodomain, (ISL1) are some of the interesting genes that were differently regulated in our study. The apoptotic pathway was not majorly influenced by either pioglitazone or exenatide in the presence of palmitate. The function and survival of β -cell seems to be controlled directly through the epigenetic control of gene expression rather than a direct effect on the apoptotic pathway. FFAs seem to contribute and play an important role in the development of β -cell failure in synergy with hyperglycemia, in obese individuals, or in subjects who are genetically more predisposed to type 2 diabetes.

Conclusion: Considering that the nutritional state directly induces the epigenetic modifications, pioglitazone and exenatide appear to normalize these epigenetic misregulations and may protect the β -cell from lipotoxic insult. The epigenetic modifications of the genome provide new promising targets for clinical diagnostics and also therapeutic purposes in the treatment of type 2 diabetes.

Mice expressing kinase negative PKCdelta in insulin secreting cells are protected from fatty acid - induced beta cell failureF. Ranta¹, A.M. Hennige¹, I. Heinzelmann¹, D. Avram¹, S.Z. Lutz¹, H. Braumüller², F. Bosch³, R. Lammers¹, S. Ullrich¹, H.-U. Häring¹¹Internal Medicine IV, University Hospital of Tübingen, Germany,²Dermatology, University Hospital of Tübingen, Germany, ³Center of Animal Biotechnology and Gene Therapy, Universitat Autònoma de Barcelona, Spain

Background and aims: The ubiquitously expressed PKCdelta is known as a pro-apoptotic serine/threonine kinase that can be activated by diverse stimuli including oxidative stress or death receptor ligands. In insulin secreting cells, controversial findings on the role of PKCdelta have been published over the years. Although diverse observations suggest that PKC isoforms others than PKCdelta are essential for proper glucose-induced insulin secretion, the second phase of secretion was impaired in PKCdelta null mice. More consistent-

ly, free fatty acid and IL1beta-activated apoptotic cell death has been found to depend on PKCdelta activation. Evidence accumulated showing that translocation into the nucleus of a cleaved, constitutively active form of PKCdelta is essential for apoptosis. Here, transgenic mice over-expressing a kinase negative (KN) PKCdelta in beta-cells were generated to study the role of PKCdelta in glucose homeostasis and beta-cell survival and function.

Materials and methods: Mice were fed a high fat diet (HFD) for 8 weeks. Blood glucose and insulin was determined after a glucose load (2 g/kg body weight, GTT) and insulin secretion was measured in isolated islets after static incubations using insulin ELISA and RIA kits. Apoptotic cell death was assessed using attached islet cell cultures with nuclear TUNEL/TOPRO3 DNA-staining. Beta-cell mass was estimated after immunohistochemical staining for insulin in pancreatic cryo-sections.

Results: Blood glucose and insulin levels were not different in animals fed a standard diet. After HFD, GTT was impaired in wild-type (wt) mice but significantly improved in KN-PKCdelta littermates. This improvement was accompanied by increased insulin levels in vivo while insulin tolerance was not significantly different between wt and transgenic mice. In isolated islets, glucose-induced insulin secretion as well as secretion augmented by palmitate, oleate, phorbol ester and forskolin in the presence of 12 mM glucose was not significantly different. As expected, palmitate but not oleate stimulated apoptotic cell death from 5.3 % to 10.9 % in wt islet cell cultures. In islet cells overexpressing KN-PKCdelta, the apoptotic rate was not affected by palmitate. In accordance, islets of KN-PKCdelta transgenic mice were significantly bigger in size than wt islets.

Conclusion: Thus, depletion of PKCdelta signalling improves glucose homeostasis after HFD due to reduced beta-cell death that finally results in increased beta-cell mass.

Identification of type 1 diabetes genes in the MHC region by a novel approach combining genetic data with information on functional pathways

C.A. Brorsson¹, N. Tue Hansen², K. Lage², R. Bergholdt¹, S. Brunak², F. Pociot¹¹Steno Diabetes Center, Gentofte, ²Center for Biological Sequence Analysis, Technical University of Denmark, Lyngby, Denmark

Background and aims: We have developed a novel method that combines SNP genotyping data with protein-protein interaction (ppi) networks to identify new genes that contribute to the risk of developing type 1 diabetes (T1D). We focused on genes located within the MHC region on chromosome 6. Using this new approach their contribution to the development of T1D could be analysed independently of the known LD with the *HLA-DRB1*, *-DQA1*, *-DQB1* genes, which is usually a hurdle in detecting genes in this region with smaller contributions.

Materials and methods: We have tested and validated this approach on a dataset generated by the Type 1 Diabetes Genetics Consortium. This comprised of 3000 SNPs located in the 4 Mb MHC-region. Initially a subset of genotypes from 1300 T1D families were analysed. Association to T1D was tested using the Transmission Disequilibrium Test (TDT) and the SNP with the lowest p-value in each gene of this region was chosen and corresponding proteins were mapped to ppi networks for identification of interaction partners. The association testing and resulting interacting protein modules were statistically evaluated using permutation. We then expanded the dataset to include 2363 T1D families genotyped for the same 3000 SNPs. Association to T1D was again tested using TDT. The dataset was stratified into *HLA-DRB1* high-risk and low-risk genotypes to detect if these genotype risk-groups confer different risk of T1D due to different ppi networks including candidates both within and outside the MHC-region.

Results: 151 genes were mapped within the protein interaction networks and their interaction partners were identified. Five protein interaction modules reached statistical significance using this approach. They contained proteins encoded both within and outside of the MHC region. Many of the identified proteins are well known in T1D pathogenesis, but the modules also contain additional candidates that have been implicated in beta-cell development and diabetic complications. Results from the stratified analysis show different significant protein interaction modules between the high, moderate and low *HLA* risk-groups.

Conclusion: In conclusion the extensive LD within the MHC-region makes it important to develop new methods for analysing genotyping data for identification of additional risk genes for T1D. The results from the stratified analysis are highly interesting and indicate that individuals with different *HLA-DRB1* risk genotypes differ at the ppi network level. Different candidates for conferring risk in the different groups are thereby directly suggested. We believe that this new approach combining genetic data with knowledge about functional pathways could provide new insight into the mechanisms underlying T1D.

Genome-wide linkage scan for type 1 diabetes: The Type 1 Diabetes Genetics Consortium

S.S. Rich¹, W.-M. Chen¹, P. Concannon¹, H.A. Erlich², C. Julier³, G. Morahan⁴, J. Nerup⁵, F. Pociot⁵, J.A. Todd⁶¹Center for Public Health Genomics, University of Virginia, Charlottesville, United States, ²Human Genetics, Roche Molecular Systems, Pleasanton, United States, ³Institute Pasteur, Paris, France, ⁴Diabetes Research Centre, Western Australia Institute for Medical Research, Perth, Australia, ⁵Steno Diabetes Center, Steno Diabetes Center, Gentofte, Denmark, ⁶Diabetes Inflammation Laboratory, Cambridge University, United Kingdom

Background and aims: Type 1 diabetes (T1D) is an autoimmune disease characterized by an autoimmune destruction of the pancreatic beta cells. T1D aggregates in families and risk is thought to be due to multiple genes and undetermined environmental triggers. While the greatest contributors to T1D genetic risk reside in the human MHC (HLA regions), other regions

of the genome are recognized to be important. The T1DGC has launched a major effort to identify genes of major effect (or clusters of genes) using a linkage strategy.

Materials and methods: A genome-wide linkage scan of ~6,000 SNPs were analyzed from 2508 affected sib pairs (ASP) from 2396 families in the T1DGC. These ASP families were obtained from 9 different cohorts in Asia-Pacific (AP), North America (NA), Europe (EU), United Kingdom (UK), the Joslin Diabetes Center (JOS), Sardinia (SAR), Denmark (DAN), Human Biological Data Interchange (HBDI), and the British Diabetes Association (BDA). Data were cleaned using PedCheck, GRR and Merlin software. at the T1DGC Coordinating Center using PedCheck and GRR software. The average information content across the genome (0.86) was good.

Results: Nonparametric linkage analyses revealed regions on chromosomes 2q, 6p, 6q, and 11p that significantly (LOD > 3.0) supported linkage. Several regions on chromosome 19 exhibit suggestive evidence (LOD between 2.5 - 2.9) for linkage. The region on 6p (HLA) is consistently seen in all linkage scans in T1D. The regions on 6q and 11p had been previously reported in some, but not all, independent linkage scans. The large sample size afforded by the CIDR 6K dataset allowed us to further explore possible heterogeneity within the data. Three models were considered - allele sharing at HLA, sex strata, and age at onset strata (with a cutoff at age 5). The regions on 2q, 6q, and 11p show similar trends in all strata suggesting they are not strongly dependent on linkage at HLA. In contrast, the region on chromosome 19 appears to be dependent on linkage at HLA. At 68 cM on chromosome 19, LOD = 2.84 among the 1233 ASPs that share 2 alleles IBD at HLA; however, LOD = 0.01 among the 1011 ASPs that share 0 or 1 alleles at HLA. The most significant findings under either "homogeneity" or any of the three heterogeneity (stratified) models were determined. Age at onset heterogeneity appears to play only a minor role in these data, but this result may reflect the limited number of ASPs (N=290) in the case that both sibs have age at onset less than 5 years.

Conclusion: These results suggest that there are important regions of the genome that may be important in defining genetic susceptibility to type 1 diabetes, either in isolation (chromosome 19) or in presence of stratification based upon HLA or gender. These effects are intriguing but require additional sample size (more ASPs) to confirm/refute these initial findings and determine the identify of specific genes residing in these regions.

Lower risk HLA genotypes account for the rising incidence of type 1 diabetes

S.G. Fourlanos¹, M.D. Varney², B.D. Tait², G. Morahan³, M.C. Honeyman¹, P.G. Colman⁴, L.C. Harrison¹¹Autoimmunity & Transplantation Division, The Walter & Eliza Hall Institute of Medical Research, Melbourne, ²Victorian Transplantation and Immunogenetics Service, Melbourne, ³Genetics Department, Western Australian Institute for Medical Research, Perth, ⁴Dept of Diabetes & Endocrinology, The Royal Melbourne Hospital, Melbourne, Australia

Background and aims: The incidence of childhood-onset type 1 diabetes (T1D) increased progressively over the last half century and has been attributed to environment, implying a lesser role for genetic susceptibility. If the environment increasingly impacts on the expression of T1D then the contribution of genetic susceptibility in newly diagnosed cases may change over time and, for the same degree of genetic susceptibility, age at diagnosis may decrease over time. To examine these possibilities, *HLA-DRB1* genes known to confer risk for T1D were analysed in relation to year of birth and age at diagnosis over the last 5 decades.

Materials and methods: Caucasian subjects (n=462) from the Australian T1D DNA Repository diagnosed with T1D before age 18 between 1950 - 2005 were *DRB1* genotyped. Subjects were grouped by decade of birth or diagnosis (1950-1969, 1970-79 1980-89, 1990-99 and 2000-05) and from the highest (DR3,4) to intermediate (DR3,3 or DR4,4; DR4,X or DR3,X) to the lowest (DRX,X, where X denotes a non-3 or non-4 allele) *HLA* genotypes for T1D risk.

Results: Mean age at diagnosis, 8.5 years (SD 4.5y), did not differ across decades. The proportion of the highest risk genotype, DR3,4, decreased significantly over time from 79% in 1950-1969 to 28% in 2000-05 (p<0.0001) (Figure 1). On the other hand, the proportion of the heterozygous intermediate risk genotypes DR4,X and DR3,X increased significantly over this period; taken together, they increased from 20% to 48% (p=0.0002). Matched for *DRB1* genotype and decade of birth, subjects were analysed for age at diagnosis.

There was no change across time in age at diagnosis for the high risk DR3,4 genotype, but for the intermediate risk genotypes, DR4,4 and DR3,3, DR4,X and DR3,X, age at diagnosis significantly decreased over time. The incidence of childhood-onset T1D in Australia has doubled in the last 20 years, from 11.3 cases per 100 000 person years in 1985 to 23.2 in 2002. The contribution of DRB1 genotypes to the increasing incidence of T1D was examined. We related the number of incident cases to specific DRB1 genotypes in the 1980s versus the current decade. From this analysis it is apparent the population incidence (cases per 100 000 person years) of T1D in subjects with the highest risk genotype DR3,4 has remained unchanged (5.3 vs. 6.5). In contrast, the number of cases with intermediate risk genotypes DR3,3 or DR4,4 (1.3 vs. 4.9) and DR3,X or DR4,X (4.4 vs. 11.1) has increased, accounting for the increase in disease incidence.

Conclusion: The rising incidence and decreasing age at diagnosis of T1D is accounted for by the impact of environment on children with lower risk HLA class 2 genes, who previously would not have developed T1D in childhood.

Genome-wide association study using pooled DNA identifies region associated with kidney disease attributed to type 1 diabetes

J.K. DiStefano, M.P. Millis, K. Anchors, D.W. Craig
Diabetes, Cardiovascular and Metabolic Diseases Division, Translational Genomics Research Institute, Phoenix, AZ, United States

Background and aims: Genetic factors play a major role in the progression of kidney disease in diabetes. To validate genes with significant effects on susceptibility to end-stage renal disease (ESRD), we performed a whole genome association study using pooled DNA from Caucasian individuals ascertained for type 1 diabetes.

Materials and methods: We utilized the Illumina Infinium II HumanHap 550 beadchip platform to genotype 555,352 SNPs in DNA pools comprised of 547 cases with ESRD and 549 controls with diabetes duration >20 years and no evidence of nephropathy. Pooled probe intensity was used to predict mean allele frequency (MAF) for each locus. Individual genotyping was performed using the iPLEX assay in conjunction with the MassARRAY platform (Sequenom).

Results: We identified 2,870 markers showing substantial differences in MAF (5.0–10.7%) between pools. Among these, we selected 103 markers for validation based on overall ranking, proximity to annotated genes, or proximity to previously identified candidate genes, and genotyped them in the individuals comprising each pool. We observed the strongest evidence for association between ESRD and markers in the carnosinase 1 gene (*CNDP1*). In specific, rs11151964, which produces a glycine to arginine substitution at position 6 in *CNDP1*, was strongly associated with ESRD (OR = 1.72 [1.29–2.29] per copy of A allele; $P = 2.00 \times 10^{-4}$). In addition, markers rs17817077 and rs12964208, both located in intron 1, were also associated with ESRD (OR = 1.38 [1.15–1.65] per copy of A allele; $P = 6.00 \times 10^{-4}$ and OR = 1.24 [1.05–1.48] per copy of A allele; $P = 0.01$, respectively).

Conclusion: Marker rs11151964 represents a novel locus for modulating risk for diabetic ESRD, providing evidence supporting a role for *CNDP1* and the carnosine pathway in the development of renal complications associated with diabetes.

143

Sib pair linkage analysis identifies susceptibility loci for proliferative retinopathy in type 1 diabetes (*The FinnDiane study*)

K.A.A. Hietala^{1,2}, C. Forsblom^{1,3}, M. Lehto¹, M. Parkkonen¹, P. Summanen², P.-H. Groop^{1,3}

¹Department of Diabetes Genetics, Folkhalsan Research Center, Helsinki,

²Department of Ophthalmology, Helsinki University Central Hospital,

³Division of Nephrology, Department of Medicine, Helsinki University Central Hospital, Finland

Background and aims: Diabetic nephropathy and diabetic proliferative retinopathy (PDR) cluster in families, an observation that cannot be accounted for by environmental factors alone. It is obvious that genetic factors play a role and therefore, the aim of this study was to find susceptibility loci for PDR by sib pair linkage analysis in siblings with type 1 diabetes (T1D).

Materials and methods: The FinnDiane Study has so far examined around 4800 patients with T1D. Among them, we identified 180 families with at least two siblings with T1D. Insulin treatment had been initiated within one year of diagnosis in all the patients and 98% were younger than 40 at the onset of diabetes. The patients with an onset > 40 years of age (9/361) had all a sibling with an age at onset ≤ 40 years. Ophthalmic records were obtained for 94 % and fundus photographs for 68% of these patients. The PDR-status was graded based on fundus photographs and/or repeated clinical ophthalmic examinations using the ETDRS-grading scale, in which values ≥ 61 represent PDR. Patients (n=361) as well as their non-diabetic relatives (n=316) were genotyped. Genomic DNA was extracted from whole blood using PureGene®, Genomic DNA Purification Kit (Gentra Systems, Minnesota, USA). The DNA-samples were genotyped using ABI 3730 DNA analyzer (Applied Biosystems, CA, USA) with ABI Linkage Mapping Set MD-10 V2.5 (Genethon map). A total of 367 autosomal markers with a mean interval of 9.6 (SD 4.1) cM and 77.7% heterozygosity were used. A Modified Haseman-Elston regression of full sib pairs (SIBPAL-program, Case Western Reserve University, Cleveland, OH, USA) treated the binary variable PDR as continuous by designating the values 2 for affected and 1 for unaffected diabetic siblings. Duration of diabetes was included as a covariate. Empirical p-values were obtained by up to 10⁶ permutations, and converted to pointwise LOD scores.

Results: The mean age at onset of diabetes was 15.5 (SD 11.5) years and duration 25.4 (SD 12.4) years. PDR was found in 118 (33%) patients. Mean number of generations was 2.0 (SD 0.5), pedigree size 5.0 (SD 1.74) and number of siblings 2.6 (SD 1.0) in a sibship. The highest singlepoint LOD-score (2.7) was observed on chromosome 10p12 and the highest multipoint LOD-score (3.01) was observed on 19q13.43.

Conclusion: The present study offers evidence of linkage for diabetic proliferative retinopathy on chromosomes 10p12 and 19q13.43. Interestingly the linkage at 19q13.43 replicates an earlier finding regarding severe retinopathy in patients with type 2 diabetes (Hallman, et al. 2007).

Independent predictive roles of genetic variants of aldose reductase on cardio-renal complications in Chinese with type 2 diabetes

Y. Wang¹, W.Y. So¹, M.C.Y. Ng¹, X.L. Yang¹, R.C.W. Ma¹, A.P.S. Kong¹, P.C.Y. Tong^{1,2}, J.C.N. Chan^{1,2}

¹Medicine and Therapeutics, The Chinese University of Hong Kong, ²Hong Kong Institute of Diabetes and Obesity, The Chinese University of Hong Kong, China

Background and aims: Aldose reductase gene (ALR2) has been implicated in the development of diabetic complications. We previously reported the independent risk association of type 2 diabetic nephropathy with z-2 allele of the 5'-(CA)_n microsatellite and C-106T promoter polymorphisms of the aldose reductase (ALR2) gene using case-control design. In this expanded cohort, we examined their predictive roles on new onset of cardio-renal complications using a prospective design.

Materials and methods: In this 8-year prospective cohort of 1074 type 2 diabetic patients (59% male, median age: 61 years; disease duration: 7 years) with a total observation period of 8592 person-years, none had clinical evidence of coronary heart disease (CHD) or chronic kidney disease (CKD) at

recruitment. Renal endpoint was defined as new onset of estimated glomerular filtration rate (eGFR) < 60 ml/min/1.73m², hospitalizations with dialysis or death due to renal disease while CHD was defined as hospitalizations with myocardial infarction, ischemic heart disease or related deaths. The 5'-(CA)_n and C-106T polymorphisms were examined by PCR followed by capillary electrophoresis and digestion with BfaI, respectively.

Results: After controlling for baseline risk factors and use of medications, ALR2 z-2 allele of (CA)_n microsatellite carriers had increased risk of renal [hazard ratio, 1.53; 95 percent confidence interval, (1.14–2.05) *p*=0.005] or combined cardio-renal endpoints [1.31 (1.01–1.72) *p*=0.047]. Carriers of ALR2 C-106T polymorphism also had increased risk of renal [1.54 (1.15–2.07) *p*=0.004] and cardio-renal endpoint [1.49 (1.14–1.95) *p*=0.004]. Compared to non-carriers, patients with 2 risk conferring genotypes had 2-fold increased risk of renal [2.41 (1.57–3.70) *p*<0.001] and combined cardio-renal endpoints [1.94 (1.29–2.91) *p*=0.002].

Conclusion: In Chinese type 2 diabetic patients, genetic polymorphisms of the ALR2 independently predict new onset of renal and combined cardio-renal endpoints, the latter largely mediated through renal disease.

Dose range effects of the new once daily GLP-1 receptor agonist AVE0010 added to metformin in type 2 diabetes

J. Rosenstock¹, R.E. Ratner², G. Boka³

¹Clinical Research, Dallas Diabetes and Endocrine Center, Dallas, United States, ²MedStar Research Institute, Hyattsville, United States, ³Clinical Investigations, Metabolism & Diabetes, sanofi-aventis R&D, Antony, France

Background and aims: The effects of glucagon-like peptide-1 (GLP-1) receptor agonists are dependent on the dose concentrations. This randomized, 13-week, double-blind, placebo-controlled, parallel-group study evaluated the dose-response effect of AVE0010, a new GLP-1 receptor agonist, in patients with type 2 diabetes (T2DM) treated with metformin.

Materials and methods: T2DM patients (N=542) with HbA_{1c} ≥7% and <9% on metformin (1.6–1.9 g/day) were randomized to add-on therapy with subcutaneous AVE0010 (5, 10, 20, and 30 µg QD or BID) or matching placebo (total daily doses in the BID groups were 10, 20, 40, and 60 µg, respectively). Primary endpoint was change in HbA_{1c} from baseline. Secondary endpoints included body weight, fasting plasma glucose (FPG), mean change in averaged self-monitored 7-point plasma glucose (MSMPG), post-prandial plasma glucose AUC_[0–4h], 2-h post-prandial glucose changes, and post-prandial glucagon AUC_[0–4h].

Results: Baseline characteristics were similar among groups: mean age 56 ± 9 years, diabetes duration 6.6 ± 5 years, HbA_{1c} 7.5 ± 0.6%, and BMI 31.9 ± 4 kg/m². 489 patients (90.2%) completed the study. Despite mildly elevated baseline HbA_{1c} there were significant placebo-subtracted decreases in mean HbA_{1c} from baseline (Table). Percentages of patients with HbA_{1c} <7% at study-end were: 47%, 52%, 68%, and 69% for 5, 10, 20, and 30 µg QD; and 51%, 65%, 62%, and 77% for 5, 10, 20, and 30 µg BID vs 32% on placebo. Least squares mean weight reductions ranged from -2.0 to -3.5 kg with 5 µg and 30 µg QD, respectively, and -2.1 to -3.9 kg with 5 µg and 30 µg BID, respectively, vs -1.9 kg with placebo. Least squares mean placebo-subtracted body weight and specific metabolic parameter changes are presented in the Table. Adverse events included transient, dose-dependent nausea (from 7.3% to 35.2% with 5 and 30 µg QD, respectively, and from 7.5% to 33.3% with 5 and 30 µg BID, respectively, vs 4.6% with placebo). Vomiting occurred in 3.6% to 18.5% with 5 µg and 30 µg QD, respectively, and 5.7% to 9.3% with 5 µg and 20 µg BID, respectively, vs 0.9% with placebo. No cases of severe hypoglycaemia were reported. Few patients discontinued treatment due to adverse events (1.8% to 11.1% with QD and 0 to 14.8% with BID vs 1.8% with placebo).

Conclusion: The GLP-1 agonist, AVE0010, significantly improved glycaemic control with meaningful HbA_{1c} reductions in patients with T2DM inadequately controlled with metformin. A clear dose-response relationship was seen within both QD and BID regimens, with similar efficacy between QD and BID. These results highlight the promising efficacy, safety and tolerability profile of a new once-daily GLP-1 agonist for the management of T2DM.

Exenatide once weekly elicits sustained glycaemic control and weight loss over 52 weeksJ. Buse¹, D. Drucker², K. Taylor³, T. Kim³, K. Wilhelm³, D. Kendall³, M. Trautmann⁴, D. Zhuang³, L. Porter³¹University of North Carolina Chapel Hill, Chapel Hill, United States,²University of Toronto, Canada, ³Amylin Pharmaceuticals, Inc., SanDiego, United States, ⁴Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, United States

Background and aims: The incretin mimetic exenatide improves glycaemic control and reduces body weight when administered twice daily (BID) in patients with type 2 diabetes. In a 30-wk randomised, open-label trial (DURATION-1: Diabetes Therapy Utilisation: Researching Changes in HbA_{1c}, Weight, and Other Factors Through Intervention with Exenatide ONce Weekly) treatment with a once weekly formulation (QW) of exenatide resulted in greater improvements in HbA_{1c} [-1.9% vs. -1.5%] and fasting plasma glucose (FPG) [-2.3 mmol/L vs. -1.4 mmol/L] than twice daily exenatide (BID) in patients (N=295, ITT) with type 2 diabetes. Both groups lost ~4 kg by wk 30. Following the 30-wk study, 258 (87.5%) subjects entered an open-ended treatment with exenatide QW.

Materials and methods: Here we describe results following 22 wks of follow-up treatment in 241 (evaluable) patients (prior to 52-wk study: baseline HbA_{1c} 8.3±1.0%, FPG 9.4±2.4 mmol/L, weight 102±20 kg, BMI 35.1±5.0 kg/m², diabetes duration 6.8±5.2 y; mean±SD).

Results: Improvements in both HbA_{1c} and FPG were sustained in patients receiving exenatide QW (n=120) for 52 wks [A1C: -2.0±0.1%; FPG -2.6±0.2 mmol/L (LS mean±SE)], while patients who switched from exenatide BID to exenatide QW (n=121) achieved similar glycaemic control by wk 52 [HbA_{1c}: -2.0±0.1%; FPG -2.4±0.2 mmol/L]. In both groups ~3 in 4 patients achieved HbA_{1c} ≤ 7.0%, while over half achieved HbA_{1c} ≤ 6.5%. Patients in both groups lost ~4 kg by wk 52. Both exenatide QW patients and those that switched from exenatide BID to exenatide QW had clinically significant reductions in systolic (-5.7±1.2 and -4.0±1.4 mmHg, respectively; ITT analysis) and diastolic blood pressure (-2.2±0.8 and -2.1±0.8 mmHg) at wk 52. Serum lipid profiles improved in both cohorts after 30 wks, but to a greater extent in subjects who received exenatide QW. However, patients who switched from exenatide BID to exenatide QW (n=121) exhibited comparable changes in serum lipids by wk 52 (total cholesterol: -0.25±0.07 vs -0.23±0.07 mmol/L; LDL: -0.09±0.06 vs -0.07±0.06 mmol/L; HDL: -0.02±0.02 vs -0.04±0.02 mmol/L; triglycerides: -15% vs -13%; exenatide QW vs exenatide BID). Exenatide QW was well tolerated. Nausea was predominantly mild and transient during the 30-wk study; cumulative incidence of patients reporting an episode of nausea was 35% in the exenatide BID cohort and 26% in the exenatide QW cohort. During the 22-wk follow-up, the incidence of nausea was ~7% in the ITT population. No hypoglycaemia occurred in patients not using

a concomitant sulphonylurea, and no major hypoglycaemia was observed, regardless of background therapy.

Conclusion: This study demonstrated sustained glucose control and weight loss over 52 wks with exenatide QW. Patients switching from exenatide BID to exenatide QW experienced improvements in glycaemic control.

Comparison of single and combined exenatide and metformin treatment on metabolic parameters and body composition in insulin-resistant obese women with polycystic ovary syndromeR. Bhushan¹, O.S. Marrioneaux¹, M. Bhushan¹, D.C. Vernor¹, K.E. Elkind-Hirsch²¹Metabolic Center of Louisiana Research Foundation, Baton Rouge,²Woman's Health Research Institute, Baton Rouge, United States

Background and aims: Given that a disturbed balance between insulin sensitivity and pancreatic β -cell activity is found in women with polycystic ovary syndrome (PCOS), early recognition and intervention such as weight loss and/or pharmacological intervention may prevent or delay the development of diabetes. In order to do so, we evaluated exenatide and metformin, alone and in combination, on metabolic profiles, body weight and fat distribution, and hormonal parameters in obese insulin-resistant women with PCOS.

Materials and methods: Sixty obese oligo-ovulatory women with PCOS were randomized to 1 of 3 treatment groups: metformin (MET; 1000 mg BID); exenatide (EX; 10 mcg BID) or combined (COM; metformin 1000 mg BID; exenatide 10 mcg BID) for 24 weeks. An oral glucose tolerance test (SI_{OGTT}) was performed with measurement of glucose (G) and insulin (I) before and after the course of treatment. Insulin sensitivity and β -cell function measures were computed from G-I values obtained during the SI_{OGTT}. Sex steroids (testosterone, sex hormone binding globulin [SHBG], free androgen index [FAI]) and adiponectin levels were determined in the fasting sample.

Results: Insulin resistance was confirmed in all study participants. Forty-two (70%) patients completed the study per protocol. COM therapy was superior to either single agent therapy in improving insulin sensitivity and reducing abdominal girth as shown in the table below. Both exenatide treatment groups were more effective in promoting weight loss and reducing androgen excess than metformin alone (p=0.003).

Conclusion: Treatment with exenatide and metformin is more effective than either medication alone in improving metabolic profiles, increasing adiponectin levels and reducing body weight, abdominal girth, and hyperandrogenism. A marked decrease in central adiposity in the COM population is noted, which could partly explain the improvements in G-I parameters and adiponectin levels. The amelioration of these factors alone could lead to the delay in progression of DM2; it is enough, at least, to warrant a prospective study.

Significantly better glycaemic control/weight reduction with human GLP-1 analogue liraglutide, than with insulin glargine: all as add-on to metformin + sulphonylurea in type 2 diabetes

D. Russell-Jones¹, A. Vaag², O. Schmitz³, B. Sethi⁴, N.M. Lalic⁵, S. Antic⁶, M. Zdravkovic⁷, G.M. Ravn⁸, R. Simo⁹

³Endocrinology & Metabolism, University of Aarhus, Denmark,

⁴Endocrinology & Metabolism, Care Hospitals, Hyderabad, India,

⁵Endocrinology & Metabolism, School of Medicine, Belgrade, Serbia,

⁶Endocrinology & Metabolism, Diabetes and Metabolic Diseases Clinic, Nis, Serbia, ⁷International Medical Affairs, Novo Nordisk A/S, Bagsvaerd, Denmark, ⁸Statistics, Novo Nordisk A/S, Bagsvaerd, Denmark,

⁹Endocrinology & Metabolism, Vall d'Hebron University Hospital, Barcelona, Spain

Background and aims: This 26-week, randomised trial compared the efficacy and safety of liraglutide (1.8 mg, once daily; OD), liraglutide placebo and open label insulin glargine, all as add-on to metformin (1 mg, twice daily; BID) and glimepiride (2–4 mg OD).

Materials and methods: In total, 581 subjects were randomised (mean age 57.5±9.9); mean body mass index 30.5±5.3 kg/m², mean HbA_{1c} 8.2±0.9 %).

Results: Liraglutide + metformin + glimepiride reduced HbA_{1c} more than glargine and placebo in combination with metformin and glimepiride (ANCOVA, $p=0.0015$ and $p<0.0001$) and more of the subjects in the liraglutide group reached HbA_{1c} ≤6.5% ($p<0.0001$). Estimated weight difference between the liraglutide and glargine groups was -3.4 kg ($p<0.0001$) and -1.4 kg between the liraglutide and placebo groups ($p=0.0001$). Glargine was individually titrated according to a patient-driven algorithm, and the average dose of glargine was 24 IU/day at the end of trial. Most common adverse events in the liraglutide group were gastrointestinal disorders (mainly nausea). Nausea occurred in approximately 15% of subjects in the liraglutide group, but was transient. Frequency of minor hypoglycaemic episodes (<3.1 mmol/L) were similar for the liraglutide and glargine groups and more frequent than in the placebo group, but did not reach statistical significance. Five subjects reported major hypoglycaemic events in the liraglutide group (only one required medical assistance, and none resulted in coma or seizures). Presence of liraglutide antibodies was 9.8%.

Conclusion: Liraglutide added to metformin and a sulphonylurea (SU) was generally well tolerated and statistically significantly improved glycaemic control, and reduced body weight in comparison to metformin and an SU alone and to glargine added to metformin and an SU.

149

Liraglutide, a human GLP-1 analogue, substantially reduces HbA_{1c} in subjects with type 2 diabetes, irrespective of HbA_{1c} at baseline

A. Vaag¹, M.A. Nauck², M. Brandle³, S. Colagiuri⁴, O. Schmitz⁵, M. Zdravkovic⁶, K. Hermansen⁷, A. Garber⁸, B. Zinman⁹

¹Steno Diabetes Centre, Gentofte, Denmark, ²Diabeteszentrum, Bad Lauterberg im Harz, Germany, ³Kantonsspital, St Gallen, Switzerland,

⁴Metabolic Health, University of Sydney, Australia, ⁵Endocrinology and Diabetes, University of Aarhus, Denmark, ⁶International Medical Affairs, Novo Nordisk A/S, Bagsvaerd, Denmark, ⁷Endocrinology, Aarhus University Hospital, Denmark, ⁸Baylor College of Medicine, Methodist Hospital, Houston, United States, ⁹Leadership Sinai Centre for Diabetes, Mount Sinai Hospital, Toronto, Canada

Background and aims: Baseline HbA_{1c} is an important factor when deciding on the pharmacological agent to use and can also determine the response to treatment. The aim of this analysis was to examine the impact of baseline HbA_{1c} on the responses to liraglutide, a once-daily human GLP-1 analogue.

Materials and methods: Data on glycaemic control from four 26-week trials and one 52-week LEAD (Liraglutide Effect and Action in Diabetes) study were stratified by baseline HbA_{1c} quartiles (Table).

Baseline characteristic	Trial				
	LEAD 1	LEAD 2	LEAD 3	LEAD 4	LEAD 5
Subjects	n=695	n=725	n=746	n=543	n=232
Concomitant OADs	glimepiride 2–4 mg	metformin 2 g	-	metformin 2 g + rosiglitazone 8 mg	metformin 2 g + glimepiride 2–4 mg
HbA _{1c} (mean, %)	8.4	8.3	8.3	8.3	8.6
HbA _{1c} (mean, quartile 1)	7.3	7.3	7.0	7.2	7.2
HbA _{1c} (mean, quartile 2)	8.1	8.0	7.7	7.9	7.9
HbA _{1c} (mean, quartile 3)	8.8	8.7	8.4	8.6	8.5
HbA _{1c} (mean, quartile 4)	9.8	9.8	9.7	10.3	9.5
Bodyweight (mean, kg)	81.9	88.1	92.6	96.3	85.5

Results: Changes in HbA_{1c} (mean (SE)) from baseline to end of trial are shown (Figure). Liraglutide added to oral antidiabetic agents (OADs) resulted in clinically meaningful reductions in HbA_{1c} across all baseline HbA_{1c} quartiles. The effect of baseline HbA_{1c} on actual HbA_{1c} reduction was confirmed by an analysis of the change in HbA_{1c} with treatment, previous OAD treatment and baseline HbA_{1c} as explanatory variables ($p<0.0001$). Treatment with liraglutide + metformin + rosiglitazone (LEAD 4) resulted in the largest decrease in HbA_{1c} compared with other regimens, irrespective of baseline

Surgical treatment for non-obese type 2 diabetic subjects: results from 1-year prospective study

B. Geloneze¹, S.R. Geloneze¹, C. Fiori¹, M. Tambascia¹, F.F. Hirsch¹, C. Stabe¹, A.C. Felici¹, B.D. Astiarraga¹, E. Chaim², J.C. Pareja²

¹Laboratory of Investigation on Metabolism and Diabetes - LIMED, University of Campinas, ²Obesity and Metabolic Surgery Unit, University of Campinas, Brazil

Background and aims: Most patients who undergo Roux-en-Y gastric bypass (RYGB) experience rapid resolution of type 2 diabetes (T2DM). These results come from more than gastric restriction and weight loss, indicating the gut as a incretin mediator. Goto-Kakizaki T2DM rats underwent duodenal exclusion, a stomach-preserving RYGB that excludes the proximal intestine, ameliorates glycaemic control suggesting that a proximal intestine bypass could be considered as an incretin-based diabetic treatment.

Materials and methods: To test this hypothesis we performed a duodenal exclusion in 15 non-obese T2DM subjects from less than 10 years, age:38–58y, no evidence of autoimmunity (negative anti-GAD), significant endogenous insulin production (C-peptide > 1 ng/mL), and documented use of insulin, but for less than 8 years. Clinical 1-year follow-up included self-monitoring blood glucose assessment to further adjustment on medical therapy based on current international guidelines.

Results: The major finding of this study was a reduction on insulin requirement (2/15 remain taking insulin at 1-year) along with improvement on fasting, postprandial glucose, and A1C levels. At baseline, all the patients had A1C above 7%, but 5 patients at 2 months, 6 at 6 months, and 5 at 1-year had A1C less than 7%. No changes in BMI, % of fat mass or fat distribution were observed. Insulin sensitivity (KITT) remained unchanged during 1-year follow-up.

Conclusion: Surgical treatment for T2DM bypassing a segment of proximal intestine in the duodenal exclusion procedure is an effective treatment for non-obese subjects independently of weight loss and changes on insulin sensitivity. We hypothesized that this clinical improvement is mediated by an enhanced incretin effect. These findings suggest a potential role of the proximal intestine in the pathogenesis of T2DM and the possibility of a new incretin-based surgical approach for the management of non-obese diabetic subjects.

ROMEO (Rethink Organization to iMprove Education and Outcomes). A 4-year multicentre randomised controlled trial of group care for the management of type 2 diabetes

M. Trento on behalf of the ROMEO investigators

Internal Medicine, Laboratory of Clinical Pedagogy, University of Turin, Italy

Background and aims: We showed previously (Diabetes Care 27;670:2004) that Type 2 diabetes (T2DM) is managed effectively by continuous systemic group education (Group Care), which substitutes traditional one-to-one visits with sessions centred on hands-on and problem-solving activities, role playing and discussions on motivation, diabetes acceptance, psychosocial and coping strategies. Sessions last 40–50 minutes, are held every 3–4 months and are followed by brief individual consultations with a physician. A multi-centre clinical trial was organised to ascertain if Group Care would perform as well in diabetes clinics throughout Italy.

Patients and Methods: 815 patients with non insulin-treated T2DM from 13 Italian clinics were centrally randomised to either Group or one-to-one Care. Operators were specifically trained and provided with a detailed operating manual and educational materials. At baseline, the two treatment groups were similar by age, gender, known duration of diabetes, BMI, HbA_{1c}, lipids, quality of life, knowledge of diabetes and health behaviours, as assessed by questionnaires. Analysis was by intention-to-treat. 592 patients from 11 clinics completed the 4-year follow-up. Results are expressed as differences (95% CI) between treatment groups, after adjusting for participating centre, gender, family history for diabetes, schooling, occupation, years of attendance in clinic and baseline values of the relevant variables.

Results: After 4 years, the patients followed by Group Care had lower HbA_{1c} [-1.49% (-1.63/-1.34)], fasting blood glucose [-19.1 mg/dl (-27.1/-11.1)], weight [-3.15 Kg (-4.21/-2.08)], BMI [-1.09 (-1.56/-0.62)], systolic [-4.4 mmHg (-7.3/-1.5)] and diastolic [-3.3 mmHg (-5.2/-1.3)] blood pressure, triglyceride [-44.8 mg/dl (-56.0/-33.5)] and total cholesterol [-25.7 mg/dl (-31.8/-19.5)], and higher HDL cholesterol [+5.2 mg/dl (+3.5/+7.0)] than those followed by traditional care. They also had better quality of life [-16.8 (-18.3/-15.2)], knowledge [+10.6 (+8.9/+12.3)] and health behaviours [+4.2 (+3.8/+4.5)]. All differences were significant at p<0.001.

Conclusion: Group Care produces better clinical, cognitive and psychological outcomes than traditional one-to-one care when applied within a structured systemic programme. However, it requires re-organization of working practices, which may account for failure of two participating clinics in implementing it.

Clinical effectiveness of oral antidiabetic drugs and insulin in the management of type 2 diabetes in UK primary care - a UK population based study

P. McEwan¹, P. Sharplin¹, M. Baldwin¹, M. Evans²

¹CRC, Cardiff Research Consortium, ²School of Medicine, University Hospital of Wales, Cardiff, United Kingdom

Background and aims: The maintenance of long term glycaemic control is important in limiting the complications associated with type 2 diabetes (T2D), driving clinical practice toward the attainment of near normoglycaemia (HbA_{1c} <7%). Injected insulin is the most effective glucose lowering agent; however, current clinical practice results in a stepwise escalation of oral antidiabetic drugs (OADs) prior to insulin initiation. This pattern of therapy may result in patients being exposed to unacceptable prolonged hyperglycaemia essentially through delaying the initiation of insulin. The aim of this retrospective cohort based study was to establish evidence that the introduction of insulin earlier in the course of the disease has better outcomes than sequential OAD therapy.

Materials and methods: We analysed the UK THIN (The Health Improvement Network) general practice database between 2001 and 2006. Patients were stratified by maximum concurrent number of oral therapies. All patients were analysed by HbA_{1c} history, relative to the time point of first, sec-

ond and third line therapy initiation. Patients progressing to insulin were also analysed by HbA_{1c} history, relative to the time of insulin initiation.

Results: The table details the number of patients and mean HbA_{1c} categorized by insulin status and maximum number of OAD usage.

OAD usage	None	One	Two	Three	Four	Total
Non-insulinised						
Number	40,924	49,534	31,433	7,473	864	130,228
Mean Age	72	70	71	66	64	71
Proportion male	0.52	0.50	0.54	0.57	0.64	0.52
HbA _{1c} *	6.4	7.1	7.6	7.9	8.2	7.1
Insulinised						
Number		4,641	9,404	2,465	68	16,578
Mean Age		70	69	67	63	68
Proportion male		0.52	0.52	0.56	0.69	0.52
HbA _{1c} **		9.2	9.6	9.7	9.9	9.6

HbA_{1c} * as recorded in 2nd quarter of 2006; HbA_{1c} ** as recorded in the quarter prior to insulin initiation. Prior to insulin initiation patients receiving OADs typically had an increase in HbA_{1c} of 0.92% in the previous year; mean HbA_{1c} was 8.58, 8.73, 9.01 and 9.51 in the 9–12 month 6–9, 3–6 and 0–3 month period prior to insulinisation respectively. Patients switching to insulin after one OAD with baseline HbA_{1c} levels >7.5%; or after 2 OADs with baseline HbA_{1c} levels >8.5% showed mean reductions of 1.5% and 2%, respectively; similar patients switching to further OADs had mean reductions of 1% and 1.5% respectively.

Conclusion: On average, patients start insulin with HbA_{1c} levels >9%. These patients had been poorly controlled for a long period of time prior to insulin initiation. Increased escalation of OADs is associated with higher mean levels of HbA_{1c} at insulin initiation. Therefore, starting insulin above a threshold HbA_{1c} of 8.5% is unlikely to achieve a target HbA_{1c} <7%. Finally, these results confirm that insulin is the most effective HbA_{1c} lowering therapy in T2D.

Paris, ¹¹Diabetes Department, CHU, Grenoble, ¹²Diabetes Department,

CHU, Tours, ¹³Diabetes Department, CHU, Besancon, France

Background and aims: To compare reimbursed diabetes care for adults in mainland France in 2001 and 2007.

Materials and methods: 7 676 subjects older than 18 years have been randomly selected in august 2007 from the claims of the French national Health Insurance System among people reimbursed of an oral hypoglycemic agent (OHA) or insulin on at least one occasion during the last 3 months. Data on reimbursed examinations and treatments have been collected and compared with data obtained with the same methodology in 2001 for the 9787 subjects included in the first ENTRED study.

Results: Gender (male = 52%) and mean age (65 years) were similar in 2001 and 2007, with a greater proportion of persons older than 75 years in 2007 (women 35% vs 28%, men 25% vs 17%). The assessment of glycemic control improved: 3 measures of HbA_{1c} during the previous year was performed for 30% of patients in 2001 vs 39% in 2007, and at least one measure for 77% in 2001 vs 87% in 2007. The biological follow-up also improved: at least one measurement of creatinin 71% vs 80%, of microalbuminuria 18% vs 26%, of blood lipids 63% vs 72%. An EKG had been performed for 30% of patients in 2001 vs 34% in 2007 and fundus examination moderately increased from 43% to 45%. The proportion of patients attending a private diabetes specialist was 11% in 2001 and 2007, but referrals to a cardiologist increased from 28% to 33%. Treatments of hyperglycemia were more aggressive in 2007: one OHA was prescribed to 47% of patients in 2001 vs 42% in 2007, two or more OHA to 33% vs 35%, insulin ± OHA to 20% vs 23%. Prescription of metformine in-

creased from 48% in 2001 to 59% in 2007, while prescription of sulfonylureas decreased from 60% to 48%. The management of CV risk factors became also more aggressive: prescription of antiplatelet therapy increased from 24% to 32%, of lipid-lowering agents from 39% to 55% (statin from 23% to 44%), of ACE inhibitors/sartans from 44% to 57% and of diuretics from 37% to 41%.

Conclusion: Although hospital care data are not yet available in this study, resulting in a partial estimation of the quality of follow-up, this study describes the management of french people with diabetes living in France based on two successive national representative samples and using similar methods. The quality of surveillance and therapeutic practices improved between 2001 and 2007, with a better implementation of the French and European guidelines. However, there are still important gaps between practices and guidelines concerning the measurements of HbA_{1c}, microalbuminuria and fundus examinations. This study will be completed with data on outcomes obtained from self administered questionnaire surveys sent to patients and physicians.

Clinical and patient reported outcomes in 5 European countries at 6 months following insulin initiation

A. Simpson¹, C. Nicolay², A. Goday³, H. Smih⁴, M.A. Charles⁵, A. Liebl⁶, M. Benroubi⁷, S. Jones⁸, A. Tynan⁴

¹EU Medical, Eli Lilly, Surrey, United Kingdom, ²EU Medical, Eli Lilly, Bad Homburg, Germany, ³Endocrinology, Hospital Del Mar, Barcelona, Spain, ⁴Health Outcomes, Eli Lilly, Surrey, United Kingdom, ⁵Dept de Recherche, INSERM, Paris, France, ⁶Centre for Diabetes and Metabolism, Fachklinik Bad Heilbrunn, Germany, ⁷Diabetes Centre, General Hospital, Athens, Greece, ⁸The Academic Centre, James Cook University Hospital, Middlesborough, United Kingdom

Background and aims: INSTIGATE is a prospective observational study in 5 European countries (France, Germany, Greece, Spain, UK) investigating patients with type 2 diabetes who initiate insulin during usual care.

Materials and methods: Data on medication, clinical outcomes, health related quality of life (HRQoL) and resource use are collected when patients initiate insulin at baseline (BL) and at regular intervals for 24 months (m). This abstract describes observed clinical and patient reported outcomes in the 6m following insulin initiation.

Results: Data were collected from 1153 patients at BL and 1051 patients at 6m. Patients initiated the following regimens; basal only 537 (46.6%), mixtures 301 (26.1%), short acting 168 (14.6%), basal bolus 123 (10.7%) and other regimens 22 (1.9%). In Germany, more patients initiated intensive regimens; 49% started short acting and 23% basal bolus regimens. In other countries the majority of patients started either a basal only regimen (56%) or a mixture (31%). At 6m 107 patients (10.2%) had changed regimen.

In all countries mean HbA_{1c} was lower at 6m however, with the exception of Germany, the majority of patients still had a HbA_{1c} level higher than the EASD/ADA target.

Figure 1. Most recent HbA_{1c} (%) – distribution by country

Changes were observed in Fasting Blood Glucose (FBG); from an overall mean of 12.2 mmol/l at BL to 7.8 mmol/l at 6m, the largest difference in mean FBG being in Greece (12.9 to 7.8 mmol/l) and the smallest in the UK (13.2 to 10.2 mmol/l). There were also changes in other clinical outcomes (table 1). The number of reported episodes of hypoglycaemia increased; a total of 215 were reported in the 3m prior to BL and 737 were reported in the 3m prior to the 6m visit.

Table 1: Other clinical outcomes - all countries

	Baseline		6 months	
	mean	SD	mean	SD
Fasting blood glucose (mmol/l)	12.2	4.32	7.8	2.47
Systolic blood pressure (mm Hg)	137.1	16.90	133.3	15.20
Diastolic blood pressure (mm Hg)	79.3	10.44	78.4	15.20
HDL (mmol/l)	1.3	0.40	1.3	0.35
LDL (mmol/l)	2.9	1.04	2.7	0.86
Total cholesterol (mmol/l)	5.1	1.23	4.7	0.98
Triglycerides (mmol/l)*	1.9	1.3–2.7	1.5	1.1–2.0

* figures reported are median and inter-quartile range as per standard reporting practice

Using the EuroQoL VAS score, individual patient reported HRQoL improved by a median of 5 points (population median scores were; 62 at BL and 75 at 6m). Median intra patient changes were higher in Germany and Greece (10 points) and lowest in France (0 points).

Conclusion: The observations indicate improvements in metabolic control following insulin initiation. HRQoL was also seen to improve, in spite of the additional demands associated with injectable therapy.

Glycaemic and blood pressure control seems harder to improve than lipid control in type 2 diabetic patients: comparison of two surveys over 5 years in Belgium

N. Paquot¹, H. Vandenberghe², A.J. Scheen³, C.E. De Block⁴, L.F. Van Gaal⁴

¹Diabetes, University of Liege, ²WPO, Pfizer WPO Belgium, Brussels,

³Diabetes, University of Liège, ⁴Diabetology, Antwerp University Hospital, Belgium

Background and aims: In order to tackle cardiovascular risk factors and prevent complications in type 2 diabetes (T2DM), European guidelines have set clear goals and recommendations for treatment in terms of glycaemic, blood pressure (BP) and lipid control. The purpose of this repeated survey over five years was to investigate the evolution in the extent to which T2DM patients received treatment and achieved the goals for glycated haemoglobin (HbA1c), total cholesterol, LDL (low density lipoprotein) cholesterol and BP as recommended by the European Task Force (ETF) for cardiovascular disease prevention.

Material and methods: A non-interventional, cross-sectional survey (OCAPI [Optimizing Cardiovascular Prevention in Diabetes]) was conducted in 2001 and repeated in 2006, which enrolled T2DM patients above 40 years (952 and 1108, respectively) at endocrinology departments spread throughout Belgium. Data was collected based on information present in the medical record of T2DM patients visiting the physician consecutively over a 2-month period. The first survey applied the goals of the second ETF (goals were respectively 6.5%, 190 mg/dL, 115 mg/dL and 130/85 mmHg for HbA1c, total and LDL-cholesterol and BP); the second survey these of the third ETF (6.1%, 175 mg/dL, 100 mg/dL and 130/80 mmHg). Still, for HbA1c we assessed the achievement of a more realistic target of <7% (as proposed by the American Diabetes Association) in both surveys.

Results: Insulin was used more widely in 2006 (74% of T2DM patients) compared to 2001 (46%; $p<0.001$), as were biguanides (58% vs 47%; $p<0.001$). Sulfonylureas were less used (17% vs 43%; $p<0.001$) and the proportion of glitazone users remained low in 2006 (4%; not measured in 2001). Over five years, more patients received antihypertensive treatment (79% vs 65%; $p<0.001$) and the use of statins had doubled (63% vs 29%; $p<0.001$). Although a higher proportion of T2DM patients reached the ETF goals for total cholesterol (52% in 2006 vs 29% in 2001; $p<0.001$) and LDL cholesterol (56% vs 43%; $p<0.001$) - even with more stringent goals in 2006 -, there was no similar improvement in BP (21% versus 19%; $p=0.472$), more particularly because persistence of high systolic BP levels in numerous T2DM patients. Glycaemic control even deteriorated (37% vs 59% below the HbA1c level of 7%; $p<0.001$) when the two surveys are compared, despite apparently more aggressive glucose-lowering therapy. The latter observation might be related to longer duration of diabetes (13 years vs 9 years; $p<0.001$) and higher body mass index (32 kg/m² vs 29 kg/m²; $p<0.001$) of the population in the second survey.

Conclusion: In a repeated cross-sectional survey over a 5 year period (2001–2006) in Belgium, HbA1c and systolic BP levels remained difficult to control in T2DM patients and the percentage of patients at goal did not increase - despite more intensive pharmacological therapy - whereas lipid goal achievement markedly improved thanks to a greater use of statins. Although partially explained by the demographic characteristics (more advanced diabetes and more overweight in the second survey), the apparent decline in glycaemic control needs further investigation and stresses the fact that even more stringent treatment is necessary to meet the goals set by the guidelines.

Diabetes care practice variation among outpatient diabetes clinics: an urgent need for quality improvement initiatives

A. Nicolucci¹, M.C.E. Rossi¹, A. Arcangeli², A. Cimino³, G. De Bigontina⁴, C. Giorda⁵, I. Meloncelli⁶, I. Otranto¹, F. Pellegrini¹, B. Pomili¹, U. Valentini³, G. Vespasiani⁶

¹Department of Clinical Pharmacology and Epidemiology, Consorzio Mario Negri Sud, S. Maria Imbaro (CH), ²A.S. Diabetes and Metabolic Diseases, AUSL 4, Prato, ³Diabetes Unit, A.O. Spedali Civili, Brescia, ⁴Diabetes Unit, Cadore Hospital, Dolomiti-Belluno, ⁵Diabetes and Metabolism Unit, ASL 8, Chieri (TO), ⁶Diabetes Unit, Madonna del Soccorso Hospital, S. Benedetto del Tronto (AP), Italy

Background and aims: Practice variation is generally considered as an important source of inappropriate care as well as of resource consumption. The Associazione Medici Diabetologi promoted a study to evaluate the extent to which process and intermediate outcome indicators varied among diabetes clinics throughout Italy.

Materials and methods: Eighty-six clinics were involved, all using electronic medical record systems. Process and intermediate outcomes indicators were identified and a software was developed, enabling the extraction of the information needed for the profiling of quality of care. Data were centrally analyzed anonymously. Between centers variability was investigated using multi-level models adjusted for patient age, gender, and clustering effect.

Results: Overall, 114,249 patients with T2DM seen during 2004 were evaluated. Between centers variability in the median proportion of patients with at least one value registered during the year (process measures) and variation in the percentage of patients reaching specific therapeutic targets (outcome measures) is shown in the table.

Rates of use of specific drug classes also markedly varied among centers: statins were used on average in 22% of the patients, but such a proportion ranged between 7% and 50% in the different centers. On the same line, ACE-inhibitors were prescribed on average to 21% of the patients, but the prescription rate ranged between 7% and 40%.

Conclusion: The high level of variability in process and outcomes of diabetes care calls for intensive efforts devoted to enhance the delivery of care. Ensuring more homogeneous levels of care through a wider adoption of existing evidence should represent a priority to reduce the clinical and economical burden of diabetes. Ongoing activities in Italy are specifically devoted to reduce between centers variability by providing reference standards identified on the basis of the “best performers” approach.

Between centers variability

Process indicators: % of patients with at least one measure of	Median [10 th - 90 th percentile]	Outcome indicators: % of patients with	Median [10 th - 90 th percentile]
HbA1c	93.2 [64.8-96.9]	HbA1c≤7%	40.7 [21.0-59.3]
Blood pressure	91.1 [18.4-98.1]	Blood pressure≤130/85 mmHg	35.2 [20.5-50.7]
Lipid profile	66.6 [14.4-89.7]	LDL-C<100 mg/dl	30.1 [22.9-37.3]
Microalbuminuria	37.4 [0.0-40.0]

High glucose-conditioned medium from endothelial cells enhances apoptosis in human retinal pericytes

E. Berrone, E. Beltramo, S. Tarallo, M. Porta
Internal Medicine, University of Turin, Italy

Background and aims: In diabetic retinopathy, pericyte survival is dependent, among other factors, on interactions with endothelial cells (EC), but little is known about the activation of pericyte apoptosis by EC in the presence of elevated glucose concentrations. We previously reported that human retinal pericytes (HRP) seem to be not affected by exposure to constant high glucose concentrations, while their apoptosis is strongly enhanced by culture on matrix produced by EC in high glucose. The purpose of this study was to evaluate HRP response to soluble factors released by EC in the medium in the presence of physiological or high glucose concentrations.

Materials and methods: Human umbilical vein EC were cultured in physiological (5.6 mM, G5.6) or high (28 mM, G28) glucose for 7 days; media from last 2 days of culture were collected and filtered (EC-CM). HRP were then cultured for 7 days in normal or high glucose only, or in normal glucose with the addition of 25 or 50% EC-CM. DNA fragmentation was measured by ELISA to assess cell apoptosis. In parallel, the expression of two genes involved in apoptosis, *bax* and *bcl-2*, was determined by RT-PCR. HRP morphology in the various conditions was evaluated by phase-contrast microscopy.

Results: Apoptosis increased significantly in the presence of 50% EC-CM produced in high glucose (1.584 ± 0.293 vs 0.202 ± 0.104 abs of controls in physiological glucose only, $p=0.005$), but not in high glucose only (0.164 ± 0.065 , $p=NS$ vs control), nor with EC-CM produced in normal glucose (25% G5.6 EC-CM: 0.292 ± 0.429 , $p=NS$ vs control; 50% G5.6 EC-CM: 0.112 ± 0.063 , $p=NS$ vs control). As regards mRNA expression, there was a clear over-expression of Bax in the presence of 50% EC-CM produced in high glucose only ($241.5 \pm 47.7\%$ of G5.6, $p=0.01$). Bcl-2 mRNA was again unchanged in all conditions, except in HRP cultured in 25-50% EC-CM produced in high glucose, where there was an evident reduction (25% G28 EC-CM: $72.8 \pm 1.7\%$ of G5.6 $p=0.000$; 50% G28 EC-CM: $60.8 \pm 7.1\%$ of G5.6 $p=0.002$). Finally, cell morphology showed modifications in the presence of 50% EC-CM produced in high glucose only, in particular the typical apoptotic aspect with cell shrinkage, cytosolic vacuoles and nucleus condensation.

Conclusion: Conditioned medium from EC cultured in high glucose increases significantly HRP apoptosis and Bax expression, while reducing bcl-2. Instead, conditioned medium from EC cultured in normal glucose does not influence HRP apoptosis. This suggests that soluble factors derived from EC are likely to play a critical role in the apoptotic response of HRP. Further elucidations about the effects of combined hyperglycaemia and EC-HRP interactions could be useful to investigate the pathogenesis of diabetic retinopathy.

158

High glucose concentration leads to differential expression of tight junction proteins in human retinal pigment epithelial cells

M. Villarroya, J. Matesanz, M. García, C. Hernández, R. Simó
Diabetes and Metabolism Research Unit, Institut de Recerca Hospital Universitari Vall d'Hebron, Barcelona, Spain

Background and aims: The breakdown of the blood-retinal barrier (BRB) due to the disruption of the tight junctions is one of the early features of diabetic retinopathy. In fact, there are two BRBs: the internal BRB, which is constituted by the endothelial cell tight junctions in the capillary bed, and the external BRB which is constituted by the tight junctions located in retinal pigment epithelial (RPE) cells. Whereas the impairment of the proteins involved in the disruption of the tight junctions of the internal BRB have been extensively studied, the information regarding this issue in RPE is scanty and there are no studies in which the expression of main tight junction proteins has been assessed simultaneously. The aim of the study is to determine the change of expression (mRNA and protein) of occludin, zonula occludens-1 (ZO-1) and claudin-1 in RPE cells using two different glucose concentrations: 5.5 mM (mimicking euglycemia) and 25 mM (mimicking hyperglycemia).

Materials and methods: ARPE-19, a spontaneously immortalized human RPE cell line, was cultured at 37°C under 5% CO₂ in medium (DMEM/F12)

supplemented with 10% fetal calf serum containing 5.5 mM D-glucose or 25 mM D-glucose. The medium was changed every 3 days. Cells were cultured for 7, 14 and 21 days. Occludin (OCLN), zonula occludens (ZO-1, TJP1) and claudin-1 (CLDN1) production was studied in Western blot (primary antibodies from Zymed Lab, 1:1000). Bands were transformed to densitometric values in a calibrated densitometer (GS-800 BIO-RAD) and normalized by beta-actin values. Real-Time PCR RQ values were obtained in ABI Prism 7000 SDS software (Applied Biosystems) using TaqMan assays for OCLN Hs00170162_m1, TJP1 Hs00268480_m1 and CLN1 Hs00221623_m1, and beta-actin was used as the endogenous reference gene (Hs9999903_m1, Applied Biosystems). All the measurements were performed at 7, 14 days and 21 days. In the same experimental conditions, cytotoxicity (LDH, Roche Applied Science) was assessed. All the results are expressed in arbitrary units after correction for beta-actin.

Results: All the tight junction proteins evaluated reached the maximum concentration at day 14. Occludin mRNA expression and protein content was similar in 5.5 and 25 mM of D-glucose at 7, 14 and 21 days. ZO-1 mRNA levels were similar in cultures maintained in 25 mM of D-glucose to those with 5.5 mM, but a decrease in protein content was observed in 25 mM at 14 (0.53 vs. 0.27) and 21 days (0.28 vs. 0.09). By contrast high glucose concentration (25 mM) produced a clear upregulation in claudin-1 mRNA expression and protein content at day 14 (mRNA levels: 1.16 vs. 1.49 . Protein content: 0.14 vs. 0.28) that persisted at 21 (mRNA levels: 1.03 vs. 2.29 . Protein content: 0.92 vs. 1.14).

Conclusion: High glucose concentration leads to differential expression of tight junction proteins in human RPE cells. The functional consequences as well as the clinical applicability of these findings require further investigation.

159

Possible involvement of cortisol-induced MR activation in diabetic nephropathy - effect of high glucose on cortisol production in human mesangial cells

Y. Matsuzawa, J. Saito, H. Ito, M. Omura, T. Nishikawa
Medicine, Yokoham Rosai Hospital, Yokohama, Japan

Background and aims: We had already reported that human mesangial cells (Msg) had the ability to produce aldosterone (Aldo), similarly to the adrenal gland and that the addition of high glucose and/or LDL to the incubation mixture enhanced Aldo production, suggesting the involvement of local Aldo production in the progression of nephropathy via autocrine/paracrine action on Msg. On the other hand, there were recent studies reporting that the nuclear receptor LXR plays a central role in sugar- or lipid-induced metabolic changes, directly regulating the cortisol (F)-metabolizing enzymes 11 β HSD-1 and 11 β HSD-2. Therefore, we examined the regulation of F production in Msg and the involvement of LXR.

Materials and methods: We cultured Msg (BioWhittaker Inc.) in MCDB131 medium, determined the levels of LXR α , LXR β , 11 β HSD-1, and 11 β HSD-2 mRNA expression by quantitative RT-PCR, and examined the effects of culture conditions, such as the LDL concentration, glucose concentration, and presence or absence of stimulation with angiotensin II (AII), on the levels of each mRNA expression. We also examined the effect of the transfection of an siRNA against LXR β on 11 β HSD-1 and 11 β HSD-2 mRNA expression.

Results: 1) Stimulation with AII reduced LXR α and LXR β mRNA expression. 2) In low-glucose (5.5 mM) medium, the level of 11 β HSD-2 mRNA expression was 5 to 6 times higher than that of 11 β HSD-1 mRNA expression. In the presence of LDL, stimulation with AII slightly enhanced 11 β HSD-1 and markedly reduced 11 β HSD-2 mRNA expressions. 3) The level of 11 β HSD-2 mRNA expression was lower in high- (25 mM) than in low-glucose medium. The level of 11 β HSD-1 mRNA expression in high- was similar to that in low-glucose medium, but markedly increased at high glucose and LDL levels under AII stimulation. 4) Transfection with a siRNA against LXR β to inhibit its function enhanced 11 β HSD-1 and reduced 11 β HSD-2 mRNA expressions.

Conclusion: We first confirmed the presence of LXR, 11 β HSD-1, and 11 β HSD-2 in human Msg, and showed that F production and its metabolic regulation occurred locally in Msg. In Msg, AII stimulation enhanced 11 β HSD-1 and reduced 11 β HSD-2 mRNA expressions. The results of the experiment with siRNA suggest that the expression of these enzymes is regulated through changes in LXR induced by AII, and that locally increased F seems to bind directly to the mineralocorticoid receptor (MR) like as binding of aldosterone to MR, particularly in the presence of high concentrations of glucose.

160

Interaction between the renin-angiotensin system (RAS) and advanced glycation end products (AGES) in the development of diabetic nephropathy

K.C. Sourris, A.L. Mibus, A. Koitka, B.E. Harcourt, A.L.Y. Tan, M.E. Cooper, J.M. Forbes

JDRF Albert Einstein Centre for Diabetes Complications, Baker Heart Research Institute, Melbourne, Australia

Background and aims: The RAS influences local hemodynamics in the diabetic kidney, acting through the binding of the hormone angiotensin II (Ang II) to two receptor subtypes, AT1 and AT2. In addition, hyperglycaemia facilitates the irreversible modification of proteins by sugars, resulting in advanced glycation end-products (AGEs), which are known metabolic contributors to diabetic nephropathy (DN). Therefore, the aim of this study was to elucidate the renal interactions between the RAS and AGE pathways once thought to be separate mediators of progressive DN.

Materials and methods: We investigated specific opposing interactions between the RAS and AGEs both in-vivo and in-vitro. In-vitro, primary mesangial cells were chronically treated for 7 days in high glucose (25mM with 10^{-7} M Angiotensin II (Ang II) or 100µg/mL AGE-modified BSA (AGE-BSA). Some groups of cells also were concomitantly administered AT1 (Valsartan, 10^{-7} M) or AT2 receptor (PD123312, 10^{-6} M) antagonists. Gene expression by real-time PCR, nuclear factor- κ B activation (NF- κ B) by DNA binding assay and reactive oxygen species (ROS) generation by flow cytometric analysis were determined. In vivo, mice deficient in either angiotensin receptor-1a (AT-1a) or the receptor for AGEs (RAGE) and their background strains; AT1-WT and C57BL/6 respectively (n=10 per group) were studied with and without streptozotocin induced diabetes (60mg/kg). At 24 weeks, peripheral blood and renal tissues were collected for analysis. In vivo, gene expression by real-time PCR, nuclear factor- κ B activation (NF- κ B) by DNA binding assay and ROS generation by chemiluminescence assay were determined.

Results: Ang II exposure increased the AT1, AT2 and RAGE receptors when compared to control treated cells with a decline in expression for AT1 and AT2 exhibited in the presence of their respective inhibitors. AGE-BSA exposure also increased expression of the AT1 receptor and RAGE, however, a decrease in AT2 receptor was observed when compared to BSA alone. Furthermore, gene expression of AT1 was not altered by either AT1 or AT2 inhibition, although AGE-induced up-regulation of RAGE was ameliorated by Valsartan. NF- κ B activity was significantly increased by treatment with AGEs but not Ang II. Importantly, this was significantly reduced in the presence of AT1 and AT2 inhibitors ($p < 0.05$). Furthermore, AGE treatment of mesangial cells induced a significant increase in ROS ($p < 0.05$) relative to the control and this was significantly reduced in the presence of AT2 inhibitor ($p < 0.05$). In-vivo, gene expression of both AT1 and AT2 receptors and RAGE were elevated in the kidneys from diabetic control mice, which was not seen in diabetic RAGE-/- mice. In addition an increase in RAGE gene expression was detected in the kidneys of diabetic AT-1a -/- and AT-WT groups. Renal nuclear NF- κ B activity was reduced with diabetes in C57BL/6 and RAGE-/- mice whilst it remained elevated in diabetic AT-WT and AT1a-/- mice. Diabetes induced an increase in renal ROS production which was not seen in RAGE-/- mice.

Conclusion: We conclude that there are interactions between the RAS and advanced glycation in the development of diabetic nephropathy. Importantly, we postulate that RAGE appears to be a common and key modulator of RAS mediators which each contribute to the development of diabetic nephropathy.

Effects of different LDL particles on inflammatory molecules in human mesangial cellsA. Solini¹, E. Santini¹, S. Baldi¹, R. Lupi², S. Madec¹, D. Chimentì¹, E. Ferrannini¹¹Department of Internal Medicine, ²Department of Endocrinology and Nephrology, University of Pisa, Italy

Background and aims: Inflammation is regarded as a key mechanism underlying glomerular damage even in chronic glomerulopathies. LDL may increase the expression of several cytokines in renal tissues, contributing in the development of glomerular disease. However, the relative role of native and glycated LDL in promoting an inflammatory response has been only partially

elucidated. This study evaluates the inflammatory and proapoptotic effect of different LDL particles in human mesangial cells (HMC), defining the intracellular signalling steps potentially responsible for these effects.

Materials and methods: HMC were stimulated with 25 and 100 µg/ml native (nLDL), oxidized (oxLDL) and glycated LDL (glyLDL) for 30, 60, 180 min, and 6 and 24 hrs for apoptosis. IL-6, CD40 and macrophage migration inhibitory factor (MIF) expression was measured by RealTime PCR and immunostaining. Supernatants were analysed for IL-6, soluble CD40 (sCD40L), fibronectin and laminin content by ELISA. Early and late apoptosis were determined by FACS. ERK1/2 and JNK2/3 activation was assessed by WB analysis.

Results: IL-6 mRNA was rapidly upregulated by all the three species (after 30 min, with 25 and 100 µg/ml nLDL: 7 ± 0.2 and 13.4 ± 0.5 ; with 25 and 100 µg/ml oxLDL: 8.7 ± 0.2 and 16.3 ± 1.3 ; with 25 and 100 µg/ml glyLDL: 7.0 ± 0.2 and 17.1 ± 0.8 fold above unstimulated cells (unst); all $p < 0.001$), and decreased within 180 min. CD40 was upregulated by oxLDL and glyLDL with a good dose-response relationship (after 30 min, with 25 and 100 µg/ml oxLDL: 2.8 ± 0.4 and 5.7 ± 0.6 ; with 25 and 100 µg/ml glyLDL: 2.3 ± 0.3 and 6.7 ± 1.1 fold above unst, both $p < 0.01$), whereas nLDL had a slower onset of effect (after 60 min, with 25 and 100 µg/ml nLDL: 2.1 ± 0.6 and 3.6 ± 0.6 fold above unst, $p < 0.01$). mRNA upregulation was paralleled by an increased release of both IL-6 (after 30 min, from 50 ± 4 to 138 ± 11 with nLDL, 131 ± 17 with oxLDL, 160 ± 12 with 100 µg/ml glyLDL all $p < 0.001$) and sCD40L (after 30 min, from 4.7 ± 0.6 to 8.7 ± 0.6 with nLDL, 15.3 ± 2.1 with oxLDL, 19.3 ± 2.3 with 100 µg/ml glyLDL, all $p < 0.001$). MIF mRNA was potentially stimulated by glyLDL and, especially, by oxLDL (after 60 min: 15.6 ± 1.7 with 100 µg/ml oxLDL and 6.8 ± 1.1 fold above unst with 100 µg/ml glyLDL, both $p < 0.001$) while 100 µg/ml nLDL minimally influenced it (1.9 ± 0.9 fold above unst). Immunostaining for MIF after treatment with oxLDL and glyLDL confirmed the observation. All LDL species activated both pathways; however, while JNK2/3 phosphorylation did not differ among the three, ERK1/2 phosphorylation was more strongly upregulated by oxLDL than either nLDL or glyLDL. nLDL did not influence fibronectin release (after 60 min: from 60 ± 11 to 66 ± 8 µg/ml/ 1.5×10^5 cells), while oxLDL and glyLDL increased it (to 103 ± 6 with oxLDL and 96 ± 9 µg/ml/ 1.5×10^5 cells with 100 µg/ml glyLDL, $p < 0.001$). The same effect was observed on laminin. LDL induced a small increase in apoptosis (unst: 15.32 ± 0.88 ; 100 µg/ml nLDL: 19.60 ± 1.65 ; oxLDL: 24.25 ± 1.91 ; glyLDL: 23.67 ± 1.47 %, $p < 0.001$ by ANOVA) only after 24 hrs. No effect on late apoptosis was observed for any of the LDL species.

Conclusion: In HMC, expression and release of IL-6 and CD40 is similarly stimulated by both native and modified LDL, while MIF is more strongly stimulated by oxLDL than glyLDL. With regard to the pattern of mesangial expansion, fibronectin and laminin are significantly upregulated by oxLDL and glyLDL. Apoptosis, if modest, is induced by all species.

Involvement of sialoadhesin-positive macrophages in microinflammation in the pathogenesis of diabetic nephropathy

N. Kajitani, K. Shikata, R. Nagase, M. Sasaki, S. Miyamoto, R. Koderia, D. Hirota, C. Sato, J. Wada, S. Nishishita, H. Makino

Medicine and Clinical Science, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Science, Japan

Background and aims: Low grade inflammation, i.e. microinflammation, is involved in the pathogenesis of diabetic nephropathy. Phenotypic change of mesangial cell is known to play a pivotal role in accumulation of extracellular matrix in diabetic nephropathy, although the state of activation and phenotype of macrophages infiltrated into diabetic kidney are still remained unclear. Sialoadhesin (Sn) is a macrophage-restricted cellular interaction molecule and a member of sialic acid binding immunoglobulin-like lectins. Sn is expressed on activated macrophage but not on monocyte. There have been several reports that Sn-positive macrophages play a role in development of chronic inflammatory diseases including rheumatoid arthritis and atherosclerosis. The aim of this study is to evaluate the phenotypic change of macrophages in diabetic kidney and to clarify the role of Sn-positive macrophage in the pathogenesis of diabetic nephropathy.

Materials and methods: Diabetes was induced in 4-week old male SD rats (n=25) by injection with streptozotocin (STZ). Non-diabetic control rats were injected with citrate buffer. Insulin-treated group was injected with NPH insulin every day. Kidneys were harvested from diabetic and control rats at 1, 4, 12, 24 weeks after injection with STZ or buffer. Renal tissues were examined by immunostaining with specific antibodies to pan macrophage (ED1), resident macrophage (ED2), Sn-positive macrophage (ED3), and MHC class II

(OX-6). Expression of α -smooth muscle actin (SMA) was investigated as a marker for the activation of mesangial cell. We also examined the expression of TGF- β 1 and Type IV collagen and histological changes. Moreover, we examined the effects of high-glucose condition or TNF- α , IL-4 and IL-6 on gene expression of Sn in cultured human monocytes (THP-1 cells).

Results: ED1 positive macrophages in diabetic glomeruli were significantly increased at 1 week after the induction of diabetes and the cell number was maintained at same level during 24 weeks. ED2 positive macrophages in the diabetic glomeruli revealed no significant difference with non-diabetic rats. The expression of Sn-positive macrophages (ED3) increased gradually from 4 weeks after induction of diabetes and revealed highest at 24 weeks. ED1 or ED3 positive cells are also positive for OX-6. Insulin treatment decreased total and Sn-positive macrophages in the glomeruli of diabetic rats to the same level of control rats. Sn-positive macrophages were concomitantly increased with expression of α -SMA, TGF- β 1 and type IV collagen and with expansion of mesangial matrix area. Gene expression of Sn was significantly increased in THP-1 cells under the existence of TNF- α . Expression of Sn was not changed by IL-6 and IL-4. High-glucose condition per se did not induce Sn expression in THP-1 cells.

Conclusion: Phenotypic changes were observed in both macrophage and mesangial cell in glomeruli of diabetic rats. Sn-positive macrophages were increased in diabetic glomeruli concomitantly with expression of α -SMA and progression of renal injuries. TNF- α might play a role in Sn expression on macrophages. Sn-positive macrophage is known to contribute to development of chronic inflammation. Our data suggest that Sn-positive macrophage may contribute to the development of microinflammation in the pathogenesis of diabetic nephropathy.

MicroRNA expression in human adipose tissue

N. Klotting¹, K. Ruschke¹, P. Kovacs², M.R. Schön³, M. Stumvoll¹, M. Bluher¹

¹Medical Clinic III, University of Leipzig, ²Interdisciplinary Centre for Clinical Research (IZKF), University of Leipzig, ³Department of Surgery, Karlsruhe, Germany

Background and aims: MicroRNAs (miRNAs) are small, noncoding RNAs, that play important regulatory roles in a variety of diverse biological processes, including development, differentiation, apoptosis as well as fat metabolism. In mammals, miRNAs have been shown to modulate adipocyte differentiation and insulin secretion. Therefore, we performed a global miRNA gene expression assay in adipose tissue from different depots of lean and obese individuals.

Materials and methods: Paired samples of visceral and subcutaneous adipose tissue were obtained from 15 Caucasian men (n = 8) and women (n = 7) who underwent open abdominal surgery. The gene expression of 155 miRNAs was carried out using the TaqMan® MicroRNA Assays Human Panel Early Access Kit (Applied Biosystems, Darmstadt, Germany).

Results: In total, we identified 106 (68%) miRNAs out of 155 miRNAs that are expressed in both visceral and subcutaneous fat. We found that 7 miRNAs significantly differing between men and women and seventeen miRNAs (11%) were significantly up-regulated in visceral compared to subcutaneous fat. Surprisingly, we found no miRNA which is exclusively expressed in either fat depot. Univariate correlation analyses revealed that several metabolic parameters, including visceral fat area, HbA1c, fasting plasma glucose, Leptin, Adiponectin as well as serum cholesterol are associated with expression levels of microRNA 17-5p, -132, -99a, -134, 181a, -145, and miRNA -197.

Conclusion: In summary, expression of selected miRNAs in human adipose tissue show sexual dimorphism and a fat depot specific expression pattern. In addition miRNA expression in human fat correlates with parameters of glucose homeostasis, obesity and fat distribution.

Regional differences in gene expression between subcutaneous and visceral adipose tissue

D. Guoxian

Department of Geriatrics, Nanjing Medical University First affiliated Hospital, Nanjing, China

Background and aims: Obese individuals with most of their fat stored in visceral tissue generally suffer greater adverse metabolic consequences than similarly obese subjects with fat stored predominantly in subcutaneous tissue. Further study was needed to explore differentially expressed genes that might be relevant to the determination of fat distribution and the associated metabolic sequelae in subcutaneous adipose tissue (SAT) and visceral adipose tissue (VAT).

Materials and methods: SAT and VAT were obtained from patients (all Chinese) attending the Department of Surgery for abdominal surgeries. A total of 73 samples were analyzed from patients (n=39) aged from 17 to 78. All subjects were not treated with any hormones. The study protocol was approved by the local research ethics committee. total RNA was isolated from paired samples of SAT and VAT from 30 adults (15 normal (BMI=22.78±1.63 kg/m²) and 15 obese patients (BMI=28.25±1.24 kg/m²). Expression differences between SAT and VAT were assessed using the paired Student's t test and independent-samples t test was used in other two samples comparison. Linear relationships were assessed by least square regression analysis. SPSS11.0 was used as statistical software.

Results: Depot-related gene expression: Adiponectin and monocyte chemoattractant protein-1 (MCP-1) mRNA expression had no difference between SAT and VAT either in normal or obese patients, while leptin mRNA expression, in both groups of subjects, was higher in SAT than in VAT (the values of VAT/SAT were 0.7 and 0.7 in normal and obese subjects respectively). In normal subjects, tumor necrosis factor- α (TNF- α) was expressed equally both in SAT and VAT. However, in obese subjects, TNF- α was expressed 1.6-fold in VAT compared to SAT. Compared with SAT, toll like receptor 4 (TLR4) expression in VAT was lower in normal patients (VAT/SAT=0.8); however, TLR4 expression in VAT was higher in obese patients (VAT/SAT=1.2). Glu-

corticoid receptor (GR) mRNA expressed higher in SAT than in VAT in normal patients, while expressed no difference in obese patients. No differences were found between SAT and VAT for peroxisome proliferator-activated receptor- γ (PPAR- γ) and 11 β -hydroxysteroid dehydrogenase type 1 (11 β -HSD1) mRNA expression neither in normal nor obese patients. Associations between metabolic and anthropometric parameters and TLR4 mRNA level: There was a positive correlation between plasma glucose concentrations and the TLR4 mRNA expression in VAT ($r^2=0.3536$, $p=0.0005$). The ratio of VAT and SAT TLR4 mRNA expression correlated positively with BMI ($r^2=0.1974$, $p=0.0139$). Relationship between TLR4 and GR mRNA level: GR mRNA expression was positively correlating with TLR4 in both SAT ($r^2=0.6285$, $p<0.0005$) and VAT ($r^2=0.2532$, $p=0.0054$). Expression of TLR4 and TNF- α mRNA in primary culture of human adipocytes: VAT was obtained from 5 normal subjects for primary culture. TLR4 mRNA was remarkably increased at the end stage of differentiation (1.5-fold, $p<0.01$). Treatment of differentiated adipocytes with 500 μ g/ml FFAs for 24 h significantly induced TNF- α mRNA expression 2.5-fold ($p<0.01$).

Conclusion: Depot-specific differences in mRNA levels of TLR4 and TNF- α , GR, Leptin were present in people. The increased GR expression and activated TLR4 pathway in human adipose tissue may reflect a causal role in visceral fat accumulation during adult.

The cytokine Interleukin-18 is involved in the regulation of lipogenic gene expression in liver

R. Stienstra, M.G. Netea, A. Hijmans, C.J. Tack

General Internal Medicine, UMC St Radboud University, Nijmegen, Netherlands

Background and aims: The development of obesity leads to increased levels of pro-inflammatory cytokines resulting in a chronic low grade inflammation. Obesity-induced inflammation is associated with metabolic abnormalities including insulin resistance. However, not all pro-inflammatory cytokines unequivocally participate in the development of obesity-induced inflammation. Whereas TNF α induces insulin resistance, interleukin-18 (IL-18) appears to have opposite metabolic effects. While the pro-inflammatory cytokine IL-18 has initially been identified as a potent inducer of interferon gamma production, recent studies have revealed an important role of IL-18 in controlling energy metabolism and improving insulin sensitivity. Animals lacking IL-18 spontaneously developed obesity and insulin resistance and treatment with recombinant IL-18 partly reversed these metabolic abnormalities. Although not much is known about the tissue-specific effects of IL-18 in controlling the development of obesity and insulin resistance, it has been demonstrated that liver expresses has high steady state levels of IL-18. Therefore, the aim of this study was to learn more about the specific metabolic role of IL-18 in liver.

Materials and methods: We performed immunohistochemistry and applied microarray analysis to compare gene expression patterns in the liver from Wild type and IL-18-/- animals. In addition, the metabolic effects of recombinant IL-18 treatment in Wild type mice were studied.

Results: Immunohistochemical analysis revealed that hepatic IL-18 is localized in macrophages and hepatocytes. Microarray analysis to compare hepatic gene expression profiles of Wild type and IL-18-/- animals uncovered that numerous genes involved in lipogenesis including SCD-1, Fatty Acid Synthase (FAS), ATP citrate lyase (ACLY) and SPOT-14 were significantly elevated in IL-18-/- mice. In line with increased lipogenic gene expression levels in liver, hepatic triglyceride content was elevated in IL-18-/- animals compared to Wild type mice. In addition, plasma analysis showed a significantly increase in plasma triglycerides concentrations in IL-18-/- animals which were mainly carried in VLDL particles. Interestingly, treatment of Wild type mice with recombinant IL-18 (rIL-18) led to suppression of many lipogenic genes in liver suggesting direct regulation by IL-18. The suppression of lipogenesis by rIL-18 was accompanied by an improvement of insulin sensitivity in Wild type mice.

Conclusion: IL-18 is localized in hepatocytes and Kupffer cells and plays an important role in controlling the hepatic expression of key genes involved in lipogenesis. As such, IL-18 may be an important link between the development of fatty liver and the induction of insulin resistance.

Increased liver fat in type 2 diabetes patients is associated with decreased hepatic glucose uptake and phosphorylation rate: studies using PET and MR spectroscopy

J.W. Smit¹, L.J. Rijzewijk², R.W. van der Meer³, M. Lubberink⁴, J.A. Romijn¹, J.J. Bax⁵, A. de Roos⁵, A.A. Lammertsma⁴, H.J. Lamb⁵, M. Diamant²

¹Endocrinology, Leiden University Medical Center, ²Diabetescenter, VU University Medical Center, Amsterdam, ³Radiology, Leiden University Medical Center, ⁴Nuclear medicine and PET research, VU University Medical Center, Amsterdam, ⁵Cardiology, Leiden University Medical Center, Netherlands

Background and aims: Type 2 diabetes mellitus (T2DM) is characterised by insulin resistance and lipid accumulation in non-adipose tissues, in particular hepatic steatosis. The aim of the present study was to investigate whether the amount of liver fat content, as measured by proton [¹H]-magnetic resonance spectroscopy ([¹H]-MRS) influences hepatic glucose uptake and the rate of glucose phosphorylation, assessed by positron-emission tomography (PET) using [¹⁸F]-fluoro-2-deoxy-glucose [¹⁸FDG] in males with uncomplicated T2DM and healthy males with normal glucose metabolism.

Materials and methods: Twenty-two men with uncomplicated T2DM treated with sulfonylureum monotherapy (mean \pm SD: age 58 \pm 4 yrs; BMI 28 \pm 4 kg \cdot m²; HbA_{1c} 7.1 \pm 0.9%) and 14 age- and BMI-matched healthy men underwent [¹H]-MRS and [¹⁸FDG]-PET of the liver, the latter under euglycaemic hyperinsulinaemic clamp conditions to determine whole-body insulin sensitivity, and MR-measurements of visceral fat. T2DM patients were divided in two groups according to median (10.3%) liver fat content, to create a T2DM-low (n=10) versus T2DM-high (n=12) liver fat group. A two tissue compartment model was used to quantify the net [¹⁸FDG] uptake (hepatic glucose uptake = net [¹⁸FDG] uptake \cdot plasma glucose) and the rate of hepatic glucose phosphorylation.

Results: Controls had similar hepatic fat content as T2DM-low subjects. Whole-body insulin resistance was highest in T2DM-high, relative to T2DM-low and controls (0.48 \pm 0.58, 0.76 \pm 0.34 and 1.29 \pm 0.57 mmol/ml/min \cdot pmol/l respectively; one-way ANOVA $p=0.001$). T2DM-high, relative to controls had the lowest hepatic glucose uptake (17 \pm 70 versus 33 \pm 15 nmol/ml/min; $p=0.003$ and the lowest rate of hepatic glucose phosphorylation (0.00464 \pm 0.00222 versus 0.00736 \pm 0.00317 min⁻¹; $p=0.028$). Hepatic glucose uptake was negatively correlated with HbA_{1c} ($r=-0.524$, $p=0.001$), visceral fat content ($r=-0.548$, $p=0.001$), alanine aminotransferase ($r=-0.428$, $p=0.009$) and non-esterified fatty acid (NEFA) levels during clamp ($r=-0.518$, $p=0.001$). Similarly, hepatic glucose phosphorylation was inversely associated with HbA_{1c} ($r=-0.451$, $p=0.006$), visceral fat content ($r=-0.506$, $p=0.002$) and NEFA levels during clamp ($r=-0.442$, $p=0.008$). Stepwise multivariate analysis in patients revealed liver fat content and HbA_{1c} to be independent determinants of hepatic glucose uptake ($R^2=0.52$, $p<0.001$).

Conclusion: By combining liver [¹H]-MRS and [¹⁸FDG]-PET we were able to show that in patients with uncomplicated and well-controlled T2DM, increased liver fat is associated with impaired hepatic glucose uptake and a decreased glucose phosphorylation rate. Liver fat content appeared the strongest predictor of decreased hepatic glucose uptake.

167

Differential effects of diets rich in medium- versus long-chain triacylglycerols on muscular lipid and acylcarnitine content do not affect glucose tolerance in rats

J. De Vogel^{1,2}, J. Hoeks², S.M. Houten³, S. Timmers^{1,2}, M.K. Hesselink⁴, P. Schrauwen^{1,2}

¹Nutrition and Health, TI Food & Nutrition, Wageningen, ²Department of Human Biology, NUTRIM, Maastricht University, ³Laboratory Genetic Metabolic Diseases, Academic Medical Centre, Amsterdam, ⁴Department of Movement Sciences, NUTRIM, Maastricht University, Netherlands

Background and aims: High-fat long-chain triacylglycerol (HFLCT) diets are associated with obesity, diabetes and insulin resistance, amongst others via accumulation of triacylglycerol and acylcarnitine levels in skeletal muscle. Medium-chain triacylglycerols (MCT) are more readily degraded and absorbed in the small intestine than LCT's and are preferentially β -oxidized. Therefore, we studied the effects of a HFMCT diet on muscle lipid storage and metabolism, and whole body glucose tolerance.

Materials and methods: During eight weeks we subjected rats to a low fat (10 energy% from fat) LCT control, a HFLCT or an isocaloric HFMCT diet (47

energy% from fat). Whole body glucose tolerance was determined after a 6hr fast with an intra peritoneal glucose load of 1.5 g/kg. Muscle triacylglycerol content was analyzed in freeze-dried and dissected muscle fibers using gas chromatography. Furthermore, acylcarnitine profiles were studied as a marker of metabolic overload to muscle mitochondria using mass spectrometry.

Results: No differences in body weight gain ($p=0.946$) or net energy uptake ($p=0.15$) were observed between the diets. Only the HFLCT increased the level of triacylglycerol compared to controls (2.06 ± 0.17 vs 1.36 ± 0.12 and 1.49 ± 0.16 $\mu\text{g}/\text{mg}$ freeze dried muscle in HFLCT, control and HFMCT respectively, $p=0.014$; $n=7-9$). The HFLCT but not the HFMCT diet increased the total amount of skeletal muscle long-chain acylcarnitines (C14:0, C16:0, C18:0, C18:1, C20:1) compared with the control diet ($p<0.05$). Whole body glucose tolerance was not significantly changed after either high fat diet compared with control (802 ± 40 , 772 ± 18 and 886 ± 18 AUC, control, HFLCT and HFMCT, respectively, $n=5-6$).

Conclusion: A diet rich in LCT, in contrast to MCT, increases intramyocellular lipid and acylcarnitine content compared to a low fat control diet. Despite these marked differences in muscular fat content, however, whole body glucose tolerance was similar between diets. This might suggest that accumulation of triacylglycerol and acylcarnitine in muscle not necessarily leads to whole body glucose intolerance.

Evaluation of intramyocellular and subsarcolemmal mitochondrial structure and function in type 2 diabetes

E. Phielix¹, P. Schrauwen¹, E.M. Kooi², V.B. Schrauwen-Hinderling^{1,2}, M.K.C. Hesselink³

¹Human Biology, ²Radiology, ³Human Movement Sciences, Maastricht University, Netherlands

Background and aims: Mitochondrial dysfunction has been implicated in the development of type 2 diabetes mellitus (T2DM). Here we examined mitochondrial content, size and density in relation to in vivo mitochondrial function in T2DM patients, first-degree relatives (FDR) of diabetic patients, and control subjects.

Materials and methods: Nine T2DM patients, 11 FDR and 8 control subjects were included, all matched for age and BMI (age (y): 62.4 ± 1.4 , 60.4 ± 0.9 and 60.0 ± 0.7 ; BMI (kg/m^2): 28.8 ± 0.8 , 29.9 ± 1.2 and 27.2 ± 0.5 ; respectively). Insulin sensitivity was determined with a hyperinsulinemic-euglycemic clamp combined with indirect calorimetry. In vivo mitochondrial function was determined as rate constant (k) of phosphocreatine recovery post-exercise using ³¹phosphorus magnetic resonance spectroscopy (³¹P-MRS). We analyzed intramyofibrillar (IMF)- and subsarcolemmal (SS) mitochondrial size (mean mitochondrial area (μm^2)), content (number of mitochondria per cell area ($\#/\mu\text{m}^2$)) and density (mitochondrial size relative to myofibrillar area for IMF mitochondria and subsarcolemmal area for SS mitochondria (%)) by electron microscopy in muscle tissue from the m. vastus lateralis.

Results: Insulin sensitivity was lower in T2DM compared to control subjects (insulin-stimulated Rd: 9.2 ± 2.2 vs. 25.0 ± 3.0 ; $p<0.05$), with intermediate values for FDR (17.1 ± 2.7 , ns). In vivo mitochondrial function was reduced in T2DM patients and FDR compared to control subjects (0.031 ± 0.003 , 0.032 ± 0.002 vs. 0.045 ± 0.005 s⁻¹; $p<0.05$; respectively). Between groups, no differences were found for IMF and SS mitochondrial size, content and density. However, SS mitochondrial content seemed to be lower in T2DM compared to control subjects (1.3 ± 0.2 vs. 2.3 ± 0.3 $\#/\mu\text{m}^2$; $p=0.13$), with intermediate values for FDR (1.8 ± 0.3 $\#/\mu\text{m}^2$), but these differences did not reach statistical significance. Joint examination of all three groups revealed that in vivo mitochondrial function correlated positively with SS mitochondrial content (Spearman's rho: 0.5; $p<0.05$). IMF mitochondrial density correlated positively with basal fat oxidation ($\mu\text{mol}/\text{kg}/\text{min}$) (Spearman's rho: 0.5; $p<0.05$).

Conclusion: From these preliminary results no significant differences were found for IMF and SS mitochondrial size, content and density between groups. Additional subjects are currently enrolled to investigate if SS mitochondrial content may underlie reduced in vivo mitochondrial function observed in type 2 diabetes.

A study of glucagon secreting cells by a novel whole pancreas tissue slice approach: NADH desensitization of a cell KATP channel contributes to glucose-inhibited glucagon release

Y.-C. Huang^{1,2}, M. Rupnik², H.Y. Gaisano¹

¹Medicine, University of Toronto, Canada, ²Medical faculty, Institute of Physiology, University of Maribor, Slovenia

Background and aims: Glucagon is released from islet α cells at low blood glucose while insulin is released from β cells when glucose levels rise. In β cells, ATP-sensitive potassium (KATP) channels act as the major link between glucose metabolism and insulin secretion. Given that α cells also express KATP channels, it remains elusive why glucagon secretion in α cells ceases when glucose metabolism is at the highest. As anaerobic glycolysis is more essential in α cells compared to β cells, we tested the hypothesis that intermediates derived from glucose metabolism such as NADH could modulate KATP channel sensitivity to ATP.

Materials and methods: We have surmounted the α cell culture limitations by employing the whole pancreas slice preparation, a technique that preserves the islet architecture and cell-to-cell communication. We optimized whole cell patch clamp approach to readily distinguish α cells, thereby boosting the α cell yield. Statistics is shown as mean \pm s.d., n indicates the number of a cells tested.

Results: α cells within tissue slices displayed apparent A-type K⁺ current and Na⁺ current which were previously found to be diminished or even completely absent in the conventional dispersed α cells system. Voltage-activated Na⁺ channel half inactivation potential was measured to be -41.4 ± 7.8 mV ($n=31$), consistent with previous studies, and the Na⁺ current amplitude in α cells yielded 287 ± 117 pA ($n=31$). α cell sizes were distributed at 3.9 ± 1.0 pF ($n=65$). Two voltage dependent Ca²⁺ current (VDCC), likely to be attributed by the reported low- and high-VDCCs, were observed. The mean Ca²⁺ current amplitude averaged -26 ± 9 pA and -41 ± 12 pA, and each peaked at -26 ± 5 mV and -1 ± 5 mV respectively ($n=34$). α cell membrane capacitance increased when $[\text{Ca}^{2+}]_i$ was elevated, indicating exocytotic activity. 72% of cells examined increased in membrane capacitance after trains of depolarization and all cells responded to photo-release of caged Ca²⁺. KATP channels opened readily when dialyzed with ATP free pipette solution, although the maximal KATP conductance between the different α cells varied significantly. 43% of cells reached a mean peak conductance of 7 ± 2 nS at 384 ± 183 s and 38% cells reached an average conductance of 15 ± 1 nS at 295 ± 176 s. 17% of cells revealed almost no KATP conductance throughout the dialysis. The peak conductance indicates the fraction of the KATP channels on the plasma membrane, while time to reach the peak KATP conductance indicates overall KATP channel sensitivity to ATP. NADH modulated a cell KATP channel sensitivity to ATP. When dialyzing 1mM NADH but ATP free pipette solution into α cells, 79% KATP conductances reached an average peak conductance of 4 ± 1 nS after 218 ± 129 s.

Conclusion: Our data validated the feasibility of studying α cells in whole pancreas tissue slice by examining the α cell electrophysiological properties. We further confirmed that glucagon exocytosis is calcium dependent. α cells can potentially be divided into discrete subpopulations according to their maximum KATP conductance. NADH has not only reduced the available fraction of KATP conductance but the sensitivity of the remaining fraction of KATP channels was also reduced. We concluded that glucose-induced inhibition of glucagon release is in part due to ATP desensitization of KATP channels by NADH.

Interleukin-6 regulates pancreatic glucagon production and the expansion of a cell mass in response to high fat feeding

H. Ellingsgaard¹, J.A. Ehses¹, E. Hammar², L. van Lommel³, R. Quintens³, G. Martens⁴, J. Kerr-Conte⁵, F. Pattou⁵, T. Berney², D. Pipeleers⁴, P. Halban², F.C. Schuit³, M.Y. Donath¹

Cell Biology, Katholieke University Leuven, Belgium, ⁴Diabetes Research Center, Brussels Free University, Belgium, ⁵Cell Therapy of Diabetes, INSERM, Lille, France

Background and aims: Interleukin-6 (IL-6) is systemically elevated in obesity and is a predictive factor to develop type 2 diabetes. The relevance and actions of IL-6 on pancreatic islet function and mass are unclear. Pancreatic islet pathology in type 2 diabetes is characterized not only by reduced beta-cell function and mass but also by increased proportion of alpha-cells relative to beta-cells, in addition to alpha-cell dysfunction.

Materials and methods: Detection of the IL-6 receptor was done by gene array and quantitative RT-PCR. Glucagon and insulin mRNA and secretion were assessed in human islets by RT-PCR and RIA for glucagon and insulin. Furthermore, Ki67, BrdU and TUNEL staining determined the effects of IL-6 on islet cell turnover and function. Glucose tolerance, insulin sensitivity, and morphometric quantification of endocrine cells were assessed in WT and IL-6 KO mice after 8 weeks and 18 weeks of high fat diet feeding.

Results: Here we show that the pancreatic islet, specifically the alpha-cell, is a primary target of IL-6 actions. Beginning with investigating the tissue-specific expression pattern of the IL-6 receptor in both mice and rats, we find the highest expression of the IL-6 receptor in the endocrine pancreas, with highest expression on the alpha-cell. The islet IL-6 receptor is functional, and IL-6 acutely increases glucagon mRNA and glucagon secretion, with no acute effect on insulin secretion. Furthermore, IL-6 stimulates alpha-cell proliferation, inhibits apoptosis, and regulates alpha-cell mass. Using IL-6 KO mice fed a high fat diet for 8 weeks, we find that IL-6 is required for high fat diet induced increased alpha-cell mass, an effect that occurs early in response to diet change. Further, after 18 weeks of high fat diet feeding, IL-6 KO mice without expansion of alpha-cell mass display increased fed glycemia due to impaired insulin secretion, despite decreased systemic glucagon, unchanged insulin sensitivity, and similar body weights.

Conclusion: Thus, we conclude that IL-6 regulates the expansion of pancreatic alpha-cell mass which may be needed for functional beta-cell compensation in response to high fat diet feeding.

Elevated plasma level of preproinsulin in newly diagnosed type 2 diabetic subjects

L. Li^{1,2}, G. Yang³, W. Chen³, K. Li³, M. Yang³

¹The Key Laboratory of Laboratory Medical Diagnostics in Ministry of Education, Chongqing Medical University, ²Department of Clinical Biochemistry, Chongqing Medical University, ³Department of Endocrinology, the Second Affiliated Hospital, Chongqing Medical University, China

Background and aims: Preproinsulin is a new regulatory peptide that consists of 34-amino acid derived from proinsulin-like growth factor II (proIGF-II). It is synthesized by pancreatic β -cells and secreted along with insulin and amylin. Previous study has demonstrated that preproinsulin enhanced pancreas secretion of insulin. Infusion of isolated pancreas with anti-preproinsulin antibodies significantly reduced glucose-mediated insulin secretion. However, the physiological effects of preproinsulin on the regulation of body metabolism are unknown, especially its role in the pathogenesis of diabetes and insulin resistance (IR). In this study we investigate whether plasma preproinsulin level is different in patients with impaired glucose tolerance (IGT) and type 2 diabetes mellitus (T2DM).

Materials and methods: Fifty patients with T2DM, 56 subjects with IGT, and 54 sex- and age-matched normal controls participated in the study. Plasma preproinsulin levels were measured with a radioimmunoassay. The relationship between plasma preproinsulin levels and anthropometric and metabolic parameters was also assessed.

Results: Plasma preproinsulin levels were found to be increased in patients with T2DM compared with IGT and controls (456 ± 14 vs. 416 ± 13 and 398 ± 13 ng/L, $P < 0.05$ and $P < 0.01$). There were significant difference between male and female in plasma preproinsulin levels (403 ± 10 vs. 432 ± 10 ng/L, $P < 0.05$). Fasting plasma preproinsulin was found to correlate positively with DBP ($r = 0.20$, $P < 0.01$), TG ($r = 0.24$, $P < 0.01$), TC ($r = 0.24$, $P < 0.01$), HDL-C ($r = 0.18$, $P < 0.05$), FFA ($r = 0.21$, $P < 0.01$), 2hOGTT ($r = 0.18$, $P < 0.05$), HbA_{1c} ($r = 0.19$, $P < 0.01$), and HOMA-IR ($r = 0.13$, $P < 0.05$) in simple regression analysis in the pooled data, while in multiple stepwise regression analysis, only DBP, TG, HDL-C and FFA were independent related factors with plasma preproinsulin levels. The multiple regression equation was: $Y_{\text{preproinsulin}} = 147.959 + 1.876X_{\text{DBP}} + 17.827X_{\text{TG}} +$

$47.869X_{\text{HDL-C}} + 59.964X_{\text{FFA}}$. The plasma preproinsulin levels were also significantly associated with T2DM even after controlling for anthropometric variables, blood pressure and lipid profile. Increasing levels of preproinsulin showed a significant linear trend and were independently associated with T2DM, especially when concentrations were analysed both by Mow Mean Scores and Cochran-Armitage Trend Test.

Conclusion: Our results of elevated preproinsulin in newly diagnosed T2DM indicate that preproinsulin may play a role in the pathogenesis of T2DM. However, further experiments need to be done to clarify the role of preproinsulin.

T2 and T3 stimulate glucose-induced insulin secretion in INS-1E cells and human islets

A. Antonelli¹, E. Santini¹, M. Bugliani², E. Barsotti¹, S. Ferrari¹, P. Fallahi¹, P. Marchetti², F. Goglia³, E. Ferrannini¹

¹Dept.Int.Med., Metabolic Unit, University of Pisa, Italy, ²Dept.Int. Med., Diabetic Unit, University of Pisa, Italy, ³Dip.Scienze Biologiche ed Ambientali, University of Sannio, Benevento, Italy

Background and aims: Recent evidence suggests that 3,5-diiodo-L-thyronine (T2), a naturally occurring iodothyronine, is biologically active. Whether T2 exerts any effect on β -cells is unknown.

Materials and methods: INS-1E cells were incubated (for 48 hours) in fresh RPMI 1640 medium containing 11 mM glucose in the presence or absence of different concentrations [0.1 nM, 1 nM, 0.1 micromolar (mM), 1 mM and 10 mM] of T2 or triiodothyronine (T3). After washing, cells were incubated for 60 min with KRB-HEPES buffer containing 3.3, 7.5, 11.0 or 20 mM glucose. The supernatants were collected for insulin determination and cellular insulin content was determined from acid-ethanol extracts. Pancreatic islets from human donors were isolated and cultured by standard procedures. The islets were then washed and incubated at 37 °C for 45 min in KRB solution containing 3.3 mM glucose, either with or without the addition of T3 or T2 (0.1 nM, 0.1 mM, 1 mM).

Results: In INS-1E cells, at medium glucose concentrations of 11.0 and 20.0 mM, insulin secretion and content were significantly ($p < 0.01$ by ANOVA) stimulated by T2 in the range 1 nM - 0.1 mM, while an inhibition ($p < 0.01$) was observed with higher concentrations (1-10 mM). T3 showed a similar pattern of stimulation, with a significant ($p < 0.01$) stimulation of insulin release and content at 0.1 - 1 mM and a significant inhibition at higher T3 concentrations (10 mM). In human pancreatic islets, insulin secretion was significantly ($p < 0.01$) stimulated by 0.1 nM and 0.1 mM T2, while an inhibition was observed with the highest concentration (1 mM). A slight increase of insulin secretion was observed with 1 mM T3.

Conclusion: In INS-1E cells and human islets, both T2 and T3 dose-dependently modulate glucose-induced insulin secretion, lower hormone concentrations being stimulatory and higher concentrations being inhibitory. These effects are detectable with lower T2 than T3 concentrations.

173

Subcutaneous fat shows higher thyroid hormone receptor- α gene expression and higher TR α 1:TR α 2 ratio than omental fat

F.J. Ortega¹, J.M. Moreno-Navarrete¹, V. Ribas², E. Esteve¹, J. Vendrell¹, W. Ricart¹, A. Zorzano², J.M. Fernandez-Real¹

¹Unidad de Diabetes, Endocrinología y Nutrición, Hospital of Girona, Spain, ²Departament de Bioquímica i Biologia Molecular, Institute for Research in Biomedicine (IRB), CIBERDEM, Barcelona, Spain, ³Unidad de Diabetes, Endocrinología y Nutrición, Hospital of Tarragona, Spain

Background and aims: Differential thyroid hormone receptor alpha (TR α) gene expression and, specifically, TR α 1:TR α 2 ratio, may explain some of regional differences in human adipose tissues. As a central regulatory factor of lipogenic and lipolytic pathways, the gene encoding TR α 1 and the TR α 1:TR α 2 ratio was identified as a candidate gene for explaining regional differences between intra-abdominal and subcutaneous human adipose tissue.

Materials and methods: In 84 samples of visceral and subcutaneous adipose tissue from 42 participants (men or women; lean or obese), we investigated TR α gene expression, TR α 1 and TR α 2 mRNA levels and the TR α 1:TR α 2 ratio (assessed by RT-PCR). Arginine-serine-rich proteins (SF2), heterogeneous nuclear ribonucleoprotein H1 (hnRNP H1) and heterogeneous nuclear ribo-

nucleoprotein A1 (hnRNP A1), three splicing proteins involved in alternative and constitutive TRa pre-mRNA splicing, and Spot 14 (S14), one of the most relevant target genes for TRa1 activated by T3, gene expression were also studied.

Results: TRa gene expression was increased ~1.45-fold in subcutaneous vs. visceral fat. TRa1 mRNA was also increased ~1.81-fold while the TRa1:TRa2 ratio was ~2.18-fold higher in subcutaneous than in visceral fat. S14 gene expression was increased by ~2.31-fold in subcutaneous vs. visceral adipose tissue and correlated significantly with TRa gene expression, TRa1 mRNA presence and, more significantly, with the TRa1:TRa2 ratio in both tissues. Moreover, hnRNP A1:SF2 ratio was decreased by ~1.31-fold.

Conclusion: Subcutaneous fat shows higher thyroid hormone receptor- α gene expression and higher TRa1:TRa2 ratio than omental fat.

Human islet amyloid peptide induced apoptosis of human liver cell line HepG2 via endoplasmic reticulum stress

X. Gu¹, R. Fan¹, K. Li¹, X. Li¹, R. Laybutt², G. Xu¹, J. Chan¹

¹Medicine and Therapeutics, The Chinese University of Hong Kong, SAR, China, ²Diabetes and Obesity Research Program, Garvan Institute of Medical Research, St Vincent's Hospital, Sydney, Australia

Background and aims: In states of insulin resistance, increased insulin requirement will lead to increased production of islet amyloid peptide (IAPP). Many studies have provided evidence that human IAPP (hIAPP) is cytotoxic in islets and the brain both *in vitro* and *in vivo*. Although liver is one of the important insulin resistant targeted organs in type 2 diabetes, the effects of hIAPP on human liver cells remain unclear. In the present study we aim to examine the hypothesis that hIAPP disrupts the homeostasis of the endoplasmic reticulum (ER) in liver cells and this promotes ER stress and apoptosis.

Materials and methods: HepG2 human liver cells were exposed to varying concentrations of hIAPP for 24 hours and MTT assay was conducted to measure the cell viability. Cell Immunofluorescent staining with anti-caspase3 antibody and DAPI were used to monitor apoptosis. Protein expression level of cleaved caspase3 was also tested by Western Blot. ER homeostasis of HepG2 cells was monitored over a time course of hIAPP treatment using markers of the ER stress response pathway, including phosphorylation of PERK and eIF2 α , and spliced XBP-1 by Western Blot. Other markers of the ER stress response pathway, including CHOP and BIP were measured by real time RT-PCR.

Results: hIAPP lead to cytotoxicity in HepG2 cells in dose-dependent pattern with the IC₅₀ of 7.74 μ mol/l. hIAPP (4 μ mol/l and 8 μ mol/l) induced typical apoptosis of HepG2 cells as evidenced by increased anti-caspase3 immunofluorescent staining and characteristic condensed apoptotic nuclei stained with DAPI. The expression of cleaved caspase-3 was also highly up regulated after hIAPP treatment by Western blot. Incubation with hIAPP (4 μ mol/l and 8 μ mol/l) resulted in phosphorylation of PERK with the peak at 2 hours after treatment and phosphorylation of eIF2 α with the peak at 4 hours after treatment. The expression of XBP-1 was also up regulated with the peak at 12 hours after treatment. However, incubation HepG2 cells with hIAPP (4 μ mol/l and 8 μ mol/l) did not significantly change the expression levels of CHOP and BIP.

Conclusion: These data demonstrated that hIAPP induced apoptosis and disrupted ER homeostasis in HepG2 liver cells.

Live imaging of glucose homeostasis in MIN6 cells and primary beta cells by fluorescence microscopy

M.T. Kaminski, S. Lenzen, S. Baltrusch

Institute of Clinical Biochemistry, Hannover Medical School, Germany

Background and aims: An increase in the intracellular glucose concentration is the stimulating signal for insulin release in pancreatic beta cells. In addition, changes in the intracellular glucose concentration mediate protein expression and modifications. The recently developed FLI1¹Pglu600 μ - δ 6 (FLIPglu) sensor based on FRET (fluorescence resonance energy transfer) is a fusion construct specifically detecting glucose. We could successfully established the FLIPglu sensor to monitor in real-time the intracellular glucose concentration in insulin-secreting cells. The aim of this study was to analyze glucose uptake and metabolism with the FLIPglu sensor in insulin-secreting MIN6 cells as well as in primary beta cells.

Materials and methods: The FLIPglu sensor was stably expressed in insulin-secreting MIN6 cells. Primary rat and mouse beta cells were transduced with a recombinant adenovirus expressing the FLIPglu sensor. The dynamic changes in the intracellular glucose concentration were analyzed in a perfusion chamber in the absence and presence of glucose and selective inhibitors of glucose uptake and metabolism, respectively, by fluorescence microscopy. FRET was calculated offline as enhanced yellow fluorescence protein (EYFP)/enhanced cyan fluorescence protein (ECFP) emission intensity ratio upon ECFP excitation.

Results: In MIN6 cells as well as in primary beta cells expressing the FLIPglu sensor changes in the intracellular glucose concentration were positively correlated with the detected changes in the EYFP/ECFP ratio upon ECFP excitation. Thus, glucose homeostasis in a living single cell could be described by calculating the rates of sugar uptake and metabolism, respectively. Glucose uptake of MIN6 cells was significantly lower upon addition of Krebs Ringer medium containing 10 mM of the glucose analogue 3-O-methylglucose in addition to 10 mM glucose in comparison to 10 mM glucose alone. In contrast, no significant changes in the glucose uptake rate were observed, when the cells were perfused with a mixture of 10 mM glucose and 10 mM 2-deoxyglucose. Glucose consumption in insulin-secreting cells was investigated by calculating the decrease of the EYFP/ECFP ratio after glucose removal. Incubation of MIN6 cells in Krebs Ringer medium supplemented with 50 mM mannose, which reduces the phosphorylation of glucose caused in the presence of 10 mM glucose a significant decrease in the glucose metabolism compared to incubation at 10 mM glucose alone.

Conclusion: Alterations in glucose homeostasis in insulin-secreting cells could be monitored using the FLIPglu sensor. Furthermore, generation of the recombinant adenoviral FLIPglu sensor construct will open the way to further elucidating glucose homeostasis in living primary beta cells of healthy individuals and those with type 2 diabetes mellitus.

Protein kinase B (PKB/Akt) α and β are required for normal metabolic regulation in the periphery but dispensable for maintenance of islet mass

F. Buzzzi¹, L. Xu¹, R.A. Zuellig¹, S.B. Bollert¹, G.A. Spinas¹, O. Tschopp^{1,2}, D. Hynx², B.A. Hemmings², M. Niessen¹

¹Endocrinology and Diabetes, University Hospital Zurich, ²Department for Growth Control, Friedrich Miescher Institute for Biomedical Research, Basel, Switzerland

Background and aims: Adaptation of islet mass and function relative to metabolic demand is required to avoid the development of type 2 diabetes. PKB is considered to be a key target downstream of IRS2 in the regulation of β -cell mass. Particularly, constitutive activation of the α isoform is sufficient to increase islet mass. Strikingly, only loss of the PKB β isoform leads to a mild metabolic phenotype, whereas PKB α and γ were found not to be required for metabolic regulation. Aim of this project is to better characterise the role of PKB isoforms in the regulation of islet mass.

Materials and methods: Phenotypic analysis of mice (between one and six months old) deficient for individual PKB isoforms and comparison with wild type littermates: assessment of body weight, random blood glucose, insulin and glucagon; analysis of glucose-stimulated insulin secretion in isolated is-

lets; immunostaining of pancreatic sections to determine islet mass, α - and β -cell mass, proliferation and apoptosis.

Results: *Pkba*^{-/-} mice were smaller (30.4±0.7g vs. 36.7±1.7g, n=6-7, $P<0.05$), had lower blood glucose (5.4±0.3mM vs. 6.3±0.7mM, n=6, $P<0.05$) and increased serum glucagon (0.22±0.1pg/ml vs. 0.03±0.02pg/ml, n=3-4, n.s.). Analysis of pancreatic sections revealed a trend toward increased α -cell mass (1.79±0.81 fold, n=3-4, n.s.) and proliferation (2.91±0.92 fold, n=3-4, n.s.). β -Cell mass and proliferation were unchanged. *Pkbb*^{-/-} mice were smaller (31.6±2.1 vs. 41.9±1.6g, n=14, $P<0.05$), had higher blood glucose levels (11.8±1.0mM vs. 6.7±0.3mM, n=11-14, $P<0.05$) and increased serum insulin (15.8±2.2ng/ml vs. 3.9±0.9ng/ml, n=13, $P<0.05$). Furthermore, islet mass was significantly increased (2.82±0.64 fold, n=4-6, $P<0.05$) with higher β -cell proliferation (2.92±1.19 fold, n=4-5, n.s.). α -Cell mass and proliferation were unchanged. Data were obtained from 5-6 months-old male mice, and analysis of younger mice and females gave similar results. *Pkby*^{-/-} mice showed no metabolic or islet phenotype.

Conclusion: Previous studies had suggested that the metabolic PKB function is not redundant in the periphery and that only PKB β is required for normal insulin sensitivity. Although our results confirm this phenotype for *Pkbb*^{-/-} mice, we have found lower blood glucose levels combined with increased glucagon levels and α -cell proliferation in *Pkba*^{-/-} mice. Lower blood glucose levels might be due to higher insulin sensitivity in the absence of PKBa. However, lower than normal blood glucose levels and compensatory increase in α -cell mass have also been observed in mice deficient for the glucagon receptor. PKBa might therefore be required for normal glucagon signalling. Importantly, PKB-deficient mice do not show loss of islet mass, in contrast to the phenotype of IRS2-deficient mice which display severe loss of β -cells at similar age. Unlike in the periphery, PKB function might therefore be redundant in β -cells. However, our results are also consistent with a recently proposed model which suggests that PKBa is required for compensatory expansion but not maintenance of β -cell mass.

In situ characterisation of plasma membrane PtdIns(4)P and PtdIns(4,5)P₂ turnover in individual insulin secreting cells

A. Wuttke, A. Tengholm

Medical Cell Biology, Uppsala University, Sweden

Background and aims: The phospholipid phosphatidylinositol 4-phosphate [PtdIns(4)P] is a key component of cellular membranes. It is generated from phosphatidylinositol via PI4-kinases and serves as precursor for the generation of phosphatidylinositol 4,5-bisphosphate [PtdIns(4,5)P₂], which in turn is important in a variety of cellular processes, including insulin secretion. Little is known about the regulation of PtdIns(4)P. The aim of this study was to investigate the kinetics of the plasma membrane pools of PtdIns(4)P and PtdIns(4,5)P₂ by in situ imaging the molecules in individual β -cells.

Materials and methods: PtdIns(4)P was measured with the PH domains from the oxysterol binding protein or four-phosphate-adaptor protein 1 fused to cyan fluorescent protein (OSBP-CFP, FAPP1-CFP), whereas PtdIns(4,5)P₂ was recorded with the yellow fluorescent protein-tagged PH domain from phospholipase C- δ (PLC δ -YFP). Localization and translocation of the biosensors were analyzed with confocal and evanescent wave microscopy in individual MIN6 β -cells. The kinetics of phosphoinositide synthesis and breakdown were determined after plasma membrane permeabilization with α -toxin.

Results: Confocal microscopy demonstrated a strong localization of the PtdIns(4)P-binding probes to the Golgi complex, consistent with the important role of the lipid in this organelle, but there was no distinct binding to the plasma membrane. In contrast, evanescent wave microscopy revealed a clear plasma membrane localization of both PtdIns(4)P-binding probes. This membrane localization was lost when the cells were permeabilized in ATP-free solution. Addition of 0.25-3 mM ATP caused dose-dependent reassociation of the PtdIns(4)P biosensors to the plasma membrane. Simultaneous imaging of PtdIns(4,5)P₂ and PtdIns(4)P revealed that PtdIns(4)P was often formed at lower ATP concentrations than PtdIns(4,5)P₂ and that the ATP-induced translocation of the PtdIns(4)P-sensing constructs usually preceded that of the PtdIns(4,5)P₂ biosensor. Inhibition of type III PI4-kinases with 200 μ M LY294002 abolished the synthesis of both PtdIns(4)P and PtdIns(4,5)P₂. However, while the fluorescence of the PtdIns(4)P biosensor OSBP-CFP started to decrease instantly with biphasic kinetics ($\tau=34\pm4$ s and 395 ± 139 s, n=11), the PtdIns(4,5)P₂ biosensor dissociated from the membrane in a monophasic manner ($\tau=291\pm47$ s, n=9) after a delay of 39 ± 3 s.

Conclusion: Simultaneous imaging of the plasma membrane pools of PtdIns(4)P and PtdIns(4,5)P₂ with evanescent wave microscopy demonstrates that the lipids undergo rapid ATP-dependent turnover with distinct kinetics and that type III PI4-kinases are essential for their synthesis. The rapid turnover of the lipids should allow fast and local generation of second messengers with maintenance of appropriate phosphoinositide levels for insulin secretion.

Crucial role for mitochondrial calcium signals in metabolism-secretion coupling in the pancreatic b-cell

A.C. Wiederkehr¹, K.-S. Park¹, O. Dupont¹, T. Pozzan², C.B. Wollheim¹

¹Department of Cell Physiology and Metabolism, University of Geneva,

Switzerland, ²Department of Biomedical Sciences, University of Padua, Italy

Background and aims: Cytosolic calcium signals are relayed into the mitochondria where calcium activates matrix dehydrogenases reflected by increases in NAD(P)H. However calcium function in the organelle remains obscure. In the pancreatic b-cell this connection between calcium and metabolism is further complicated by the fact that increased nutrient availability raises NAD(P)H levels prior to calcium activation. Here we have evaluated the role of mitochondrial calcium by expressing a calcium buffering protein in the organelle.

Materials and methods: A number of adenovirus-based probes were employed in this study: Ad-cytoAequorin (cytosolic calcium), Ad-mitoAequorin (mitochondrial calcium), Ad-Luciferase (cytosolic ATP), Ad-mitoAlpHi (mitochondrial pH). Kinetic changes of these parameters during metabolism-secretion coupling were analysed 2-3 days after infection of either INS-1E cells or intact rat islets. We have further generated an adenovirus expressing the calcium binding protein S100G fused to a mitochondrial targeting sequence (Ad-mitoS100G) to buffer the mitochondrial calcium rises.

Results: The activation of islet β -cells by glucose results in a rapid onset of the net ATP response followed by a slow increase reaching new steady-state levels 10-15 minutes following glucose activation. In the absence of extra cellular calcium, which prevents both the cytosolic and mitochondrial calcium signal, the ATP response was similar over the first 5 minutes but strongly inhibited thereafter. The results underline the importance of calcium signals in the generation of the high energy compound and coupling factor ATP. Neither alkalinisation of the mitochondrial pH (associated with an increase in delta pH) nor hyperpolarisation of the electrical gradient across the inner mitochondrial membrane evoked by glucose, were altered by the calcium signal. Therefore calcium specifically affects ATP generation in the β -cell without influencing the electrochemical potential, the driving force for the ATP-synthase. To investigate the role of mitochondrial calcium specifically, we massively over-expressed the calcium binding protein S100G in the mitochondrial matrix using Ad-mitoS100G. Over-expression of the transgene indeed buffered mitochondrial calcium responses to glucose by 60%, while the rise due to plasma membrane depolarization (30mM KCl) was lowered by 50% in INS-1E cells. Mitochondrial calcium buffering also reduced the glucose dependent increase of insulin secretion by 56%, whereas the KCl response was only slightly reduced by 16%. General cell function was unaffected by mitochondrial calcium buffering, in as much as basal insulin secretion and insulin content were not changed.

Conclusion: Our results demonstrate that mitochondrial calcium plays a central role in metabolism-secretion coupling possibly affecting the generation of a number of mitochondria-derived coupling factors including ATP.

Beta-arrestin 1: a new molecular partner essential for long term GLP-1 actions in pancreatic beta cells

J. Quoyer¹, C. Longuet², C. Broca¹, S. Costes¹, N. Linck¹, G. Bertrand¹, J. Bockaert¹, S. Dalle¹

¹Team Avenir, Physiopathology of beta-cells, INSERM U661, CNRS 5203, Université de Montpellier (IFR3), Institut de Génétique Fonctionnelle, Montpellier, France, ²Department of Medicine, University of Toronto, Canada

Background and aims: Therapeutic strategies for the treatment of type 2 diabetes based on activating the G-protein coupled GLP-1 receptor on pancreatic beta-cells and enhancing GLP-1 actions are intensively developed. Classically, upon GLP-1 receptor activation adenylyl cyclase is activated by

Gas coupling and cAMP is generated. This leads in turn to cAMP-dependent activation of second messenger pathways such as PKA and ERK1/2 (p44/42 MAP kinase) pathways which are known to play key roles in beta-cell function and survival. Here, we investigated the role of beta-arrestin 1, a scaffold protein known to mediate desensitization, internalization and signaling of G-protein coupled receptor, on the spatiotemporal regulation of the ERK1/2 pathway linked to GLP-1 receptor activation.

Materials and methods: MIN6 cell line, isolated rat islets and human islets were used. Beta-arrestin 1 was invalidated by siRNA. Protein expression and phosphorylation of ERK1/2 and Bad were analysed by western blot. Cellular distribution of beta-arrestin 1 and ERK1/2 was determined by subcellular fractionation and confocal microscopy.

Results: Beta-arrestin 1 was found to be expressed in mouse, rat and human pancreatic beta-cells. We found that GLP-1 (10 nM)-activated receptor stimulates the ERK1/2 signaling cascade by two temporally distinct pathways dependent, respectively, on Gas/PKA and beta-arrestin 1. Gas/PKA-dependent ERK activation was rapid, transient (maximum stimulation observed at 5 min), and blocked by H89 (a PKA inhibitor, 10 μ M) but insensitive to siRNA-mediated depletion of beta-arrestin 1. By contrast, beta-arrestin 1-dependent ERK1/2 activation was slower but more sustained in duration. It was insensitive to H89 but was completely blocked by the depletion of beta-arrestin 1 by siRNA. Remarkably, following GLP-1 stimulation, ERK1/2 associate with beta-arrestin 1 and remain located in the beta-cell cytoplasm. This allows activated ERK1/2 to favour the serine 112 phosphorylation state of the proapoptotic Bcl-2 family member Bad resulting in its proapoptotic inactivation.

Conclusion: These findings show for the first time the existence of a beta-arrestin 1-dependent, G-protein-independent, pathway linked to the GLP-1 receptor leading to sustained ERK1/2 activation. We propose that such signaling pathway may contribute to the special long term efficacy of GLP-1 in beta-cells and may serve as a prototype for a generation of new therapeutic GLP-1 receptor ligands.

insulin gene transcription. On the other hand, the increase in S6K1 activation may contribute to the glucose-dependent effect of GLP-1 on beta-cell proliferation.

Effect of GLP-1 on AMPK, mTOR and p38 MAPK pathways in pancreatic beta cells

K. Bellmann, M. Barbuta, A. Marette

CRML, Centre Hospitalier de l'Université Laval, Québec, Canada

Background and aims: In type 2 diabetes, a decline in functional beta-cell mass causes insulin deficiency leading to hyperglycemia. Insulin secretion from beta-cells is driven by glucose and also in great part by incretins, such as GLP-1, released by the L-cells of the intestine. Indeed, it is thought that GLP-1 is a major contributor to insulin release after an oral glucose challenge. In addition to its positive effect on insulin secretion, GLP-1 also improves beta-cell growth and survival. However, the signaling pathways involved in GLP-1 action on beta-cell function and proliferation remain poorly understood. It has been proposed that AMPK, a key regulator of cellular energy homeostasis, is negatively associated with insulin release. Furthermore, activation of AMPK down-regulates the mTOR pathway, a nutrient sensor and positive effector of beta-cell growth. On the other hand, it has been shown that activation of the p38 MAP kinase pathway is implicated in insulin gene transcription. Until now, only few studies have explored the effect of GLP-1 on mTOR and p38 MAPK signaling in pancreatic beta-cells and whether these signaling pathways are linked to AMPK. In this study, we have therefore evaluated the effects of the incretin GLP-1 on the phosphorylation of AMPK, p38 MAPK and the mTOR pathway in beta-cell lines.

Materials and methods: Several beta-cell lines (RINm5F, β -TC3 and MIN-6) were used to evaluate the effect of GLP-1 on AMPK, p38 MAPK, mTOR and its downstream effector S6K1.

Results: GLP-1 was found to transiently reduce AMPK, as revealed by its phosphorylation on Thr172 in all cell lines tested. Maximal inhibition of AMPK activation was observed after 30 minutes of GLP-1 treatment and returned to baseline levels 2 h post-incretin treatment. Whereas GLP-1 failed to modulate mTOR phosphorylation, a 2 h treatment with the incretin was shown to increase the phosphorylation of its downstream effector S6K1 and this activation was maintained until 4 h of GLP-1 treatment. Interestingly, we also observed a transient increase in p38 MAPK phosphorylation reaching a peak at 1 h post GLP-1 treatment followed by a slow decline until 4 h after incretin exposure.

Conclusion: Since activation of AMPK has been reported to inhibit insulin secretion our data suggest that the transient reduction of AMPK phosphorylation following GLP-1 treatment may contribute to the incretin action on insulin release. Moreover, the observed activation of p38 MAPK may increase

Good overnight closed-loop glucose control in children and adolescents with type 1 diabetes following ingestion of large, rapidly and slowly absorbed evening meal

R. Hovorka¹, C.L. Acerini², J. Allen¹, L.J. Chassin¹, A.F. Larsen¹, D. Mundt², A. De Palma², M.E. Wilinska¹, D.B. Dunger²

¹Institute of Medical Sciences, University of Cambridge, ²Department of Paediatrics, University of Cambridge, United Kingdom

Background and aims: In type 1 diabetes (T1D), large evening meal is accompanied by large prandial insulin dose increasing the risk of nocturnal hyper- and hypoglycaemia due CHO/prandial insulin mismatch. We investigated overnight closed-loop (CL) insulin delivery in children and adolescents with T1D to evaluate the performance of CL following ingestion of rapidly and slowly absorbed large dinner.

Materials and methods: Six children and adolescents with T1D treated by CSII (M1; age 15.1±2.2 years; BMI 22.8±4.5 kg/m²; duration diabetes 6.6±4.4 years; A1C 9.1±2.4%; basal dose 27±13 U/day; bolus dose 27±18 U/day; mean±SD) received overnight CL at a clinical facility on two separate nights 1–4 wks apart. In random order, the subjects ate either rapidly or slowly absorbed dinner matched for carbohydrates (CHO) (rapid vs slow: CHO 129±34 vs 129±34 g; glycaemic load 113±29 vs 40±8; energy distribution 68:12:20 vs 54:29:17% CHO:fat:protein; recommended daily energy intake 32±6 vs 41±11%). Following dinner and prandial insulin (17±6 vs 17±7 U; rapid vs slow) at 18:00h, CL was performed between 18:30–08:00 the next day. Real-time subcutaneous (sc) continuous glucose monitoring (CGM) data was fed into a model predictive controller (MPC) every 15 minutes, which calculated sc insulin infusion for manually adjusted insulin pump. Blood glucose (BG) was sampled every 15min and measured with 3h delay.

Results: *CGM data.* Following rapidly absorbed dinner, 4h incremental glucose area-under-curve (IAUC) was significantly higher (Table). This was accompanied by a non-significant increase in CL insulin delivery. From midnight, glucose excursions were comparable, see Figure showing median (IQ range). Overall, overnight glucose control was good and comparable between two study nights as assessed by mean glucose, time in glucose target 3.9–8.0mM, Kovatchev's Low BG Index (LBGI), Chassin's Grade A+B efficacy rating, and Grade E+F hypo/hyperglycaemia risk index (Table). *BG data.* Compared to CGM data, similar glucose control was observed except higher LBGI [1.4 (0.3–3.5) vs 1.3 (0.9–1.5)] due to CGM overestimation of low glucose values.

Conclusion: In children and adolescents with T1D, 12h overnight CL with MPC results in safe and efficacious glucose control following the ingestion of large evening meal irrespective of its composition.

Comparison of CL following rapidly and slowly absorbed dinner [mean±SD or median (IQR)]

	Rapid	Slow	P
Glucose at 18:30 (mM)	9.0 ±4.4	11.1 ±5.2	NS
Glucose IAUC 18:00 to 22:00 (mM/240min)	798 ± 767	–396 ± 517	0.03
Overnight glucose (mM)	8.4 ±1.9	8.6 ±2.2	NS
Time in target 3.9–8.0mM (%)	59 (49–63)	61 (43–68)	NS
LBGI	0.1 (0.0–1.1)	0.2 (0.0–0.3)	NS
Grade A+B (%)	45 (40–52)	51 (38–65)	NS

Marked improvement of glycaemic control, and more time in euglycaemia without increase of hypoglycaemia with CIPII compared to CSII in type 1 diabetes

S.J.J. Logtenberg^{1,2}, N. Kleefstra^{1,2}, S.T. Houweling², K.H. Groenier³, H.J.G. Bilo^{1,4}

¹Diabetes Centre, Isala Clinics, Zwolle, ²Medical Research Group, Langerhans, Zwolle, ³General Practice, UMCG, Groningen, ⁴Internal Medicine, UMCG, Groningen, Netherlands

Background and aims: To investigate whether continuous intraperitoneal insulin infusion (CIPII) delivered with an implantable pump is safe and provides equal or superior glycaemic control with less episodes of hypoglycaemia as compared to intensive subcutaneous insulin therapy (SC; multiple dose injections (MDI) or continuous subcutaneous insulin infusion (CSII)) in poorly controlled type 1 diabetes patients.

Materials and methods: Open-label, randomized controlled cross-over trial. After a 3-month qualification phase, during which optimization of insulin therapy was targeted, patients who had a HbA_{1c} >7.5% and/or ≥5 hypoglycaemic events/week were randomized to receive either 6 months CIPII followed by 6 months SC or vice versa with a washout phase (max. 4 weeks) in between. Treatment adjustments were done according to protocol. IP insulin was delivered through an implantable pump (MIP 2007C, Medtronic). Glycaemic control was assessed after 3 and 6 months in both phases with HbA_{1c}; frequency of hypoglycaemic events (<4.0 mmol/L) as measured with self monitoring of blood glucose; time spent in euglycaemia (4.0–10.0 mmol/L) as measured with continuous glucose monitoring. General linear models were used to test differences, taking treatment order into account.

Results: *Baseline characteristics:* 11 males, 13 females; mean (SD) age 43.6 (11.8) years; mean diabetes duration 22.6 (10.6) years; mean HbA_{1c} 8.6 (1.1) %; HbA_{1c} >7.5% in 20 subjects; hypoglycaemic events ≥5/week in 14 subjects. After randomization groups were comparable regarding clinical characteristics. One subject was lost to follow-up (start IP insulin).

Outcomes: HbA_{1c} at different points in the study are shown in Figure 1 for both groups. HbA_{1c} improvement with CIPII was better compared to SC after both 3 and 6 months (p=0.006 and p=0.025, respectively).

Figure 1: HbA_{1c} (%) at different time points in study for both groups.

Mean (SD) number of hypoglycemic events during the baseline phase was 4.1 (2.7) per week. During the CSII phase this was 4.0 (2.6), as compared to 3.5 (2.3) per week in the CIPII phase ($p=0.073$).

Mean percentage of time spent in euglycemia at baseline was 45.1 (12.9) %. After 6 months CIPII and SC, this percentage was 52.9 (19.6) and 41.8 (18.5), respectively ($p=0.003$).

Conclusion: CIPII improved glycemic control without increase (trend toward decrease) of hypoglycemic events and increasing time spent in euglycemia. Therefore, in selected subjects with type 1 diabetes, CIPII will be of use for those that do not reach acceptable glycemic control on MDI or CSII.

Effect of the long-acting insulin analogue detemir on IGF-I axis in humans

F. Porcellati¹, P. Candeloro¹, P. Rossetti¹, C.G. Fanelli¹, N. Ricci Busciantella¹, E. Ghigo², G.B. Bolli¹

¹Internal Medicine, University of Perugia, ²Internal Medicine, University of Turin, Italy

Background and aims: The IGF-I system plays a critical role in cellular survival and proliferation. Recent evidence from both physiologic and clinical studies, suggests that it may also be important in the processes underlying carcinogenesis. Elevated circulating IGF-I concentrations have been associated with an increased risk of colon, breast, lung and prostate cancer. Insulin may be an important mediator of IGF-I effects on carcinogenesis through inhibition of hepatic synthesis of IGF binding proteins-1 (IGFBP-1), which, in turn, regulate IGF-I bioavailability. Insulin detemir (ID), with respect to regular human insulin (RHI), has a lower affinity for both insulin and IGF1 receptors. Nevertheless ID is formulated at a four time greater concentration on molar basis vs RHI, with resulting much higher plasma insulin concentrations. Therefore it is possible that ID and RHI exert differential actions in the modulation of IGF-I axis. The aim of our study was to assess the effects of an i.v. infusion of equipotent doses of ID and RHI on plasma concentrations of IGF-I, IGFBP-1, and IGFBP-3. Ten normal, non-diabetic subjects (M/F 6/4, age 36 ± 7 years, BMI 22.9 ± 2.6 kg/m²) were studied on 2 occasions at random, during i.v. infusion of either ID (2 mU/kg/min and 4 mU/kg/min 240–300 min) or RHI (1 mU/kg/min 0–240 min and 2 mU/kg/min 240–300 min) with variable glucose infusion (GIR) to clamp plasma glucose (PG) at 90 mg/dl.

Results: PG was not different between studies ($p>0.2$). Plasma insulin concentrations were on average 11 times greater with ID than HI (AUCs: 845 ± 90 μ U/ml/min vs 83 ± 20 μ U/ml/min). GIR with ID was lower than RHI during the first 105 min ($p<0.05$) but later was no different until the end of studies (9 ± 0.5 vs 9.5 ± 0.3 mg/Kg/min, $p>0.2$). There were no significant changes in plasma GH concentrations during both ID and RHI infusion, without any differences between the two insulins ($p>0.2$). Similarly plasma IGF-I concentrations (ID 147 ± 16 , HI 155 ± 15 ng/ml) and BP-3 (ID 2.6 ± 0.2 RHI 2.5 ± 0.2 μ g/ml) ($p>0.2$). In contrast insulin infusion resulted in a suppression of plasma BP-1 concentrations (only data of 6 out of 10 subjects are reported) without differences between ID (baseline 11.9 ± 3 , endpoint 5.9 ± 1) and HI (baseline 11.1 ± 2.4 , endpoint 4.4 ± 1) (ng/ml, $p>0.2$).

Conclusion: the greater plasma insulin concentrations obtained with ID exert similar effects on IGF-I axis as compared to RHI. Additional studies are needed to confirm these results in patients with insulin-treated diabetes mellitus.

Evaluation of long-term clinical benefits associated with early versus late initiation of insulin in type 2 diabetes patients in the UK

E. Sarpong¹, C. Pratoomsoot², G. Goodall², R. Hayes¹, W.J. Valentine²

¹Eli Lilly and Company, Indianapolis, United States, ²Health Economics and Outcomes Research, IMS Health, Basel, Switzerland

Background and aims: Recent data have shown that, despite poor glycaemic control, initiation of insulin is frequently delayed (by up to 8 years) and this may have a substantial effect on clinical outcomes in patients. The aim of this study was to evaluate the long-term clinical impact of delaying insulin initiation.

Materials and methods: A published and non-product specific diabetes model was used to project long-term clinical outcomes associated with type 2 diabetes in terms of life expectancy, cumulative incidence and time free of

complications. The model utilises findings from landmark clinical and epidemiological studies to simulate the long-term incidence and progression of diabetes and its associated complications. Cohort details were derived from published data on UK patients failing glycaemic control with OADs (mean age 64.2 years, duration of diabetes 3.8 years, HbA_{1c} 9.07% and BMI 30.1 kg/m²). The base case analysis compared the clinical outcomes of an immediate initiation of insulin versus a delay of eight years. In both scenarios (early and late), initiation of insulin was assumed to decrease HbA_{1c} by 1.37% and was associated with an overall hypoglycaemic event rate of 570 per 100 patient years.

Results: Early initiation of insulin was associated with an improvement in average life expectancy of 0.46 years versus delayed insulin initiation (9.94 ± 0.32 versus 9.48 ± 0.30 years). Patients experienced both an increase in the mean time free of complications and a reduced incidence of complications overall. A summary of the clinical benefits associated with early versus delayed initiation of insulin over patient lifetimes, expressed in terms of time to onset of complications (years), is given in the table below. A reduction in the lifetime cumulative incidence of complications was also associated with early insulin initiation versus delay in insulin initiation (data not shown). Additional analyses demonstrated that reducing the length of the delay for the initiation of insulin still resulted in substantial clinical benefits. Even when the delay was reduced to 2, 4 or 6 years there were still notable clinical benefits.

Conclusion: Published data indicates that there is a substantial number of type 2 diabetes patients on oral combination therapy in poor glycaemic control in the UK. In our modelling analysis, immediate initiation of insulin therapy was associated with improvements in survival and diabetes-related complication rates compared to delayed insulin therapy in this group of patients.

Time to onset of selected complications (years)

Complication	No delay	Insulin delayed by 8 years	Difference
Acute myocardial infarction	8.7 years	8.0 years	+0.7 years
Stroke	9.0 years	8.6 years	+0.4 years
Severe vision loss	9.6 years	9.1 years	+0.5 years
End-stage renal disease	9.9 years	9.4 years	+0.5 years
Lower-limb amputation	9.8 years	9.3 years	+0.5 years

Adding a single dose of insulin glulisine at breakfast or main meal to basal insulin and oral antidiabetic therapy; which patients of the OPAL study benefit most?

M. Lankisch¹, K. Ferlinz², W.A. Scherbaum³, for the OPAL Study Group
¹Medizinische Klinik III, Kardiologie, Herzzentrum Wuppertal, Wuppertal, Germany, ²sanofi-aventis Deutschland GmbH, Berlin, Germany, ³Heinrich-Heine-University, Düsseldorf, Germany

Background and aims: Most patients with Type 2 diabetes (T2DM) treated with oral antidiabetic drugs (OADs), will ultimately require insulin therapy to maintain tight glycaemic control. While a single daily injection of long-acting basal insulin glargine (GLAR) and OAD therapy is highly effective, a more intensive insulin regimen may be required if HbA_{1c} targets are not met. In patients on GLAR+OADs, we show the results of adding a single daily prandial dose of insulin glulisine (GLU) at breakfast or main meal.

Materials and methods: A 26-wk, randomised, multicentre study was conducted in T2DM patients ($n=316$ per protocol set), poorly controlled (HbA_{1c} >6.5 – 9.0%) on previous GLAR+OADs. Patients (FBG ≤ 6.7 mmol/L [≤ 120 mg/dL]) were stratified by the main meal (breakfast, lunch or dinner), determined by the highest postprandial blood glucose (BG) level, and randomised to GLU+GLAR+OADs (GLAR as basal insulin) with GLU given at breakfast ($n=162$) or main meal ($n=154$). Here, we describe the patient profiles at baseline between the two arms. The primary aim was to demonstrate equivalence in baseline to endpoint HbA_{1c} change between both arms.

Results: Baseline demographics for the overall, breakfast and main meal groups were similar (Table). Patients had an average age >60 yrs, obese (>30 kg/m²) and had suboptimally controlled T2DM (FBG ~ 6 mmol/L and HbA_{1c} $\sim 7.3\%$). Overall, HbA_{1c} significantly improved from baseline to endpoint ($p<0.0001$), while both arms were equivalent in terms of HbA_{1c} change (equivalence margin=0.4%; Table). BG values improved significantly within

each arm for most pre- and post-meal timepoints. Overall, 30.7% of patients achieved $HbA_{1c} \leq 6.5\%$ (27.8% breakfast and 33.8% main meal arms; $p=0.21$). For those patients with baseline $HbA_{1c} > 7.0\%$, 44.1% achieved $HbA_{1c} \leq 7.0\%$ at endpoint (36.5% breakfast and 52.2% main meal arms; $p=0.028$; Table). Mean GLAR dose was unchanged (baseline vs endpoint: 31 vs 32 U/day breakfast and 27 vs 27 U/day main meal arms) whereas GLU dose increased (starting dose of 5 U/day vs 11 and 12 U/day, respectively). The rate of on-treatment hypoglycaemia ($BG \leq 3.3$ mmol/L [≤ 60 mg/dL]) was 3.21 events/patient year ($n=393$ safety set) for the overall group (2.72 and 3.69 events/patient year for the breakfast and main meal arms, respectively).

Conclusion: Here, we identify and describe the profile of patients with sub-optimally controlled T2DM on basal insulin who are potential candidates for intensification of their GLAR+OADs regimen by adding 1 injection of prandial insulin. In these patients, adding GLU at breakfast is equivalent to GLU given at main meal in lowering HbA_{1c} with similar rates of hypoglycaemia between the two treatment arms. For patients with $HbA_{1c} > 7.0\%$ at baseline, a trend towards a higher number of patients achieving $HbA_{1c} \leq 7.0\%$ at endpoint was seen in the main meal versus breakfast arm.

Patients with $HbA_{1c} > 6.5$ – 9.0% at baseline	Overall N=316	Breakfast N=162	Main meal N=154

Superior efficacy of a basal-bolus regimen with insulins glargine and glulisine versus a two-injection pre-mixed insulin regimen in type 2 diabetes patients - results of the GINGER study

A. Fritsche¹, M. Larbig², S. Böhler¹, H.-U. Häring¹ on behalf of the GINGER Study Group

¹Department of Internal Medicine, University Hospital Tübingen,

²Sanofi-aventis Deutschland GmbH, Berlin, Germany

Background and aims: Pre-mixed insulin regimens are widely used in patients with Type 2 diabetes mellitus (T2DM). However, this approach suffers from poor flexibility in daily therapeutic routine, with the risk of hypoglycaemic events and insufficient glycaemic control. Therefore, the purpose of this study was to compare an intensified insulin therapy using insulin glargine (glargine) and insulin glulisine (glulisine) with a conventional therapy using pre-mixed insulin in patients previously on pre-mixed insulin. The aim was to demonstrate superior efficacy as measured by glycaemic control.

Materials and methods: The GINGER study was a 52-week, open, randomised, multinational, multicentre clinical trial comparing the efficacy and safety of mealtime rapid-acting glulisine and glargine once daily ($n=153$) in a basal-bolus regimen with an optimised conventional therapy of two sc injections per day of pre-mixed insulin ($n=157$) in T2DM patients inadequately controlled with their previous pre-mixed insulins. At baseline, the characteristics of participants (49% female) were (mean \pm SD): age, 61 \pm 8 years; BMI, 30.1 \pm 3.7 kg/m²; diabetes duration, 13 \pm 6 years; and insulin use, 5 \pm 4 years.

Results: Superiority of an intensified insulin therapy with glargine and glulisine versus a conventional therapy with pre-mixed insulin was confirmed in terms of significantly better glycaemic control (HbA_{1c} change from baseline to endpoint Δ : -0.5%; $p=0.0001$; 95% confidence interval [-0.71, -0.24]; ANCOVA adjusted for country, metformin and baseline; full analysis set; see table). The number of patients who reached $HbA_{1c} \leq 7.0\%$ at endpoint was significantly higher with glargine-glulisine versus pre-mixed insulin (68 [47%] vs 43 [28%]; $p=0.0004$). Glargine-glulisine provided significantly better mean daytime blood glucose ($p=0.0033$) and postprandial blood glucose ($p < 0.0001$) versus pre-mixed insulins. Fasting blood glucose showed a tendency for a more pronounced decrease with glargine-glulisine versus pre-mixed insulin ($p=0.0684$). Compared with patients on pre-mixed insulin, patients were treated with higher mean daily insulin doses at endpoint with glargine-glulisine (98.0 \pm 48.7 vs 91.3 \pm 44.3 U; $p=0.0003$) and showed slightly greater weight gain (+3.6 \pm 4.0 vs +2.2 \pm 4.5 kg; $p=0.0073$). The number of on-treatment hypoglycaemic events observed with glargine-glulisine and pre-mixed insulin was 14.0 and 18.5 events/patient-year, respectively ($p=0.2385$).

Conclusion: An intensified basal-bolus insulin therapy using glargine and glulisine results in a significantly superior glycaemic control compared with pre-mixed insulin therapy in a population with long-standing insulin-treated diabetes. Notably, the better glycaemic control in the glargine-glulisine arm was not associated with a higher rate of hypoglycaemia compared with the pre-mixed insulin group.

	Once-daily glargine and mealtime glulisine		Twice-daily pre-mixed insulin		p-value
	Baseline	Endpoint	Baseline	Endpoint	Difference between groups at endpoint*
HbA_{1c} (%)	8.6 \pm 0.8	7.3 \pm 1.2	8.5 \pm 0.9	7.7 \pm 1.1	-

EUropean Core Indicators in Diabetes

F. Storms¹, A. Fagot Campagna²¹EBM, CBO the Dutch Institute for Quality in Health Care, Utrecht, Netherlands, ²Département des Maladies Chroniques et Traumatismes, Institut de Veille Sanitaire, Saint Maurice, France

The **aim** of Eucid is to collect and compare data about risk factors for diabetes, complications and quality of care indicators in member or future member countries of the European Union.

Methods: 19 countries provided data for a list of 36 indicators by age-band, which were representative at a regional or a national level, for 2004, 2005 or 2006. Methods (surveys, registries, administrative databases) were provided. Data were age-standardized for comparisons performed in the general population.

Results: - Among the least available indicators, incidence of blindness in people with diabetes was provided by only 4 countries, and impaired fasting glucose in general population by 2.

- The standardized prevalence of diabetes varied from 2.6% in Finland to 7.6% in Cyprus; crude incidence of diabetes (0–14 yrs) from 11 in Spain to 60 per 100,000 in Finland; standardized prevalence of overweight (25–74 yrs) from 37% in Germany to 60% in Cyprus; standardized mortality rates linked with diabetes from 7 in Luxembourg to 56 per 100,000 in Finland. - Among people with diabetes (>25 yrs), process indicators ranged: for HbA1c testing once a year, from 51% in Ireland to 99% in the Netherlands, France and Belgium; for lipid testing, from 45% in Ireland to 99% in the Netherlands; for microalbuminuria testing, from 25% in Finland to 97% in the Netherlands; for fundus examination, from 12% in Ireland to 84% in the Netherlands.

- Risk factors in people with diabetes varied: HbA1c >7%, 32% in Sweden and Ireland to 83% in Cyprus; total cholesterol >5 mmol/l, 14% in Ireland to 68% in Cyprus; microalbuminuria, 9% in Finland to 41% in England; blood pressure >140/90 mmHg, 17% in France to 46% in Sweden; smoking, 10% in Ireland to 37% in Denmark.

- Complication incidence rates were: dialysis and transplantation, 4 in Cyprus to 149 per 100,000 in Scotland; stroke, 37 in Cyprus to 2675 in Germany; myocardial infarction, 21 in Cyprus to 2135 in Austria; major amputation, 78 in Scotland to 574 in Spain.

Conclusion: While European epidemiologic systems can provide diabetes indicators, major indicators as blindness are still missing. Most of the European countries achieve remarkable good testing of people with diabetes. Risk factors and outcomes vary across countries, reflecting a mixture of genetic background, societal and cultural factors, organisation of diabetes care as well as public health policies. The results of Eucid will be used within countries to try to influence these policies.

Implications of diabetes mellitus for temporal changes in left ventricular geometry and function. The MONICA/KORA Augsburg Cohort Study

M.R.P. Markus¹, J. Stritzke¹, J. Wellman², S. Duderstadt¹, W. Lieb¹, A. Luchner³, A. Döring⁴, U. Keil², H. Schunkert¹, H.W. Hense²¹Medical Clinic II, University of Lübeck Medical School, ²Institute of Epidemiology and Social Medicine, University Hospital of Münster, ³Clinic and Policlinic for Internal Medicine II, University Hospital of Regensburg, ⁴Institute of Epidemiology, GSF - National Research Center for Environment and Health, Neuherberg, Germany

Background and aims: Several studies suggest that diabetes mellitus is one of the most important risk factors for the development of systolic and diastolic heart failure. However, details of the mechanisms of this process are still unclear. We investigated the long-term consequences of diabetes on the heart in a prospective population-based study.

Materials and methods: The population-based MONICA/KORA-Augsburg cohort study provided anthropometric, biochemical and echocardiographic data for 1005 individuals examined during a baseline survey in 1994/95 and

a follow-up investigation ten years later. We defined three groups of individuals: who were persistently, at both examinations, non diabetics (nonDM, i. e.; defined as no history of diabetes and not using medications for glycemic control at both examinations; n = 811), who were persistently diabetic (PDM, i. e., defined as disease known to the patient as reported by standard questionnaire or the use of antidiabetic medications or insulin or non-fasting glucose blood levels ≥ 200 mg/dl; n = 34) and who presented incident diabetes at follow-up (incDM; n = 19). We evaluated prospectively the impact of diabetes on the 10-year changes in left ventricular (LV) mass indexed to height^{2.7} (in g/m^{2.7}), left ventricular end-diastolic diameter (LVEDD in mm), wall thickness (WT = septal + posterior wall thickness in mm), relative wall thickness (RWT, WT in mm divided by in mm), left atrial diameter (LA in mm) and the ratio of early diastolic peak transmitral flow and early diastolic peak myocardial relaxation velocities (E/EM) using linear regression models adjusting for age and sex and other relevant confounders including systolic blood pressure.

Results: For the relative changes over the ten years period, there was a positive trend across the three groups for LV mass^{2.7} (p=0.011), LVEDD (p=0.002) and LA (p=0.020). Specifically, compared the mean difference with the non-DM group, the PDM group, had a bigger relative increase of 12.6% (95% confidence interval: 4.20% to 20.9%, p=0.003) in the LV mass^{2.7}, 6.0% (2.70% to 9.30%, p<0.001) in LVEDD and 6.50% (1.90% to 11.1%, p=0.006) in LA. Finally, in 2004/5, the PDM group showed a higher ratio of E/EM than the nonDM group (11.6 [10.5 to 12.8] versus 9.83 [9.66 to 10.0], p=0.002).

Conclusion: Over a period of ten years, incident and prevalent diabetes mellitus are associated with significant changes in left ventricular geometry and mass, mostly attributable to a pattern of eccentric remodelling. Left atrial enlargement and a worse diastolic function were also observed. All associations were independent of cofactors and confounders.

Complement C3, but not C4, is independently associated with the metabolic syndrome and prevalent cardiovascular disease: the CODAM study

M.M.J. van Greevenbroek¹, C.J.H. van der Kallen¹, I. Ferreira², C.G. Schalkwijk¹, E.E. Blaak³, E.J.M. Feskens⁴, C.D.A. Stehouwer¹¹Dept of Internal Medicine / Cardiovascular Research Institute Maastricht (CARIM), Maastricht University, ²Dept of Internal Medicine / Dept of Clinical Epidemiology and Medical Technology Assessment, Maastricht University Hospital, ³Dept of Human Biology/Nutrition and Toxicology Research Institute Maastricht (NUTRIM), Maastricht University, ⁴Dept of Human Nutrition, Wageningen University, Netherlands

Background and aims: Increased plasma concentrations of complement C3 and C4 have been implicated in cardiovascular disease (CVD). This association may, at least partly, be related to their increase in the metabolic syndrome (MetS). C3 plays a pivotal role in complement activation via the classical, the alternative, as well as the mannan-binding lectin pathway. C4, on the other hand, is a component of the classical and the lectin pathway.

Research question: Are plasma concentrations of C3 and C4 independently associated with (components of) the MetS and, if yes, are they also independently associated with CVD?

Materials and methods: Relations between C3, C4, the MetS (NCEP-ATP 2005) and CVD were studied in the CODAM (cohort study on diabetes and atherosclerosis Maastricht) population. CODAM subjects (n=574) were selected from a large population-based cohort on the basis of an increased risk of type 2 diabetes and CVD. Associations of C3 and C4 (z-scores) with each component of the MetS were analysed using linear regression (Model(s) A: C3 or C4 as independent variables, adjusted for sex and age, with each component of the MetS as dependent variables; Model(s) B (full model): as model A but with C3 and C4 as independent variables). Associations with presence of the MetS and CVD were determined using logistic regression analyses.

Results: C3 and C4 were higher (p<0.001) in plasma of subjects with the MetS (n=312; C3, 1.94 \pm 0.31 g/L and C4, 0.30 \pm 0.07 g/L) than in those without (n=259; C3, 1.63 \pm 0.28 g/L, and C4, 0.28 \pm 0.07 g/L). C3 and C4 were significantly associated with most components of the MetS (Model(s) A); waist

(C3, $p<0.001$; C4, $p<0.001$), [ln]triglycerides (C3 $p<0.001$; C4, $p=0.001$), HDL-cholesterol (inversely; C3, $p<0.001$; C4, $p<0.001$), blood pressure (C3, $p<0.001$; C4, $p=0.002$), and fasting glucose (C3, $p<0.001$; C4, $p=0.3$). C3 and C4 were also associated with a marker of inflammation, a common feature of the metabolic syndrome ([ln]CRP, C3, $p<0.001$; C4, $p<0.001$). Next, when C3 and C4 were included simultaneously in the full regression models only C3, but not C4, was independently associated with the individual components of the MetS. In contrast, both C3 and C4 contributed significantly to prediction of [ln]CRP. In a full logistic regression model, C3 was significantly associated with the MetS, while C4 was not (Odds Ratio (OR) [95% CI] C3 = 3.81 [2.92–4.98], OR C4 = 0.87 [0.70–1.08]). Lastly, C3 was associated with prevalent CVD in a full model ($n=144$; OR C3=1.63 [1.31–2.04], while C4 was not (OR C4= 0.88 [0.70–1.10]).

Conclusion: In the CODAM population, C3 and C4 both show strong associations with various components of the MetS, and with the syndrome itself, but after mutual adjustments only C3 was independently associated with (components of) the MetS. Moreover C3, but not C4, is independently associated with prevalent CVD in the CODAM population, despite our finding of independent associations of both C3 and C4 with inflammation.

Cytokines, advanced glycation end-products, leptin, adiponectin and diabetes: a nested case-control study

P.Z. Zimmet, D.J. Magliano, B. De Courten, J. Forbes, J.E. Shaw
The Baker IDI Heart and Diabetes Institute, Melbourne, Australia

Background and aims: Low grade, chronic inflammation, cytokines and advanced glycation end-products (AGEs) have all been suggested to be involved in the pathogenesis of diabetes. However, the extent to which any one of these factors is independent of the others in relation to the development of diabetes is unclear. We examined the prospective relationship of markers of inflammation (high sensitivity C reactive protein (CRP), migratory inhibitory factor (MIF), interleukin 6 (IL6), intracellular adhesion molecule (ICAM), leptin, adiponectin and serum levels of advanced glycation end-products (AGEs), and the soluble receptor for AGE - sRAGE with incident diabetes in a nested case-control study from the Australian, Diabetes, Obesity and Lifestyle Study (AusDiab).

Materials and methods: AusDiab was a population-based national study established in 1999/2000 with a five year follow-up in 2004/2005. An oral glucose tolerance test was performed at both time points. A nested case-control study was conducted on 224 cases of incident diabetes and 233 controls, who remained free of diabetes at the five year follow-up. CRP was measured in stored fasted sera from baseline (1999/2000) using a chemiluminescent immunoturbidimetric assay. IL6, MIF and sRAGE were measured using high sensitivity ELISA, and ICAM, leptin and adiponectin were measured using a bioplex assay. AGEs concentrations were determined using an Ne carboxymethyllysine sensitive monoclonal in an 'in house' indirect ELISA. Multivariate logistic regression was used to explore the relationship between inflammatory markers, cytokines and diabetes, adjusted for age and sex. CRP, MIF, IL6, adiponectin, leptin, sRAGE, and AGEs were tested in models using sex-specific derived quartiles or tertiles, and in a continuous form.

Results: Mean levels of cytokines were significantly different between cases and controls (age and sex adjusted) for leptin ($p<0.01$), CRP ($p<0.01$), sRAGE ($p=0.03$) and ICAM ($p<0.01$), but not for AGEs ($p=0.61$), adiponectin ($p=0.09$), IL6 ($p=0.12$), and MIF ($p=0.52$). In age and sex adjusted logistic regression, those with CRP levels in the top tertile (vs. bottom) were more likely to have diabetes [OR 95% CI: 2.3 (1.4–3.6)]. This relationship remained significant after adjustment for sRAGE or AGEs, but lost significance with adjustment for BMI or waist circumference. Similarly, in age-sex adjusted models, those in the top quartile (vs. bottom) of ICAM [OR: 1.9 (1.1–3.3)], were more likely to develop diabetes but with further adjustment for BMI, this lost significance. Those in the top quartile (vs. bottom) of sRAGE were less likely to develop diabetes [OR: 0.6 (0.4 – 1.0)] in age-sex adjusted models but this lost significance after adjustment for waist circumference or BMI. In age-sex adjusted models, those in the top quartile of leptin [2.3 (1.3 – 4.3)] or the top quartile of leptin-waist ratio [OR: 1.9 (1.1 – 3.6)] were more likely to develop diabetes.

Conclusion: Elevated levels of circulating sRAGE appear to be associated with a lowering of diabetes risk, while CRP increased the risk of diabetes. Such associations were independent of age and sex and each other, but not from obesity. Furthermore, leptin-waist ratio, but not any of the other in-

flammatory markers or cytokines, was independently associated with incident diabetes.

Glycaemic control and cardiovascular complications and death in type 2 diabetes: an observational study in 17,691 patients

K. Eeg-Olofsson¹, J. Cederholm², P.M. Nilsson³, B. Zethelius², S. Gudbjörnsdóttir¹, B. Eliasson¹

¹Dept of Medicine, University of Gothenburg, ²Dept of Public Health and Caring Sciences, Uppsala University, ³Dept of Clinical Sciences Medicine, Lund University, Sweden

Background and aims: The role of improved glycaemic control in reducing cardiovascular disease (CVD) complications in diabetes is currently under debate. The aim of this study was to describe the association between glycaemic control and cardiovascular complications in type 2 diabetic patients using data from the Swedish National Diabetes Register.

Materials and methods: 17,691 type 2 diabetic patients, age 18 to 85 years and no previous coronary heart disease (CHD) or stroke, were identified 1997–1998 and followed for six years. A Cox regression analysis was performed with HbA1c as predictor and first incident fatal or non-fatal CHD ($n=2280$), stroke ($n=1376$), CVD ($n=3339$) and all cause mortality ($n=1707$) as outcome measures. Endpoint events were retrieved by data linkage to the Swedish Cause of Death and Hospital Discharge Registers. Case fatality rate was calculated by logistic regression.

Results: Mean baseline characteristics: age 64.4 ± 11.5 years, diabetes duration 8.4 ± 7.3 years, HbA1c (DCCT standardized) $7.6\pm 1.3\%$; 49.1% used antihypertensive treatment and 10.8% were treated with lipid lowering drugs, 13.9% were smokers and 21.4% had microalbuminuria (MA). Increasing HbA1c by one unit increased the risk of CHD by 13%, hazard ratio (HR) 1.13 (95% CI 1.10–1.17), after adjustment for age, sex, diabetes duration, smoking, MA, antihypertensive and lipid-lowering treatment. The risk of stroke, CVD and all cause mortality also increased, HR 1.09 (1.05–1.14), HR 1.12 (1.09–1.15) and HR 1.12 (1.08–1.16), respectively. Comparing patients at different HbA1c intervals, with HbA1c 6.0–6.9% as reference, showed that patients with HbA1c 7.0–7.9% had 33% higher risk (HR CI 1.18–1.49) of fatal or non-fatal CHD, adjusted for age and sex. Patients with HbA1c 8.0–8.9% had 56% higher risk (HR CI 1.37–1.77) whereas patients with HbA1c 5.0–5.9% had 8% lower risk, although not statistically significant (HR CI 0.76–1.11). The same patterns were seen regarding stroke and CVD. An HbA1c increase by one unit also increased the risk of a CVD event to be fatal, odds ratio 1.07 (CI 1.003–1.14).

Conclusion: This large observational study of an unselected sample of type 2 diabetic patients in clinical practice, demonstrates a gradually increasing risk of CHD, stroke, CVD and all cause mortality with increasing HbA1c levels independently of well known risk factors.

Progression from normal glucose tolerance to impaired fasting glycaemia and impaired glucose tolerance: differential roles of insulin resistance and beta cell dysfunction

K. Færch¹, A. Vaag², J.J. Holst³, O. Pedersen^{4,5}, C. Glümer⁶, K. Borch-Johnsen^{1,5}

¹Department of Epidemiology, Steno Diabetes Center, ²Department of Pathophysiology, Steno Diabetes Center, ³Department of Biomedical Sciences, The Panum Institute, Copenhagen, ⁴Department of Molecular Genetics, Steno Diabetes Center, Gentofte, ⁵Faculty of Health Sciences, University of Aarhus, ⁶Research Centre for Prevention and Health, Capital Region of Denmark, Glostrup, Denmark

Background and aims: We aimed at examining whether defects in insulin sensitivity and/or insulin secretion differed between different groups of pre-diabetic individuals and most importantly whether these defects were apparent in the normoglycaemic state five years prior to the development of isolated impaired fasting glycaemia (i-IFG), isolated impaired glucose tolerance (i-IGT) and combined IFG/IGT.

Material and methods: Prospective data from the Danish population-based non-pharmacological intervention study Inter99 were used. Individuals with normal glucose tolerance (NGT) at baseline and i-IFG, i-IGT, IFG/IGT or normal glucose tolerance (NGT) at the 5-year follow up were included ($n=3,145$). Estimates of insulin sensitivity (ISI), acute insulin response (AIR)

and beta cell function (Disposition Index, $DI = ISI \cdot AIR$) were calculated at baseline and after 5 years of follow up based on glucose and insulin levels during an OGTT.

Results: Five years prior to the pre-diabetic diagnosis individuals who later developed i-IFG exhibited insulin resistance, defective insulin secretion and consequently reduced DI ($p < 0.05$ vs. NGT, Table 1). Those who subsequently progressed to i-IGT were more insulin resistant ($p < 0.05$), but had normal AIR ($p = 0.877$ vs. NGT), and thereby the same reduction in DI ($p = 0.768$) as those developing i-IFG. At the 5-year follow-up, those with i-IGT had lower insulin sensitivity ($p < 0.001$), equally reduced AIR ($p = 0.186$), and consequently more pronounced beta cell dysfunction ($p < 0.001$) than those with i-IFG. IFG/IGT individuals exhibited worse defects than the other pre-diabetic groups.

Conclusion: Defective absolute insulin secretion followed by insulin resistance characterise the transition to i-IFG, while insulin resistance with secondary beta cell failure is likely to cause the development of i-IGT. The pre-diabetic states i-IFG and i-IGT may thereby have different aetiological origins with implications for future prevention and treatment of overt type 2 diabetes.

Table 1 Characteristics of individuals with incident i-IFG, i-IGT, IFG/IGT or NGT (n = 3,145).

	NGT → NGT (n = 2,842)	NGT → i-IFG (n = 83)	NGT → i-IGT (n = 192)	NGT → IFG/IGT (n = 28)	$p < 0.05$

Candesartan attenuates vascular pathology in Ren-2 rats with diabetic retinopathy

J.L. Wilkinson-Berka¹, G. Tan¹, M.E. Cooper², A. Miller¹

¹Immunology, Monash University, Melbourne, ²JDRF Danielle Alberti Centre for Diabetic Complications, Diabetes and Metabolism Division, Baker Heart Research Institute, Melbourne, Australia

Background and aims: Angiotensin II blockade is currently being evaluated as a treatment for diabetic retinopathy. We aimed to determine if the angiotensin type 1 receptor (AT1-R) blocker, candesartan, improves vascular pathology and modulates the expression of angiogenic and inflammatory mediators and renin-angiotensin system components in retina of rats with hypertension and diabetes.

Materials and methods: Streptozotocin diabetes was induced in transgenic Ren-2 rats, which are hypertensive and overexpress renin and angiotensin II in extra-renal tissues including the retina. At 8 weeks of age, female Ren-2 rats were randomised to the following groups; (1) non-diabetic control, (2) diabetic control and (3) diabetic + candesartan (5mg/kg/day, gavage). Animals were studied for 1 and 20 weeks of diabetes. N=6 to 11 rats per group. Systolic blood pressure (SBP) was measured by a tail cuff method. Leukostasis was evaluated by counting adherent leukocytes in whole retina following in vivo perfusion with Concavalin A. Acellular capillaries (devoid of pericytes and endothelial cells) were counted per high powered field of retina following trypsin digestion of whole retina. Real-time PCR was performed for vascular endothelial growth factor (VEGF), intracellular adhesion molecule-1 (ICAM-1), osteopontin, (pro)renin receptor, AT1a-R and aldosterone synthase.

Results: SBP was similar in non-diabetic and diabetic Ren-2 rats after 1 (241±5.1 mmHg, non-diabetic; 239±6.3 mmHg, diabetic) and 20 weeks (230.3±2.4 mmHg, non-diabetic; 235.4±3.6 mmHg, diabetic). Candesartan slightly reduced SBP in 1 week diabetic Ren-2 rats (208.5±5.6 mmHg) and normalised SBP in 20 week diabetic Ren-2 rats (123.1±3.6 mmHg) to Sprague Dawley control (122.4±2.9 mmHg). In the 1 week study, retinal leukostasis was increased in diabetic Ren-2 rats (249.8±59.1/retina) compared to age-matched non-diabetic control (30.1±7.8/retina, $P < 0.01$). Candesartan reduced leukostasis in diabetic Ren-2 rats to the level of non-diabetic control (29.0±5.6/retina, $P < 0.01$ to diabetic control). Candesartan was similarly effective in the 20 week study. Acellular capillaries were increased in diabetic Ren-2 rats (4.66±0.56/field) compared to non-diabetic Ren-2 rats (1.37±0.16/field), and in diabetic rats were reduced with candesartan to the level of non-diabetic control (1.22±0.19, $P < 0.005$ to diabetic control). Candesartan attenuated changes in diabetes-related gene expression of retinal VEGF, ICAM-1 and renin-angiotensin system components.

Conclusion: These findings indicate that the AT1-RB, candesartan, attenuates retinal vascular pathology in hypertensive diabetic Ren-2 rats consistent with a potentially retinoprotective effect of this agent in diabetic retinopathy. Supported by: Astra Zeneca

Diabetic retinal neurodegeneration is associated with mitochondrial oxidative stress and it is ameliorated by angiotensin receptor blocker

K.C. Silva, M.A.B. Rosales, S.K. Biswas, J.B. Lopes de Faria,

J.M. Lopes de Faria

Faculty of Ciencias Medicine, State University of Campinas, Brazil

Background and aims: In addition to be a very frequent disease in patients with diabetes mellitus (DM), hypertension is the major risk factor associated with the development of diabetic retinopathy (DR). DR displays features of neurodegeneration disease with loss of neural cells and glial reaction. Oxidative stress mechanisms were described to be involved into the pathogenesis of DR. This investigation sought to determine whether hypertension exacerbates the oxidative stress induced-apoptosis in neural retinal cells and if high blood pressure control abrogates neurodegeneration in the retina from diabetic hypertensive rats.

Materials and methods: Streptozotocin induced diabetes was carried out in spontaneously hypertensive rats (SHR) and compared with normotensive

control Wistar Kyoto rats (WKY). Diabetic SHR rats were randomized to receive no antihypertensive treatment (Sd) or an angiotensin receptor blocker (ARB) antihypertensive drug (losartan, 200 mg/L). After 12 weeks, rats were sacrificed and the retinas were collected. At least five animals were used in each group for each experiment. The results were compared by analysis of variance (ANOVA) followed by Fisher's protected least-significant difference test.

Results: Apoptosis of retinal cells, evaluated by terminal deoxynucleotidyl transferase (TdT)-mediated dUTP-biotin nick-end labeling (TUNEL) assay, were higher in diabetic WKY compared with non diabetic control (2.3 ± 0.9 vs 0.55 ± 0.1 , $p=0.03$) and the concomitance of hypertension and diabetes further increased retinal apoptotic cells (4.4 ± 2.0 , $p=0.0003$). Apoptotic cells showed neural and glial markers as indicated by specific antigens. The biochemistry marker of apoptosis, caspase-8 expression, was elevated only in diabetic SHR rats ($p=0.01$). The superoxide production in retinal tissue was increased in presence of DM (10 ± 3 vs 22 ± 6 for control and diabetic WKY, $p=0.03$) and accentuated in diabetic hypertensive rats (40 ± 10 , $p=0.0002$). The reduced glutathione, an important antioxidative defense, was found reduced in diabetic SHR (140 ± 54 vs 56 ± 10 for control SHR and Sd, $p=0.0005$). As a result, an extensive retinal oxidative damage, estimated by nitrotyrosine (NT) and 8-hydroxy 2'-deoxyguanosine (8-OHdG) expressions, were higher in diabetic WKY (2.0 ± 0.1 vs 3.2 ± 0.2 , 6.0 ± 0.2 vs 11 ± 0.5 for NT and 8-OHdG, $p<0.0001$ and $p=0.003$, respectively) and worsened in diabetic SHR rats (3.7 ± 0.26 and 30 ± 2.6 for NT and 8-OHdG, $p<0.0001$). To evaluate a possible role of mitochondria in superoxide production, the expression of Bcl-2, an antiapoptotic mitochondrial protein and uncoupling protein-2 (UCP-2) were evaluated by western blot assays. The retinal expressions of Bcl-2 and UCP-2 were diminished in both diabetic groups (67 ± 7 vs 42 ± 17 and 60 ± 9 vs 45 ± 7 , $p<0.05$ for Bcl-2; 42 ± 27 vs 36 ± 7 and 53 ± 14 vs 36 ± 2 , $p=0.03$ for UCP-2, for control vs diabetic WKY and control vs diabetic SHR, respectively). The antihypertensive treatment with losartan reestablished all the evaluated parameters.

Conclusion: These observations suggest that hypertension exacerbates the mitochondrial oxidative stress-induced apoptosis of retinal cells and the ARB ameliorated the retinal neurodegeneration in a model that combine diabetes and hypertension. This beneficial effect may be due to reestablishment of oxidative retinal status by reducing superoxide production and improving the antioxidative defense.

Activation of angiotensin II signalling pathways in high glucose-treated rat retinas

F. Pricci¹, L. Gaddini¹, M. Villa^{1,2}, A. Matteucci¹, C. Mallozzi¹, A.M. Di Stasi¹, F. Malchiodi-Albedi¹, T.C. Petrucci¹

¹Cell Biology and Neuroscience, Istituto Superiore di Sanità, ²Medical Retina Unit, G.B. Bietti Foundation for the Study and Research in Ophthalmology, Rome, Italy

Background and aims: The vascular impairment in Diabetic Retinopathy (DR) have been deeply studied in the past. On the contrary, little is known about the neuroglial alterations, which may be present also before overt vasculopathy, as recently observed. Neuroglial damage could be linked to the excess glucose disposal which can activate several signalling pathways. Among these, the retinal renin-angiotensin system (RAS) could play a pivotal role in view of its well-known alterations in diabetic retina and its action on vasculature and tissue remodelling.

Aim of this study was to verify the possible involvement of RAS signalling in neuroglial dysfunction in an *in vitro* experimental model of diabetic retinopathy.

Materials and methods: We used retinal tissue cultures explanted from Sprague-Dawley rats and exposed to normal glucose (NG: 5.5 mM), high glucose (HG: 30 mM), iso-osmolar mannitol (M: 5.5 mM glucose+24.5 mM mannitol) for 48 h \pm the Angiotensin-Converting Enzyme (ACE)-inhibitor enalaprilat (200 μ M).

Results: In retinal cultures exposed to HG, but not to NG or M, Western blot (WB) analysis revealed an increase in protein tyrosine phosphorylation, especially in specific bands identified as proline-rich tyrosine kinase 2 (pPyk2-Tyr402) (+80 \pm 9%) and as phospholipase C γ 1 (pPLC γ 1-Tyr783). Immunohistochemistry confirmed the increased pPyk2 in HG, throughout the retinal layers, in both glial and neuronal cells. In NG, in contrast, positivity was only detected in endothelial cells. An increased Glial Fibrillar Acidic Pro-

tein (GFAP) reactivity was also observed by immunohistochemistry and WB, suggesting a process of reactive gliosis. Further analysis in HG conditions showed an increase in c-src and lyn tyrosine kinase activities (40% \pm 17 and 63% \pm 5, respectively), and an activation of both p44/42 MAPK (Erk 1/2) and transcription factor pCREB-Ser133. Enalaprilat reverted both the increase in protein tyrosine phosphorylation and activation of CREB, in agreement with the hypothesis that RAS signalling pathway was activated in HG. RAGE (a receptor for Advanced Glycosylation End-products-AGEs) expression was evaluated to verify if the observed modifications were related to AGEs in HG-treated retina. No induction of the receptor was observed. In contrast, treatment with glycated BSA (200 μ g/ml) effectively upregulated RAGE.

Conclusion: These results strongly suggest that RAS signalling pathway is activated in HG-treated retinas and may have a role in diabetic neuroglial impairment

KIOM-79 long-term treatment inhibits the development of diabetic retinopathy and AGEs accumulation in retinal tissue

J. Kim, C.-S. Kim, E.J. Sohn, Y.M. Lee, D.S. Jang, J.S. Kim

Department of Herbal Pharmaceutical Development, Korea Institute of Oriental Medicine, Daejeon, Republic of Korea

Background and aims: KIOM-79 is the 80% ethanol extracts of parched *puerariae radix*, gingered *Magnoliae cortex*, *Glycyrrhizae radix*, and *Euphorbiae radix*. Our previous studies reported that KIOM-79 inhibits advanced glycation end products (AGEs) formation and prevents diabetic nephropathy in STZ induced diabetic rats. In this study, we evaluate the potential preventive effect of KIOM-79 on diabetic retinopathy in Zucker diabetic fatty (ZDF) rat, an animal model of type II diabetes.

Material and methods: Six week-old male ZDF rats were treated with KIOM-79 (50mg/kg body weight) once a day orally for 13 weeks. The retinas were collected at 13 weeks and examined the retinal vascular damage using whole-mount preparation of the retinas.

Results: Serum levels of AGEs by ELISA were significantly reduced in ZDF rats treated with KIOM-79 ($p<0.05$ vs vehicle). And the immunohistochemical analysis was shown that the numbers of AGEs positive cells were significantly reduced in ZDF rats treated with KIOM-79 ($p<0.05$ vs vehicle). In periodic acid-Schiff staining of trypsin-digested retinal preparations, severe changes included pericytes ghost, acellular formation of capillaries were observed in ZDF rats, but in ZDF rats treated with KIOM-79, these changes were observed rarely. Furthermore, Fluorescein angiography of retina injected with fluorescein-dextran revealed that the changes of retinal vasculature (non-perfusion of fluorescein, fluorescein leakage and vessel narrowing) were significantly reduced in ZDF rats treated with KIOM-79 compared with ZDF rats treated with vehicle ($p<0.05$).

Conclusion: These results indicate that the treatment with KIOM-79 is useful in inhibiting the AGEs accumulation in retinal tissue and has a preventive effect on the development of diabetic retinopathy.

Figure 1. Effects of KIOM-79 on retinal vascular damage. In retinal vessel pattern analysis (upper panels), pericyte ghost (arrow) and acellular capillary (arrowhead) were observed in ZDF rats. In fluorescein angiography (middle panels), arrowhead and arrow indicate non-perfusion areas and vessel narrowing (magnified inset), respectively. Quantitative analysis of acellular formation, pericyte ghost and retinopathy score of retinal vessels revealed that KIOM-79 inhibits the acellular formation and reduces the pericyte loss. Nor, normal lean rat; DM, ZDF rat; KIOM-79, ZDF rat treated with KIOM-79. All data were expressed as mean \pm SD

Long-term siRNA strategy regulates fibronectin overexpression and improves vascular lesions in retinas of diabetic rats

S. Roy¹, S. Nasser¹, D. Graves², S. Roy¹

¹Medicine and Ophthalmology, Boston University School of Medicine, ²Oral Biology, Boston University School of Dental Medicine, United States

Background and aims: To regulate abnormal gene expression associated with diabetic retinopathy, a long-term microvascular complication of diabetes, a sustained gene regulatory strategy is much desired. Having recently shown siRNA approach to be effective in long-term cell culture studies in reducing high glucose-induced fibronectin (FN) overexpression, in this study, we have investigated the efficacy of siRNA strategy *in vivo* as a long-term modulatory strategy for regulating altered gene expression in retinal vascular cells of diabetic rats. Time course studies conducted in rat retinas indicated siRNA efficacy up to 6 weeks.

Materials and methods: To determine long-term efficacy of siRNA strategy, three intravitreal injections at 1.5, 3, and 4.5 months of diabetes were performed with 3 μ M siRNA targeted to FN transcript in streptozotocin-induced diabetic rats. Control rats were either uninjected or injected with scrambled siRNA. After 1.5 months following the third injection, that is, at the end of 6 months of diabetes, retinal FN protein expression, basement membrane (BM) thickness, pericyte loss and acellular capillaries were assessed. At the time of sacrifice, blood samples were collected and evaluated for HbA1c level.

Results: Western blot analyses showed a significant increase in FN expression in retinas of diabetic rats compared to that of non-diabetic control rats (188 \pm

4.2% of control vs. 100 \pm 7.4% of control, $p < 0.002$). FN expression was significantly downregulated in retinas of diabetic rats injected with siRNA compared to those of uninjected diabetic control eyes and diabetic eyes injected with scrambled siRNA (145 \pm 9.9% of control vs. 188 \pm 4.2% of control, $p = 0.03$; 145 \pm 9.9% of control vs. 183 \pm 5.7% of control, $p = 0.032$, respectively). Electron microscopy analysis showed a significant increase in BM thickening in the diabetic rats compared to those of non-diabetic control rats (62.5 \pm 5 nm vs. 51.5 \pm 4.8 nm, $p < 0.001$). A significant reduction of retinal capillary BM thickness was observed in eyes injected with siRNA compared to those of uninjected diabetic control eyes and diabetic eyes injected with scrambled siRNA (56.4 \pm 2.8 nm vs. 62.5 \pm 5.0 nm, $p = 0.03$; 56.4 \pm 2.8 nm vs. 63.7 \pm 3.9 nm, $p < 0.01$, respectively). Both acellular capillaries and pericyte loss were significantly increased in the diabetic rats (194 \pm 21% of control; 154 \pm 16% of control; $p < 0.01$, respectively), and long-term FN-siRNA treatment partially but significantly reduced the number of acellular capillaries and pericyte loss compared to those of diabetic (122 \pm 14%, 118 \pm 12% of control, $p < 0.02$, respectively) or diabetic rats treated with scrambled siRNA (116 \pm 21%, 109 \pm 15% of control, $p < 0.04$, respectively). Increased HbA1c levels confirmed hyperglycemic condition in the diabetic rats compared to non-diabetic control rats (11.5 \pm 1.9% vs. 5.4 \pm 0.8%, respectively).

Conclusion: Results from this study suggest that siRNA approach may have potential for long-term beneficial effect on vascular lesions associated with diabetic retinopathy.

Increased retinal HSP27 expression in early experimental diabetes

D. Burt, S. Pinach, E. Berrone, I. Miceli, M. Porta, P. Cavallo Perin, G. Gruden

Department of Internal Medicine, University of Turin, Italy

Background and aims: Diabetic retinopathy is characterised by microvascular abnormalities, apoptosis, and loss of retinal ganglion cells (RGC). Diabetes is known to induce oxidative stress in the retina and this has been pathogenetically associated with retinal neurodegeneration. Heat shock protein 27 (HSP27), a member of the small family of heat shock proteins, exists in a phosphorylated/non phosphorylated state (HSP27/P-HSP27). The expression of HSP27 is upregulated under various conditions of stress including oxidative stress and HSP27 exhibits cytoprotective activity. The aim of this work was to determine whether retinal HSP27 expression is increased in experimental diabetes in parallel with markers of oxidative stress.

Materials and methods: Eight-week old C57BL/6J mice (n=7) were rendered diabetic by intraperitoneal injection of streptozotocin (55 mg kg⁻¹). Animals were considered diabetic if blood glucose levels were over 250 mg/dl three weeks after the injection. Mice (n=5) sham-injected with sodium citrate buffer were used as non-diabetic control animals. Ten weeks after the onset of diabetes the animals were sacrificed, eyes enucleated, and retinas extracted. Blood glucose and glycated haemoglobin levels were measured by glucose-oxidase and latex method, respectively. HSP27 mRNA levels were determined by RT-real-time PCR on RNA extracts from whole retinas. HSP27 and P-HSP27 expression were evaluated by immunohistochemistry using specific anti-HSP27 and anti-phospho-HSP27 antibodies. The signal was revealed using the LSAB+ system-HRP, quantified blinded by two independent observers, and expressed as percentage area of positive staining in 7 randomly selected fields per section. Expression of nitrotyrosine and Cu/Zn superoxide-dismutase (SOD), markers of oxidative stress, was assessed by immunohistochemistry and immunofluorescence, respectively.

Results: Blood glucose and glycated haemoglobin were significantly higher in diabetic animals as compared to non-diabetic control animals. In the whole retina from diabetic animals there was a significant (p<0.05) fourfold increase in HSP27 mRNA levels as compared to controls. Furthermore, immunohistochemical analysis showed that both HSP27 and P-HSP27 expression were significantly greater in the retina from diabetic mice than in the retina from control animals (HSP27: 21.6 ± 3.4 vs. 3.9 ± 1.8, p<0.005; P-HSP27: 26.4 ± 17.6 vs. 5.14 ± 2.9; percentage area, p<0.05) and localised to the RGC layer. Double immunostaining for Thy-1, a RGC specific marker, confirmed that HSP27 was overexpressed predominantly by RGC. In the retinas from diabetic mice there was also a significant increase in the expression of markers of oxidative stress (nitrotyrosine: 18.3 ± 6.6 vs. 3.5 ± 1.5; p<0.001; Cu/Zn SOD: 25.5 ± 4.3 vs. 2.3 ± 2.87; percentage area, p<0.0001) localized to the RGC layer.

Conclusion: In early experimental diabetes there is an overexpression of both total and phosphorylated HSP27 in RGC that parallels enhanced expression of markers of oxidative stress. Induction of HSP27 may represent a defence mechanism in response to increased oxidative stress in the diabetic retina.

Reversible induction of insulin resistance by adipokines in human megakaryocytes

A.J. Gerrits, E. Gitz, A.C. Koekman, J.-W.N. Akkerman

Department of Clinical Chemistry and Haematology, University Medical Center Utrecht, Netherlands

Background and aims: Diabetes mellitus (DM) patients have a 2-8 fold increased risk for cardiovascular disease (CVD) and suffer from microvascular (nephropathy, retinopathy) and macrovascular (peripheral arterial disease) complications. We demonstrated previously in normal platelets that insulin signals through Insulin Receptor Substrate-1 (IRS-1) and inhibits Ca²⁺ mobilization by interfering with the suppression of cAMP, a platelet inhibitor. Platelets from type 2 DM patients have become insulin resistant and their platelets aggregate better than controls. This hyperaggregability might be a cause for the increased CVD risk. In the present project we search for the cause of this insulin resistance. Obese subjects have abnormal levels of plasma adipokines and are prone to develop insulin resistance. Platelets show only minor protein synthesis and their properties are determined during their synthesis by the megakaryocyte. We investigated whether adipokines change the synthesis of platelet properties in the megakaryocyte.

Materials and methods: In suspensions of megakaryocytic CHRF-288-11 cells incubated with adipokines and plasma from an obese individual, we measured (i) insulin inhibition of thrombin-induced Ca²⁺ mobilization, (ii) aggregation induced by arachidonic acid, (iii) IRS-1 signaling to protein kinase Ba,β (AKT1,2) induced by insulin.

Results: Insulin (0.1-100nM) inhibited Ca²⁺ mobilization by 20 ± 7% at 1 nM (p<0.05) and by 47 ± 3% at 100 nM (p<0.0005). Inhibition was mimicked by prostacyclin and blocked by an adenylyl cyclase inhibitor confirming that insulin controls cAMP. Incubation with adipokines in concentrations 10 fold the physiological range showed that leptin, resistin, PAI-1 and RBP-4 but not IL-6, TNFα and visfatin made cells resistant to insulin for up to 7 days. After a 2 hrs incubation insulin sensitivity was rescued by cantharidin, but longer incubation made cells unresponsive to this serine phosphatase inhibitor. The protein synthesis inhibitors puromycin and cycloheximide failed to change the rapid induction of insulin resistance, revealing a transcription-independent mechanism. The adipokine-induced insulin resistance revealed at the level of Ca²⁺ also showed at the level of protein kinase B activation and made aggregation of megakaryocytes insensitive to inhibition by insulin. A preliminary experiment with blood from an obese subject showed that her plasma could replace the insulin resistance inducing adipokines whereas plasma from lean subjects could not.

Conclusion: Leptin, resistin, PAI-1 and RBP-4 induce insulin resistance in megakaryocytes by interfering with IRS-1. The resistance is reversible during short, and irreversible during prolonged incubation indicative for a transcription-independent and -dependent mechanism. This is a first report of insulin resistance induced by adipokines in the precursor of platelets, the megakaryocyte, and a possible explanation for the hyperactivity of platelets and increase in CVD risk when obese subjects develop type 2 diabetes mellitus.

Adiponectin and skeletal muscle: pathophysiological implications during stress

J. Jortay¹, M. Senou², L. Noel¹, M.-C. Many², S.M. Brichard¹

¹Unit of Endocrinology and Metabolism, Université catholique de Louvain,

²Unit of Experimental Morphology, Université catholique de Louvain, Brussels, Belgium

Background and aims: Adiponectin (ApN) is a hormone exclusively secreted by adipocytes under normal conditions. This adipokine exhibits insulin-sensitizing and anti-inflammatory properties as well as modulatory effects on oxidative stress thereby thwarting several disorders belonging to the metabolic syndrome. We have recently shown that ApN was induced in *tibialis anterior* muscle of mice injected with lipopolysaccharide (LPS) and in C2C12 myotubes cultured in the presence of pro-inflammatory cytokines.

We have hypothesized that this expression of ApN in muscle could be viewed as a local protective mechanism to counteract excessive inflammatory reactions and oxidative damage.

To test this hypothesis, we examined whether muscles of ApN-knockout (ApN-KO) mice exhibit higher degree of oxidative stress and apoptosis than those of wild-type (WT) mice when challenged by LPS and whether these abnormalities may be corrected by local administration of ApN.

Materials and methods: ApN-KO mice (with virtually undetectable circulating ApN) were used and compared to WT mice. Mice were injected with ip lipopolysaccharide (LPS) or saline. 24 h later, mice were killed and *tibialis anterior* muscles were collected for immunohistochemistry. In additional experiments, muscle transfer of ApN gene was performed in anesthetized ApN-KO mice by injection of ApN cDNA containing-plasmid (pcDNA3.1-ApN) followed by electroporation in one *tibialis anterior*, the contro-lateral muscle being electroporated by a control plasmid. Ten days after electroporation, ApN was overexpressed only in the muscle injected with ApN cDNA without any rise in circulating levels of the adipokine. Mice were then challenged by LPS as described above.

Results: We first confirmed that WT mice displayed a positive labelling for ApN in myocytes after LPS, but not after saline, injection. We next found that muscles of ApN-KO exhibited myotube degeneration when compared to WT mice, especially after challenge by LPS. We searched for the underlying mechanisms. Even in the basal state (after saline), myotubes of ApN-KO displayed a positive immunolabelling for 3 markers of oxidative stress (peroxiredoxin 3/5 and heme oxygenase-1) as well as for a lipid peroxidation product (hydroxynonenal). The pro-inflammatory cytokine (TNF- α) and a marker of apoptosis (caspase-6) were also already present in the basal state in muscle of these ApN-KO mice, but not in those of WT mice. After LPS injection, immunoreactivity for these markers was much more stronger in muscle of ApN-KO mice, while being only slightly detected in WT mice. Finally, we demonstrated that transfer of ApN gene prevents muscle damage in ApN-KO mice challenged by LPS. Thus, muscular electroporation with pcDNA3.1-ApN markedly reduced the expression of oxidative markers, hydroxynonenal, TNF- α and caspase-6 when compared to the contro-lateral untreated muscle.

Conclusion: The presence of ApN appears to be crucial to counteract locally excessive and deleterious inflammatory reactions, oxidative stress and subsequent apoptosis. These results may have repercussions in the pathogenesis of the metabolic syndrome where chronic inflammation and oxidative stress play determinant roles.

Distribution and characteristics of adiponectin R1 and R2 receptor mRNA gene expression in human visceral and subcutaneous adipose tissue

J.H. Pinkney¹, S.P.Y. Wong¹, D. Kerrigan², K. Kos¹, J.P.H. Wilding¹
¹Obesity Research Group, University of Liverpool, ²Bariatric Surgery, University Hospital Aintree, Liverpool, United Kingdom

Background and aims: Adiponectin (ADN) is secreted by adipose tissue, and exerts metabolic actions in liver, skeletal muscle and vascular tissues. Reduced expression of ADN may contribute to development of type 2 diabetes. ADN acts through two receptors, R1 and R2 expressed in target tissues, and R2 is the main receptor in liver and muscle. These receptors activate AMPK and have been shown to play a role in the regulation of fatty acid and glucose metabolism. Whilst there is paucity of data from human studies on AT-derived ADN receptor expression, a disruption of the R2 gene in mice was shown to mimic features of human Type 2 diabetes. The aim of this study was to characterise expression of ADN receptors in human subcutaneous and visceral adipose tissue regions.

Materials and methods: Samples of subcutaneous (SCAT) and visceral adipose tissue (VAT) were obtained from 18 lean volunteers and 39 obese well characterised subjects undergoing bariatric surgery. R1 and R2 mRNA were quantified by RT-PCR using QuantiTect® Multiplex PCR (Qiagen, Crawley, UK), with prevalidated primers and Quantiprobe®, on a ROTORGENE-2000 analyser (Corbett Research, Cambridge, UK). β -actin was the house-keeping gene.

Results: R2 receptor/ β -actin expression ratios indicated far more abundant expression of R2 than R1 in both VAT (median (interquartiles) 7.6(5.4–10.5) $\times 10^{-3}$ vs 2.07(0.53–7.9) $\times 10^{-5}$; $p < 0.001$) and SCAT (8.1 (6.1–10.7) $\times 10^{-3}$ vs 2.1(0.3–8.4) $\times 10^{-5}$; $p < 0.001$). However, there were no differences in R1 or R2 mRNA expression between lean and obese subjects (0.38 $< p < 0.77$), unlike

adiponectin mRNA; and expression was unaffected by age or gender. R1 expression in VAT correlated inversely with serum ADN ($r = -0.37$; $p < 0.01$), but neither R1 in SCAT, nor R2 in VAT or SCAT correlated with serum levels. In marked contrast to findings with serum ADN and expression of ADN mRNA, receptor mRNA expression in VAT and SCAT was unrelated to plasma insulin, insulin sensitivity, BMI or waist circumference (all $p > 0.05$). When examined against a panel of adipokines, R1 and R2 expression in VAT and R1 in SCAT correlated with expression of MMIF-1 mRNA (all $r \geq 0.35$; $p < 0.02$).

Conclusion: R2 is the predominant receptor isoform expressed in human VAT and SCAT, and is expressed at similar levels at both sites. In marked contrast to ADN itself, receptor expression shows no apparent relationships with metabolic syndrome parameters. Our study does therefore not confirm the proposed pivotal role of R2 in the pathogenesis of insulin resistance found in mice. ADN receptors in adipose tissue may therefore play a separate role in rodent and mice adipose tissue physiology. Further insight is necessary in the autocrine and paracrine effects of ADN in human adipose tissue.

RNA oligonucleotides improve metabolic syndrome by targeting retinol binding protein4 gene in high fat fed mice

Y. Tan¹, R. Dale², L.-Q. Sun², M.A. Kamal¹, X. Qu¹

¹Medical and Molecular Biosciences, University of Technology Sydney, Australia, ²Research & Development, Oligos Etc., Inc, Wilsonville, United States

Background and aims: Retinol binding protein 4 (RBP4) is a newly discovered adipokine, which plays a role in insulin resistance and obesity. The aim of this study was to examine whether down-regulation of the RBP4 expression could impact on abnormalities of glucose and lipid metabolism seen in metabolic syndrome.

Materials and methods: RNA oligonucleotides (RNA oligos) were designed to be complementary to the 5'-untranslated region, start codon or termination regions of the RBP4 gene and chemically modified with 2'-O-methyl and a 3'-butanol tag. In vitro activity of the RNA oligonucleotides was determined in 3T3-L1 adipocytes with the aid of Lipofectamine™ 2000 and assayed by Real-time PCR. High fat diet (HFD) fed mice were used. 3 groups of HFD mice ($n = 8$) received treatment with saline (5 ml/kg, HFD control), rosiglitazone (RSG, 10 mg/kg) or RNA oligos (25 mg/kg) every second day for 4 weeks. By the end of the treatment, animals were subjected to insulin tolerance test (i.p. ITT 1U/kg) and glucose tolerance test (i.p. GTT 2g/kg). The levels of serum glucose, insulin, triglycerides (TG) and non-esterified fatty acids (NEFAs) were measured. The RBP4 levels in the serum and adipose tissue and the level of glucose transport 4 (Glut 4) in skeletal muscles were examined by Western blotting.

Results: RBP4 mRNA levels in RNA oligos transfected 3T3-L1 cells were significantly lower compared with control cells, indicating that the expression of RBP4 mRNA was inhibited by the RNA oligos. In vivo study showed that RSG and RNA oligo treatments did not affect whole body weight but significantly reduced the weight of abdominal adipose tissues (1.01 ± 0.15 vs 0.71 ± 0.10 and 0.64 ± 0.05 g, $P < 0.05$). Compared with the control, both RSG and RNA oligos treatment significantly reduced blood glucose levels (8.72 ± 0.24 vs 6.47 ± 0.20 and 6.58 ± 0.48 mmol, $P < 0.001$ and 0.01 , respectively) and the corresponding values for serum insulin were 15.62 ± 2.87 , 6.70 ± 1.60 and 9.88 ± 1.37 μ U/ml, respectively ($p < 0.05$). Following an i.p. injection of glucose, there were significant reductions in area under curve (AUC) of the blood glucose concentration-time profiles in RSG and RNA oligos treated mice. The AUC[glu] was 2617 ± 287 for HFD control vs 1907 ± 105 and 2043 ± 112 , $p < 0.05$. RSG and RNA oligos treatments also enhanced insulin-mediated glucose disposal during i.p. ITT: AUC [glu] was 925 ± 61 vs 745 ± 74 and 795 ± 27 , respectively. Both RSG and RNA oligos attenuated the rise in NEFA associated with HFD feeding (0.62 ± 0.04 and 0.64 ± 0.08 mmol compared with 0.79 ± 0.07 mmol in HFD mice). RNA oligos but not RSG significantly reduced serum TG level (0.42 ± 0.03 mmol in RNA oligo group vs 0.52 ± 0.07 in RSG group and 0.55 ± 0.06 mmol in HFD group, $P < 0.05$). Western blotting revealed that RNA oligos significantly inhibited the expression of RBP4 in adipose tissue and enhanced GLUT4 expression in skeletal muscle. Although RSG up-regulated GLUT 4 expression in muscle it had no significant effect on RBP4 expression in adipose tissues. Both RNA oligos and RSG significantly reduced the circulating RBP4 levels.

Conclusion: RNA oligonucleotides targeting RBP4 could improve hyperlipidaemia and glucose-intolerant conditions associated with HFD feeding, sug-

gesting that RBP4 may be a new molecular target for potential treatment of metabolic syndrome and potentially for prevention of type 2 diabetes.

Relationship between serum retinol binding protein 4 and liver fat content in subjects without known diabetes

H. Yan¹, X. Gao¹, M. Liu¹, Q. Gu², B. Zhang³, X. Li⁴

¹Endocrinology and Metabolism, Zhongshan Hospital, Fudan University, Shanghai,

²Geriatrics, Zhongshan Hospital, Fudan University, Shanghai,

³Geriatrics, 10th People's Hospital of Shanghai, Tongji University, Shanghai,

⁴Endocrinology and Metabolism, Dalian University Affiliated Zhongshan Hospital, Dalian, China

Background and aims: Previous studies have shown that adipose-derived serum retinol-binding protein 4 (RBP4) levels are increased in insulin-resistant mouse models and in subjects with insulin resistance or type 2 diabetes. However, fewer studies researched the association of serum RBP4 and liver fat content. The purpose of this study was to investigate the relationship between serum RBP4 and liver fat content in subjects with nonalcoholic fatty liver disease (NAFLD) and without known diabetes.

Materials and methods: 106 patients diagnosed as fatty liver by ultrasonography (male/female:61/45; aged 47.44±14.16 years) were enrolled. Subjects with known diabetes, chronic virus hepatitis, and those with alcohol consumption (≥30g/d in male and ≥20g/d in female) were excluded. Anthropometrics and laboratory tests including lipid profile, OGTT glucose and insulin level after 75g glucose load were measured. Serum RBP4 was detected by ELISA and validated by quantitative Western blotting. Insulin resistance was represented by HOMA-IR in all patients. Insulin Sensitivity index (ISI) was determined by hyperglycemic clamp technique in 17 subjects. Liver CT scan was used to determine fat content in the whole liver.

Results: Liver fat content in all subjects distributed from 0% to 34.72%. When liver fat increased by quartile order [$<3.11\%$ ($n=26$), $\geq 3.11\% \sim <6.34\%$ ($n=27$), $\geq 6.34\% \sim <10.82\%$ ($n=27$), $\geq 10.82\%$ ($n=26$)], serum RBP4 level was 47.09±1.19, 53.11±8.74, 52.81±1.52, 53.54±9.86mg/L respectively ($p>0.05$). Pearson correlation analysis demonstrated that RBP4 levels associated with liver fat content ($r=0.202$, $p=0.049$), waist circumference ($r=0.209$, $p=0.041$), WHR ($r=0.347$, $p=0.001$), HDL-c ($r=-0.356$, $p=0.001$), triglyceride ($r=0.322$, $p=0.002$), systolic blood pressure ($r=0.226$, $p=0.027$), diastolic blood pressure ($r=0.228$, $p=0.025$) and sex ($r=-0.409$, $p=0.000$). However, there were no significant associations of RBP4 and age, BMI, hip circumference, total cholesterol, LDL-c, fasting and 2 hour serum glucose and insulin, HOMA-IR, ISI (all $p>0.05$). Multiple linear regression analysis revealed that RBP4 was correlated with WHR ($p=0.018$), but not with liver fat content ($p=0.437$) (table 1).

Table 1 Multiple Linear Regression Analysis of RBP4

Model	Unstandardized Coefficients B	Unstandardized Coefficients Std. Error	Standardized Coefficients Beta	p value
WHR	67.837	28.019	0.424	0.018
Waist circumference	-0.389	0.213	-0.337	0.071
Sex	-4.819	2.590	-0.203	0.066
HDL-c	-6.937	4.975	-0.154	0.167
Triglyceride	1.308	1.038	0.134	0.212
Systolic blood pressure	0.060	0.074	0.106	0.414
Liver fat content	0.173	0.222	0.092	0.437
Diastolic blood pressure	0.053	0.141	0.051	0.707

Conclusion: Our results showed that RBP4 was associated with WHR, but not with liver fat content. It suggested that the level of RBP4 was mainly affected by visceral fat accumulation.

204

Epicardial adipose tissue gene expression in metabolic syndrome

M. D'Adamo¹, V. Guglielmi¹, A. Bellia¹, B. Miccheli¹, S. Costa¹, B. Carteni¹, C. Del Giudice², G. Donadel¹, D. Lauro¹, M. Federici¹, L. Chiariello², R. Lauro¹, P. Sbraccia¹

¹Internal Medicine, University of Rome Tor Vergata, ²Surgery, University of Rome Tor Vergata, Italy

Background and aims: Epicardial Adipose Tissue (EAT) is situated predominantly on the right-ventricular free wall and the left-ventricular apex, has been shown to have a high capacity for non-esterified fatty acid (NEFA) release and is proposed as a source of this preferred metabolite for the myocardium. Furthermore EAT accumulation has been related to clinical and anthropometrical parameters of Metabolic Syndrome.

Aim of our study was to evaluate adipokines expression pattern and macrophage infiltration rate of EAT in metabolic syndrome.

Materials and methods: To this aim we studied 10 subjects who underwent cardiac surgery for either coronary artery by-pass graft (CABPG) or valvular disease: 5 patients with metabolic syndrome (3M/2F; BMI 27.6±2.6; waist 98.5±7.0; 5/5 Hypertensive on treatment; 3/5 dyslipidemic; 4/5 CABP) (MS) e 5 patients without metabolic syndrome (3M/2F; BMI 26.8±2.8; waist 91.2±12.37; 3/5 Hypertensive on treatment; No dyslipidemia, 2/5 CABP) (No-MS).

EAT biopsy (~0.5 g) was performed during surgery and total RNA was extracted, reverse transcribed, amplified and, by means of Real-time PCR, we evaluated the expression level of major adipokines (adiponectin, leptin, TNF-α, IL-6), and macrophage markers CD68 and CD14.

Results: Expression levels of insulin-sensitizing-adipokine adiponectin were significantly lower in the MS group compared to control group (27.3 ± 3.5 vs 43.7 ± 4.6 relative amounts, $p<0.02$), whereas leptin expression levels were higher in the MS group (77.6 ± 15.5 vs 32.7 ± 4.6 relative amounts, $p<0.05$). Inflammatory cytokines TNF-α and IL-6 show a similar expression pattern in the two groups, with MS group showing very high expression levels compared to No-MS group (TNF-α 147.7 ± 21.5 vs 44.7 ± 9.6 relative amounts, $p<0.005$; IL-6 55.8 ± 7.5 vs 12.7 ± 2.6 , relative amounts $p<0.01$).

These data, along with an increased expression of macrophage markers (CD68 108.7 ± 12.5 vs 12.4 ± 2.6 relative amounts, $p<0.005$; CD14 53.8 ± 8.5 vs 9.7 ± 2.6 relative amounts, $p<0.01$), reveals a large macrophage infiltration in EAT from subjects with Metabolic Syndrome.

Conclusion: These data suggest that: 1) EAT has an adipocytokine expression pattern similar to abdominal visceral adipose tissue; 2) the increased expression of inflammatory cytokine in EAT of subjects with Metabolic Syndrome, might contribute to the cardiovascular component of the Syndrome.

Visceral adipose stromal secretome triggers early events in atherothrombotic endothelial injury

F. Hanzu¹, M. Palomo², M. Diaz-Ricart², P. Gomez³, M. Garaulet³, S. Casas¹, R. Gomis¹

¹Diabetes and Obesity Laboratory, Endocrinology and Nutrition Unit, Hospital Clinic / IDIBAPS, Barcelona, ²Hemotherapy and Haemostasis, Hospital Clinic, Barcelona, Spain, ³Nutrition, University of Murcia, Spain

Background and aims: Central abdominal obesity is a major risk factor for atherothrombotic morbidity/mortality. Dysfunction of endothelium is a key event in the initial step of cardiovascular disease. This study aims to determine the direct role of adipose tissue secretome fractions from obese subjects in the early atherothrombotic endothelial injury and to identify biomolecules implicated.

Materials and methods: Abdominal subcutaneous and visceral (omental) adipose tissue was obtained from morbid (BMI: 40–45 kg/m²), obese males (n=6), without other cardiometabolic associated risk factors (no alteration of glucose metabolism, no dyslipidemia, no major cardiovascular disease) undergoing bariatric surgery. Fat pads were separated in stromal and adipocyte cell fraction. Resulted cell types were incubated with nonfetal medium (24h) to obtain the secretome. *Stromal/adipocytes, respectively visceral/subcutaneous conditioned medium (CM) containing the secretome of adipose tissue fractions* were further utilised. *Human endothelial cells (EC)* were grown, respecting the Jaffe method, using human sera. Studies were carried out using EC monolayer and extracellular matrix (ECM) generated by EC. Semiconfluent EC were incubated for 24 h with 100% CM or have been cocultured for 7 days with a medium containing 20% CM - of adipose tissue fractions from morbid obese. Expression of adhesion molecules in EC and prothrombotic ECM proteins were determinate by immunogold labelling and qRT-PCR. Images were analysed by computerized morphometry. Cellular adhesion on ECM under flow conditions was studied. Cellular proliferation was assessed through analysis on light microscopy and cell cycle evaluation using PI staining flow cytometry on a FACScan (FACS Calibur).

Results: Exposure of EC to adipose tissue CM fractions induces an increased presence of adhesion receptors on EC monolayer (*sVCAM-1*, *sICAM-1*, *sE-CAM-1*) and expression in prothrombotic (*v.Willebrand factor*) ECM proteins and platelet adhesion under reologic flow conditions. qRT-PCR shows increased mRNA levels for all corresponding genes. Highest expression was induced by obese visceral stromal secretome fraction. Microscopic analysis of EC exposed to CM fractions shows alteration in cell morphology. Cell cycle analysis by flowcytometry using DNA histograms with coefficients of variations <7% are indicating a characteristic pattern of cell cycle for control EC with 20.2±2.6% of cells in S+G2M phase and an heterogeneous pattern for EC exposed to CM fractions. A tendency to increase cell death after exposure to visceral stromal conditioned medium was observed.

Conclusion: Results of this study indicate the causative role of stromal, non-adipocyte cell fraction secretome of visceral morbid obese adipose tissue in the initiating endothelial injury events of atherothrombotic disease. Those, advancing in understanding of early endothelial injury mechanism in obesity, will permit future target suppression of various proinflammatory cascades in adipocytes which specifically represent an exciting new therapeutic opportunity for cardiovascular diseases.

Differences in vascular activity between Exenatide and GLP-1 in rat conduit arteries ex vivo

T. Nyström¹, D. Nathanson¹, Ö. Tütüncü¹, A. Bulhak², J. Pernow², Å. Sjöholm¹

¹South Hospital, Karolinska Institutet, ²Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden

Background and aims: Glucagon-like peptide-1 (GLP-1) is a promising drug decreasing blood glucose in type 2 diabetes. In addition, its salutary effects in endothelial dysfunction, heart failure and myocardial infarction are of high interest. Recently, we demonstrated that Exenatide rapidly activate endothe-

lial nitric oxide synthase in endothelial cells. Exenatide is a GLP-1 mimetic which exerts its effects via the GLP-1 receptor with almost the same potency as for GLP-1 in terms of lowering blood glucose. However, it remains elusive whether Exenatide exerts any vasoactive effects.

The aim of this study was to investigate whether Exenatide affects basal vascular tone, compared to GLP-1, and protects against endothelial dysfunction in rat femoral arterial rings.

Materials and methods: Thirty-eight male Sprague-Dawley rats were anesthetized and killed by excision of the heart. The femoral arteries were removed and put in organ baths. The contractile function of the vascular segments was tested by administration of phenylephrine (10⁻⁵ mol/l). Endothelium-dependent and endothelium-independent relaxations were determined by administration of acetylcholine (ACh) and sodium nitroprusside (SNP) added to the organ baths at cumulatively increasing concentrations (10⁻⁹–10⁻⁵ mol/l and 10⁻⁹–10⁻⁶ mol/l), respectively. Exenatide and GLP-1 were added to the organ baths at cumulative increasing concentrations (10⁻¹³–10⁻⁹ and 10⁻¹³–10⁻⁸ mol/l, respectively) during baseline tension to evaluate contractile effects *per se*. In separate parallel experiments, endothelial dysfunction was induced by incubating with a triglyceride rich fat emulsion (Intralipid[®]) at two different concentrations 0.5 and 2 % for 20 minutes. To investigate whether Exenatide protects against endothelial dysfunction, Exenatide (10⁻⁹ mol/l) was added to the organ baths prior to Intralipid[®].

Results: ACh and SNP induced concentration-dependent relaxations, demonstrating a valid working model. Exenatide applied during basal tension was without any discernable contractile or relaxant effect on the femoral artery rings. The maximum relaxation induced by Exenatide on the pre-contracted rings was only 3 %, compared to 18 %, 87 % and 100 % relaxations induced by GLP-1, ACh and SNP, respectively (P<0.001). Preincubation with 0.5 and 2 % Intralipid[®] elicited a significant reduction in ACh-induced relaxation by 29 % and 35 %, respectively (P<0.01). No such reduction was seen in SNP-induced vasorelaxation, revealing an endothelium-dependent dysfunction by Intralipid[®]. Exenatide did not protect against Intralipid[®]-induced endothelial dysfunction. Finally, to ascertain that the Exenatide preparation we used was biologically active, both Exenatide (10⁻¹¹ mol/l) and GLP-1 (10⁻⁹ mol/l) significantly increased insulin secretion from rat islets *in vitro*.

Conclusion: We show in a rat model that there is a significant difference in vasorelaxant properties between Exenatide and GLP-1. Furthermore, Exenatide could not confer any acute protective effects against lipid-induced endothelial dysfunction. In conclusion, Exenatide may not have the same influence on vascular tissue as GLP-1.

Exendin-4 upregulates eNOS phosphorylation and promotes proliferation of human coronary artery endothelial cells through the PI3K/Akt pathway

Ö. Tütüncü¹, D. Nathanson², Å. Sjöholm², T. Nyström², Q. Zhang¹

¹Karolinska Institutet, Research Center, Stockholm South Hospital,

²Karolinska Institutet, Internal Medicine, Stockholm South Hospital, Sweden

Background and aims: Endothelial cells have a robust capacity to grow and participate in angiogenesis, which underlies the maintenance of intimal layer integrity. We previously showed that endothelial cells express the GLP-1 receptor and that GLP-1 ameliorates endothelial dysfunction in type 2 diabetic patients with coronary heart disease. Exendin-4 is a stable GLP-1 receptor agonist and has been approved for clinical use against type 2 diabetes. In contrast to its effect on metabolism and endothelial function, the role of GLP-1 and its analogue on endothelial cell growth is not known. We therefore examined the effect of exendin-4 on endothelial cell growth as well as eNOS phosphorylation regulation in human coronary artery endothelial cells (HCAECs).

Materials and methods: HCAECs were incubated with or without (10 nM) exendin-4 in serum-deficient medium in the presence of 5 mM glucose for 48 h. Phosphorylation and expression of endothelial nitric oxide synthase (eNOS) and Akt were examined after 48 h incubation by Western blotting using anti-phospho-eNOS (Ser-1177), anti-eNOS, anti-phospho-Akt (Ser 473), and anti-Akt antibodies, respectively. Beta-actin was used as loading control. ³H-thymidine incorporation was assayed in 96-well plates as a measure of DNA synthesis after 48 h incubation with the reagents. Cell viability was assessed using Trypan-blue exclusion.

Results: Exendin-4 treatment (10 nM, 48 h) promoted DNA synthesis in HCAECs after 48 h incubation in 5 mM glucose, evaluated by thymidine in-

corporation, and neogenesis was confirmed by an increased cell number. To address the involvement of eNOS in proliferation, Western blotting with the use of antibodies against phospho-eNOS and eNOS was performed. Long-term treatment with exendin-4 enhanced the phosphorylation state of eNOS even when normalized for eNOS expression. We next examined the effects of the eNOS inhibitor L-NAME and the PI3K inhibitor LY294002 to determine whether exendin-4-induced cell proliferation was eNOS- and PI3K-dependent. Exendin-4-induced proliferation was completely inhibited by treatment with 1 mM L-NAME and partially suppressed by 2 μ M LY294002, suggesting involvement of eNOS and PI3K/Akt in exendin-4-induced proliferation. Exendin-4-induced eNOS phosphorylation was also inhibited by treatment with L-NAME and LY294002, respectively. These data suggest that Akt is involved in exendin-4-induced eNOS phosphorylation. Akt, which lies downstream of PI3K, is known to activate eNOS and thereby trigger NO production. Effects of exendin-4 on Akt phosphorylation were next examined. Western blotting with the use of antibodies against phospho-Akt and Akt revealed that exendin-4 significantly increased Akt phosphorylation in HCAECs, even when normalized for total Akt, and the exendin-4-induced Akt phosphorylation was inhibited by treatment with LY294002.

Conclusion: We have shown that PI3K/Akt pathway contributes to exendin-4-induced HCAEC proliferation and eNOS activation. The PI3K/Akt pathway is known to play important roles in endothelial cells, including cell survival and migration. These novel findings add yet other beneficial properties of exendin-4, increasing its clinical utility in type 2 diabetic patients in whom endothelial dysfunction is a salient feature that adversely affect their survival.

Interaction between beta cells and their capillaries: impact of hyperglycaemia. An *in vivo* model using chimeras

C.N. Chougnnet, S. Calderari, H. Kempf, J.-M. Gasc, P. Corvol, E. Larger
Chaire de médecine expérimentale INSERM U833, Collège de France, Paris, France

Background and aims: The islets of Langerhans have a dense vascular network, with highly specialized endothelial cells. Animal data suggest that failure to maintain an intact islet vasculature may be a key feature in the course of type 2 diabetes. To study the relationships between beta and endothelial cells, we created pancreatic chimeras. We grafted embryonic chick pancreases under the kidney capsule of severe combined immuno-deficient (SCID) mice. These inter species grafts enabled us to separately study endocrine (of avian origin) and endothelial (of murine origin) cells. Using this model, we have studied the impact of hyperglycemia on the interaction between endocrine and endothelial cells.

Materials and methods: Seven week-old female mice were made diabetic by a single intraperitoneal injection of streptozotocin (160mg/kg, in citrate buffer) and only the mice with random blood glucose level above 200mg/dl were further studied. Embryonic chick pancreases, obtained at day 14 post-incubation, were microdissected and grafted under the kidney capsule of SCID mice, one embryonic pancreas per mouse. Two weeks later, the transplanted pancreas was analyzed. The macroscopic vascularization was observed after a systemic injection of fluorescein. The microscopic graft vascularization, endocrine and exocrine differentiation were analyzed by immunohistochemistry. To better characterize the interaction between mouse and chick cells, we used an avian-specific retrovirus, the RCAS (Replication-Competent Avian sarcoma-leukosis virus long terminal repeat with a Splice acceptor) system, which can be used for stable transfection of dividing avian cells. This study was carried out along the principles of laboratory animal care.

Results: 1) In control mice, two weeks after transplantation, the pancreatic mass had increased, and the graft was well vascularized. The pancreas was well differentiated with insulin, glucagon and amylase positive cells. The microvascularization was dense and of murine origin as detected by nestin-immunohistochemistry, an endothelial marker that is specific for mouse, as shown in control experiments. 2) In hyperglycemic mice, the pancreatic development was decreased, whereas beta cell density was increased. In all experiments (n=5), we observed large blood-filled spaces suggesting abnormal blood vessels that were however not lined by murine endothelial, nestin-positive, cells. 3) In the first control RCAS experiments, we used an RCAS carrying the gene encoding the green fluorescent protein (RCAS-GFP). Chick pancreases were infected *in vitro* with the RCAS-GFP for 1 hour before transplantation. Two weeks later, we detected green fluorescence in the entire graft, whereas no fluorescence was detected in mouse tissues.

Conclusion: To study the interaction between beta cells and endothelial cells, we have developed a new and original model of inter-species transplantation that allowed us to create chimeras. We obtained chimeric pancreases consisted of chicken endocrine cells and mouse endothelial cells. Hyperglycemia induced large vascularization defects. Furthermore, the RCAS system should provide tools to alter specifically the development of beta cells, but not that of their capillaries.

Impaired vascular insulin signalling in subcutaneous microvascular endothelial cells in type 2 diabetes

S. Gogg, U. Smith, P.-A. Jansson
Department of Molecular and Clinical Medicine, Sahlgrenska Academy, University of Göteborg, The Lundberg Laboratory for Diabetes Research, Göteborg, Sweden

Background and aims: The culture of microvascular endothelial cells (MVEC) from different organs is a widely used experimental model. However, the methodological problems with extraction and culture of subcutaneous MVEC from small tissue samples have not been resolved. In this study, we established a method for extraction and culture of human MVEC from small tissue biopsies obtained from the subcutaneous adipose tissue (SAT).

We have previously shown that insulin-resistance is associated with an impaired insulin signaling, due to a reduced expression of the key docking protein IRS-1, in human subcutaneous adipose tissue. Therefore, we also studied the effect of insulin in subcutaneous MVEC from both healthy and type 2 diabetic (T2D) subjects.

Materials and methods: Subcutaneous needle biopsies were obtained from T2D patients and healthy control subjects. The tissue (4g) was incubated in sterile medium containing collagenase. After 50 min the digest was filtered through a sterile mesh and centrifuged. Two fractions were obtained, the floating isolated adipose cells and the lower fraction containing the stromal-vascular cells. The latter were seeded in endothelial growth media and the MVEC were selected by using the Dynabeads magnetic cell sorting system (CD 31 Microbeads). Immunofluorescence with von Willebrand factor, uptake of acetylated LDL, the cobblestone morphology and tube formation were used to characterize the cells. The Western blot and RT-PCR techniques were applied for protein- and gene expression analysis.

Results: We found that insulin receptor expression was low but there was a clear insulin-stimulated tyrosine phosphorylation of the receptor in both T2D and control MVEC. IRS-1 protein expression was markedly decreased in MVEC from T2D subjects. This reduction was also reflected by the reduced activation and serine phosphorylation of the downstream protein PKB/Akt. We also found an increased basal and insulin-stimulated phosphorylation of the MAP kinases, ERK1/2, in cells from diabetic subjects compared to controls. Interestingly, endothelin-1 (ET-1) mRNA levels were significantly increased in the MVEC from diabetic subjects. Addition of ET-1 to the culture medium increased basal MAPK phosphorylation in both control and T2D MVEC. PD98059, a specific MAPK inhibitor, prevented the effect of ET-1 and also decreased the activation of MAPK. Furthermore, the addition of the ET_A and ET_B receptor antagonists, BQ123 and BQ788, decreased the effect of ET-1 on MAPK activation.

Conclusion: We describe a method for primary MVEC culture obtained from small SAT samples. We found that MVEC from T2D patients have a reduced IRS-1 protein expression and an impaired insulin-stimulated PKB/Akt activation, whereas activation of ERK1/2 was increased in the basal state. Consistent with this we also found increased ET-1 mRNA levels in cells from diabetic subjects. Increased expression of ET-1 could be responsible for the MAPK activation seen in MVEC of T2D subjects, since this effect was prevented by PD98059 indicating the involvement of ERK1/2 activation in the ET-1 pathway. ET-1 has been shown to regulate insulin signaling by decreasing the tyrosine phosphorylation and expression of IRS-1 in adipose tissue. It is possible that similar mechanisms occur in the MVEC of SAT.

Effects of hyperglycaemia on Nrf2 and p53 antioxidant transcriptional activity in HUVECs

B. Schisano, C.R. Radford, A.L. Harte, K.C. Mc Gee, P.G. McTernan, A. Ceriello
Diabetes and Metabolism, CSRI University of Warwick, Coventry, United Kingdom

Background and aims: Cellular stress initiates a pro-oxidant response within cells which in turn activates transcriptional factors such as NRF2 and p53. Nrf2 has been shown to induce NQO1 and recent studies have identified a p53 induced anti-oxidant gene, TIGAR. However p53 may have a second role, suppressing the Nrf2-dependent transcription of antioxidant genes. This negative control on the Nrf2 transactivation appears to be aimed to prevent the generation of a too strong antioxidant intracellular environment that could hinder the induction of apoptosis. These evidences suggest p53 as a key factor for the cell's survival after exposure to cellular stress, a condition also present in hyperglycaemic. The aim of this study is to investigate whether hyperglycaemia can trigger an Nrf2/p53 mediated oxidative stress response and, more specifically, what the effects of chronic versus oscillating hyperglycaemia are on this pathway in HUVECs.

Materials and methods: HUVECs were grown for 3 weeks either in 5 mmol/l glucose, with 25 mmol/l mannitol for osmolarity normalisation, or in 30 mmol/l glucose or alternating 12 hours in normal glucose (5 mmol/l) with 12 hours in high glucose (30 mmol/l). Equal amounts of protein lysates (20 µg) were used for protein expression analysis by western blotting.

Results: Cells exposed to oscillating glucose (O-GLC) showed a significantly elevated protein expression of TIGAR compared with cells treated with normal (5mM) glucose (N-GLC) and high glucose (H-GLC) (TIGAR: O-GLC 3.5 ± 0.3 OD units vs N-GLC 1.0 ± 0.3 OD units*, O-GLC 3.5 ± 0.3 OD units vs H-GLC 1.9 ± 0.3 OD*; $p < 0.05$ data). A significant difference in TIGAR protein expression was also found between cell cultured in normal glucose compared with high glucose (N-GLC 1.0 ± 0.3 OD units vs H-GLC 1.9 ± 0.3 OD units $p < 0.05$). Bax was significantly increased in oscillating glucose compared with either normal glucose or high glucose (BAX: N-GLC 1.5 ± 0.3 OD units vs O-GLC: 2.7 ± 0.3 OD units**, H-GLC 1.8 ± 0.6 OD units vs O-GLC: 2.7 ± 0.5 OD units*; $p < 0.05$; ** $p < 0.01$); Nrf2 was significantly increased in both oscillating and high glucose, compared to normal glucose HUVECs (Nrf2: N-GLC 0.5 ± 0.2 OD units vs O-GLC: 1.1 ± 0.3 OD units*; H-GLC 1.1 ± 0.3 OD units vs N-GLC 0.5 ± 0.2 OD units*; $p < 0.05$; ** $p < 0.01$), but no significant difference was observed between high and oscillating glucose (H-GLC 1.1 ± 0.3 OD vs O-GLC: 1.1 ± 0.3 OD units $p = \text{N.S.}$). Furthermore NQO1 showed only a modest increase in oscillating glucose compared with either normal or high glucose treated HUVECs (NQO1: N-GLC 0.7 ± 0.3 OD units vs O-GLC: 1.0 ± 0.3 OD units*; H-GLC 0.5 ± 0.2 OD units Vs O-GLC: 1.0 ± 0.3 OD units*; $p = \text{N.S.}$).

Conclusion: Our findings indicate that oscillating and chronic high glucose induces a p53 mediated intracellular antioxidant response that limits the induction of Nrf2 antioxidant genes such as NQO1. Additionally, this is the first study to indicate that hyperglycaemia triggers TIGAR mediated induction of a p53 anti-oxidant response which further appears dependent on the length and pattern of glucose exposure. This may result in a more stressful condition for the cell which has clear implications for hyperglycaemic conditions induced in type 2 diabetes and cardiovascular disease.

OP 36 Apoptotic mechanisms in beta cells

Alterations in microRNA expression contribute to cytokine-induced pancreatic β -cell dysfunction

E. Roggli, S. Gattesco, R. Regazzi
DBCM, University of Lausanne, Lausanne, Switzerland

Background and aims: In Type I diabetes mellitus pancreatic β -cells are the target of an autoimmune reaction and are exposed to proinflammatory cytokines, such as IL-1 β , TNF α and IFN γ . Chronic exposure to cytokines has a detrimental impact on pancreatic β -cell functions leading to reduction in insulin content, defects in insulin secretion and sensitization towards apoptosis. In this study, we investigated the possible involvement of microRNAs in this phenomenon. MicroRNAs form a recently discovered class of non-coding RNAs that regulate gene expression by sequence-specific inhibition of target mRNA translation.

Materials and methods: The mouse insulin-secreting cell line MIN6 was exposed to IL-1 β or to a mixture of cytokines including IL-1 β , TNF α and IFN γ , after which microRNAs expression was profiled by microarray analysis. The results were confirmed by quantitative Real time-PCR measurements both in the insulin-producing cell lines MIN6 and INS-1E, and in isolated human pancreatic islets. The microRNAs induced by cytokines were over-expressed individually in MIN6 cells to test for their impact on the synthesis and secretion of insulin and for their effect on β -cells apoptosis. Moreover, to evaluate the contribution of microRNAs to IL-1 β -mediated β -cell dysfunction, the rise in the expression of each microRNA elicited by the cytokine was prevented using antisense oligonucleotides (antagomiRs).

Results: We observed that IL-1 β and TNF α increase the expression of miR-21, miR-34a and miR-146. We found that the induction of miR-34a triggered by the cytokines was linked to the activation of the p53 pathway while the rise in the expression of miR-146 was due to the activation of the NF κ B signaling cascade. Overexpression of these three microRNAs led to defects in insulin synthesis, insulin secretion and apoptosis that reproduce the effects of IL-1 β . Moreover, transfection of the cells with antagomirs, that prevent the rise of miR-34a or miR-146 elicited by IL-1 β , partially protected the cells from cytokine-induced apoptosis.

Conclusion: Taken together, our findings suggest that at least part of the deleterious effects of cytokines on β -cell functions may be attributed to alterations in the level of specific microRNAs.

212

High glucose activates hypoxia inducible factors 1 and 2 in cultured rat islets and INS1-E cell monolayers

M. Bensellam, J.-C. Jonas
Unit of Endocrinology and Metabolism, Université catholique de Louvain, Brussels, Belgium

Background: We have previously tested the effects of a 18h culture in 2, 5, 10 and 30 mmol/l glucose (G2, G5, G10 and G30) on the transcriptome of cultured rat islets and have identified 18 clusters with distinct glucose-dependent mRNA profiles. Of these, genes that were up-regulated between G10 and G30 are particularly interesting as they may contribute to beta-cell glucotoxicity or protection against it. Besides genes involved in the unfolded protein response, this cluster contains most glycolytic enzymes and other genes typically induced by hypoxia, such as *Adrenomedullin* (*Adm*).

Hypothesis and aims: High glucose, which increases O₂ consumption in beta-cells, may induce hypoxia and thereby cause glucotoxicity. In this study, we tested whether overnight culture in high glucose activates the hypoxia-inducible transcription factor HIF in cultured rat beta-cells.

Materials and methods: Male Wistar rat islets were precultured for one week in serum-free RPMI medium containing 10 mmol/l glucose (G10) and 5 g/l BSA, during which islets with signs of central necrosis were systematically discarded. INS1-E cells were cultured as monolayers (passage 72 to 80) in the presence of 10% FBS. Rat islets and INS1-E cells (70% confluence) were then cultured 18h in the presence of increasing glucose concentrations (G2, G5, G10 and G30) with various test substances and at different O₂ concentrations (1%, 20% or 60% corresponding to a pO₂ of 7.6, 152 and 456 mmHg). The

protein levels of HIF1 α and HIF2 α regulated subunits and their dimerization partner HIF1 β (also called ARNT) were measured by Western blot. *Gene* to *Tbp* mRNA ratios were determined by real-time RT-PCR. The results are means \pm S.E. for 3–6 experiments.

Results: Compared with G2, culture in G30 induced a significant ~4-fold increase in the protein levels of HIF1 α and HIF2 α in INS1-E cell nuclear extracts. These changes were accompanied by nuclear translocation without changes in total protein levels of HIF1 β . High glucose also significantly up-regulated the *Gene* to *Tbp* mRNA ratio for several HIF target genes (*Adm*, *Glyceraldehyde phosphate dehydrogenase*, *Aldolase A*, *Lactate dehydrogenase A*). These glucose effects, which were confirmed in whole rat islets, were mimicked by a 6h exposure to a low pO₂ (1% O₂) or by a 18h treatment with 10–30 μ mol/l CoCl₂, a known activator of HIF. In contrast, they were almost completely inhibited by 60% O₂ or by various agents that inhibit Ca²⁺ influx and insulin secretion (250 μ mol/l diazoxide, 1 μ mol/l nimodipine and 1 μ mol/l clonidine) and thereby likely reduce without suppressing the glucose stimulation of beta-cell O₂ consumption. In comparison with HIF target genes, *Thioredoxin interacting protein* (*Txnip*), one of the most glucose-responsive genes in cultured rat islets, was regulated in a completely different manner. Thus, the *Txnip* to *Tbp* mRNA ratio was not increased by CoCl₂ and 1% O₂, and its increase by G30 was not reduced by 60% O₂ and was markedly enhanced by diazoxide, nimodipine and clonidine.

Conclusion: High glucose induces HIF1 α and HIF2 α protein stabilization, HIF1/2 α -HIF1 β dimer translocation to the nucleus, and increased expression of glycolytic enzymes and other HIF target genes in cultured rat beta-cells. These effects likely result from the glucose stimulation of ATP utilization and O₂ consumption which may induce beta-cell hypoxia. These effects could contribute to *in vitro* beta-cell glucotoxicity not only in whole islets but also in insulin-secreting cells cultured as monolayers.

Role of mitochondrial ROS for increased incidence of autoimmune diabetes induced by natural variant of the F₀F₁-ATP synthesis (ATP8) gene

L. Wester Rosenlöf¹, X. Yu¹, C. Koch², H. Weiss², M. Tiedge², S. Ibrahim¹

¹Immunogenetics, University of Rostock, ²Medical Biochemistry and Molecular Biology, University of Rostock, Germany

Background and aims: Conplastic mouse strains with FVB mitochondria on NOD/LtJ background (NOD-mt^{FVB/N}) showed significantly higher incidence of diabetes compared to NOD/LtJ. Three genes are polymorphic between the NOD and FVB mitochondrial genomes from which the ATP8 subunit of the F₀F₁-ATP synthesis complex gene most likely affects the diabetes incidence. It was the aim of our study to elucidate the mechanism by which the ATP8 variant affects beta cell and immune cell function in C57BL/6J-mt^{FVB/N}, NOD-mt^{FVB/N}, NOD/LtJ and C57BL/6J-mt^{AKR/J} conplastic strains.

Materials and methods: The activity of the F₀F₁-ATP synthesis complex, mitochondrial ROS production and the ratio between state 3; state 4 mitochondrial respirations were measured in normoglycaemic mice. Serum concentrations of insulin-autoantibodies (IAA) in NOD-mt^{FVB/N} and NOD/LtJ mice were monitored over a 40 week period. Immune cell repertoire, activation marker expression, apoptosis and number of cell cycles followed T cell stimulation *in vitro* were analysed by flow cytometry. For lipotoxicity studies C57BL/6J-mt^{FVB/N} and C57BL/6J-mt^{AKR/J} were fed a high fat diet for 12 weeks. The mice were analysed for blood glucose, serum insulin, glucose tolerance, insulin sensitivity and glucose-stimulated insulin secretion from isolated islets.

Results: The ATP8 polymorphism does not affect the *in vitro* activity of the F₀F₁-ATP synthesis complex on the NOD/LtJ and C57BL/6J background. It also does not affect the mitochondrial state 3; state 4 respiration, but the mitochondrial ROS production was significantly higher ($p < 0.05$) in FVB derived mitochondria both on the NOD/LtJ and C57BL/6J background. A significantly higher IAA production ($p < 0.05$) was found in the NOD-mt^{FVB/N} mice compared to the NOD/LtJ mice, but no significant differences in leukocyte repertoire or consequences of *in vitro* T cell activation (activation marker expression, number of cell division or apoptosis) could be detected on NOD/LtJ or C57BL/6J background. Feeding C57BL/6J-mt^{FVB/N} mice with a high fat diet resulted in a significant impairment of glucose tolerance, lower serum insulin in fasted state and lower glucose stimulated insulin secretion in isolated islets. Blood glucose, body weight and insulin sensitivity was not affected in comparison to the C57BL/6J-mt^{AKR/J} control strain.

Conclusion: Our data indicate that the ATP8 variant leads to beta cell dysfunction and ROS production in particular under conditions of lipotoxicity. The beta cell dysfunction accelerates autoimmunity on the NOD background

without compromising the cellular immune system by the ATP8 mutation. The study emphasizes the role of mitochondrial ROS for the susceptibility of beta cells to autoimmune destruction.

Sustained expression of spliced XBP-1 is deleterious to primary beta cells

F. Allagnat¹, F. Christulia¹, P. Pirot¹, S. Lortz², D.L. Eizirik¹, A.K. Cardozo¹

¹Laboratory of Experimental Medicine, ULB, Brussels, Belgium, ²Institute of Clinical Biochemistry, Hannover Medical School, Hannover, Germany

Background and aims: A tight control of endoplasmic reticulum (ER) homeostasis is important for beta cell function and survival. IL-1 β + IFN- γ deplete beta cell ER Ca²⁺ stores, leading to ER stress and apoptosis. Cytokine-induced ER stress is characterized by induction of the IRE-1 α and PERK pathways and by a defective ATF6 and XBP-1 activation. ATF6 and XBP-1 are required for the up-regulation of ER-chaperones, and their impaired activation may deprive beta cells from a crucial defense mechanism against ER stress. Against this background, we overexpressed the spliced (active) form of XBP-1 in beta cells and examined whether this increases their resistance to cytokine-induced ER-stress and apoptosis.

Materials and methods: Recombinant adenoviruses expressing the spliced (active) form of mouse XBP-1s (AdXBP-1s) and, as controls, enhanced green fluorescence protein (AdeGFP), luciferase (AdLUC), truncated spliced mouse XBP-1 (AdtXBP-1s) and truncated unspliced (inactive) mouse XBP-1 (AdtXBP-1u) were used to infect dispersed rat islets and FACS purified beta cells. Expression of XBP-1s and key downstream genes and proteins were measured by real time RT-PCR and/or Western blot. Luciferase assays were performed with a construct containing the unfolded protein response (UPR) element, a binding site for XBP-1. Cell viability was evaluated by HO 342 and propidium iodide. Cells were exposed to IL-1 β (50 U/ml) + IFN- γ (500 U/ml), cyclopiazonic acid (CPA, 25 μ M) or tunicamycin (5 μ g/ml).

Results: Following infection of dispersed rat islet cells there was an efficient expression of mouse XBP-1s at the mRNA (XBP-1s/GAPDH: non-infected 3 \pm 2; AdeGFP 1 \pm 1; AdXBP-1 146 \pm 55) and protein levels (10-fold higher in AdXBP-1s-infected cells than in non-infected or AdeGFP-infected cells). The exogenous XBP-1s protein was active as shown by a 17-fold induction of the UPR reporter in cells infected with AdXBP-1s, as compared to non-infected cells ($n=8$; $p<0.001$). On the other hand, no induction was found in cells infected with AdeGFP or AdtXBP-1u. AdXBP-1s also induced a significant increase in the expression of the XBP-1s target genes EDEM-1 and PDI-P5 (EDEM-1/GAPDH: non-infected 0.14 \pm 0.04; AdXBP-1 0.28 \pm 0.08; PDI-P5/GAPDH: non-infected 1.14 \pm 0.32; AdXBP-1 2.01 \pm 0.58, $n=4-5$, $p<0.05$). Unexpectedly, overexpression of XBP-1s induced apoptosis in dispersed islets cells. Apoptosis was related to XBP-1s activity, since it was not observed in cells infected with AdLUC or AdtXBP-1u (% apoptosis: non-infected 18 \pm 2; AdLUC 19 \pm 2; AdtXBP-1u 18 \pm 1; AdXBP-1s 34 \pm 1; $p<0.02$ for AdXBP-1s vs. non-infected). Moreover, when comparing different viruses there was a significant correlation between XBP-1s activity and apoptosis ($R^2=0.66$; $p<0.04$). These pro-apoptotic effects of sustained XBP-1s expression were confirmed in FACS purified beta cells. Overexpression of XBP-1s did not augment IL-1 β + IFN- γ or CPA-induced islet cell death, while it increased tunicamycin-induced death. The increased apoptosis levels observed in cells overexpressing XBP-1s was not due to ER stress, since there was no induction of ER stress markers as evaluated by real time PCR.

Conclusion: Sustained overexpression of XBP-1s is pro-apoptotic in beta cells, suggesting that a tight control of the ER stress pathways is crucial to preserve beta cell viability.

Background and aims: Transplantation of pancreatic islets isolated from organ donors constitutes a promising alternative treatment for type1 diabetes,

however, it is severely limited by the shortage of organ donors. Ex-vivo expansion of islet cell cultures appears as an attractive strategy, however, maintenance of human islets has been a difficult task since islet fate in culture is, in part, determined by the balance between pro- and anti-apoptotic mediators. Previous results from our laboratory have demonstrated a significant beneficial effect of rhPRL treatment on cell proliferation and secretory function of human islet primary cultures. Therefore, in the present study, we set out to explore the role of rhPRL in human beta-cell survival.

Materials and methods: Human pancreatic islets were isolated after ductal distension of the pancreas and tissue digestion with Liberase HI, following the automated method of Riccordi et al, with some modifications. After isolation, islet cultures were pre-treated in the presence or in the absence of rhPRL (300 ng/mL) and then subjected to serum starvation or cytokines treatment for 24 or 48 h. Insulin beta cell content was analyzed by Newport Green staining and apoptosis was evaluated by DNA fragmentation (propidium iodide staining) and phosphatidyl serine externalization (Annexin-V staining). Both were quantified by flow cytometry (FACS) analysis. We also analyzed the expression of anti- and pro-apoptotic Bcl-2 gene family members by qRT-PCR. Additionally, using a specific synthetic substrate, we also evaluated caspase activity by fluorimetric assays.

Results: In order to establish whether rhPRL treatment would increase beta-cells survival, primary cultures of human pancreatic islets were treated with rhPRL and subjected to serum starvation or cytokines treatment. The proportion of simultaneous Newport green- and propidium iodide-positive cells was significantly lower in the presence of rhPRL ($p < 0.05$) under both serum-deprived and cytokine-treated conditions, when compared to control cells. Accordingly, a decreased rate of phosphatidyl serine externalization was observed upon rhPRL treatment under both cell death-inducing conditions, when compared to control cells ($p < 0.05$). In order to identify the mechanisms through which lactogens induce beta-cell survival, we studied the mRNA ratio between the anti-apoptotic Bcl-2 family and the pro-apoptotic Bax genes. Stimulation of human islet cells with rhPRL increased the Bcl-2 family/Bax mRNA ratio compared to control cells under both cell death-inducing situations. Moreover, caspase activity was lower in islet cultures which were pre-treated with the lactogen and then subjected to cytokines treatment than in cytokines-treated cells.

Conclusion: Our study provides, for the first time, relevant evidence for a protective effect of lactogens on both serum deprivation- and cytokine-induced human beta-cell apoptosis. Furthermore, the gene expression results suggest that rhPRL improves beta-cell survival, at least in part, by inhibition of cell death pathways controlled by the Bcl-2 gene family members.

6 days and the medium was analysed for intact GLP-1. Sections of paraffinized pancreas from control *P. obesus* were stained for glucagon, insulin and PC 1/3.

Results: *P. obesus* that had been fed a HE diet and were diabetic had increased levels of intact GLP-1 in the portal vein compared to control animals (8.5 ± 1.1 pM ($n=32$) and 3.6 ± 0.3 pM ($n=12$), respectively). For non-responders the level was 4.3 ± 0.5 pM ($n=10$). For all animals the level of intact GLP-1 in the aorta was below the detection limit of the assay. We found a significantly increased content of intact GLP-1 in pancreas tissue from diabetic animals compared to control animals (11.4 ± 2.2 pmol/g tissue ($n=9$) and 3.9 ± 1.0 pmol/g tissue ($n=3$), respectively). Interestingly, the non-responders seemed to have further increased pancreas content of intact GLP-1 (38.2 ± 1.4 pmol/g tissue ($n=2$)). We found that islets isolated from diabetic animals released more intact GLP-1 relative to glucagon than islets from control animals (GLP-1/glucagon ratio 0.02 and 0.0034 respectively). The bioactivity of the produced GLP-1 was confirmed by activation of the human GLP-1 receptor expressed in BHK cells. *In vitro* mimic of the diabetic condition (high glucose) led to a ~ 6 fold higher release of intact GLP-1 from control islets compared to control islets maintained in low glucose. Triple fluorescent staining of *P. obesus* pancreas sections verified the presence of PC1/3 in some glucagon cells.

Conclusion: In this study we find up-regulation of the active form of GLP-1 from alpha-cells in *P. obesus* when the animals are challenged with a diabetogenic diet. Our results are in agreement with the hypothesis that GLP-1 released from alpha-cells is involved in promoting beta-cell mass and function under challenging circumstances such as diabetes.

Up-regulation of GLP-1 from alpha cells - a protective mechanism against diabetes?

A.K. Hansen¹, T.B. Bödvarsdóttir¹, D.N.E. Lykkegaard¹, R. Heller², J.J. Holst³, A.E. Karlsen¹

¹Diabetes Biology, Novo Nordisk A/S, Maaloev, ²Developmental Biology, HRI, Gentofte, ³Biomedical Sciences, University of Copenhagen, Denmark

Background and aims: It is well established that GLP-1 has proliferative and anti-apoptotic effects on pancreatic beta-cells. The neighbouring alpha-cells produce proglucagon peptides and thus may liberate intact GLP-1 if prohormone convertase enzyme 1/3 (PC 1/3) is present. This alpha-cell GLP-1 can have paracrine effects on beta-cells. We hypothesise that alpha-cell GLP-1 may be up-regulated in situations when an increase in the functional beta-cell mass is needed, such as diabetes. The gerbil *Psammomys obesus* (*P. obesus*) is an animal model of nutritionally induced diabetes and was in this study used to investigate the hypothesis that alpha-cell GLP-1 is up-regulated during the development of diabetes.

Materials and methods: Diabetes was introduced in *P. obesus* by transferring animals from a low energy (LE) to a high-energy (HE) diet. Control animals were maintained on LE diet. Animals were categorised as diabetic when blood glucose levels exceeded 10 mM. Animals on HE diet that did not develop diabetes were categorised as non-responders. At the time of sacrifice blood samples were drawn from the portal vein and the aorta and the plasma concentrations of bioactive GLP-1 were measured. From a subset of animals the whole pancreas was removed, snap-frozen and subsequently analysed for intact GLP-1 content. From another subset of animals the islets were isolated and plated in a 96-well plate with 10 islets/well. After overnight incubation the medium was removed and analysed for levels of glucagon and intact GLP-1. Islets from control animals were incubated in 3 mM or 30 mM glucose for

Thiamine and benfotiamine normalize apoptosis of human retinal pericytes on high glucose-conditioned extracellular matrix

E. Beltramo, E. Berrone, S. Tarallo, M. Porta
Dept Internal Medicine, University of Turin, Italy

Background and aims: Thickening of basement membrane and pericyte loss are well-known early events in the pathogenesis of diabetic retinopathy. In previous experiments, we reported reduced adhesion, but no changes in apoptosis, in bovine retinal pericytes cultured on extracellular matrices (ECMs) produced by human endothelial cells in high hexose concentrations, probably due to glycation of matrix proteins. Subsequently, we showed that human retinal pericyte (HRP) apoptosis is strongly affected by matrix produced in high glucose probably due to impairment of the Bcl-2/Bax ratio. The behaviour of human cells was therefore different from that observed with bovine pericytes, underlining the importance of establishing species-specific cell models. For this reason, we created an immortalized human retinal pericyte line (Bmi-HRP), with the same morphology and metabolic characteristics of the wild-type cells (WT-HRP) from which it was derived. The aim of this study was to verify if thiamine and its lipophilic derivative benfotiamine, which have been shown to counteract glucose-induced apoptosis in vascular cells, are able to correct enhanced HRP apoptosis in the presence of high glucose-conditioned ECMs.

Materials and methods: Conditioned ECMs were obtained by growing human endothelial cells (HUVEC) for 7 days in culture media containing physiological (5.6 mmol/l) or high (28 mmol/l) D-glucose with or without 50 and 100 μ mol/l thiamine and benfotiamine. Cells were then lysed and ECM fixed by NH_4OH . Wild-type (WT-HRP) and immortalized HRP (Bmi-HRP) were cultured for 7 days in physiological glucose only on these conditioned ECMs. Pericyte apoptosis was evaluated measuring DNA fragmentation by ELISA; the expression of two molecules known to be involved in glucose-mediated apoptosis, Bcl-2 with a pro-proliferating and Bax with a pro-apoptotic function, was measured by RT-PCR and their concentration by ELISA. A decrease in the ratio Bcl-2/Bax is a marker of increased apoptosis.

Results: Both types of pericytes showed the same behaviour. Apoptosis of HRP was greatly enhanced by high glucose-conditioned matrix in comparison with physiological glucose ECMs (WT-HRP: 1.23 ± 0.48 abs units vs 0.06 ± 0.02 , $p=0.002$; Bmi-HRP: 2.12 ± 0.24 vs 0.05 ± 0.01 , $p=0.000$) and this was confirmed by Bcl-2/Bax ratio, both for mRNA expression (WT-HRP 0.43 ± 0.21 vs 1.62 ± 0.69 , $p=0.006$; Bmi-HRP: 0.47 ± 0.09 vs 1.01 ± 0.22 , $p=0.000$) and protein concentration (WT-HRP 0.02 ± 0.01 vs 0.11 ± 0.07 , $p=0.02$; Bmi-HRP: 0.09 ± 0.03 vs 0.20 ± 0.12 , $p=0.03$). Both thiamine and benfotiamine were able to reverse this effect: DNA fragmentation in WT-HRP and Bmi-HRP cultured on ECMs produced by HUVEC in high glucose plus thiamine and benfotiamine at both concentrations was fully normalized, as well as Bcl-2/Bax expression and concentration.

Conclusion: Thiamine and benfotiamine are able to counteract the apoptotic effect of high glucose-conditioned ECM on human retinal pericytes, probably reducing the glycation of matrix proteins, which, in turn, can lead to damaging interactions between pericytes and their surrounding microenvironment and, finally, to the onset of diabetic retinopathy.

Effects of high glucose and thiamine on the balance between matrix metalloproteinases and their tissue inhibitors in vascular cells

S. Tarallo, E. Beltramo, E. Berrone, P. Dentelli, M. Porta
Internal Medicine, University of Turin, Italy

Background and aims: Capillary pericytes disappear early and selectively in the course of diabetic retinopathy. Pericyte survival depends on interactions with extracellular matrix (ECM) proteins, which are degraded by matrix metalloproteinases (MMP). Elevated glucose concentrations can influence ECM synthesis and degradation, acting on the expression of MMPs and their tissue inhibitors, TIMPs. We reported previously on reduced adhesion of pericytes cultured on ECM produced by endothelium in high glucose and its correction by thiamine. In this paper, we now aimed at verifying the effects of thiamine and benfotiamine on the expression and activity of MMP-2, MMP-9 and TIMPs in human vascular cells in high glucose.

Materials and methods: Human retinal pericytes (HRP) and umbilical vein endothelial cells (HUVEC) were cultured in 5.6mM or 28mM glucose, with or without thiamine (T) or benfotiamine (BT). MMP-2, MMP-9, TIMP-1, TIMP-2 and TIMP-3 mRNA expression was determined by RT-PCR and activity by gelatin zymography and activity by gelatin zymography; TIMP-1 concentrations were measured by ELISA.

Results: In HRP, MMP-2 activity, though not expression, increased in high glucose ($123.7 \pm 11.8\%$ of G5.6, $p<0.05$) and was reduced by thiamine ($94.5 \pm 11.7\%$ of G5.6, $p<0.05$) and benfotiamine ($78.4 \pm 26.9\%$ of G5.6, $p<0.05$); TIMP-1 expression increased in high glucose plus thiamine ($118.7 \pm 30.0\%$ of G5.6, $p<0.05$) and benfotiamine ($118.2 \pm 30.2\%$ of G5.6); MMP-9 was not expressed. In HUVEC, MMP-9 and MMP-2 expression did not change in high glucose, while their activity increased (MMP-2: $130.2 \pm 24.9\%$ of G5.6, $p<0.05$; MMP-9: $120.0 \pm 19.1\%$ of G5.6, $p<0.05$); thiamine and benfotiamine had no effects. TIMP-1 expression was unchanged in HUVEC. Neither glucose nor thiamine modified TIMP-2 and TIMP-3 expression. TIMP-1 concentrations did not change in either HRP or HUVEC.

Conclusion: High glucose may imbalance the MMP/TIMP regulation, leading to increased turnover of ECM. Thiamine and benfotiamine may correct the increase in MMP-2 activity due to high glucose in human pericytes, while increasing TIMP-1.

High glucose causes a decrease in expression of thiamine transporters in human proximal tubule epithelial cells *in vitro*

J.R. Larkin, P.J. Thornalley
Clinical Sciences Research Institute, University of Warwick, Coventry, United Kingdom

Background and aims: It has been shown recently that both type 1 and type 2 diabetic patients have markedly decreased plasma concentrations of thiamine whilst maintaining nutritional sufficiency of the vitamin. Low plasma thiamine concentration was linked inversely to renal clearance of thiamine - attributed to decreased re-uptake of thiamine in the renal tubule epithelium. Similar decreases in plasma thiamine concentration and increases in thiamine clearance were found in streptozotocin-induced diabetic rats, and were also associated with decreased expression and activity of the thiamine pyrophosphate-dependent enzyme transketolase. Transketolase is a critical rate-controlling enzyme of the pentose phosphate pathway which helps resist adverse effects of high glucose concentration and the development of nephropathy and other microvascular complications in diabetes. In diabetic patients, low plasma thiamine concentration was also linked inversely with abnormally high plasma levels of soluble vascular cell adhesion molecule-1 - a marker of microvascular and macrovascular disease. The cause of increased thiamine clearance in diabetes remains unknown. Thiamine clearance is normally minimised by efficient re-uptake of thiamine from the glomerular filtrate by the thiamine transporters of renal proximal tubule epithelial cells. The aim of this study is to investigate if hyperglycaemia changes the expression of the thiamine transporter THTR-1 in human renal tubule epithelial cells *in vitro*.

Materials and methods: The HK-2 cell line was used as a model source of human proximal tubule epithelium cells. HK-2 cells were cultured in D-MEM/F-12 medium supplemented with 10% foetal bovine serum and 23 nM thiamine - a typical physiological level - for five days before harvesting. Cultures contained either a low glucose concentration (5 mM) or high glucose concentration (26 mM). After culture, cells were lysed and the membrane fraction separated by centrifugation (20,000xg, 30 min, 4 °C). Proteins of the membrane fraction were separated by 12% SDS-PAGE, transferred to nitrocellulose membrane and blotted with anti-THTR-1 antibodies (Alpha Diagnostics), stripped of antibody and re-blotted for the housekeeping protein β -actin with a second anti- β -actin antibody (AbCam, UK). Western blotting results are expressed as a THTR-1/ β -actin band intensity ratio.

Results: Thiamine transporter antigen was present in HK-2 cell membrane extracts as a protein of ca. 50 kDa in SDS-PAGE analysis. The THTR-1/ β -actin band intensity ratio was decreased 58% in cultures of HK-2 cells with high glucose concentration, relative to low glucose concentration controls. Intensity ratio: low glucose 0.255; high glucose 0.107 ($p<0.01$, $n=4$).

Conclusion: High glucose concentration decreased the expression of the thiamine transporter in human proximal tubule HK-2 epithelial cells *in vitro*. This is expected to decrease uptake of thiamine across the tubular epithelium. A similar effect of hyperglycaemia *in vivo* may contribute to the increased clearance and plasma deficiency of thiamine in experimental and clinical diabetes.

Thiamine status and risk of early renal function decline in type 1 diabetic patients

A. Adaikalakoteswari¹, B. Perkins², A.S. Krolewski³, N. Rabbani¹, P.J. Thornalley¹

¹Clinical Sciences Research Institute, University of Warwick, Coventry, United Kingdom, ²Toronto General Hospital, University of Toronto, Canada, ³Section on Genetics and Epidemiology, Joslin Diabetes Center, Boston, United States

Background and aims: Discovery of novel metabolic factors linked to diabetes may inform interventions for treating the early phenotypes of diabetic nephropathy: microalbuminuria (MA) and early renal function decline (ERFD). In view of the observed plasma thiamine deficiency in diabetes, we aimed to identify association of thiamine status with the onset of MA and with subsequent ERFD.

Materials and methods: Of 943 subjects recruited in 1991 with normoalbuminuria (NA) as part of the 1st Joslin Kidney Study, 86 of 109 who developed new onset MA had sufficient (>10y) follow-up after onset and had stored urine available from within 3 years of onset. We ranked them according to glomerular filtration rate (GFR) slope estimated by cystatin-C measured at least 3 times over a mean of 12 years. The outer tertiles of GFR slope were selected to produce a study group of 52 subjects with MA: 25 had ERFD defined as GFR loss exceeding 3.3% per year, while 27 had stable renal function. Urine from 30 subjects with longstanding NA was used for comparison. Plasma and urine were analysed for thiamine content by pre-column derivatization HPLC with fluorimetric detection. Log₁₀ transformed plasma and urinary thiamine concentration (nM) and thiamine fractional excretion TFE (%) data were analysed parametrically.

Results: Although markedly lower as compared to the non-diabetes literature, the mean log[plasma thiamine concentration] was not significantly different between MA and NA groups (1.0131 vs 0.9815). There was, however, a significant increase of log[plasma thiamine concentration] in MA subjects with ERFD compared to those with stable renal function (0.964 vs 1.148; $P<0.05$). However, the urinary thiamine measures showed higher concentration and excretion in MA than in NA groups: the mean log[urinary thiamine/creatinine] was 1.409 vs 1.076 ($P<0.001$) and the log[TFE] was 2.961 vs 2.688 ($P<0.001$). In addition, those with MA and ERFD had higher urinary thiamine concentration and excretion as compared to those with stable renal function: the mean log[urinary thiamine/creatinine] was 1.534 vs 1.204, respectively ($P<0.02$) and the log[TFE] was - 2.685 vs - 2.833, respectively ($P<0.05$). These differences were not confounded by age or sex. In a logistic regression model, log[urinary thiamine concentration] and glycated haemoglobin HbA_{1c} were independently associated with ERFD.

Conclusion: We conclude that increased urinary thiamine is associated both with processes that lead to the onset of microalbuminuria and furthermore to processes that lead to initiation of early renal function decline. In light of evidence in animal models of diabetes in which thiamine supplementation prevents the development of early stage nephropathy, these clinical results imply that thiamine supplementation in humans may represent one approach to preventing the onset of microalbuminuria and the initiation of renal function loss in patients with type 1 diabetes.

Role of a diabetes risk score in screening obese patients for metabolic syndrome, dysglycaemic states and cardiovascular risk

E. Cosson, E. Hamo Tchatchouang, M. Nguyen, H. Ba, I. Banu, P. Valensi
Department of Endocrinology, Diabetology, Nutrition, Paris Nord University - CRNH IdF, Paris, France

Background and aims: The Findrisk score has been developed in a Finnish population to evaluate the 10-yr risk of incident diabetes and validated subsequently in another Finnish cohort. An association has also been reported between this score and glycemic disorders and metabolic syndrome. The aim of this study was to evaluate whether this score correlates at the time of evaluation with metabolic syndrome, dysglycemic states and cardiovascular risk in patients with BMI ≥ 25 kg/m².

Materials and methods: An oral glucose tolerance test was performed in 1274 patients referred consecutively to our department (Jan 1998-Oct 2005) for overweight or obesity. Prediabetes and diabetes were defined according to WHO 1999 criteria, and metabolic syndrome according to IDF criteria. After exclusion of 328 patients without available score or with undetermined metabolic syndrome, and of 26 patients with fasting blood glucose (BG) ≥ 7 mM, 920 patients (769 women), 39 \pm 15 years, BMI 37 \pm 7 kg/m², were included.

Results: Prediabetes (impaired glucose tolerance, impaired fasting glucose or both) and diabetes were found in 20.5% and 4.4% of the population, respectively. The patients were categorized according to their diabetes risk score value (<10, 10-14, 15-19, and >19). Increasing score categories correlated with age, the prevalence of metabolic syndrome, BMI, waist circumference, systolic, diastolic and pulse blood pressure, HbA_{1c}, fasting and 120-min after glucose load BG and insulinemia, HOMA insulin resistance index, triglycerides, LDL-cholesterol, alanine aminotransferase and gamma-glutamyl transpeptidase levels ($p<0.01$ to 0.001). These correlations were still significant after age adjustment ($p<0.001$). The prevalence of prediabetes and diabetes increased with increasing score categories (2.7, 11.3, 62.5, and 60%; $p<0.001$, and 0.0, 1.5, 7.2, and 30.2%; $p<0.001$, respectively). The increase of HOMA index with score categories was independent of the presence or not of metabolic syndrome, with a higher value when metabolic syndrome was present.

Conclusion: In overweight or obese patients, 1- the Findrisk score correlates with current metabolic syndrome, insulin resistance, glycemic status, and cardiovascular risk; 2- this score may be useful to select the patients to be screened for these conditions.

222

Perceived risk of type 2 diabetes in Australian women with a recent history of gestational diabetes mellitus

M.K. Morrison¹, C.C. Collins², J.M. Lowe²

¹Health & Education Division, Diabetes Australia-NSW, Sydney, ²Faculty of Health, University of Newcastle, Australia

Background and aims: Despite the well documented risks of type 2 diabetes in women with a history of Gestational Diabetes Mellitus (GDM), there is some evidence to suggest that women with prior GDM do not perceive themselves to be at increased risk. The aim of this study was to describe the risk perceptions of a national sample of Australian women with a recent history of GDM.

Materials and methods: Participants were women aged 18 years and over, diagnosed with GDM between 2003-2005, sampled from the National Diabetes Services Scheme (NDSS) database. Cross sectional data was collected via written postal survey and included a self-reported risk perception scale.

Results: Of the 4098 women invited, 1372 eligible women consented to participate (response rate 36%). Respondents who were currently pregnant or subsequently diagnosed with type 2 diabetes were excluded from analysis ($n=196$). Mean age (\pm SD) was 35.6 \pm 4.9yr, 72% were Australian born, 19% spoke a language other than English and 1.1% were indigenous Australians. Up to 3 years post GDM, mean (\pm SD) self-reported BMI was 27.1 \pm 6.36 and more than half (57%) of the participants were overweight or obese. Thirty two percent (32%) of women perceived that they were low or very low risk for developing type 2 diabetes, 42% moderate risk, 20% high and 6% very high risk. Using logistic regression analysis, factors associated with a high or very high level of perceived risk were BMI >25 kg/m² (OR 4.3 95% CI[2.9, 6.1]), a family history of diabetes (OR 3.6 95% CI[2.6, 5.2]), use of insulin during

pregnancy (OR 1.9 95% CI[1.3, 2.6]) and being born in Australia (OR 1.5 95% CI[1.0, 2.2]). No two-way interactions between these factors were significant and the model was a good fit using Hosmer and Lemeshow test.

Conclusion: Although women with known risk factors for type 2 diabetes such as obesity and family history were more likely to perceive their risk as high or very high, the majority of this sample of women with previous GDM did not perceive that they were high risk for type 2 diabetes. Interestingly women who used insulin during pregnancy or were Australian born were more likely to perceive their risk as high. Overall these results suggest a need for increased awareness of GDM as an independent risk factor for type 2 diabetes.

Metabolic syndrome as guide to treatment of people with IGT with acarbose: a post hoc analysis of the STOP-NIDDM trial results

M. Hanefeld¹, A. Karasik², C. Koehler¹, T. Westermeier³, G. Saunders⁴, J.-L. Chiasson⁵

¹Center for Clinical Studies, GWT-TUD GmbH, Dresden, Germany,

²Department of Nuclear Medicine, Chaim Sheba Medical Center, Tel Hashomer, Israel, ³Bayer Vital GmbH, Leverkusen, Germany, ⁴G. Saunders Enterprises Inc., Drayton Valley, Canada, ⁵Department of Medicine, Université de Montréal, Canada

Background and aims: The metabolic syndrome (MetS) is associated with an odds ratio of ~4 for development of diabetes. The aim of the study was to analyse the independent and joint effects of the components of MetS on the incidence of diabetes in people with impaired glucose tolerance (IGT) and to assess the number needed to treat (NNT) with acarbose by MetS status.

Materials and methods: Double-blind placebo controlled trial, 1,368 patients, follow-up time 3.3 years. MetS by ATP III definition with fasting plasma glucose of ≥ 6.1 mmol/l as limit for impaired fasting glucose (IFG), post hoc analysis of the STOP-NIDDM trial.

Results: IFG, hypertriglyceridemia, low HDL-cholesterol and hypertension as single traits significantly increased the risk for diabetes with hazard ratio (HR) of 1.5, 1.4, 1.3 and 1.2 resp. Overall MetS resulted in a HR of 1.6 ($p < 0.0001$).

The annual incidence for diabetes in the placebo group with MetS was 18.7% vs. 11.2% without MetS.

Acarbose reduced the incidence to 13.5% and 9.4% resp. resulting in a number needed to treat (NNT) for patients without MetS of 16.5 and with MetS of 5.8. In multivariate analysis with established risk factors as continuous variables and MetS and treatment group as categorical variable acarbose, FPG, post challenge PG, HbA_{1c}, triglycerides and leucocytes were independent predictors of diabetes but not MetS.

Conclusion: MetS components except large waist independently predict diabetes in people with IGT but in combination confer no higher risk as expected from single traits. Acarbose reduces incidence of diabetes in people with and without MetS. However those with MetS have a distinctly higher benefit. Thus MetS labels a very high risk group in people with IGT which should have a priority for medical intervention.

ACTos NOW for the Prevention of Diabetes (ACT NOW) Study

D. Tripathy¹, M.A. Banerji², G.A. Bray², T.A. Buchanan², S. Clement², R.R. Henry², A. Kitabchi², S. Mudaliar², N. Musi¹, R. Ratner², P. Reaven², D. Schwenke², F. Stentz², R.A. DeFronzo¹

¹Diabetes, Medicine, University of Texas Health Science Center at San Antonio, United States, ²Diabetes, Medicine, ACT NOW Investigators, San Antonio, United States

Background: Impaired glucose tolerance (IGT) is a prediabetic state characterized by insulin resistance and impaired insulin secretion. ~10% of IGT individuals have evidence of diabetic retinopathy (DPP) and peripheral neuropathy has been reported in 5-10% of IGT subjects in other studies. Therefore, interventions targeting IGT have assumed added clinical importance.

Methods: ACT NOW is a randomized double-blind, placebo-controlled study to examine whether treatment of IGT with pioglitazone (PIO) can prevent/delay development of type 2 diabetes mellitus (T2DM). 602 IGT subjects (age = 52.3 y; BMI = 34.3 kg/m², 42% male; FPG = 105±0.3 mg%; 2-h PG

[OGTT] = 168±1 mg%; HbA_{1c} = 5.5±0.01%) were recruited in 8 US centers over 2 years and followed for an additional 2 years or until development of diabetes. IGT subjects were required to have FPG ≥ 95 mg% and at least one other high risk characteristic. All subjects had OGTT with insulin/C-peptide, lipid profile, inflammatory markers, and ankle-arm blood pressure. At 5 centers carotid IMT, DEXA, and FSIVGTT were performed. At entry, insulin sensitivity (Matsuda Index [MI] and S_i) was reduced by 48% ($p < 0.0001$) and insulin secretion/insulin resistance (disposition) index was decreased by 78% ($p < 0.0001$) compared to 102 age/BMI/gender-matched normal-glucose-tolerant controls identified during screening. IGT subjects were randomized to PIO (45 mg/day) or placebo (PLAC) and returned every 3 months for FPG/HbA_{1c} and annually for OGTT. Diagnosis of diabetes (FPG ≥ 126 or 2-h PG ≥ 200) was confirmed by repeat OGTT. At time of diagnosis of diabetes or at study end (4 years), all studies were repeated.

Results: 45 PLAC-treated subjects developed diabetes vs 10 PIO-treated subjects (6.8% vs 1.5% per year), representing a 78% decrease in IGT conversion to T2DM ($p < 0.000001$). 42% of individuals in PIO vs 28% in PLAC returned to NGT at study end ($P < 0.0005$), while the 2-h PG decreased by 28±0.4 vs 13±0.3 in PIO vs PLAC ($P < 0.005$). Insulin sensitivity (Matsuda Index, 4.3 ± 0.4 to 7.1 ± 0.6, $P < 0.0005$) and insulin secretion/insulin resistance index (3.1 ± 0.2 to 5.1 ± 0.4, $P < 0.0005$) improved in PIO and were unchanged in PLAC. Weight gain (3.9 vs 0.8 kg) and edema (22 vs 15%) were more frequent in PIO. There were 2 cases of CHF (PIO- 1, PLAC-1). There were 13 bone fractures (8 in PIO and 5 in PLAC) and all were related to trauma.

Conclusion: Pioglitazone markedly reduced, by 78%, the conversion of IGT to T2DM in association with improved beta cell function and reduced insulin resistance. Pioglitazone was safe and well tolerated during this 4 year study.

Automated detection of hypoglycaemia induced EEG-changes recorded by subcutaneous electrodes in type 1 diabetic subjects - the brain as a biosensor

C.B. Juhl¹, K. Højlund², R. Elsborg³, M.K. Poulsen², P. Selmar⁴, C. Christiansen⁵, H. Beck-Nielsen²

¹Department of Medicine, Esbjerg Sygehus, Esbjerg, ²Department of Endocrinology, Odense University Hospital, ³Hyposafe A/S, Lyngby,

⁴Department of Neurophysiology, Roskilde Sygehus, ⁵Nordic Bioscience A/S, Copenhagen, Denmark

Background and aims: Recurrent and severe hypoglycemia is a complication to tight glycemic control in patients with type 1 diabetes. Hypoglycemia unawareness is a common condition associated with increased risk of severe hypoglycemia. Cerebral hypoglycemia increases theta-activity and reduces alpha activity in the electroencephalogram (EEG) as recorded by standard scalp electrodes. The aim of the present study was, in order to develop a hypoglycemia alarm, to test the hypothesis that specific changes in the EEG during hypoglycemia can be recorded by subcutaneous electrodes and processed by a general mathematical algorithm and that a significant hypoglycemia signal can be obtained before the development of severe cognitive failure.

Materials and methods: Fifteen patients with type 1 diabetes were studied. Subcutaneous electrodes were placed at the area of Cz and C3 and EEG signals were recorded during insulin-induced hypoglycemia. The cognitive function was evaluated by repeated cognitive testing and the counterregulatory hormones glucagon, adrenalin and noradrenalin were measured. EEG signals were subjected to quantitative analysis by an automated mathematical algorithm with a predefined threshold of hypoglycemia. The study was terminated when the subjects showed obvious signs of cognitive dysfunction as judged by the investigator.

Results: During the experiment all subjects experienced symptoms of hypoglycemia. Counterregulatory hormones increased significantly from plasma glucose = 3.0mmol/l to the termination of the study. Significant EEG-changes were detected by the automated mathematical algorithm in all subjects. Plasma glucose at the time of EEG changes was 2.5 ± 0.3 mmol/l (range 2.0 - 3.4 mmol/l). At the time of study termination plasma glucose was 2.0 ± 0.3 mmol/l (range 1.6 - 2.7 mmol/l) and all subjects had reduced cognitive function. Significant EEG changes occurred 29 ± 28 minutes (range 3 - 113 minutes) before termination of the study. In 13 out of 15 subjects EEG changes occurred before significant loss of cognition.

Conclusion: Previously defined changes in EEG following hypoglycemia were confirmed by recordings from subcutaneous electrodes. The changes could be detected by the automated algorithm applied. The time from significant EEG changes to loss of cognition was, in most cases, sufficient for the patient to correct hypoglycemia.

The medial amygdala; part of the central hypoglycaemia-sensing network?

L. Zhou, Z. Sang, S.N. Brown, R.J. McCrimmon

Internal Medicine (Endo), Yale University, New Haven, United States

Background and aims: Specialized glucose-sensing neurons within the ventromedial hypothalamus (VMH) are recognized to play a major role in the detection of hypoglycaemia. In rodents pharmacological or genetic manipulation of VMH glucose-sensing neurons has a marked effect on counterregulatory responses to acute hypoglycaemia. We recently demonstrated that the activity of glucose-sensing neurons in the VMH was significantly modulated by Urocortin III (UCNIII) via its action on Corticotrophin Releasing Hormone Receptor type-2 (CRHR2). The nerve terminals that release UCN III into the VMH arise from cell bodies in the medial amygdala (MeA). This region is also known to contain glucokinase mRNA, which suggested that the MeA may form an additional part of a glucose-sensing network linking the amygdala to the hypothalamus.

Materials and methods: To further investigate this hypothesis acute hyperinsulinemic (20 mU/kg/min) hypoglycaemia (~3.9 mmol/l) studies were performed in two groups of chronically catheterized male Sprague-Dawley rats. Thirty minutes prior to the start of the mild hypoglycemia clamp one group

of rats (n=6) were microinjected with 2-deoxyglucose, (2-DG, a non-metabolizable form of glucose, 10 mM solution at $0.04 \mu\text{l min}^{-1}$ for 30 min) into the MeA. The control group (n=6) were injected with aECF at same infusion rate. Blood for hormone analysis was taken under basal and experimental conditions. On completion of the clamp the rats were euthanized, after which their brains were perfused for later immunostaining.

Results: Additional glucopenic stress amplify the glucagon (181 ± 34 pg/ml vs 111 ± 18 pg/ml; $P < 0.05$) and epinephrine (2337 ± 637 pg/ml vs 1101 ± 252 pg/ml; $p < 0.05$) responses to hypoglycaemia compared to control group.

Conclusion: These studies suggest that the MeA is an additional glucose-sensing center that contributes to the detection of hypoglycemia and initiation of a glucose counterregulatory response. Moreover, the UCNIII/CRHR2 neural pathway may provide a link between hypothalamic and amygdala glucose-sensing neurons that allows for a more integrated response to acute hypoglycaemia.

Habituation of regional brain activation during hypoglycaemia in Type 1 Diabetes: a [¹⁵O]-H₂O PET study

M.M. Teh¹, J.T. Dunn², Y. Samarasinghe¹, P. Choudhary¹, P.K. Marsden², L.J. Reed³, S.A. Amiel¹

¹Department of Diabetes and Endocrinology, King's College London School of Medicine, ²PET Imaging Centre, St Thomas' Hospital, London, ³King's College London, Institute of Psychiatry, United Kingdom

Background and aims: Central mechanisms of hypoglycaemia awareness (HA) are not well understood, although neuroimaging studies of brain glucose metabolism have shown differences in activation in multiple brain networks during hypoglycaemia. We investigated the central correlates of HA in healthy subjects and type 1 diabetes (T1DM) using [¹⁵O]-H₂O positron emission tomography, to measure regional changes in brain perfusion. To identify differences in central mechanisms of hypoglycaemia awareness between men with T1DM and HA and hypoglycaemia naive male volunteers, using high resolution [¹⁵O]-H₂O PET, together with monitoring of symptoms and counterregulatory hormones.

Materials and methods: Twelve sequential [¹⁵O]-H₂O PET brain scans were obtained in 10 healthy non-diabetic male and 7 hypoglycaemia aware male type 1 diabetic subjects. These were acquired at 10 min intervals before, during and after a one-stepped hypoglycaemic clamp. Hypoglycaemia symptoms, counterregulatory hormonal responses and mood were measured after each scan. PET data were analysed with statistical parametric mapping (SPM).

Results: Despite a greater degree of hypoglycaemia in the T1DM group (2.4 ± 0.3 mmol/l vs 2.7 ± 0.3 mmol/l, $p < 0.01$), adrenaline responses were less (9.9 nmol/l/50 min vs 23.4 nmol/l/50 min, $p < 0.05$); cortisol responses were flattened (-55.6 nmol/l/50min vs 938 nmol/l/50min, $p < 0.02$) and changes in symptom scores were not different (38 vs 43, $p = 0.64$ for adrenergic scores, 44 vs 26, $p = 0.06$ for neuroglycopenic). The diabetic group felt more drowsy (7.1 vs 3.6, $p = 0.02$); troubled (-1.2 vs -4.4, $p < 0.05$) and sick (6.6 vs 2.8, $p < 0.05$). In the cerebral responses to hypoglycaemia, healthy subjects showed a stronger response in the amygdala and the sub-genual anterior cingulate cortex, than T1DM. In contrast, a stronger dorsolateral prefrontal cortical response was seen in the T1DM subjects ($p < 0.05$, cluster corrected).

Conclusion: The non-diabetic group achieved a greater counterregulatory endocrine response associated despite being exposed to a lesser hypoglycaemia challenge. Increased activation of the anterior cingulate and the amygdala in this group may underpin these differences in autonomic activation and between the two groups. The attenuation of responses in the T1DM subjects suggests habituation within brain networks which subserve stress responses in T1DM subjects. In contrast, the increased prefrontal responses to hypoglycaemia in this group suggest engagement of conscious and effortful problem solving responses to this stressor.

BOLD brain activation in response to a cognitive challenge during hypoglycaemia among T1DM subjectsA.M. Jacobson¹, N. Bolo², G. Musen¹, D. Simonson³, K. Weinger¹, A. Raji³, P. Renshaw²¹Psychiatry, Joslin Diabetes Center, Boston, ²Psychiatry, McLean Hospital, Belmont, ³Medicine, Brigham and Womens Hospital, Boston, United States

Background and aims: Acute hypoglycemia is known to impair cognitive ability. Working memory, which is involved in maintaining and manipulating information for immediate retrieval, is greatly affected by hypoglycemia. Working memory plays an important role in complex cognitive skills such as driving and maintaining a list of items or actions. Despite the impact of hypoglycemia on working memory little is known about the underlying brain activation mechanisms that support this function. The aim of this study was to evaluate brain activation and cognitive performance during laboratory-induced hypoglycemia in both T1DM patients (who commonly experience at least mild hypoglycemic episodes as a consequence of the disease) and non-diabetic control patients.

Materials and methods: Using blood oxygenation level dependent (BOLD) functional magnetic resonance imaging at 3T during a hyperinsulinemic clamp, we compared brain activation responses to a working memory task (WMT) in patients with T1DM (n=7; 5 M; age 37 ± 12) and non-diabetic controls (n=7, 7M; age 30.4 ± 8) during euglycemic (5.0mmol/l) and hypoglycemic (2.8mmol/l) conditions. Cognitive performance on the WMT was assessed by percent correct and reaction time.

Results: During euglycemia, we observed brain BOLD activation responses to the WMT ($P < 0.05$) that were similar for both groups. Activation was decreased during hypoglycemia in comparison to euglycemia for both groups ($P < 0.001$). However, T1DM patients showed less of a drop in activation during hypoglycemia when compared to controls. Specifically, this effect was found for parts of the dorsolateral prefrontal cortex (superior and inferior frontal gyri), and limbic cingulate regions ($P < 0.001$), when comparing regional %BOLD signal changes by ANOVA. No significant differences in task performance were found between either subject groups or glycemic conditions.

Conclusion: Decreases in task-related BOLD activation during hypoglycemia were less pronounced for patients with T1DM compared to non-diabetic controls while behavioral performance was conserved. This suggests that cerebral metabolism or physiology was altered in patients, possibly as the result of an adaptation of brain metabolism to antecedent hypoglycemic episodes or to hyperglycemia. To achieve the same level of cognitive performance T1DM patients maintained higher levels of brain activation than controls during hypoglycemia. This suggests that the patients' brain energetic metabolism underlying activation was increased in order to sustain the same level of cognitive performance.

BOLD brain activation for T1DM and Control Subjects in Response to the WMT during euglycemia and hypoglycemia

Long term effects of a new treatment and education programme for insulin treated diabetic patients with hypoglycaemia problems (HyPOS)B. Kulzer¹, N. Hermanns¹, T. Kubiak², M. Krichbaum¹, T. Haak¹¹Research Institute of Diabetes Academy Mergentheim, FIDAM, Bad Mergentheim, ²Psychological Department, University of Greifswald, Greifswald, Germany

Background and aims: HyPOS is a treatment and education program for insulin treated diabetic patients. It is conducted in group sessions (4 - 6 participants) and consists of 5 lessons. It's focussed on causes and improvement of hypoglycaemia unawareness, modification of dysfunctional glycaemic targets and health beliefs related to development and chronification of hypoglycaemia problems. Short term evaluation of HyPOS showed a significant improvement of hypoglycaemia awareness and a significant reduction of mild hypoglycaemic episodes after 6 months compared to a control group. This study examines the long-term effect of HyPOS on the incidence of severe hypoglycaemic episodes (defined as requiring glucose or glucagon injections).

Materials and methods: 135 type 1 diabetic patients (HbA1c $7.3 \pm 0.9\%$; diabetes duration 21.6 ± 11.0 yrs., age 46.0 ± 12.8 yrs) participated in this study. In this follow-up assessment 2 years after the end of treatment 82.3% of the original sample (66 patients in the control group, CG; participation rate 82.5% vs. 69 patients in HyPOS, participation rate 82.1% $p = .95$) participated: The mean follow up time was highly comparable in HyPOS and the CG (CG 24.5 ± 2.7 vs. HyPOS 24.3 ± 3.2 months; $p = .62$). Hypoglycaemia awareness and incidence of severe hypoglycaemia were assessed by questionnaire and validated by telephone interview.

Results: Severe hypoglycaemic episodes were reduced from 0.87 events per patient and year at baseline to 0.14 events per patient and year in HyPOS. In the control group event rate per patient and year were reduced from 0.87 to 0.27. The reduction was significantly greater in HyPOS than in the CG ($p = .04$). Proportion of patients with at least one severe hypoglycaemic episode was also significantly reduced in HyPOS compared to CG (HyPOS from 37% to 13%; CG from 40.9% to 27.3%). The hazard ration for a severe hypoglycaemic episode was 0.4 (0.16 - 0.96 $p = .04$) in HyPOS compared to CG. Thus relative risk for having a severe hypoglycaemic episode was reduced by 60%. The course of glycaemic control was highly comparable (HyPOS baseline $7.2 \pm 0.9\%$ to $7.1 \pm 0.9\%$; CG baseline $7.4\% \pm 1.0$ to 7.3 ± 1.1 ; $p = .84$).

Conclusion: Severe hypoglycaemic episodes are a cause of diabetes related distress and also a potentially dangerous complication in diabetic patients. Furthermore they are also causing high costs, because of the necessary emergency treatment. Participation in HyPOS could reduce the incidence of severe hypoglycaemic episodes in a long term follow-up, without compromising glycaemic control. Therefore HyPOS seems to be an effective tool for treating insulin treated diabetic patients with hypoglycaemic problems.

Medical School, University of Warwick, Coventry, United Kingdom,

⁹Endocrinology, Hosp. Universitario Virgen Macarena, Sevilla, Spain,¹⁰LifeScan Inc., Milpitas, United States

Background and aims: Carbohydrates (CHO) counting is an effective strategy to promote dietary freedom, quality of life, and glycaemic control, but its

widespread use is limited by the complex educational approach. The Interactive Diary for Diabetes (DID) is an electronic diary, a bolus calculator and a telemedicine system based on the communication between patient and specialist by SMS through mobile phones. It enables patients to match the insulin to desired CHO intake on a meal by meal basis without the complexities of the standard education needed to teach CHO counting. The aim of this study was to evaluate whether the DID could represent a valid alternative to standard CHO counting education in terms of metabolic and weight control.

Materials and methods: Adults with type 1 diabetes were randomised to the DID educational program (Group A, N=67) or to standard education for CHO counting (Group B, N=63). Patients randomised to Group A attended a 2 weeks course to learn the use of DID. Patients in Group B received a standard education lasting up to 3-months, to learn how to adjust insulin doses on the basis of CHO content of the meals. Patients were seen after 3 and 6 months from randomization. During the 3 study visits data on HbA_{1c}, fasting blood glucose (FBG), body weight, blood pressure and lipid profile were collected. A hierarchical linear model for repeated measurements was used to assess differences over time between groups.

Results: Out of 130 patients enrolled, 80 individuals completed the study and were included in this analysis. The mean age of participants was of 36.3±9.8, while the mean diabetes duration was of 16.6±10.7 years; 49.2% of the patients were males, and 21.7% were treated with CSII. After six months of follow, HbA_{1c} levels decreased in both groups (Group A: from 8.1±0.8 to 7.7±0.8; Group B: from 8.35±0.7 to 8.0±1.3; between groups comparison p=0.8). Body weight was almost unchanged in Group A (from 68.1±11.8 to 68.9±13.4 kg), while it increased from 69.0±13.4 to 70.8±13.6 kg in Group B (p=0.34). FBG decreased in Group A (from 175±82 to 165±71 mg/dl), while it increased in Group B (from 181±59 to 195±81 mg/dl) (p=0.23). No changes in blood pressure and lipid profile were detected.

Conclusion: These preliminary results suggest that the use of DID is at least as effective as the traditional educational approach to CHO counting, but allows to avoid the complexities of CHO counting, thus allowing dietary freedom to a larger proportion of individuals with T1DM. The final analysis including all randomized patients will provide more accurate estimates of the comparative benefits of the two educational approaches.

Randomised controlled evaluation of “modular” versus “full course” patient education programmes for insulin-treated patients with type 2 diabetes and previous experience with patient education

M.A. Nauck, H. Schulze, C. Nagel-Reuper, S. Golla

Diabeteszentrum Bad Lauterberg, Bad Lauterberg im Harz, Germany

Background and aims: Patients with type 2 diabetes need education programs at different stages of their disease. Repeated participation in similar education programs with unchanged composition and content may reduce motivation. Therefore, we have developed a “modular” patient education program that allows the patients and their treatment teams to select topics (covered over 1–2 h) of specific interest to their actual situation. The aim of the present evaluation is to demonstrate the effectiveness of our “modular” patient education program in comparison to repeated participation in a standard course.

Materials and methods: Hospitalized patients with type 2 diabetes treated with insulin (mostly intensified regimens) were randomized to another standard patient education course or a “modular” patient education program (n = 75 for both). 71 patients participated in the standard course, 72 in the “modular” education (men/women: 28/43; 31/42; age 61 ± 10/62 ± 8 years; BMI 34.5 ± 5.9/34.5 ± 6.2 kg/m²; diabetes duration 15 ± 9/16 ± 8 years; insulin treatment for 7 ± 6/8 ± 5 years; insulin dose 96 ± 57/93 ± 67 IU/d; HbA_{1c} 8.7 ± 1.5/8.1 ± 1.4 %; means ± SD). Immediately after the educational measures, diabetes-related knowledge and patient satisfaction were assessed. One year later, HbA_{1c}, body weight, and achievement of individually chosen treatment goals were determined. Statistics: ANOVA, if appropriate for repeated measures; Fisher’s exact test. The hypothesis was that “modular” patient education was at least non-inferior (drop in HbA_{1c} between baseline and one year later not different by more than 0.4 %).

Results: 62 patients could be evaluated after a repeated standard course, and 63 patients after modular patient education. HbA_{1c} significantly dropped in both groups (−0.8 [−1.1/−0.5] %/−0.6 [−0.9/−0.2] %; p < 0.0001; mean ± 95% confidence interval), with no significant difference between groups (p = 0.48). Non-inferiority criteria were met. Body weight remained constant in both groups (no significant changes or differences). The duration of patient educa-

tion measures was shorter for “modular” training than for standard courses (10.4 ± 2.2 h vs. 15.9 ± 2.5 h, p < 0.0001). The amount of time required for patient education measures significantly correlated with the duration of the hospital stay (r² = 0.342, p < 0.0001). Duration of hospital treatment tended to be shorter with “modular” training (11.9 ± 3.5 vs. 13.0 ± 4.1 days; p = 0.064). Patient satisfaction was good and not different comparing both approaches.

Conclusion: Regarding metabolic and body weight control results were similar for “modular” and standard patient education, while the time required for educational measures was less for “modular” education. Since the time required for educational measures is a significant determinant of total treatment duration, “modular” patient education may be of interest to patients in specialized hospital departments and practices.

Integrated diabetes health care network (IDN) in telemedicine-supported health care delivery

E. Salzsieder¹, P. Augstein¹, L. Vogt¹, K.D. Kohnert¹, P. Boddenberg²,

E. Lewin², V. Heuzeroth³

¹Research, Institute of Diabetes, Karlsburg, ²Management, PHTS

Telemedizin, Düsseldorf, ³Management, BKK Taunus, Frankfurt, Germany

Background and aims: Progress in basic and clinical research has introduced the development of new strategies for treatment of diabetes. The innovative Karlsburg Diabetes Management System (KADIS[®]) was developed and experimentally verified over almost two decades. When combined with telemedicine-based communication (TeleDIAB[®]) and continuous glucose monitoring (CGM), KADIS[®] has the potential to provide effective, evidence-based support to doctors in their daily efforts to optimize glycemic control. It was the aim of this project to demonstrate the feasibility of improving diabetes control in conventional diabetes care by implementing KADIS[®] and TeleDIAB[®] in an integrated diabetes health care network.

Materials and methods: Based on a contract for integrated health care provision (IV contract) between the health care insurance company BKK Taunus, the telemedicine provider PHTS Düsseldorf, the Diabetes Service Center and the Institute of Diabetes Karlsburg KADIS[®]-based decision support and telemedicine-based communication technology (TeleDIAB[®]) was implemented into an integrated health care network to facilitate information exchange between patients, physicians, and health care professionals under daily life conditions. The interactive diabetes management system KADIS[®] enables individualized evaluation of glucose profiles in association with metabolic interventions (Metabolic Fingerprint) and to display online-trended patient-specific metabolic data and simulates the outcome of treatment recommendations. The Metabolic Fingerprint characterizes glycemic status by visualization of relationships between the continuously monitored glucose profiles and causal endogenous and exogenous factors and enabled evidence-based identification of “weak points” in glycemic control. Using KADIS[®]-based simulation, physician recommendation are generated in the form of patient-focused decision support that enables elimination of weak points. The outcome of KADIS[®]-based support in routine diabetes care was evaluated by comparing HbA_{1c} levels and 24-hours glucose profiles before and after the intervention.

Results: At present there are 384 diabetic patients permanently included into the integrated diabetes health care network, which are treated by 132 General Practitioners and 30 Diabetes Specialists. Application of KADIS[®] based decision support reduced HbA_{1c} during the follow-up by 0.2% (7.1% to 6.9%) after 3 months and by 0.4% (7.1% to 6.7%) after 6 months in routine diabetes care. The reduction in HbA_{1c} was strongly related to significantly improved 24-hours glucose profiles.

Conclusion: Application of KADIS[®] in combination with CGM and telemedicine-based communication in integrated health care networks has high potential for improving outpatient diabetes care and management considering daily life conditions.

Cd4 T cell reactivity to the major diabetes autoantigen Slc30A8 in newly diabetic subjects

H.W. Davidson, J. Rockell, R. Wagner, J.M. Wenzlau, D. Zipris, J.C. Hutton, P.A. Gottlieb

Barbara Davis Center for Childhood Diabetes, University of Colorado
Denver, Aurora, United States

Background and aims: ZnT8 (Slc30A8), an islet-specific zinc transporter is a major target of humoral autoimmunity in type 1A diabetes, with more than 60% of patients having ZnT8-autoantibodies at diagnosis. As the generation of high affinity class-switched antibodies is a CD4 T cell dependent process it is likely that disease associated ZnT8-specific T cells are also present in some or all newly diabetic individuals. These may potentially be targets of immunotherapies designed to prevent or ameliorate the course of disease. We therefore investigated whether ZnT8-specific, gamma interferon producing CD4 T cells are amplified in the peripheral blood of diabetic subjects.

Materials and methods: Peripheral blood mononuclear cells were obtained from 21 newly diabetic subjects and 12 age and HLA matched controls in accordance with institutionally approved human subjects protocols. PBMCs (1,000,000) were cultured for 48h with 23 pools of overlapping 20-mer peptides (2 peptides / incubation at 10µg/ml spanning the entire 369 amino acid primary sequence of ZnT8). After replating into 96 well plates coated with anti gamma interferon antibody (300,000 cells/ well) the reactive precursor frequency was identified by ELISPOT analysis. Data was normalized to the stimulation index relative to a DMSO control. Responses to the T1D antigens proinsulin, GAD and IA2 and the mitogen ConA served as positive controls. Non-parametric statistical analyses (Mann Whitney) were performed using GraphPad Prism 4 software. The ability of individual 15mer peptides to bind recombinant HLA DR3 and DR4 molecules were assessed using Proimmune REVEAL technology. Individual HLA DRB1 and DQA and DQB haplotypes were determined by a PCR based sequence specific oligonucleotide probe system (Roche).

Results: DR3 binding sites were focused in the hydrophobic core (aa100-200) and C-terminal (aa268-369) domain respectively. 16 DR4 binding sites were mapped 8 of which were also found in the C-terminal region. When considered as a group, significant ELISPOT responses were detected in diabetic subjects relative to controls to 3 peptides in the C-terminal cytosolic region and a fourth in the second cytosolic loop ($p<0.03$ - 0.05 , $n=21$). Individually, 14 of the 21 T1D subjects carried high risk DR3 and/or DR4 alleles and ELISPOT responses to the defined DR3 or 4 binding regions in these subjects varied from one to all (mean 5.6 peptides). Only 2 of the 21 diabetic subjects showed no response to any ZnT8 peptide ($SI<3$).

Conclusion: ZnT8 is an important autoantigen recognized by T-cells as well as autoantibodies in type 1 diabetes. The T-cell responses appeared to be focused in the same region as the autoantibody response, a feature that is also observed in other diabetes autoantigens such as GAD and IA2. Positive responses were seen with peptides in regions where binding to HLA molecules associated with diabetes susceptibility (DR3 and DR4) were evident, but also to other peptides suggesting participation of other class II binding specificities.

T-lymphocyte autoimmune activity measured at the single cell level is associated with residual β -cell function in type 1 diabetes

C. Pfleger, G. Meierhoff, H. Kolb, N.C. Schloot on behalf of the p520/521 Study Group

Institute for Clinical Diabetes Research, German Diabetes Center, Leibniz Institute at Heinrich-Heine-University, Düsseldorf, Germany

Background and aims: In the context of a large placebo controlled intervention trial in recent type 1 diabetes we have tested the hypothesis that the activation status of autoimmune T cells in peripheral blood is related to the quantity or activity of insulin-producing islet cells as reflected by residual β -cell function.

Materials and methods: 50 adult (mean age 27.26 ± 8.1 years) and 49 pediatric patients (mean age 10.9 ± 2.8 years) with recent onset type 1 diabetes were

included in the DiaPep277 Trial and received 0.2/1.0/2.5 mg or 0.2/1.0mg DiaPep277, respectively or placebo at 0, 4, 26 and 52 weeks. We investigated the secretion of Th1 associated IFN- γ and Th2 associated interleukin (IL)-5, IL-10 and IL-13 by peripheral mononuclear cells (PBMC) upon stimulation with diabetes related antigens peptide fragment of Islet Antigen 2 (pIA2), heat shock protein 60 (hsp60) or glutamic acid decarboxylase (GAD65), at the single cell level by ELISPOT according to the Peakman protocol. The area under the curve (AUC) of serum C-peptide concentrations after stimulation with glucagon was used as measure of residual β -cell function. Since sex, age, BMI, DiaPep277 treatment, HLA and HbA1c represented potential confounder; we adjusted for these factors in a regression model analyzing the relation of cytokine response and β -cell function.

Results: At baseline, mean two months after diagnosis, PBMC of adults showed a positive association of residual β -cell function with IL-13 cytokine secretion upon stimulation with pIA2 ($p=0.04$), whereas there was a negative association with IFN- γ secretion ($p=0.038$). Likewise, PBMC of children at baseline (two months after diagnosis) also exhibited a positive association of residual β -cell function with IL-13 secretion in response to stimulation with pIA2 ($p=0.034$). The same was found after stimulation with hsp60 ($p=0.024$), but IFN- γ secretion was not related to AUC C-peptide levels.

At 8 weeks, both age groups had preserved an association of AUC C-peptide concentrations with cytokine secretion. In adults, there was a positive association with the IL-13 response to hsp60 ($p=0.038$). In children, there was a positive association with the IL-5 response to hsp60 ($p=0.044$) and a negative association for the secretion of IFN- γ in response to pIA2 ($p=0.047$) and GAD65 ($p=0.045$).

After 30 weeks, only children exhibited some association between residual β -cell function, for the IL-13 response upon stimulation of PBMC with GAD65 ($p=0.019$). At 56 or 78 weeks neither adults nor children showed an association of autoimmune responsiveness and AUC C-peptide concentrations.

Conclusion: Cytokine secretion of PBMC upon stimulation with β -cell antigens was associated with β -cell function during the first months after diagnosis of type 1 diabetes and lasted longer in children compared to adults, which can be interpreted as a more aggressive immune response and/or insulinitis in pediatric patients. Increased IFN- γ response was associated with lower β -cell function whereas increased IL-5 or IL-13 response was associated with better β -cell function except for the latest time point. The loss of β -cell function related PBMC responses over time may be due to regression of insulinitis activity or caused by exogenous insulin treatment that may dampen reactivity of immune cells to β -cell antigens.

Estrogens prevent the development of auto-immune diabetes in NOD mice

P. Gourdy^{1,2}, L. Pham Van Linh³, M.-L. Ahui³, D. Damotte⁴, F. Bayard², J.-F. Arnal³, A. Herbelin³

¹Service de Diabétologie, Maladies Métaboliques et Nutrition, CHU Rangueil, Toulouse, ²Inserm u858, Institut de Médecine moléculaire de Rangueil, Toulouse, ³UMR8147, CNRS et Université Paris Descartes, Hôpital Necker, Paris, ⁴Service de d'Anatomie et de Cytologie Pathologique, Hotel-Dieu, Paris, France

Background and aims: Although the incidence of diabetes is higher in female than in male non obese diabetic (NOD) mice, the influence of estrogens in this prototypic model of auto-immune diabetes has not been clearly identified. However, in the last years, estrogens were demonstrated to modulate immune responses, natural killer T (NKT) and regulatory T (Treg) lymphocyte biology, and also to prevent pancreatic beta cells from apoptosis. Thus, we aimed to study whether in vivo exposure to estrogens influences diabetes development in NOD mice.

Materials and methods: Wild type, RAG^{-/-}, J α 18^{-/-} (NKT-deficient) and CD28^{-/-} (Treg-deficient) NOD female mice were used. The effect of chronic 17 β -estradiol (E2) administration was assessed in female mice implanted with subcutaneous pellets delivering a physiological and constant dose of the hormone (80 µg/kg/day). The influence of endogenous estrogens was assessed by the comparison of ovariectomized mice with intact sham-operated mice. At least 15 mice per group were included in each experiment.

Results: Chronic E2 administration from 4 to 30 weeks of age exerted a strong preventive effect against spontaneous diabetes incidence in NOD female mice. Indeed, whereas 80% of the untreated control mice developed diabetes during the follow-up period, none of the E2-treated mice were affected ($p<0.001$). A similar protective effect was observed in the model of ac-

celerated diabetes induced by cyclophosphamide in NOD mice (diabetes appeared in 60% of control mice, but in none of the E2-treated mice, $p < 0.001$). Histological analysis of pancreatic islets demonstrated that E2 treatment was associated with a significant reduction in spontaneous insulinitis in 10-week-old mice. Furthermore, the titers of anti-insulin antibodies were significantly lower in both 17- and 30-week-old E2-treated mice. Then, splenocytes from 30-week-old NOD mice chronically treated or not with E2 were transferred to RAG^{-/-} NOD mice and induced diabetes in a similar extent, suggesting that E2 treatment does not influence the development of diabetogenic cells. Thus, to study the respective involvement of NKT and Treg cells in the preventive effect of estrogens, J α 18^{-/-} and CD28^{-/-} NOD mice were treated with E2. Interestingly, the hormone exerted a full protective effect in both models, ruling out a crucial role of these lymphocyte subpopulations. Finally, we demonstrated a significant protective effect of endogenous estrogens. Indeed, ovariectomy at 4 weeks of age led to an acceleration of the apparition of diabetes in both the spontaneous and the cyclophosphamide-induced models of diabetes in NOD mice.

Conclusion: Our results demonstrate that chronic exposure to estrogens prevents insulinitis and the development of diabetes in NOD mice. Although the mechanisms mediating this beneficial effect remain to be definitely elucidated, we ruled out the involvement of NKT and Treg lymphocytes. This protective effect could explain the age-related gender dimorphism in type 1 diabetes incidence recently reported by Scandinavian epidemiological studies. Finally, activation of the estrogen pathway could represent a new research area for diabetes prevention.

Mesenchymal stem cells protect NOD mice from diabetes by recovery of regulatory T cells

A.-M. Madec¹, E. AbouMrad¹, R. Mallone², G. Afonso³, A. ElJaafari⁴, C. Thivolet¹;

¹Faculte de Medecine Lyon-Sud, INSERM U.870/INRA 1235, Oullins,

²Hopital St Vincent de Paul, INSERM U.561, Paris, ³Hopital St Vincent de Paul, INSERM U.561, Paris, ⁴Hopital Edouard Herriot, EA 4061, Lyon, France

Background and aims: Due to their modulatory T cells properties and/or the immunosuppressive local milieu that they create, Mesenchymal Stem Cells (MSCs) are considered as beneficial agents for autoimmune disease therapy. Here, we examined the capacity of MSCs isolated from BALB-b mouse bone marrow to prevent autoimmune diabetes in the NOD mouse model.

Materials and methods: Prevention of insulinitis or clinical diabetes was evaluated after a single I.V. injection of 103 to 106 MSCs in a 4wk-old female NOD or following their co-injection with 5.106 diabetogenic T cells in 8-12wk old male irradiated NOD mice. Five days after cell cotransfer, we analyzed the frequency of CD4+FOXP3+ expression within spleen T cell population from NOD mice treated by 106 MSCs. FoxP3 mRNA levels were also quantified. In vivo cell homing was assessed by monitoring CFE labeled T cells or MSCs. In vitro, cell proliferation and cytokines production were assessed by adding graded (102 to 105 per well) doses of irradiated MSCs to insulin B9-23 peptide (ins B9-23) specific T cell lines (7.5.105 per well) in the presence of 1.5.106 irradiated splenocytes pulsed with 10 microM ins B9-23.

Results: During cotransfer experiments, 105 or 106 MSCs reduced the capacity of diabetogenic cells to infiltrate pancreatic islets and to transfer diabetes ($p < 0.001$). Although they did not modify T cell homing to the thymus, spleen or pancreatic lymph nodes, MSCs preferentially migrated to spleen and pancreatic lymph nodes to reach a statistically significant peak five days after cell transfer. Injection of diabetogenic T cells resulted in a decrease of FoxP3+ cells, which was recovered by cotransfer of MSCs and diabetogenic cells as assessed by CD4+FoxP3+ staining ($2.9 \pm 0.3\%$ versus $4.9 \pm 1.2\%$; $p < 0.01$) and measurement of FoxP3 mRNA levels (mean \pm SD relative expression rate, 2.32 ± 0.3 versus 5.23 ± 0.5 ; $p < 0.001$). Finally, MSCs inhibited ins B9-23 antigen-specific proliferative responses in vitro in a dose-dependent fashion from 75% with 102 MSCs to 100% with 105 MSCs. This effect correlated with an increase in IL-10 production from 94 ± 20 pg/mL to 1041 ± 96 pg/mL respectively.

Conclusion: Taken together, our results strongly suggest that MSCs inhibit autoimmune beta cell destruction in NOD mouse by recovery of regulatory T cells. MSCs should thus offer a novel immunotherapeutic approach for autoimmune diabetes and islet transplantation.

Recessive mutations in the *INS* gene; a novel common cause of permanent neonatal diabetes in consanguineous pedigrees

E.L. Edghill, J. Locke, S.E. Flanagan, A.-M. Patch, L.W. Harries, S. Ellard, A.T. Hattersley

Institute of biomedical and clinical science, Peninsula Medical School, Exeter, United Kingdom

Background and aims: Permanent Neonatal Diabetes (PNDM) diagnosed in the first 6 months of life is commonly caused by heterozygous mutations in *KCNJ11*, *ABCC8* or *INS* genes. Recessive mutations in *GCK* and *ABCC8* can also cause non-syndromic PNDM but recessive *INS* mutations have not been described. We hypothesised that homozygous mutations in the *INS* gene could cause PNDM and these would be most likely in subjects born to consanguineous parents.

Materials and methods: We investigated 25 patients of consanguineous descent with non-syndromic PNDM diagnosed before 6 months of life. We screened *INS*, *GCK*, *KCNJ11* and *ABCC8* by direct sequencing. In addition we used Multiplex Ligation-dependent Probe Amplification (MLPA) to test for *INS* deletions.

Results: We identified 9 mutations in the known genes; 5 homozygous *GCK* mutations, 2 homozygous *ABCC8* mutations and 2 heterozygous *KCNJ11* mutations. We also identified five novel homozygous mutations in *INS*; M11 (n=2), Q62X, IVS2-15G>A and c.-331C>G (n=3) in 7 patients. MLPA revealed a homozygous *INS* gene deletion (M1_Q62del), after PCR of exon 1 and exon 2 consistently failed. The c.-331C>G variant and the IVS2-15G>A variant was not found in control population subjects. Patients with a homozygous mutation are diagnosed earlier ($p = 0.005$) and have a much lower birth weight ($p > 0.0001$) [median age of diagnosis 0.85 weeks (0.14–7.1), centile birth weight <1st (0.0002–0.3)] compared to heterozygous *INS* mutation carriers [(9 weeks, 0–26), centile <5 (0–87)].

Conclusion: We have shown that homozygous mutations in *INS* are a novel cause of PNDM and are the most common cause (32%) of recessively inherited non-syndromic PNDM. The genetic aetiology can now be defined in the majority of patients with PNDM from consanguineous families.

Atypical endoplasmic reticulum (ER) stress in cell and animal models of MODY3

C. Kirkpatrick, M. Baqu  , H. Wang, B. Gauthier, C.B. Wollheim

Dept. of Cell Physiology and Metabolism, University of Geneva, Switzerland

Background and aims: ER stress occurs when the protein folding and processing capacity of the ER is perturbed, either by increased protein load or by interference with the folding machinery. The typical response of a cell to ER stress is to upregulate transcription of ER chaperones (such as BiP) and the transcription factors Atf4 and Xbp1. Pancreatic β -cells are particularly susceptible to ER stress and evidence for its involvement in diabetes has been observed in multiple animal models and in human disease (Wolfram and Wolcott-Rallison syndromes). We examined whether ER stress also occurs in MODY3, caused by mutations in the transcription factor Hnf1 α , using both cultured cells and diabetic mouse islets carrying a dominant-negative (DN) variant of Hnf1 α . The transgenic mice express the dominant-negative gene only in the β -cells, which have been observed to have dilated ER cisternae and fewer mature secretory granules, providing ultrastructural evidence that ER function may be perturbed in this model.

Materials and methods: INS r9 cells expressing DN-Hnf1 α under the control of the Tet-On system were cultured in RPMI with doxycycline to induce the transgene, or cyclopiazonic acid (CPA) to induce ER stress. Mouse islets were isolated by collagenase digestion and either cultured for 24 hours in RPMI to allow recovery from the stress of isolation or immediately used for RNA extraction. Q-RT-PCR was performed on cell and islet extracts. Cell viability was analysed by MTT assay.

Results: INS DN-Hnf1 α cells showed an atypical ER stress response on induction of the transgene, with increased mRNA levels of SERCA2b, the ER-associated transcription factors Atf4 and CHOP and the pro-apoptotic gene PUMA, but decreased levels of other ER stress markers including BiP, calreticulin, protein disulphide isomerase (PDI), Xbp1 and the β -cell specific

SERCA3. In cells with ER stress induced by CPA, upregulation of some of the ER stress genes (BiP, calreticulin, PDI and SERCA2b) was attenuated when DN Hnf1 α was induced. A consensus Hnf1 α binding site was found in the Xbp1 promoter region, suggesting that this gene may be directly regulated by Hnf1 α . INS DN-Hnf1 α cells were more sensitive to CPA-induced cell death when the transgene was induced. Similarly, when ER stress gene expression was compared between DN-Hnf1 α and control mouse islets, expression of Xbp1, BiP, calreticulin, PDI and SERCA3 was lower in the DN-Hnf1 α islets.

Conclusion: These data show that in cell and animal models of MODY3 levels of ER chaperone and folding enzyme mRNA are attenuated at the basal level and in response to chemically induced ER stress. However, mRNA levels of other ER stress-associated genes (Atf4, CHOP and SERCA2b) were more abundant in the presence than the absence of DN-Hnf1 α in the cell model, unlike the expected ER stress response where chaperones and transcription factors are upregulated simultaneously. Insufficient chaperone production as a result of DN-Hnf1 α expression may sensitise the ER of these cells to stress, making them more prone to apoptosis. The results suggest that DN-Hnf1 α directly downregulates Xbp1 expression, and as a consequence of Xbp1 loss the β -cells have lower levels of ER chaperones and are sensitised to ER stress.

Permanent neonatal diabetes caused by an in-frame deletion in the N-terminus of Kir6.2

T.J. Craig¹, K. Shimomura¹, S. Flanagan², S. Ellard², A. Hattersley², F.M. Ashcroft¹

¹Physiology, University of Oxford, ²Institute of Biomedical and Clinical Science, Peninsula Medical School, Exeter, United Kingdom

Background and aims: We identified a novel mutation in *KCNJ11* (Kir6.2), the pore-forming subunit of the K_{ATP} channel, that causes permanent neonatal diabetes mellitus (PNDM), and characterised its functional consequences. This mutation results in an in-frame deletion of 5 amino acids (A28 to R32) from the N-terminus of Kir6.2.

Materials and methods: Electrophysiology of K_{ATP} channel function, surface expression assays, and protein-protein interaction assays were performed in *Xenopus* oocytes. Oocytes were coinjected with cRNA coding for SUR1 and mutant or wild-type Kir6.2. In some experiments we used Kir6.2 Δ C, a C-terminal 36-amino acid truncated Kir6.2, which traffics to the cell surface in the absence of SUR1.

Results: Deletion of residues 28–32 produced a 6-fold decrease in the IC₅₀ for ATP inhibition of Kir6.2/SUR1 currents. This can be attributed to an increase in the channel open probability (Po) from 0.23 (wild-type) to 0.8 (mutant; $P < 0.05$). The mutation had no effect on the Po or ATP sensitivity of Kir6.2 Δ C currents. Thus these data suggest deletion of residues 28–32 disrupts the interaction between Kir6.2 and SUR1. The first five transmembrane domains (TMD0) and the linker between transmembrane domains 5 and 6 (CL3 linker), are required for the ability of SUR1 to influence the Po (and thereby ATP sensitivity) of Kir6.2. When mutant Kir6.2 Δ C was coexpressed with TMD0, there was no effect on the channel properties, and co-immunoprecipitation studies showed no difference in binding of TMD0 and Kir6.2 Δ C. However, when Kir6.2 Δ C was coexpressed with TMD0+CL3 of SUR1, the 5aa deletion caused a significant ($P < 0.05$) increase in Po: from 0.58 for wild-type Kir6.2 to 0.74 for mutant. Thus it is likely the 5aa deletion mutation disrupts an interaction between the N-terminus of Kir6.2 and the CL3 linker of SUR1.

Conclusion: We show here that an in-frame deletion (A28 to R32) in *KCNJ11* can cause neonatal diabetes. This deletion selectively disrupts an interaction between the CL3 linker of SUR1 and Kir6.2, thereby increasing the Po of the K_{ATP} channel and reducing its sensitivity to inhibition by ATP.

Mitochondrial A3243G DNA mutation leads to decreased insulin sensitivity in skeletal muscle accompanied by failing beta cell dysfunction

M.M. Lindroos¹, K. Majamaa², P. Nuutila¹, P. Iozzo¹, A. Mari³, A. Tura³

¹Turku PET Centre, University of Turku, Finland, ²Department of Neurology, University of Turku, Finland, ³Institute of biomedical engineering, National Research Council, Pisa, Italy

Background and aims: Diabetes in adulthood is characterized by low insulin sensitivity but most of the gene variants associated with diabetes affect the

β -cell insulin secretion. Also mitochondrial DNA point mutation A3243G leads finally to failing insulin secretion while most of its carriers develop diabetes. The aim of this study was to assess the role of insulin sensitivity in this most common form of mitochondrial diabetes.

Materials and methods: Eight non-diabetic A3243G carriers with a proper glycaemic control (Hb-1AC $< 6.1\%$), seven patients with overt A3243G diabetes and 13 age and physical activity matched healthy subjects were studied. Skeletal muscle and whole body insulin sensitivity was measured using positron emission tomography and 2- [¹⁸F]fluoro-2-deoxyglucose tracer during euglycemic hyperinsulinemia. Parameters of β -cell function were derived from an oral glucose tolerance test by mathematical modelling based on C-peptide deconvolution. In particular, β -cell glucose sensitivity was calculated as the slope of the dose-response function relating glucose concentration to insulin secretion. A parameter quantifying early insulin release was also obtained from the model.

Results: Among the A3243G mutation carriers whole body insulin sensitivity was 30% lower than those in healthy subjects, and was similar to the values in the patients with overt A3243G diabetes ($P = 0.003$). As compared to the healthy subjects the skeletal muscle insulin sensitivity was decreased by 62% both in the A3243G mutation carriers and in the patients with overt diabetes (55 ± 9 , 21 ± 5 , and 21 ± 4 $\mu\text{mol} \cdot \text{min}^{-1} \cdot \text{kg}^{-1}$, $P = 0.0031$). β -cell glucose sensitivity was progressively impaired across the groups, being highest in healthy subjects, decreased in A3243G carriers and lowest in the A3243G patients with overt diabetes (137 ± 15 , 82 ± 15 and 22 ± 14 $\text{pmol} \cdot \text{min}^{-1} \cdot \text{m}^{-2} \cdot \text{mM}^{-1}$, $P = 0.002$). Additionally, as compared to controls and to non-diabetic A3243G carriers, early insulin release was decreased in the A3243G patients with overt diabetes (686 ± 82 , 902 ± 228 and 103 ± 50 $\text{pmol m}^{-2} \cdot \text{mM}^{-1}$ $P = 0.0014$).

Conclusion: Subjects harbouring the A3243G mutation have decreased muscle and whole body insulin sensitivity before the glucose control is compromised, whereas beta-cell function deteriorates gradually and is markedly impaired in overt mitochondrial diabetes.

Measures of autonomic nervous system function in the diabetes control and complications trial/epidemiology of diabetes interventions and complications study (DCCT/EDIC)

R. Pop-Busui¹, P.A. Low², B.H. Waberski³, C.L. Martin⁴, E.L. Feldman⁵, J.W. Albers⁶, C.L. Sommer⁷, P.A. Cleary³, W.H. Herman⁶

¹Division of Metabolism Endocrinology and Diabetes, University of Michigan, Ann Arbor, ²Neurology, Mayo Clinic, Rochester, ³The Biostatistics Center, The George Washington University, Rockville, ⁴Michigan Diabetes Research and Training Center, University of Michigan, Ann Arbor, ⁵Neurology, University of Michigan, Ann Arbor, ⁶University of Michigan Health Systems, University of Michigan, Ann Arbor, ⁷Autonomic Reading Center, Mayo Clinic, Rochester, United States

Background and aims: The DCCT demonstrated that intensive diabetes treatment (INT) significantly slowed the decline in R-R variation compared to conventional therapy (CONV) in type 1 diabetes. Longitudinal EDIC follow-up has shown that the former INT group continues to have a lower cumulative incidence of retinopathy and nephropathy years after DCCT completion, despite similar levels of glycemic control. Using the long-term follow-up data from the DCCT/EDIC cohort, we evaluated whether the former INT group continues to experience a lower risk of developing cardiac autonomic neuropathy (CAN) compared to the former CONV group.

Materials and methods: All tests of CAN performed during the DCCT (R-R response to paced breathing, Valsalva ratio and postural testing) were conducted in 1,001 DCCT subjects (N=504 INT; N=497 CONV) during the 13th and 14th year of EDIC follow-up. The Wilcoxon rank-sum test estimated the treatment group differences in the change in each measure from DCCT closeout to EDIC. Changes in measured variables within groups were compared using analysis of covariance, with adjustments made for closeout values, age, sex, and use of beta-blockers.

Results: In EDIC year 13-14, R-R variation was significantly higher in the INT (29.8 ± 19.1) compared with the CONV (26.1 ± 17.2) group ($p=0.0012$). The change in R-R variation from DCCT closeout was -11.3 ± 18.5 in the INT and -13.1 ± 18.3 in the CONV and the difference in Valsalva ratio was -0.20 ± 0.40 in the INT and -0.27 ± 0.42 in the CONV ($p<0.05$). Based on the DCCT definition of CAN as R-R< 15, 24.5% of the INT group were diagnosed with CAN compared with 30.2% in the CONV group in EDIC year 13-14, ($p<0.05$). Additional ongoing analyses of R-R variation as well as Valsalva and postural testing will further evaluate the rate of CAN development and odds of emergent CAN during EDIC.

Conclusion: During EDIC, CAN as measured by R-R response to paced breathing, progressed in both groups, but the prevalence of CAN in year 13-14 remained significantly higher in the former CONV group than in the INT group. The benefits of former intensive therapy extend to measures of CAN 14 years after trial end.

Raised thalamic blood volume in painful diabetic neuropathy: clues to the pathogenesis of neuropathic pain in diabetes?

D. Selvarajah¹, I.D. Wilkinson², P.D. Griffiths², C.J. Emery¹, S. Tesfaye¹

¹Diabetes Research Department, Royal Hallamshire Hospital, Sheffield,

²Academic Unit of Radiology, University of Sheffield, United Kingdom

Background and aims: The pathogenesis of pain in diabetic neuropathy (DN) remains unknown and as a result there are no fully effective treatments. The thalamus plays a crucial role in modulating and processing all sensory information to the brain. Recently there have been reports of thalamic neuronal dysfunction in patients with painless-DN, and we sought to investigate if these were accompanied with abnormalities in blood flow.

Materials and methods: Eighteen right-handed, male subjects with type 1 diabetes and 5 healthy volunteers (HV) were recruited. Detailed neurophysiological assessments and pain symptom scores were undertaken. Based on these assessments subjects were divided into no-DN (n=6), painful- (n=5) and painless-DN (n=7). Cerebral parenchymal perfusion was assessed by

tracking the passage of an iv bolus of contrast agent (gadolinium-chelate) using a multi time point, T2* weighted EPI sequence on a 1.5T magnetic resonance imaging system. Haemodynamic anatomical regions supplied by the anterior cerebral artery [ACA], middle cerebral artery [MCA] and posterior cerebral artery [PCA]) were studied. We also looked at perfusion through the thalamus using the caudate nucleus as a control.

Results: In all three vascular territories, in the resting state and assuming equivalent intracranial resonance properties, diabetic subjects had larger relative cerebral blood volume (rCBV) compared to HV (ACA mean \pm SD, 264.4 ± 55.2 vs 205.3 ± 57.2 , $p=0.05$; MCA 244.6 ± 43.3 vs 189.0 ± 55.2 , $p=0.03$; PCA 248.4 ± 43.8 vs 190.8 ± 36.5 , $p=0.01$). However, there was a non significant trend towards longer bolus transit time and greater relative cerebral blood flow (rCBF) in diabetic subjects. Subjects with painful-DN had significantly higher thalamic rCBV compared to the other study groups (painful DN, 234.3 ± 45.1 , No-DN, 196.5 ± 78.7 , painless DN, 203.1 ± 171.7 ; $p=0.045$). Subjects with painful-DN also had the longest contrast bolus transit time compared with other groups. In contrast, subjects with painless DN had lowest thalamic rCBF compared to other groups. There were no significant differences in the perfusion characteristics of the caudate nucleus between subgroups.

Conclusion: In this preliminary study, we found that diabetic subjects had global increased rCBV in all major cerebral artery territories. This suggests impaired vasoreactivity with a persistent resting state cerebral vasodilation, similar to observation in the diabetic kidney. Painful-DN is accompanied by increased thalamic blood volume; in keeping with previous studies demonstrating increased peripheral nerve blood flow. Conversely, subjects with painless-DN lowest thalamic blood flow suggesting a greater degree of microvascular impairment. As similar observations were not found in the caudate nucleus, this suggests that unique pathophysiological microvascular changes are occurring within the thalamus that may provide important clues to the pathogenesis of neuropathic pain in diabetes.

Association of reduced glyoxalase-1 activity and painful peripheral neuropathy in diabetes mellitus patients

I. Konrade¹, M. Dambrova², E. Skapare³, J. Klovins⁴, A. Lejnieks⁵, S.B. Stoyanov⁶, P.M. Humpert⁶, P.P. Nawroth⁶, A. Bierhaus⁶

¹Dep. of Endocrinology, Riga Stradins University, Latvia, ²Laboratory of Pharmacology, Latvian Institute of Organic Synthesis, Riga, Latvia, ³Faculty of Pharmacy, Riga Stradins University, Latvia, ⁴Genome Center, Latvian Biomedical Research and Study Centre, Riga, Latvia, ⁵Clinic "Linezers", Riga Stradins University, Latvia, ⁶Department of Medicine I and Clinical Chemistry, University of Heidelberg, Germany

Background and aims: Glyoxalase-1 (GO-1) is a central part of the cellular defense to detoxify reactive dicarbonyls such as methylglyoxal, glyoxal and other alpha-oxoaldehydes, which are potent precursors of Advanced Glycation Endproduct (AGEs). Experimental animal models have provided evidence that reduced detoxification of AGEs by GO-1, engagement of the receptor RAGE and RAGE-dependent sustained activation of the proinflammatory transcription factor NF- κ B significantly contribute to functional deficits in diabetic neuropathy (DN). Since we have recently demonstrated that GO-1 controlled reactions modulate pain in rodent models of DN, we studied the relationship between GO-1 activity and painful peripheral DN in patients with type-1 and type-2 diabetes.

Materials and methods: GO-1 enzymatic activity was determined in blood samples of 70 type-1 diabetic patients (56% (39) female, age 38.6 ± 14.9 years; HbA_{1c} $9.06 \pm 2.1\%$) and 67 age- and sex-matched non-diabetic controls as well as in 66 type-2 diabetic patients (56% (37) female, age 55.6 ± 9.8 years; HbA_{1c} $8.31 \pm 1.91\%$) and 48 matched age- and sex-non-diabetic controls. All patients were diagnosed for peripheral DN by neuropathy disability score and by measuring current perception threshold. Patients were deemed to have neuropathic pain, if pain for which no other cause could be found lasted for at least 6 months and at least 40 mm on the 100-mm visual analogue scale was scored. GO-1 activity was measured in blood samples by a standardized spectrophotometrical assay. Blood samples were also tested for lipids, C-peptide and inflammatory markers. In addition, all samples were screened for the presence of three SNPs (rs2736654, rs1130534 and rs1049346) in the GO-1 gene using MALDI TOF mass spectrometry.

Results: In non-diabetic control subjects, the average GO-1 activity was $7.46 \mu\text{mol/min/ml}$. In type 1 diabetic patients with (n=35) and without (n=35) painful peripheral DN the activity of GO-1 was $6.73 \pm 1.03 \mu\text{mol/min/ml}$ and $8.16 \pm 1.13 \mu\text{mol/min/ml}$ ($p<0.001$), respectively. In type-2 diabetic patients

with (n=30) and without (n=37) painful peripheral DN, GO-1 activity was 6.87 ± 1.21 $\mu\text{mol}/\text{min}/\text{ml}$ and 8.0 ± 1.23 $\mu\text{mol}/\text{min}/\text{ml}$ ($p < 0.001$), respectively. Even though GO-1 activity in both, type-1 and type-2 diabetes correlated positively with two SNPs studied (rs1130534 and rs1049346), none of them was associated with painful DN. In multivariate models, only reduced activity of GO-1 was associated with painful DN ($\beta = -0.45$, $p < 0.001\beta$ in type 1 DM patients and $\beta = -0.33$, $p < 0.01$ in type 2 DM patients).

Conclusion: Our results demonstrate for the first time that decreased GO-1 enzyme activity in blood samples of both, type 1 and type 2 DM patients is associated with painful DN.

Neurochemical abnormalities within sensory pathways in the brain in diabetic neuropathy

R.A. Gandhi¹, D. Selvarajah¹, C. Emery¹, I. Wilkinson², S. Tesfaye¹

¹Diabetes Research Unit, Royal Hallamshire Hospital, Sheffield, ²Academic Unit of Radiology, University of Sheffield, United Kingdom

Background and aims: Pain is the most distressing symptom of diabetic peripheral neuropathy (DN). Although clear pathological abnormalities have been identified at the level of the peripheral nerve and spinal cord in DN, there is only limited understanding of why some patients suffer severe chronic pain whilst others have painless symptoms. A better understanding of the pathogenesis of painful and painless DN is crucial for the development of novel, mechanism-based treatments. There is growing evidence that central mechanisms play an important role.

Materials and methods: 110 subjects with type 1 diabetes (20 no DN, 30 sub-clinical DN, 30 painful DN and 30 painless DN) and 20 healthy volunteers (HV) underwent detailed clinical and neurophysiological assessments (Dyck's NIS(LL)+7 staging criteria). Proton magnetic resonance spectroscopy of the left thalamic nucleus and somatosensory cortex was performed to measure established markers (N-acetylaspartate [NAA]) of neuronal function using long echo time (LET) and neuronal integrity using short echo time (SET) sequences.

Results: In the thalamus, at LET (Fig. 1), subjects with painless DN had significantly lower NAA:Creatine ratio (1.55 ± 0.22 [mean \pm SD]) compared to other groups [HV (1.80 ± 0.23), no DN (1.85 ± 0.20), sub-clinical DN (1.79 ± 0.23), painful DN (1.75 ± 0.19), ANOVA $p < 0.001$]. There were no significant inter-group differences at SET. In the somatosensory cortex, no inter-group differences were seen at LET. At SET (Fig. 2), the painless DN group had lower NAA (0.62 ± 0.08), compared to HV (0.73 ± 0.15) and no DN (0.68 ± 0.13), $p = 0.03$. Subjects with painful DN had intermediate levels (0.66 ± 0.10).

Conclusion: These results imply change in neuronal physiology or function, rather than neuronal loss, within the thalamus (the gateway to the somatosensory cortex) in painless but not painful DN. It is possible that relative preservation of thalamic neuronal function is necessary for the transmission of abnormal peripheral signals to higher centres and the perception of chronic pain in DN. The results within the somatosensory cortex, in contrast, are suggestive of neuronal loss in subjects with DN and may be reflecting local cerebral parenchymal atrophy.

Independent role of fatty acid profile and insulin resistance in steatosis: a population-based study in elderly men

U. Risérus, H. Petersson, T. Cederholm, B. Vessby

Public health and caring sciences, Uppsala university, Sweden

Background and aims: Fatty liver (steatosis) has been proposed to promote insulin resistance and metabolic disorders. Steatosis may partly be driven by dietary and endogenously produced fatty acids. The link between steatosis and fatty acid profile is however unexplored in large populations, and it is unclear if such potential associations may be independent of insulin resistance and obesity. We aimed to investigate the associations between liver fat biomarkers and serum fatty acid profile, and examined if such associations may be explained by insulin resistance, obesity or other related metabolic and hormonal factors.

Materials and methods: In a population-based cross-sectional sample (n=583) of 70-year old men (Uppsala Longitudinal Study of Adult Men; UL-SAM) with complete data on serum fatty acid profile, alanine aminotransferase (ALT) concentrations (as marker of steatosis), directly measured insulin sensitivity (determined by hyperinsulinemic euglycemic clamp), adiponectin concentrations and lifestyle factors (abdominal obesity, i.e. waist circumference, physical activity, smoking and alcohol consumption) was investigated. In addition, to estimate endogenous fatty acid metabolism, fatty acid desaturase activities (Stearoyl-CoA desaturase (SCD), $\Delta 6$ -desaturase, and $\Delta 5$ -desaturase) were estimated by product-to-precursor fatty acid ratios in cholesteryl esters. Associations were assessed by univariate and multivariate linear regression, and P-values below are standardized (1 SD) regression coefficients.

Results: A fatty acid profile in serum cholesteryl esters characterized by increased proportions of palmitoleic, oleic, γ -linolenic and dihomo- γ -linolenic acid, and decreased proportions of linoleic acid, as well as increased activities of $\Delta 6$ -desaturase and SCD-1 were significantly related to ALT concentrations, even after adjusting for lifestyle factors and insulin resistance (multivariate model 1: all P-values $P < 0.05$). These relationships remained if subjects with diabetes and cardiovascular disease were excluded (n=391). Serum linoleic acid proportions mainly reflect dietary intake of this fatty acid, whereas monounsaturated fatty acids and dihomo- γ -linolenic acid mainly reflect dietary intake of saturated fat and/or SCD-1 activity and $\Delta 5$ -desaturase activity, respectively. In a second multivariate model where additional metabolic factors were added, only SCD-1 activity index (multivariate model 2: $P = 0.0009$) and insulin sensitivity (model 2: $P < 0.0001$) were independent determinants of steatosis, whereas waist circumference, triglycerides, high density lipoprotein cholesterol, non-esterified fatty acids, and adiponectin were not significant predictors.

Conclusion: Although dietary biomarkers such as serum linoleic acid were inversely related to steatosis, especially strong independent associations between steatosis and endogenous fatty acids were evident in this population of elderly men. Interestingly, the latter associations were independent of insulin resistance, obesity and lifestyle factors. In summary, a high SCD-1 activity index and insulin resistance were the two major independent determinants of steatosis. Controlled studies will be required to investigate causality and to further examine the role of dietary fatty acids and insulin resistance in steatosis.

Efficacy and safety of low-carbohydrate, mediterranean, and low-fat diet strategies for weight loss - a two year dietary intervention randomized controlled trial (DIRECT)

I. Shai¹, D. Schwarzfuchs², Y. Henkin³, D. Shahar¹, I. Greenberg¹, R. Golan¹, D. Fraser¹, O. Tangi-Rozental¹, Z. Schwartz², E. Sheiner², J. Thiery⁴, G.M. Fiedler⁴, M. Blüher⁴, M. Stumvoll⁴, M.J. Stampfer⁵

¹Epidemiology, Ben Gurion University, Beer-Sheva, Israel, ²Medicine, Nuclear Research Center Negev, Dimona, Israel, ³Cardiology, Soroka University Medical Center, Beer-Sheva, Israel, ⁴Medicine, University of Leipzig, Germany, ⁵Medicine, Harvard University, Boston, United States

Background and aims: Trials comparing effectiveness and safety of alternative diets are frequently limited by short follow-up and high dropout rates.

Materials and methods: In a two-year Dietary Intervention Randomized Controlled Trial (DIRECT) we randomized 322 moderately obese (age=52yrs, body-mass-index=31kg/m², 86% men) to one of three diets: low-fat restricted-calorie, Mediterranean restricted-calorie or low-carbohydrate non-restricted-calorie. The trial was conducted in an isolated workplace, with an integrated clinic. We displayed daily diet-group-specific colored food labels in the exclusive workplace cafeteria.

Results: Retention was 95% after one year and 85% after two, with no adverse events. In repeated dietary analyses, the Mediterranean diet-group consumed the highest dietary fiber and monounsaturated/saturated fat ratio ($P<.05$). The low-carbohydrate diet-group consumed the least carbohydrates, highest fat, protein and cholesterol, and had higher urinary ketones ($P<.05$). Caloric deficit was similar among groups. Weight loss was 2.9kg for low-fat, 4.4kg for Mediterranean, and 4.7kg for low-carbohydrate, P diet-group*time<.001 (-3.3kg, -4.6kg, and -5.5kg respectively among 272 who completed the 2-year intervention). Favorable changes in liver function biomarkers, adiponectin, leptin, and c-reactive-protein were similar. Triglycerides and high-density-lipoprotein-cholesterol were more favorable in the low-carbohydrate, with 20% reduction in total-cholesterol:high-density-lipoprotein-cholesterol ratio compared to 12% for low-fat ($P=.01$). Changes in fasting glucose and insulin were more favorable on Mediterranean diet among 36 diabetics (P -interaction diabetes*Mediterranean-diet*time<.001 for glucose).

Conclusion: This long-term trial suggests that Mediterranean and low-carbohydrate diets are effective safe alternatives to low-fat. The more favorable effects on lipids (low-carbohydrate) and on glycemic control (Mediterranean) suggest that personal preferences and metabolic considerations can govern individualized tailoring of dietary intervention.

Background and aims: Evidence suggests that dietary fatty acid composition affects insulin sensitivity. The LIPGENE Human Dietary Intervention Study is a multi-centre, pan-European, randomised, controlled trial with the aim of determining the relative efficacy of reducing dietary SFA consumption, by altering quality and reducing the quantity of dietary fat, on metabolic risk factors of the metabolic syndrome (MetS).

Materials and methods: 417 free-living subjects with the MetS received one of four dietary treatments for 12 weeks: (1) High-fat (38% energy) SFA-rich diet (HFSFA); (2) High-fat (38% energy), MUFA-rich diet (HFMUFA); (3) Low-fat (28% energy), high-complex carbohydrate diet (LFHCC) and (4) Low-fat (28% energy), high-complex carbohydrate diet, with 1.24 g/d LC n-3 PUFA (LFn-3PUFA). An IVGTT, lipoprotein analysis, cytokines, adhesion molecules, coagulation factors and isoprostane levels were determined pre- and post-intervention.

Results: Dietary fat modification had no significant effect on insulin sensitivity (S_i), or any of the other IVGTT parameters, HOMA-IR or QUICKI. The effect of the four dietary treatments was determined in volunteers with a habitual high- or low-fat intake pre-intervention, defined as being above or below the median (36% of Total Energy). S_i was significantly lower following the high-fat, SFA-rich diet ($P=0.021$) in subjects with a habitual low-fat intake pre-intervention. The sensitivity to SFA was more applicable to females wherein S_i was reduced following the high-fat, SFA rich diet. HOMA-IR was also reduced in females following the high-fat MUFA diet ($P<0.05$). Plasma

TAG concentrations showed a significant diet*time interaction ($P=0.006$), whereby plasma TAG concentrations were significantly reduced following the HFSFA diet and the LFn-3PUFA diet ($P=0.018$ and $P=0.005$, respectively). These effects were more apparent in males. Plasma total HDL-cholesterol concentrations showed a significant diet*time interaction ($P=0.005$), whereby HDL-cholesterol levels were significantly increased by the two high-fat diets, HFSFA and HFMUFA post-intervention ($P<0.0005$ and $P=0.006$, respectively). Reducing dietary SFA did not alter markers of inflammation or coagulation associated with insulin resistance.

Conclusion: The effectiveness of dietary fat modification was dependent upon pre-intervention dietary fat intake. Several markers of lipid metabolism were improved particularly by the low-fat diet with LC n-3 PUFA supplementation. Also interestingly the lipid lowering efficacy of the LC n-3 PUFA intervention was most evident in males.

Effect of high and low glycaemic index diets on skeletal muscle and liver substrate storage and utilisation during exercise

M.I. Trenell^{1,2}, P. Thelwall¹, K. Thomas³, E. Stevenson³

¹Clinical Medical Sciences, Newcastle University, ²Newcastle Magnetic Resonance Centre, Newcastle University, ³Sports Science, Northumbria University, Newcastle upon Tyne, United Kingdom

Background and aims: Carbohydrates which are rapidly absorbed into the circulation, termed high glycaemic index, produce higher peak circulating glucose levels and require greater peak insulin production than carbohydrates which are absorbed slower, termed low glycaemic index. Postprandial hyperglycemia and hyperinsulinaemia hold significant implications for substrate storage and oxidation in people with or without adequate glycaemic control. Insulin promotes glycogen storage but high circulating levels may hold sustained effects on adipose tissue lipolysis, decreasing the supply of lipids to skeletal muscle for oxidation. The reduced capacity to oxidise lipids places a greater reliance upon anaerobic energy sources, thus reducing metabolic flexibility. The aim of this study was to evaluate the effect of high and low glycaemic index foods upon substrate storage and oxidation in both skeletal muscle and liver during exercise.

Materials and methods: Nine male endurance trained cyclists (age 33 ± 6.9 yrs, mass 76.3 ± 7.0 kg, VO_{2max} 61.5 ± 5.0 ml·kg⁻¹·min⁻¹) took part in a randomised cross-over design study. Participants completed a 90 min cycle at 70% VO_{2max} and were then provided with a high or low glycaemic index (73 vs. 35) mixed meal diet to be consumed over the following 12h. Carbohydrate was provided at 8 g·kg body mass with 11% protein and 17% fat content. The following day after a 10 hour fast, the 90 min cycle was repeated and metabolic parameters measured. ¹H and ¹³C Magnetic resonance spectroscopy were used to evaluate intra-myocellular triglyceride and glycogen content of the vastus lateralis and glycogen content of the liver immediately before and after exercise. Blood samples were collected at 15 min intervals throughout exercise. Substrate oxidation was calculated from expired air samples.

Results: Mean power output held for the 90 minute cycle was 247 ± 13 watts. Circulating NEFA concentrations were significantly reduced throughout exercise following the high compared to the low glycaemic index diet. Intra-myocellular lipid oxidation during exercise was significantly increased following a high in comparison with the low glycaemic index diet (1.6 ± 0.2 vs. 1.0 ± 0.3 μ mol/g). There were no differences in the oxidation of glycogen in skeletal muscle (68 ± 5 vs. 76 ± 8 mmol/l) or liver (71 ± 4 vs. 65 ± 8 mmol/l) between the high and low glycaemic index trials. There were no differences in whole body substrate oxidation, heart rate, glucose, lactate or insulin concentrations during exercise following high or low glycaemic index recovery diets.

Conclusion: (1) The consumption of high glycaemic index carbohydrates in recovery from exercise reduce NEFA availability during exercise and increases reliance on intra-myocellular lipid as a substrate source during moderate intensity exercise. (2) The glycaemic index of carbohydrates consumed during a 24 h recovery period does not influence utilisation of glycogen by skeletal muscle or liver. In combination, these results suggest that mixed meals differing only in glycaemic index influence the supply and oxidation of lipid during exercise independent of carbohydrate oxidation in people with adequate glucose control. Further studies investigating this effect in people with impaired glucose control are warranted.

AHNAK - a novel regulator of GLUT4 gene expression: role in insulin resistance

D. Ben Yosef, M. Armoni, C. Harel, E. Karnieli
Endocrinology, Diabetes and Metabolism, Rambam Medical Center,
Technion, Haifa, Israel,

Background and aims: Obesity and type 2 diabetes (DM2) are associated with reduced GLUT4 expression and function in adipocytes, hyperlipidemia and insulin resistance. We have previously shown that high levels of arachidonic acid (AA) repress GLUT4 promoter activity via specific promoter region (GLUT4-P) but the mediator remained elusive. Our aim was to identify the protein/s mediating GLUT4 gene repression upon chronic exposure to AA and examine their role in diabetes I.

Methods and results: Nuclear extracts from AA-treated H9C2 cardiomyocytes were subjected to GLUT4-P-biotin-avidin affinity column, followed by mass spectrometry analysis. This analysis detected that AHNAK, a giant phosphoprotein known to be involved in calcium and lipid metabolism, is attached to GLUT4-P. Transient co-expression in primary adipocytes of expression vectors for either C-terminal, middle or N terminal parts of AHNAK, resulted in 60±5%, 70±3% and 80±3%, ($p<0.05$) repression of GLUT4-P activity, respectively. Repression could be partially relieved by insulin (100 nM, 24 hrs). ChIP assay showed specific binding of AHNAK middle part to GLUT4-P. Silencing of AHNAK gene in adipocytes, resulted in significant 2-fold increase in cellular Glut4 protein levels, and protection of cellular Glut4 protein against AA-induced depletion. In cardiac and skeletal muscle biopsies obtained from STZ diabetic rats, AHNAK mRNA levels were increased 290 ±30% and 270±15% ($p<0.05$), respectively, compared to control. Interestingly, upon 8 days insulin therapy AHNAK mRNAs returned to control level.

Conclusion: Increased cellular level of AHNAK is associated with reduced GLUT4 expression, and contributes to lipotoxicity-induced insulin resistance. Our data introduce AHNAK as a novel regulator of GLUT4 gene expression and a potential molecular target for diabetes and obesity treatment.

Direct effect of inhibition of TCF7L2 expression on insulin action in cultured human skeletal muscle cells

A.E. Brown, S.J. Yeaman, M. Walker
Institute of Cellular Medicine, Newcastle University, United Kingdom

Background and aims: The recent genome-wide association studies have highlighted a number of genes, variants within which are associated with the development of type 2 diabetes. There is increasing evidence that variants within these genes, in particular, *TCF7L2*, may be associated with reduced insulin sensitivity. *TCF7L2* is a member of the Wnt signalling pathway and is important in regulating gene expression. A recent study reported that *TCF7L2* is one of several genes in the Wnt signalling pathway that is downregulated in the gastrocnemius muscle of transgenic mice who over accumulate glycogen in muscle but the mechanisms behind this are unclear. Therefore, the aim of this study is to examine whether *TCF7L2* plays a role in insulin action in skeletal muscle.

Materials and methods: Expression of *TCF7L2* in cultured myoblasts and myotubes was determined by quantitative PCR and Western blotting. Cultured myoblasts were transfected with short interfering RNAs (siRNAs) specific for *TCF7L2* in order to inhibit expression of this gene. All studies described were performed 48h after transfection. Quantitative PCR and Western blotting were employed to assess the extent of inhibition of *TCF7L2* expression compared with cells transfected with a scrambled control. Insulin-stimulated glucose uptake and glycogen synthesis was measured to assess the effects of *TCF7L2* inhibition on insulin action. Insulin signalling was examined using antibodies specific for phospho-PKB and GSK3.

Results: Expression of *TCF7L2* in cultured human skeletal muscle cells was confirmed by quantitative PCR and Western blotting. This showed that expression of *TCF7L2* is reduced by 2.5-fold in myotubes compared with myoblasts. Transfection of myoblasts with siRNAs resulted in a 72% reduction in *TCF7L2* expression compared with the scrambled control. Inhibition of *TCF7L2* was confirmed at the protein level by Western blot-

ting. Both basal and insulin-stimulated glycogen synthesis were significantly increased by *TCF7L2* inhibition. Basal levels were increased in the *TCF7L2* inhibited cells compared to the scrambled controls (169.7±28.2 vs 123.3±23.2 pmol/min/mg; $p=0.01$). Insulin-stimulated glycogen synthesis also increased from 341.5±45.6 pmol/min/mg to 515.1±51.5 (vs scrambled control, $p=0.0004$) respectively. An increase in insulin-stimulated glucose uptake was also observed in *TCF7L2*-inhibited cells compared with the scrambled control (90.1±15.3 pmol/min/mg vs 54.8±4.7, $p=0.03$, respectively). Insulin signalling, as assessed by the phosphorylation state of PKB^{Ser473} and GSK-3^{Ser21/9}, was normal in cells transfected with *TCF7L2* siRNAs. mRNA expression of the glucose transporter, *GLUT1*, was significantly increased in *TCF7L2*-inhibited cells compared to scrambled control, ($p=0.008$).

Conclusion: We have confirmed that *TCF7L2* is expressed in cultured human skeletal muscle cells. By inhibiting expression of this gene, both basal and insulin-stimulated glycogen synthesis and insulin-stimulated glucose uptake are significantly increased without any measurable differences in the activation of intermediates in the insulin signalling pathway. These effects on glucose metabolism may be mediated via increases in the expression of the basal glucose transporter, *GLUT1*.

Inhibition of phosphoinositide 5-phosphatase Sac3 links insulin signalling with GLUT4 translocation in 3T3L1 adipocytes

A. Shisheva, D. Sbrissa, O. Ikononov
Physiology, Wayne State University, Detroit, United States

Background and aims: Our previous studies have shown that silencing of the sole enzyme for phosphatidylinositol (PtdIns) (3,5)₂ synthesis, PIKfyve, and/or its associated activator ArPIKfyve reduces insulin-regulated glucose transport and GLUT4 surface arrival in 3T3L1 adipocytes, concomitant with a decrease in a PtdIns(3,5)₂ intracellular pool. These data implicate PtdIns(3,5)₂ as a positive regulator in insulin responsiveness. Concordantly, insulin action increases PtdIns(3,5)₂ production associated with intracellular membranes derived from 3T3L1 adipocytes in *in vitro* labeling assays. However, insulin-dependent regulation at the level of the PIKfyve activity and/or ArPIKfyve-PIKfyve association has not been observed. Recently we have identified a novel 5-phosphatase, Sac3, to hydrolyze PtdIns(3,5)₂, and to physically associate with the PIKfyve-ArPIKfyve protein complex in different cell types, including 3T3L1 adipocytes. In this study we have examined whether perturbations in Sac3 protein and/or activity result in gain of insulin responsiveness and whether Sac3 hydrolyzing activity is targeted by insulin action in 3T3L1 adipocytes.

Materials and methods: Sac3 protein levels were manipulated by electroporating 3T3L1 adipocytes with Sac3 siRNAs or with cDNAs of GFP-Sac3^{WT} and the GFP-Sac3^{D488A} phosphatase-deficient mutant. Electroporations with control siRNAs and cDNAs were run in parallel. To study GLUT4 dynamics, cDNAs of HA-GLUT4-GFP or (Myc)₇-GLUT4 were co-electroporated. The phosphatase activity associated with immunopurified Sac3 was determined by the malachite-green assay in the presence of different C₆-phosphoinositide substrates. Glucose transport and the surface accumulation of ectopically-expressed GLUT4 were determined by the 2-deoxyglucose assay and quantitative immunofluorescence microscopy in non-permeabilized cells, respectively.

Results: Silencing of Sac3 (by ~70%) resulted in significant gain of insulin-induced 2-deoxyglucose transport at both submaximal (1 nM; 132%) and maximal (100 nM; 128%) insulin doses, without altering the basal levels. Sac3 depletion was also associated with a significant increase (140%) in surface HA-GLUT4-GFP (measured by the cell-surface-to-total ratio) under submaximally activating insulin doses. The percentage of the (Myc)₇-GLUT4-expressing cells that displayed a complete plasma membrane rim in response to insulin increased by 32% upon co-expression of the phosphatase inactive GFP-Sac3^{D488A} mutant. In contrast, expression of enzymatically active GFP-Sac3^{WT} inhibited the (Myc)₇-GLUT4 arrival to the cell surface. Importantly, in response to acute insulin there was a marked decrease (~2-fold) of *in vitro* Sac3 phosphatase activity towards PtdIns(3,5)₂, but not PtdIns(4,5)₂ or PtdIns(3,4,5)₃ substrates.

Conclusion: Our observations in 3T3L1 adipocytes suggest that acute insulin increases the PIKfyve/ArPIKfyve-produced PtdIns(3,5)₂ signal by inhibiting the PtdIns(3,5)₂ hydrolyzing activity of the Sac3 phosphatase. Silencing of Sac3 or expression of an inactive Sac3 mutant potentiates insulin responsiveness of GLUT4 translocation and glucose transport presumably by

further increases in PtdIns(3,5)P₂ levels. Thus, pharmacological inhibition of Sac3 activity may improve insulin responsiveness.

Adrenaline induces insulin resistance by altering glycogen synthase phosphorylation in human skeletal muscle

J.W. Eriksson^{1,2}, T. Ruge³, Y.-C. Lai⁴, M.K. Svensson⁵, J. Jensen⁴

¹Institute of Medicine, Lundberg Laboratory for Diabetes Research, Gothenburg University, Sweden, ²Clinical Development, AstraZeneca R&D, Mölndal, Sweden, ³Surgery, Umeå University, Sweden, ⁴Physiology, National Institute of Occupational Health, Oslo, Norway, ⁵Institute of Medicine, Nephrology, Gothenburg University, Sweden

Background and aims: Sympathoadrenergic activation with accompanying elevation of circulating catecholamines is known to antagonize insulin action, and it contributes to insulin resistance during psychological or physical stress. In the present study, we investigated the effect of adrenaline in vivo on insulin-mediated glucose and fat metabolism and on regulation of protein kinase B (PKB) and glycogen synthase (GS) phosphorylation in human skeletal muscle.

Materials and methods: Ten healthy subjects (5M/5F, age 31±2, mean±SE) received a 240 min i.v infusion of adrenaline (0.05 µg/kg/min, to mimic a high physiological level) and saline, respectively, on separate days according to a cross-over protocol. After 120 min, a hyperinsulinemic euglycemic clamp (56 mU/m²/min) was started and it continued until 240 min. Skeletal muscle biopsies (m tibialis anterior) were performed at 120 and 240 min, but also on the following day. Muscle GS and PKB activities were investigated, including insulin-mediated changes in phosphorylation status.

Results: Adrenaline infusion increased blood glucose concentrations by ≈ 50 % compared to saline (p<0.01). FFA, glycerol, TG and lactate levels were also elevated by adrenaline (p<0.05). The hyperinsulinemic clamp normalized blood glucose and suppressed FFA (to the same levels with or without adrenaline) within 30 min. However, glucose infusion rate during the last hour was ≈ 60 % lower during adrenaline infusion compared to saline (M-value 4.2±0.5 vs 11.2 mg · kg FFM⁻¹ · min⁻¹, p<0.001). Insulin infusion increased skeletal muscle PKB Ser⁴⁷³ phosphorylation and co-infusion of adrenaline did not alter this. Adrenaline alone did not influence PKB Ser⁴⁷³ phosphorylation. Insulin increased GS fractional activity and decreased GS Ser⁶⁴¹ and Ser^{645,649,653,657} phosphorylation. In the presence of adrenaline, insulin did neither activate glycogen synthase or dephosphorylate GS Ser⁶⁴¹. GS Ser⁷ phosphorylation was not influenced by adrenaline. The glycogen content was reduced in skeletal muscle the day after adrenaline infusion.

Conclusion: Adrenaline did not influence insulin-stimulated PKB phosphorylation but completely blocked insulin-mediated GS activation and Ser⁶⁴¹ dephosphorylation. Adrenaline-mediated hyperglycemia was normalized by insulin within 30 min, but glucose utilisation during the hyperinsulinemic euglycemic clamp was reduced by 60 %. The data suggest that altered glycogen synthase phosphorylation and activity in skeletal muscle contribute to whole-body insulin resistance in situations with sympathoadrenergic activation.

Inflammation and endothelial dysfunction in children with type 1 diabetes mellitus

B. Rami¹, T. Hoertenhuber², M. Elhenicky², C. Hoebaus², E. Schober¹,

G. Schernthaner³, G.-H. Schernthaner²

¹Pediatrics and Adolescent Medicine, Medical University of Vienna,

²Medicine II, Medical University of Vienna, ³Medicine I, Rudolfstiftung Hospital Vienna, Austria

Background and aims: Advances in diabetes treatment have resulted in a decline of the microvascular complications, namely neuropathy and retinopathy, in patients with childhood onset type 1 diabetes mellitus (T1DM) but also in T2DM. However, recent studies have proven, that despite the dramatic improvements in treatment, the macrovascular disease (MVD) morbidity and mortality in patients with T1DM compared to the healthy background population stayed at an advanced level, resulting in a total loss of lifetime between 5 and 20 years. Since the mechanisms are not completely understood, we decided to investigate inflammation and endothelial dysfunction in children with T1DM and to compare the results to healthy control subjects.

Materials and methods: We included 175 children, 140 with T1DM, 35 served as control group (CO). As a general marker of subclinical systemic vascular inflammation, we chose C-reactive protein (CRP), as early marker of endothelial dysfunction, we investigated endothelial progenitor cells (EPC). EPC are cells that circulate in the peripheral blood and are involved in neovascularisation, endothelial dysfunction and predict MVD morbidity and mortality in humans. Circulating pluripotent progenitor cells (CPC; CD34+/CD133+) and EPC (CD34+/CD133+/CD309+) were enumerated by direct immunostaining technique and recorded on a flow cytometer. Statistical analysis included unpaired student's t test, correlation analysis as well as multivariate linear regression modelling, as appropriate.

Results: The patients (T1DM) and controls (CO) were matched for age (14±3 years) and gender (49.2% female). EPC but not CPC were significantly impaired in children with T1DM compared to CO (609±359 vs 1137±504, p<0.001). Other significant differences were found in systolic blood pressure (115±15 vs 101±8 mmHg, p<0.001), pulse (88±16 vs 80±11, p=0.001), LDL-cholesterol (90±28 vs 83±15 mg/dl, p=0.03), and glucose levels (154±83 vs 90±8 mg/dl, p<0.001), and CRP (112±14 vs 101±8 mg/dl, p<0.001), each T1DM vs CO. Patients (T1DM vs CO) did not differ for diastolic blood pressure (63±9 mmHg), size (161±15 cm), weight (57±18 kg), BMI (22±4 kg/m²), total cholesterol (176±33 mg/dl), triglyceride (116±92 mg/dl), HDL-cholesterol (64±15 mg/dl), VLDL-cholesterol (20±11 mg/dl), serum creatinine (0.8±0.4 mg/dl), GGT (17±7 U/l), ASAT (25±10 U/l) and ALAT (31±8 U/l) (given are mean of all patients). Multivariate regression analysis revealed that HbA1c was the single strongest predictor of EPC levels in our study cohort (beta=-0.355, p<0.001) and that BMI and triglyceride levels were the strongest predictors of CRP levels (beta=0.264, p<0.001; beta=0.189, p=0.009, respectively). Remarkably, EPC and CPR were not associated with one another.

Conclusion: In conclusion, this is the first study investigating both inflammation and endothelial dysfunction (by EPC measurements) in children with type 1 diabetes mellitus. EPC are significantly reduced and CRP levels are elevated in children with T1DM. The missing association of CRP and EPC in our study cohort, suggests a from inflammation independent demerit effect on EPC in children with T1DM.

Endothelial dysfunction and inflammation partially explain the association between soluble RAGE and cardiovascular disease and albuminuria in type 1 diabetes: The EURODIAB StudyJ.W.M. Nin¹, I. Ferreira², C.G. Schalkwijk¹, M.H. Prins³, N. Chaturvedi⁴, J.H. Fuller⁵, C.D.A. Stehouwer²¹Department of Internal Medicine, University of Maastricht, Netherlands,²Department of Internal Medicine, University Hospital Maastricht,Netherlands, ³Department of Clinical Epidemiology & MTA, UniversityHospital Maastricht, Netherlands, ⁴National Heart and Lung Institute,Imperial College London, United Kingdom, ⁵Department of Epidemiology

and Public Health, Royal Free and University College London Medical School, United Kingdom

Background and aims: The interaction between AGEs and the receptor for AGE (RAGE) have been proposed as a potential mechanism linking hyperglycaemia to vascular complications in diabetes, possibly through the increased inflammatory activity and endothelial dysfunction they provoke. We have therefore investigated 1) whether soluble RAGE (sRAGE) is associated with increased cardiovascular disease (CVD) and microvascular complications (i.e. albuminuria, retinopathy) in type 1 diabetic patients; and 2) the extent to which any such associations are explained by markers of inflammation (CRP, TNF α , IL6), endothelial dysfunction (sVCAM-1, sE-selectin) and AGEs (CML, CEL and pentosidine).

Materials and methods: The study population consisted of 477 subjects (234 women; mean age 42 \pm 10 yrs) from the EURODIAB Prospective Complications Study. We used linear regression analyses to investigate the differences in sRAGE levels (expressed by the regression coefficients β (in ng/ml) and respective 95%CI) between subjects with vs. without complications; this was first analyzed with adjustments for age, sex, duration of diabetes, HbA1c and traditional risk factors (smoking, BMI, dyslipidemia, MAP), and then with successive adjustments for the potential pathophysiological mechanisms listed above.

Results: Subjects with CVD (n=116) had greater levels of sRAGE than those without CVD (who also did not have any microvascular complications; n=178). However, this difference was mainly observed in men, but not in women: β =0.19 (95%CI:0.01;0.37) and β =0.08 (95%CI:-0.06;0.22, $p_{\text{sex-interaction}}$ =0.014), respectively. In men, these differences were attenuated after further adjustment for markers of endothelial function [β =0.15 (95%CI:-0.02;0.32)] and of inflammation [β =0.14 (95%CI:-0.02;0.31)]. sRAGE was also increased in the presence and across the levels of severity of albuminuria: β =0.02 (95%CI:-0.08;0.12) and β =0.09 (95%CI:-0.01;0.19) in subjects with micro- (n=72) and macro- (n=112) vs. normo-albuminuria (n=293), respectively (p -trend=0.077). These differences were greatly attenuated after adjustments for endothelial dysfunction [β =-0.01 (95%CI:-0.11;0.09) and β =0.05 (95%CI:-0.05;0.15), p -trend=0.336] and inflammation [β =-0.02 (95%CI:-0.11;0.08) and β =0.05 (95%CI:-0.05;0.14), p -trend=0.375]. Finally, sRAGE was also increasingly greater (but not significantly so) in the presence and across the severity of retinopathy: β =0.03 (95%CI:-0.06;0.13) and β =0.08 (95%CI:-0.03;0.18) in subjects with non-proliferative (n=123) and proliferative (n=141) vs. without retinopathy (n=213), respectively (p -trend=0.145).

Conclusion: sRAGE is associated with greater CVD (particularly among men) and albuminuria in type 1 diabetic subjects, and these associations may be explained, at least in part, by greater inflammatory activity and endothelial dysfunction.

255

Endothelial dysfunction and low-grade inflammation precede the increase in urinary albumin excretion in type 1 diabetes: a 20-yr longitudinal studyI. Ferreira¹, P. Hovind², C.G. Schalkwijk^{1,3}, H.-H. Parving^{4,5}, P. Rossing², C.D.A. Stehouwer^{1,3}¹Department of Internal Medicine, University Hospital Maastricht, Netherlands, ²Steno Diabetes Center, Gentofte, Denmark, ³Cardiovascular

Research Institute Maastricht, University of Maastricht, Netherlands,

⁴Department of Medical Endocrinology, University Hospital ofCopenhagen, Denmark, ⁵Faculty of Health Science, University of Aarhus, Denmark

Background and aims: Microalbuminuria is a predictor of widespread severe microangiopathy and macroangiopathy in type 1 diabetic patients. Patients with microalbuminuria show generalized dysfunction of the vascular

endothelium and chronic inflammation, but it is not known to what extent these pathophysiological mechanisms may, in fact, precede the development of microalbuminuria. We have therefore investigated, in a 20-year prospective study, 1) whether the longitudinal developments of markers of inflammation (CRP and sICAM-1) and endothelial dysfunction (sICAM-1 and sVCAM-1) (main determinants) were associated with urinary albumin excretion (UAE) (main outcome); and 2) the extent to which the increase in those markers preceded the increase in UAE.

Materials and methods: Study population consisted on 277 type 1 diabetic patients (114 women) from an outpatient diabetic clinic (Gentofte, Denmark), who were consecutively admitted, upon diagnosis, between Sep'79-Aug'84 (mean age at diagnosis 27.5 \pm 13.8 yrs; 216 adults). These patients attended the outpatient clinic every 3 or 4 months, throughout a total follow-up period of >20 yrs [median follow-up duration = 18 yrs (range 1.0-21.5)], as part of their routine evaluation. This included the assessments of UAE (mg/24h), HbA1c, BMI, blood pressure, creatinine, cholesterol, and smoking status. CRP, sICAM1 and sVCAM1 were recently measured in blood samples collected throughout the whole longitudinal period. We used generalized estimating equations (GEEs) to investigate, longitudinally, with concomitant and time-lag models, the associations hypothesized and results hereby obtained are expressed by longitudinal regression coefficients (respective 95%CI). All analyses were adjusted for sex, age and the other risk factors assessed (listed above).

Results: Per year, UAE increased by 6.1%, CRP by 1.2%, sICAM-1 by 1.0% (all p <0.01), whereas no increase was observed in sVCAM-1 levels. In a concomitant model (i.e. the association between the determinants and outcome assessed at the same time point), the longitudinal development of logCRP and sICAM-1 (but not of sVCAM-1) was positively and independently associated with logUAE [β =0.067 (0.001;0.134), p =0.042 and β =0.369 (0.186;0.552), p <0.001, respectively]. When a 2-yr time-lag model was fitted (i.e. the association between the determinants at a given time point with UAE 2-yrs later), only sICAM-1 was positively associated with logUAE [β =0.277 (0.017;0.538), p =0.037]. In a 4-yr time-lag model, however, the association between sICAM and logUAE was attenuated and was no longer significant: β =0.204 (-0.077;0.486, p =0.155).

Conclusion: In type 1 diabetes, UAE, endothelial dysfunction and low-grade inflammation (as reflected by CRP and sICAM-1) are inter-related and progress in parallel. In, addition, endothelial dysfunction/inflammation precedes (by 2 to 4 years) the increased of UAE, and therefore may predict the development of (micro)albuminuria in type 1 diabetes.

256

Role of reactive oxygen species in mediation of sphingomyelinase induced vascular dysfunctionZ. Benyo¹, A. Magyar¹, P. Örsy¹, Á. Donkó², B. Horváth¹¹Institute of Human Physiology and Clinical Experimental Research,²Department of Physiology, Semmelweis University, Budapest, Hungary

Background and aims: Sphingolipids, derived from sphingomyelin metabolism, have been implicated as mediators of inflammatory processes in diabetes. Sphingomyelinase (SMase) catalyzes the conversion of sphingomyelin to ceramide, a biologically active compound and precursor of other sphingolipid mediators. In the present study we aimed to analyze the influence of SMase activity on vascular functions and to assess the role of reactive oxygen species (ROS) in mediating its effects.

Materials and methods: Carotid artery segments were prepared from wild type (WT) and transgenic mice overexpressing CuZn superoxide dismutase (SOD-tg) or deficient in the NAD(P)H oxidase isoform NOX2 (NOX2-ko). Vasoconstrictor responses to 124 mM K⁺ or 10 μ M phenylephrine (Phe) as well as endothelium dependent relaxations induced by acetylcholine (ACh) after precontraction with 10 μ M Phe have been analyzed in vitro by isometric tension recording. Phe- and ACh-induced tension changes have been normalized for the K⁺-induced contraction and the precontraction, respectively. Superoxide production has been visualized with the fluorescent dye dihydroethidium (DHE) and determined in the vascular endothelial and smooth muscle layers by confocal microscopy.

Results: Incubation of the vessels with 10 μ M ceramide for 30 minutes resulted in a strong increase of DHE staining both in the endothelial and smooth muscle layers indicating the stimulation of superoxide production by both cell types. The changes of the vascular reactivity induced by incubation with 0.5 U/ml neutral SMase (nSMase) are summarized in Table I. The contractile effect of 124 mM K⁺ was similar in WT, SOD-tg and NOX2-ko vessels and remained unaltered after incubation with nSMase. In contrast, nSMase reduced

Table I. Vascular reactivity in the different experimental groups before and after nSMase incubation

Vasoactive agent	WT, before nSMase	WT, after nSMase	NOX2-ko, before nSMase	NOX2-ko, after nSMase	SOD-tg, before nSMase	SOD-tg, after nSMase
124 mM K ⁺ (mN)	5.3±0.5	5.9±0.5	5.4±0.3	5.7±0.4	4.9±0.4	4.6±0.5
10 μM Phe (%)	75±2	60±2**	69±7	49±8***	69±5	75±5
10 nM Ach (%)	-43±8	-33±7**	-58±7	-43±3*	-65±2 [#]	-42±2***

Phe-induced contraction in WT and NOX2-ko but not in SOD-tg vessels. Interestingly, the relaxant effect of ACh under resting conditions was significantly (**p*<0.05) stronger in SOD-tg vessels as compared to WT controls and NOX2-ko vessels also showed a tendency of enhanced relaxations indicating that superoxide production may constitutively suppress NO-mediated vasodilatations. Incubation of the vessels with nSMase resulted in a reduction of ACh-induced relaxations in all experimental groups.

Conclusion: Enhanced activity of the SMase pathway stimulates endothelial superoxide release and suppresses endothelium-dependent relaxations of the carotid artery but there is apparently no causal relationship between these effects. On the other hand, sphingolipid mediators also stimulate superoxide generation of the vascular smooth muscle and diminish adrenoreceptor-mediated contractions without influencing the contractile effect of cell membrane depolarization. Since SMase decreased Phe-induced contractions in NOX2-ko but not in SOD-tg carotid arteries its effect appears to be mediated by NOX2-independent superoxide production.

Syndapin I/PACSIN 1 participates in inositol hexakisphosphate-induced endocytosis via its SH3 domain in beta cells

S.-N. Yang¹, G. Yang¹, J. Yu¹, B. Qualmann², M.M. Kessels², L. Yu¹, P.-O. Berggren¹;

¹The Rolf Luft Research Center for Diabetes and Endocrinology, Karolinska Institutet, Stockholm, Sweden, ²Institute for Biochemistry I, Friedrich Schiller University Jena, Germany

Background and aims: Endocytosis is a fundamental cellular process. It works in concert with exocytosis to ensure adequate exchange between the intracellular milieu and extracellular environment, and thereby cellular homeostasis. Endocytic-exocytic cycles guarantee structural and functional components in the plasma membrane, cytoplasm and nucleus by exquisitely recycling membrane proteins and lipids. Syndapin I/PACSIN 1 has been identified as a new member of the family of endocytic proteins. It harbors an α-helical region forming an F-BAR domain at its N-terminus, two arginine-proline-phenylalanine (NPF) motifs in its middle and a Src homology 3 (SH3) domain at its C-terminus. The SH3 domain interacts with dynamin 1, synaptojanin, synapsin I and the neural Wiskott-Aldrich syndrome protein. Such SH3 domain-specific interactions play a crucial role in dynamin-mediated endocytosis. The molecular details of the endocytic machinery in the β cell have not been well clarified. In the present study, we expressed the syndapin I SH3 domain in β cells to disrupt the interaction between endogenous syndapin I/PACSIN 1 and other endocytic proteins in a dominant-negative fashion and subsequently evaluated inositol hexakisphosphate (InsP₆)-induced endocytosis in these syndapin I SH3 domain-expressing cells.

Materials and methods: Experiments were performed in mouse β-cells and a series of insulin-secreting cell lines using patch-clamp recording, immunoblot analysis, immunostaining and confocal microscopy.

Results: Immunoblot analysis and immunofluorescence labeling/confocal microscopy show that mouse islet β cells as well as insulin-secreting HIT-T15, INS-1, MIN6-m9 and RINm5F cells exhibit specific syndapin I/PACSIN 1 immunoreactivity. Capacitance measurements reveal that dominant-negative interference with endogenous syndapin I/PACSIN 1 protein complexes by expression of the syndapin I SH3 domain significantly slows down endocytosis elicited by intracellular application of InsP₆. However, patch clamp analysis illustrates that incorporation of GST-syndapin I SH3 domain into the mouse β cell does not influence whole cell Ca²⁺ currents.

Conclusion: Our data demonstrate that the key endocytic protein syndapin I/PACSIN 1 is present in β cells. Its SH3 domain specifically mediates InsP₆-induced β cell endocytosis. However it is unable to convey appreciable impact on voltage-gated Ca²⁺ channel activity in β cells, although Ca_v1.2 and Ca_v1.3 pore-forming subunits are equipped within proline-rich SH3 binding sites. In the physiological context, glucose rapidly elevates a series of signaling molecules, such as ATP, Ca²⁺ and InsP₆, in pancreatic β cells which ultimately results in insulin exocytosis followed by endocytosis. Interestingly, InsP₆ not only promotes insulin exocytosis, but also facilitates β cell endocytosis through syndapin I/PACSIN 1, which obviously plays an important role in the maintenance of pancreatic β cell function. Hence, this novel molecular mechanism mediating the stimulatory effect of InsP₆ on endocytosis provides insights into how β cells preserve structures and components in their different subcellular compartments to guarantee cellular homeostasis.

Tmem27 role in islets physiology

J. Altirriba^{1,2}, S. Casas¹, A. Barberà¹, R. Gasa^{1,2}, M.J. Ramírez³, S. Ros⁴, A. Gutiérrez³, M.C. Ruiz de Villa⁵, M. Julià^{1,2}, R. Gomis^{1,2}

¹Diabetes and Obesity Laboratory, IDIBAPS, ²CIBER de Diabetes y Enfermedades Metabólicas Asociadas, CIBERDEM, ³Experimental Laboratory of Nephrology and Transplantation, Hospital Clinic, ⁴Institute for Research in Biomedicine, Scientific Park, ⁵Department of Statistics, UB, Barcelona, Spain

Background and aims: Tmem27 is an HNF1 α target expressed in β cells, whose role is controversial. While one group concluded that an increased expression induces pancreatic β cell proliferation, another one stated that its rise enhances glucose stimulated insulin exocytosis. We aim to study Tmem27 to characterize its function and biochemistry in the islets.

Materials and methods: Wistar rats were treated with tungstate for 40 days. At the end of the treatment, islet proliferation was assessed by immunohistochemistry and in isolated islets glucose induced insulin secretion, Tmem27 and insulin expression were determined. Control islets were infected with Ad-Tmem27-myc and Ad- β -Gal to determine glucose induced insulin secretion and proliferation. TMEM27, INSULIN, SNAPIN, CYCLIN E1, CDK 2, CYCLIN D1 and CDK 6 levels were assessed in human islets by qPCR, establishing its correlation. Protein extracts of Ad-Tmem27-myc INS-1E cells were treated with heparinase, calf intestinal phosphatase, N-glycosidase F or O-glycosidase. Colocalisation analysis of Ad-Tmem27-myc with membrane, Golgi, endoplasmic reticulum and insulin were performed. Islets, hepatocytes and mouse proximal tubular renal cells were isolated and infected with Ad-Tmem27-myc.

Results: Tmem27 function: Islets from treated (T) rats compared to untreated (UT) show decreased mRNA levels of insulin (fold change -2.26 $p < 0.01$) and Tmem27 (fold change -3.08 $p < 0.01$) with a significant correlation between both ($p = 0.72$ $p < 0.001$). Moreover, T animals have decreased glucose induced insulin secretion (UT 140.42 vs T 62.56 IU/islet/90 min, $p < 0.01$) and morphometric analysis reveals increased islet proliferation (UT 4.03 vs T 32.90 nuclei PCNA+/mm² islet $p < 0.001$). Therefore, treatment leads to a decrease expression of Tmem27 similarly to what happens with insulin expression, secretion and insulinemia; whereas the islet proliferation is increased. Control rat islets infected with Tmem27 (compared to β -Gal infection) show an increased glucose induced insulin secretion (20.87 vs 40.88 IU/islet/90 min [β -Gal vs Tmem27] $p < 0.05$), whereas there is no differences in islet proliferation. In human islets, TMEM27 expression strongly correlates with INSULIN ($p = 0.87$ $p < 0.01$) and SNAPIN ($p = 0.73$ $p < 0.05$) but no significant correlation is found with CYCLIN E1, CDK 2, CYCLIN D1 and CDK 6. **Tmem27 biochemistry:** Confocal analysis of INS-1E infected with Tmem27 shows that Tmem27 is present in Golgi, plasma membrane and colocalizes with a 30% of insulin granules. Characterization of Tmem27 fragments by Western blot demonstrates that in INS-1E Tmem27 is N-glycosylated but not O-Glycosylated, and neither heparinized nor phosphorylated. Finally, infection of islets, hepatocytes and proximal tubular cells (tissues where Tmem27 expression have been described) with Tmem27 proves that islets and proximal tubular cells have the capacity for cleaving this protein, whereas hepatocytes don't.

Conclusion: Our results support the hypothesis that Tmem27 role in β cell function is involved in insulin secretion but not in β cell proliferation. Moreover, they suggest that islets and proximal tubular cells can cleave Tmem27.

Low, but physiological, concentration of GLP-1 stimulates insulin secretion independent of the cAMP-protein kinase A pathway

M. Shigeto¹, M. Katsura², M. Matsuda¹, S. Ohkuma², K. Kaku¹

¹Diabetes and Endocrine Division, Department of Medicine, ²Pharmacology, Kawasaki Medical School, Kurashiki, Japan

Background and aims: Glucagon-like peptide-1 (GLP-1) concentration used in previous *in vitro* experiments was far from the level of *in vivo*. Alteration of plasma GLP-1 concentration at pM order lowers blood glucose concentration. The postprandial GLP-1 concentration is only 20 pM, even in the presence of DPP-IV inhibitors. This slight change in GLP-1 concentration, however, has a large impact on blood glucose concentration. The aim of this study is to examine GLP-1 action mechanism at a physiological concentration on pancreatic insulin secretion *in vitro*.

Materials and methods: MIN6 cells (passages 20 - 30) were cultured in modified DMEM in tissue culture flasks. For determination of insulin secretion, the cells were preincubated for 30 min in 7.0 mM glucose containing KRB-HEPES buffer. The cells were pretreated with verapamil, dantrolene and BAPTA for 60 s before GLP-1 stimulation. KT5720 was added 20 min before stimulation.

Results: A high concentration of GLP-1 (10 nM) stimulated intracellular cAMP accumulation and insulin secretion was significantly inhibited by KT5720, a selective inhibitor of PKA. A relatively lower concentration of GLP-1 (1 pM) also increased insulin secretion significantly. The GLP-1 dose-dependency on insulin secretion was significantly observed at GLP-1 concentrations greater than 100 pM, but not significant over the range of 1 pM to 100 pM of GLP-1. The intracellular accumulation of cAMP was increased by treatment with 100 nM forskolin, and also was increased by addition of 100 pM or more GLP-1 with a dose-dependent manner. On the other hand, low concentrations of GLP-1 (~10 pM) failed to increase the intracellular cAMP accumulation. Insulin secretion stimulated by 10 nM GLP-1 was significantly, but not completely, inhibited by 100 nM KT5720. In contrast, insulin secretion induced by 1 pM GLP-1 was not affected by KT5720, suggesting an existence of the cAMP-PKA-independent pathway. The time course of insulin secretion showed a marked increase at 420–660 s after an addition of 1 pM GLP-1 (Phase 1), following with oscillations in insulin release (Phase 2). This increase in insulin secretion was completely inhibited by addition of BAPTA, an intracellular Ca²⁺ chelating agent, but not by KT5720. The first half of Phase 1 insulin secretion was inhibited by addition of 3 μ M verapamil, a L-type voltage-dependent calcium channel blocker. A similar waveform of insulin secretion was noted even in the absence of extracellular Ca²⁺. The latter half of Phase 1 was inhibited by 1 μ M dantrolene, a blocker of calcium efflux from endoplasmic reticulum, and Phase 2 insulin secretion also was partially inhibited. Simultaneous addition of dantrolene and verapamil completely inhibited Phase 1 insulin secretion.

Conclusion: The present data clearly demonstrate that low GLP-1 concentrations comparable to *in vivo* blood concentrations promoted insulin secretion independent of the cAMP-PKA pathway. This effect is dependent on the intracellular Ca²⁺ concentration. Thus our results strongly suggest the possibility that the signal-transducing pathway of GLP-1 action on pancreatic insulin secretion involves both cAMP-PKA-dependent and -independent mechanisms, which are dependent on GLP-1 concentration. Studies of GLP-1 at physiologic concentrations may lead to new developments in studies of pancreatic β -cell function.

Role of mTOR in inhibition of glucose-induced insulin secretion by glucocorticoids in rat INS-1E cells

M.M.L. Linssen¹, B. Guigas¹, J. Kriek¹, G.C.M. van der Zon¹, M. Diamant², D.M. Ouwens¹

¹Molecular Cell Biology, Leiden University Medical Center, Netherlands,

²Endocrinology, Vrije Universiteit Medical Center, Diabetes Center, Amsterdam, Netherlands

Background and aims: Synthetic Glucocorticoids (GCs) are generally prescribed anti-inflammatory and immunosuppressive agents to treat for example Rheumatoid Arthritis, Asthma and many other diseases, because of their very potent characteristics. A great disadvantage of these therapeutics is the fact that an excess of GCs can lead to unfavourable changes in glucose-, lipid- and protein metabolism associated with the development of insulin resistance and overt diabetes. One of the signalling pathways affected by GCs is the mammalian target of rapamycin (mTOR) pathway, in which GCs inhibit mTOR via induction of REDD1 and activation of tuberous sclerosis complex 2 (TSC2). mTOR has also been implicated in the regulation of beta-cell survival. Here, we determined whether dysregulation of the mTOR pathway contributes to inhibition of glucose-stimulated insulin secretion (GSIS) by glucocorticoids in INS-1E cells.

Materials and methods: INS-1E rat insulinoma cells were incubated with either Prednisolone (700 nmol/l) or Dexamethasone (300 nmol/l) (20hrs). After 2 hrs glucose- and serum starvation, cells were exposed to glucose (2.5 or 20 mmol/l, 30 min) and insulin secretion and protein expression were determined. For gene silencing, cells were transduced with lentiviral vectors encoding rat specific shRNA.

Results: Stimulation of INS-1E cells with glucose, led to a 2.8-fold induction of GSIS. This response was abrogated 30% by the mTOR inhibitor rapamycin. Exposure with dexamethasone and prednisolone reduced GSIS up to 40%. Furthermore, the glucose-induced stimulation of mTOR-Ser2481 phospho-

rylation, and its downstream target ribosomal protein S6-Ser236 and 4E-BP1-Thr70 were markedly reduced in cells treated with GCs. No differences between prednisolone and dexamethasone were observed. The inhibitory effects of GCs were absent in cells in which TSC2 was silenced by shRNA. Similar results were obtained in cells lacking FK506 binding protein 38 (FKBP38), another upstream regulator of mTOR-activity.

Conclusion: Both prednisolone and dexamethasone reduced glucose induced insulin secretion and phosphorylation of mTor and its downstream targets 4E-BP1 and ribosomal protein S6 in insulin secreting cells. Silencing the mTOR regulators FKBP38 or TSC2 abolished the inhibitory effects of GCs. These findings implicate an important role of mTor as a signalling intermediate in the unfavourable effects of prednisolone and dexamethasone on insulin secretion.

Early programming of islets antioxidant activities and mitochondrial function by maternal low protein diet

N.H. Theys, B. Reusens, C. Remacle

Institute of Life Sciences, Université catholique de Louvain, Louvain-la-Neuve, Belgium

Background and aims: Foetal environment can determine long-term susceptibility to Type 2 diabetes. We have shown that the vulnerability of the foetal and adult β -cells against reactive oxygen species (ROS) can be influenced by the nutritional status of the mother during gestation and lactation. Moreover, new findings indicated that programmed mitochondrial dysfunction may be a key adaptation of the foetus to survive in utero in an altered nutritional environment. In this context, our aim was to investigate whether maternal low protein diet may programme the antioxidant activity and the mitochondrial function in the islets of the progeny.

Materials and methods: Wistar rats were fed a control diet containing 20% protein (C group) or an isocaloric low protein diet (LP) containing 8% protein during gestation only (LPR group) or until weaning (LPT group), after which offspring received the control diet. The antioxidant capacity was studied in 21.5 day-old foetuses and at 5 days, 28 days, 6 weeks, and 3 months in isolated islets from male rats. The mitochondrial function was studied at 3 months in C and LPR progeny.

Results: In foetal islets, SOD (superoxide dismutase) activity was not influenced by the maternal LP diet whereas GPX (glutathione peroxidase) activity was significantly lower in LP foetuses ($p<0.05$). CAT (catalase) activity was very low at this stage and was unaffected by the LP diet. The gene expression of antioxidant enzymes was unchanged in LP foetal islets compared to C. In the newborn, SOD activity was lower in LPR offspring compared to C. At 3 months, this activity was higher in LPR ($p=0.05$) and in LPT islets ($p<0.001$). This could be linked to an increased SOD1 mRNA level in both progeny ($p<0.05$) and a SOD2 expression slightly higher in LPT islets. CAT activity was so low for many samples from LP animals that it could not be detected, particularly in LPT islets. Moreover, the level of CAT transcripts was well below 50% in islets from LP animals compared to controls ($p<0.05$ vs LPT; $p<0.01$ vs LPR). Lower GPX activity was measured in LPR newborns ($p<0.01$) as well as at 28 days in both LPR and LPT islets ($p<0.01$). The lower GPX activity was no more observed thereafter. A significant increase in c-Myc expression ($p<0.05$ vs LPT; $p<0.01$ vs LPR) and a reduced insulin mRNA level ($p<0.05$) were observed in LPR and LPT islets. PDX1 (pancreatic and duodenal homeobox-1) expression was unchanged. In response to 16.7 mM glucose, ATP production was blunted in LPR islets ($p=0.07$) while the insulin secretion was unaffected. The expression of mtDNA encoded gene ATP synthase (subunit 6) declined in LP rats ($p<0.05$) while the expression of subunit of complex I (ND4L) was higher ($p<0.01$). The expression of genes coding for enzymes involved in the TCA cycle was also affected with a reduced in citrate synthase and malate dehydrogenase transcripts ($p<0.05$).

Conclusion: Consequences of the maternal LP diet on the antioxidant status of the offspring provide evidence that the environment during early life exerts considerable long-term effects. An increased SOD activity may reflect an efficient metabolism of superoxide anion supply from mitochondrial electron transport chain. This will finally result in an increased H_2O_2 production which can be involved in overexpression of c-Myc in β -cells, that may cause downregulation of insulin gene expression. Our study highlighted that mitochondria are important targets linking molecular and physiological impacts of the foetal programming.

Maternal obesity influences the phenotype of the offspring due to altered intrauterine milieu and modifies the wiring of the POMC cells in the arcuate nucleus in mice

B. Sarman¹, M. Shanabrough¹, E. Borok¹, Z.-W. Liu¹, J. Bruening², X.-B. Gao¹, T. Horvath¹

¹Department of Obstetrics, Gynecology and Reproductive Sciences, Yale University, School of Medicine, New Haven, United States, ²Department of Mouse Genetics and Metabolism, Institute for Genetics, University of Cologne and Center of Molecular Medicine Cologne, Germany

Background and aims: We tested the hypothesis whether the altered perinatal metabolic milieu due to maternal hyperglycemia and/or obesity in

C57Bl/6 mice leads to a metabolic phenotype in the offspring and if it modifies the wiring of the POMC (pro-opio-melanocortin) cells the main anorexiogenic component in the arcuate nucleus.

Materials and methods: All POMC cells expressed GFP driven by the POMC promoter. Data is expressed as the average \pm standard deviation (SD). We placed 8 weeks old female mice on either high fat (HF) or low fat normal diet (ND). After six weeks the body weights (bw:g) and plasma glucose levels (gl:mg/dl) of the groups were significantly different, (bw: HF: 26.74 ± 1.3 vs. ND: 22.74 ± 1.2 ; $p=0.005$; gl: HF: 200.86 ± 20.18 vs ND: 118.17 ± 2.99 $p<0.001$). Females from both groups were set up as breeders and the bw of these litters were monitored. At weaning, all progeny were placed on ND until postnatal day 60. At day 60 the 2 groups were divided into subgroups maintained on either ND (ND/nd, HF/nd) or HF diet (ND/hf, HF/hf). We monitored the bw for 12 weeks and at day 144 we measured glucose, insulin and body fat. At days 60 and 144 mice from each litter were processed for synaptic analysis of POMC.

Results: Offspring from mothers on HF diet weighed more than those from ND dams during lactation. After weaning, when all offspring were on ND the bw difference diminished within two weeks, and remained indistinguishable until day 60. At the end of the study, HF/hf offspring gained more weight than any other group in the study; their plasma glucose was significantly higher ($p<0.01$). The synaptic input organization of POMC neurons from 21 day old mice from mothers kept on HF diet was significantly different from that of ND reared mice: the ratio of inhibitory to excitatory synapses was shifted towards inhibitory contacts in the offspring of HF fed compared to ND mothers. At day 60 similar differences were seen in the input organization of POMC cells even though there were no weight differences between groups. The analysis of the wiring of POMC cells at day 144 is ongoing.

Conclusion: Our results confirm that the mouse (like the rat) is an excellent model to study the molecular and neurobiological mechanisms through which maternal obesity results in metabolic phenotype in the offspring. We showed that overfeeding of mothers does not result in a obesity of the offspring while they are kept on ND, however, they are vulnerable to diet-induced obesity. Further, synaptic input organization of the melanocortin cells is altered in offspring from obese mothers which favors a suppressed melanocortin tone. This change likely contributes to diet induced obesity.

Progression of body composition during a eight-years follow-up study of adults born SGA

T. Meas^{1,2}, S. Deghmoun², E. Carreira², C. Levy-Marchal^{3,4}

¹Internal medicine, Université, Paris 7, ²U690, INSERM U690, ³INSERM, U690, ⁴Université Paris 7, Denis Diderot, Paris, France

Background and aims: Increased fat mass has been reported both in children and adults born small for gestational age (SGA). The theory of the “developmental mismatch” suggests that the predictive adaptative response during the phase of developmental plasticity under poor *in-utero* conditions assists the survival of the fetus and optimizes the phenotype for the probable environment of the mature organism. When the post-natal environment is different, this mismatch increases the risk of metabolic disease. This theory predicts that fat mass, which is considerably reduced in SGA newborns, would increase after birth and that the excess of body fat in young adults born SGA would be more pronounced with increasing age.

Materials and methods: Subjects were selected from a community-based cohort where 389 subjects born full-term SGA (Birth Weight $< 10^{\text{th}}$ percentile) were considered as exposed to fetal growth restriction and 462 adapted for gestational age (AGA) subjects, ($25^{\text{th}} < \text{BW} < 75^{\text{th}}$ percentile) as not exposed. Anthropometric measurements were measured at 22 and 30 yr of age and body fat was evaluated by multifrequency bioelectrical-impedancemetry at 30 yr.

Results: Ponderal index at birth was significantly lower in the SGA group (24.2 ± 2.6 vs 26.5 ± 1.6 kg/m³; $p=0.001$). At 22 and 30 years of age, mean body mass index (BMI) was not significantly different between the two groups, however, both groups gained weight, BMI and waist circumference. The proportion of obese subjects at 30 yr was significantly increased in the SGA group (12.1% versus 6.5%, $p=0.02$). During the 8 yr-follow-up the progression of BMI was significantly greater in SGA (1.8 ± 2.6 versus 1.4 ± 2.6 kg/m²; $p=0.03$). At 30 yr, percent body fat was significantly higher in SGA (23.5 ± 8.7 versus 21.9 ± 8.0 %, $p=0.01$), which difference persisted after adjustment on age, gender and gain in BMI and for the same gain in BMI body fat was significantly further increased in the SGA group in comparison to the AGA ($p=0.02$ for the statistical interaction).

Conclusion: SGA subjects when adults have an accelerated gain in BMI resulting in a higher body fat content. Our data suggest that the excess of fat mass in SGA subjects could result not only from catch-up in early infancy but also from a long-term and persistent effect of “developmental mismatch”.

Prevalence and predictors of overweight in offspring with a first-degree relative with type 1 diabetes

S. Hummel, S. Kreichauf, M. Pflüger, C. Winkler, M. Hummel, A.G. Ziegler
Immunology, Diabetes Research Institute, Munich, Germany

Background and aims: Offspring of mothers with type 1 diabetes (T1D) have been reported to be at increased risk for overweight. This analysis was performed to study the prevalence of overweight in a prospective cohort of offspring with a first-degree relative (FDR) with (T1D) and to identify predictors of overweight in this population.

Materials and methods: Data on weight and height were collected at age 2, 5 and 8 years from 1483 children born in Germany between 1989 and 2005 and participating in the prospective BABYDIAB (n=1214) or BABYDIET study (n=269). All children had a FDR with T1D, including 910 with a mother with T1D. Overweight was defined as BMI percentile ≥ 90 , adjusted for sex and age. Data on birth weight/height and smoking during pregnancy were collected at birth, breastfeeding data at age 3 months, 9 months and 2 years. To identify predictors of overweight, a multiple logistic regression analysis was performed.

Results: At 2 and 5 years of age, prevalence and risk for overweight was significantly higher in offspring of mothers with T1D compared to offspring of non-diabetic mothers (14.4% vs. 10.5%, OR 1.4; 95%CI: 1.04-2.0, $p=0.03$ and 13.1% vs. 7.2%, OR 1.9; 95%CI: 1.2-3.1, $p=0.004$) while at 8 years prevalence for overweight was comparable in offspring of mothers with and without T1D (12.4% vs. 11.4%). Risk for overweight throughout childhood was increased in offspring of non-diabetic mothers who were large for gestational age (LGA) and decreased if they were breastfed ≥ 26 weeks. In contrast, in offspring of mothers with T1D, LGA status and breast feeding affected risk for overweight at early ages but not at 8 years. Smoking during pregnancy had no effect on weight development in both offspring of mothers with and without T1D.

Conclusion: These data suggest that in offspring of mothers with T1D risk for overweight is increased only during the first years of life compared to offspring of mothers without T1D and that reducing birth weight and increasing breastfeeding duration would help to decrease the prevalence of overweight during childhood in both offspring of mothers with and without T1D.

SUR mutation in type 1 diabetes: autoimmunity prevents sulfonylurea rescue of diabetes caused by SUR1 mutation. Results from the Hvidøre Study Group

S. Pörksen¹, L. Laborie², L. Nielsen¹, H. de Wet³, E. Schvarcz⁴, T. Sandal², J. Åman⁵, P. Swift⁶, P. Hougaard⁷, F. Ashcroft³, A. Molven⁸, M. Knip⁹, L. Hansen¹, P.R. Njølstad², H.B. Mortensen¹

¹Department of paediatrics, Glostrup University Hospital, Glostrup, Denmark, ²Department of Clinical Medicine, University of Bergen, Norway, ³Laboratory of Physiology, The University, Oxford, United Kingdom, ⁴Department of Medicine, University Hospital, Örebro, Sweden, ⁵Department of paediatrics, University Hospital, Örebro, Sweden, ⁶Children's Hospital, Leicester Royal Infirmary, Leicester, United Kingdom, ⁷Department of Statistics, University of Southern Denmark, Odense, Denmark, ⁸The Gade Institute, University of Bergen, Bergen, Norway, ⁹Hospital for Children and Adolescents, University of Helsinki, Helsinki, Finland

Background and aims: Idiopathic diabetes presents without type 1 diabetes-associated autoantibodies. Absence of autoantibodies is also a characteristic of neonatal diabetes due to mutations in *KCNJ11* or *ABCC8*. We compared disease progression of autoantibody-negative and autoantibody-positive children during the first 12 months after disease onset, and investigated whether mutations in the *KCNJ11*, *ABCC8*, *HNF1A*, *HNF4A* or *INS* genes can explain some cases of idiopathic diabetes.

Materials and methods: We followed 261 newly diagnosed diabetic children and adolescents from 18 centers in 15 countries. Residual β -cell function, proinsulin release, blood glucose levels, HbA_{1c}, insulin requirement and autoantibodies were measured at 1, 6 and 12 months after diagnosis. The genes *KCNJ11*, *ABCC8*, *HNF1A*, *HNF4A* and *INS* were sequenced in subjects autoantibody-negative at diagnosis.

Results: Twenty-four patients (9.2%) tested negative for GADA, IA-2A, and ICA autoantibodies after one month. Autoantibody-negative subjects did not differ in sex, ethnicity, age, HLA or *INS*-VNTR genotypes. They had higher residual β -cell function ($P = 0.002$), lower blood glucose excursions ($P = 0.004$), received less insulin ($P = 0.05$) and lower HbA_{1c} ($P = 0.02$) 12 months after diagnosis. None had mutations in *KCNJ11* but one patient had a heterozygous mutation leading to the substitution of arginine (CGC) by cysteine (TGC) at residue 1530 of the *ABCC8* gene encoding SUR1. He was 13 years old at diagnosis and had no relatives with diabetes. He became positive for IA-2A antibodies 6 months after diagnosis. Functional analyses showed that the channel was highly sensitive to sulphonylureas. However, there was no effect of sulfonylurea treatment after 4 weeks on 1.0–1.2 mg/kg/24h. None of the 6 autoantibody negative patients with a family history of diabetes had mutations in *HNF1A* or *HNF4A*. There were no *INS* gene mutations in the autoantibody negative group.

Conclusion: GADA, IA-2A, and ICA autoantibody-negative children have slower disease progression including preservation of residual β -cell function and improved glycaemic control 12 months after diagnosis. Mutations within *ABCC8* may be a, so far, unidentified reason for autoantibody negative childhood onset diabetes, also after the neonatal period. Superimposed type 1 diabetes in the present case may leave SU treatment ineffective.

266

Correlation between the soluble levels of cytotoxic T-lymphocyte associated antigen 4 (CTLA-4) and polymorphisms of CTLA-4 and programmed death receptor 1 (PD1) in type 1 diabetes

F. Perez-Bravo¹, S. Momim¹, B. Angel¹, E. Codner², E. Carrasco³

¹Genetic Epidemiology, INTA-University of Chile, Santiago, Chile, ²Endocrinology, IDIMI- Hospital San Borja Arriarán. Medicine Faculty, Santiago, ³Diabetes Unit, Hospital San Juan de Dios. Faculty of Medicine, Santiago, Chile

Background and aims: Multiple genes are likely to be involved in type-1 diabetes and other immune diseases. In particular, type 1 diabetes may be influenced by Programmed Death-1 (PD-1) receptor, an inhibitory molecule which has been demonstrated to play a role in the regulation of immune responses. To explore the contribution of the PD-1 gene polymorphisms involved in type-1 diabetes (T1D) as well as the relationship between the PD-1 gene and sCTLA4 concentrations.

Materials and methods: 189 incident cases of type 1 diabetes children and 235 healthy children less 15 years old were included in this study. Haplotypes for the polymorphic restriction sites of the PD-1 gene and CTLA-4 were obtained by DNA amplification using PCR, followed by the restriction fragment length polymorphism (RFLP) method. Screening for soluble CTLA4 was done using an ELISA assay. The statistical analysis was performed using the online SHESIS package.

Results: We found that PD-1.9 T/T may play a protective role in the development of T1D. Our results show that the sCTLA-4 was different among patients and controls (2.57 ± 0.18 ng/ml versus 1.18 ± 0.57 , $p < 0.001$). In T1D the sCTLA-4 levels were different when we considered the allele dosage of CTLA-4 polymorphism, showing a modified effect of G allele on the sCTLA-4 concentrations ($*P < 0.04$)

Table 1: PD1 haplotypes and CTLA-4 in T1D patients.

Conclusion: Consistent with the higher serum sCTLA-4 levels observed in other autoimmune diseases, our results suggest that sCTLA-4 may be a risk factor for T1D. Our data suggest a possible regulation effect of the "G" CTLA-4 allele over sCTLA-4 across the PD-1 protector or susceptibility genotype.

PD 1.5 - PD 1.9 Haplotype	+ 49 A/G CTLA-4 Dosage	Concentrations of sCTLA-4 (ng/ml)
T - T	A	0.25 ± 0.12
T - T	G	0.57 ± 0.31
T - C	A	2.50 ± 1.70
T - C	G	$5.89 \pm 3.21^*$
C - C	A	1.68 ± 1.09
C - C	G	$2.38 \pm 0.53^*$

Can HLA-DQ, PTPN22- and CTLA4 polymorphisms explain the putative association between childhood atopic dermatitis and lower subsequent risk of type 1 diabetes?

L.C. Stene¹, K.S. Rønningen¹, M. Bjørnvold², D.E. Undlien^{3,4}, G. Joner^{5,6}

¹Division of Epidemiology, Norwegian Institute of Public Health, Oslo, ²Institute of Medical Genetics, Faculty division, Ullevål university hospital, University of Oslo, ³Department of Medical Genetics, Ullevål university hospital, Oslo, ⁴Institute of Medical Genetics, Faculty Division, Ullevål university hospital, University of Oslo, ⁵Department of Pediatrics, Ullevål university hospital, Oslo, ⁶Faculty of Medicine, University of Oslo, Norway

Background and aims: Established susceptibility loci for type 1 diabetes are important in immune regulation and may play a role also in atopic disorders, potentially explaining the inverse association between atopic dermatitis and subsequent risk for type 1 diabetes reported in several studies. Some previous studies have investigated whether susceptibility genes for atopy are associated with type 1 diabetes or vice versa, but no previous study has studied the role of genetic factors where information on both diabetes and atopy has been available in the same individuals. We aimed to directly assess whether HLA-DQ, CTLA4 and PTPN22 genes could explain the putative association between childhood atopic dermatitis and lower subsequent risk of type 1 diabetes.

Materials and methods: We designed a case-control study with 339 incident cases of type 1 diabetes identified in The Norwegian childhood diabetes registry, and 985 population-based control children. DNA was collected, and physician-diagnosed childhood atopic dermatitis was ascertained by a questionnaire administered to the parents of children with and without type 1 diabetes.

Results: The previously reported association between atopic dermatitis and lower risk of type 1 diabetes was confirmed (odds ratio: 0.61, 95% confidence interval: 0.40–0.95) and this was consistent in sub-groups defined by HLA-DQ, CTLA4 and PTPN22 genotypes. The odds ratio was essentially not influenced by adjustment for genetic variation at these loci (adjusted odds ratio: 0.55, 95% confidence interval: 0.32–0.92), showing that these genetic factors could not explain the observed inverse relation between atopic dermatitis and type 1 diabetes.

Conclusion: In this first study of its kind, we demonstrated directly that the observed inverse association between atopic dermatitis and type 1 diabetes could not be explained by established diabetes susceptibility genes HLA-DQ, CTLA4 or PTPN22.

Genetic predisposition for celiac disease in children with type 1 diabetes mellitus

J. Pedras¹, P. Jarosz-Chobot², J. Polanska³, M. Minkina-Pedras⁴, U. Siekiera⁵
¹Department of Cardiology, District Hospital, Tychy, ²Depart. of Pediatric, Endocrinology and Diabetes, The Medical University of Silesia, Katowice, ³The Faculty of Automatic Control, Electronics and Computer Science, The Silesian University of Technology, Gliwice, ⁴Depart. of Pediatric, Endocrinology and Diabetes, Upper Silesia Center Health of Child, Katowice, ⁵HLA and Immunology Lab, Regional Blood Center, Katowice, Poland

Background and aims: Type 1 diabetes mellitus (T1DM) and celiac disease (CD) frequently occur together. Some genetic polymorphisms may significantly modify the risk of CD in subjects with T1DM. The aim of the study was to evaluate genetic predisposition in class HLA (locus DRB1, DQB1) and by gene polymorphisms of tumor necrosis factor- α (TNF- α), interferon- γ (IFN- γ), interleukin-6 (IL-6), interleukin-10 (IL-10).

Materials and methods: 33 children (18 girls and 15 boys) with positive tissue transglutaminase tTG were selected during a routine screening carried out in 513 children with T1DM. In all cases, small intestine biopsy was performed. HLA was identified in the locus DR and DQ. HLA alleles and polymorphisms were determined using PCR with sequence-specific primers. This group was compared to the group of children with T1DM only. The following factors were similar in both groups: number of patient, sex, onset of T1DM.

Results: According to biopsy results silent CD was diagnosed in 24 children (72.72%) cases and latent form CD in 9 (27.27%) cases. Mean age at onset of T1DM was 6.41 ± 3.27 years. CD was diagnosed after 15.34 ± 16.08 months of T1DM duration. Haplotype DRB1*03 DQB1*02 was present in 25 children (75.76%). Alleles DRB1 and DQB1 were significantly more frequent ($p=0.014$; $p=0.006$ respectively) in T1DM with CD than in patients with T1DM only. Another common haplotype for CD - DRB1*04 DQB1*03 was found in 17 children (51.51%). Only in 4 cases no haplotypes mentioned were present. We found positive statistical significance in TNF- α - 308A genotype between the examined group and the group with T1DM ($p=0.024$). We did not find association between IFN- γ , IL-6 and IL-10 polymorphisms and celiac susceptibility.

Conclusion: CD in children with T1DM seems to be modified by presence of haplotype DRB1*03 DQB1*02 and by a variant of allele TNF- α - 308A.

Common variants in or around the JAZF1, CDKN2A/2B, CDKAL1 and WFS1 genes discriminate between autoimmune and non-autoimmune diabetes

E. Bakhtadze¹, E. Lindholm¹, V. Lyssenko¹, H.J. Arnkvist², J. Bolinder³, J.W. Eriksson^{4,5}, S. Gudbjörnsdóttir⁴, L. Nyström⁵, M. Landin-Olsson⁶, L.C. Groop¹

¹Clinical sciences-Diabetes and Endocrinology, Lund University, Malmö,

²Department of Clinical and Experimental Medicine, Linköping University, Linköping, ³Department of Medicine, Karolinska University, Stockholm,

⁴Department of Medicine, Sahlgrenska university hospital, Göteborg,

⁵Department of Medicine, Umeå University, ⁶Endocrinology, Lund University, Sweden

Background and aims: To study whether common variants in novel T2D genes can discriminate between autoimmune and non-autoimmune diabetes in young (15–34 years) and middle-aged (40–59 years) subjects.

Materials and methods: We genotyped the following SNPs: PPARG (rs1801282), IGF2BP2 (rs4402960), WFS1 (rs10010131), CDKAL1 (rs7754840), JAZF1 (rs864745), CDKN2A/2B (rs10811661), HHEX (rs1111875) and KCNJ11 (rs5912) and measured GADA, IA-2A antibodies and fasting C-peptide concentrations in 1,642 young (15–34 years) and 1,619 middle-aged (40–59 years) Swedish diabetic patients. Patients were classified as Ab+ if one antibody was positive and negative (Ab-) if they had no antibodies.

Results: Altogether, 67% of the young and 13% of the elderly patients were Ab+. Young Ab+ patients had lower prevalence of JAZF1 (recessive model)

AA (23% vs. 32%; $p=0.0003$) and CDKN2A/2B (recessive model) TT (67% vs. 74%; $p=0.0078$) than young Ab- patients. Middle-aged Ab+ patients had a decreased prevalence of WFS1 (recessive model) GG (29% vs. 36%; $p=0.045$) and CDKAL1 (recessive model) CC (8% vs. 15%; $p=0.02$) genotypes.

Conclusion: The lower frequency of variants in (or close to) JAZF1, CDKN2A/2B, WFS1 and CDKAL1 in antibody-positive individuals suggest that the mechanisms by these variants increase susceptibility to T2D do not involve autoimmune phenomena.

Association of (C1858T) polymorphism in the PTPN22 gene and latent autoimmune diabetes in adults (LADA) at Ukrainian population

T. Tikhonova¹, S. Shtandel², M. Fedetz³, O. Khijnyak¹, N. Kravchun⁴, T. Levchenko¹, O. Fedetz⁵, N. Velikhik¹, H. Svetlova-Kovalenko²

¹Department of Age Endocrinology, Institute of Endocrine Pathology

Problems, Kharkov, Ukraine, ²Laboratory of Pathophysiology and Medical Genetics, Institute of Endocrine Pathology Problems, Kharkov, Ukraine,

³Department of Cellular Biology and Immunology, Institute of Parasitology and Biomedicine, Granada, Spain, ⁴Department Pharmacotherapy of

Endocrine Diseases, Institute of Endocrine Pathology Problems, Kharkov, Ukraine, ⁵Department of Cell Biology, Clinical Laboratory, Kharkov, Ukraine

Background and aims: The Protein Tyrosine Phosphatase Non-receptor type 22 (PTPN22) gene encodes for lymphoid-specific phosphatase, the powerful T-cell activation inhibitor. Today many studies have showed an association between the C1858T polymorphism (Arg620Trp) of the PTPN22 gene and type 1 diabetes mellitus (T1DM) in various populations. The aim of the study was to examine the association of the PTPN22 gene polymorphism C1858T with the predisposition to latent autoimmune diabetes in adults (LADA) in Ukrainian population.

Materials and methods: The study was performed in the group, that consist of 321 patients with T1DM classical clinical form, 38 individuals with LADA (age of manifestation 45.52 ± 1.83 yrs, with anti islet, GADA antibodies and low C-peptide levels), 57 patients with type 2 diabetes mellitus (T2DM) and 253 healthy Kharkov inhabitants. The GADA, IA2A and ICA antibodies were measured with RIA. The presence of different variants of the PTPN22 gene polymorphism was estimated using the DNA sequencing method. Genotype and allelic distributions of the C1858T polymorphism were comparing using the χ^2 test.

Results: LADA patients had the higher C1858T polymorphism of PTPN22 gene frequency, than T1DM, T2DM and control data in Kharkov population: Trp/Trp genotype was 21.05 % vs 6.54 % ($\chi^2_{\text{LADA-T1DM}}=7.78$; $p=0.005$), 5.26 % ($\chi^2_{\text{LADA-T2DM}}=4.12$; $p=0.042$), 0.79 % ($\chi^2_{\text{LADA-control}}=35.00$; $p=0.000$), respectively; 1858T allele frequency was 43.42 % vs 21.96 % ($\chi^2_{\text{LADA-T1DM}}=15.89$; $p=0.000$), 28.07 % ($\chi^2_{\text{LADA-T2DM}}=4.12$; $p=0.042$), 13.86 % ($\chi^2_{\text{LADA-control}}=37.71$; $p=0.000$), respectively. Data of our study data suggested more powerful association C1858T polymorphism of PTPN22 gene in LADA patients in comparison to those with T1DM: for Trp/Trp genotype - $OR_{\text{LADA}} = 33.47$ (6.75–165.67) vs $OR_{\text{T1DM}} = 8.79$ (2.03–37.71); for 1858T allele - $OR_{\text{LADA}} = 4.78$ (2.82–8.02) vs $OR_{\text{T1DM}} = 1.75$ (1.28–2.40).

Conclusion: It has been shown, that C1858T polymorphism of PTPN22 gene like in T1DM plays the important role in the LADA genetic predisposition in Ukrainian population. More powerful the polymorphism association with LADA in comparison to T1DM was shown also.

271

Genetic risk factors for patients with Latent Autoimmune Diabetes (LADA) including insulin resistance genes. Results from the HUNT StudyE. Pettersen¹, V. Grill², K. Kvaloy³, F. Skorpen²

¹Norwegian University of Science and Technology, Institute of cancer research and molecular medicine, Levanger, Norway, ²Norwegian University of Science and Technology, Institute of cancer research and molecular medicine, Trondheim, Norway, ³Norwegian University of Science and Technology, Institute of public health and general practice, Levanger, Norway

Background and aim: Previous studies have indicated that Latent Autoimmune Diabetes of the Adult (LADA) shares some genetic risk with type 1 diabetes (T1D). However, data from the North Trøndelag Health (HUNT) study, containing cross-sectional data from 64,500 men and women (aged >20), indicate that phenotypes of LADA and type 2 diabetes (T2D) are similar and that insulin resistance factors such as obesity are strong risk factors for both. These findings suggest that LADA shares genetic features with T2D including propensity for insulin resistance. This notion was tested by comparing genetic associations in T1D, T2D and LADA patients.

Materials and methods: DNA samples collected from the HUNT study (1995–96) were used for analysis. We analysed 10 single nucleotide polymorphisms (SNPs) within six candidate genes for T1D and 22 SNPs within 21 candidate genes for insulin resistance and T2D in 120 T1D patients, 126 LADA patients, 1090 T2D patients and 1503 age and gender matched healthy non diabetic controls. Patients starting insulin treatment within six months of diagnosis were classified as T1D if they also were antiGAD positive or had fasting C-peptide levels <150 pmol/l. Patients were classified as LADA if they were antiGAD positive and had not been treated with insulin within 12 months of diagnosis. T2D cases were antiGAD negative and without insulin treatment within one year of diagnosis. The results were adjusted for gender, age and BMI by logistic regression.

Results: *INS* (rs689 and rs3842753) and *PTPN22* (rs2476601) were strongly associated with T1D ($p=6.9 \times 10^{-5}$, $p=0.0002$ and $p=1.5 \times 10^{-5}$ respectively) but did not show association with LADA ($p=0.60$, $p=0.37$ and $p=0.16$). For the T2D associated genes, the CC/CT genotypes of rs7961581 (upstream of *TSPAN8*) was associated with both T2D ($p=0.033$, OR=1.21 [1.02–1.44]) and LADA ($p=0.0097$, OR=1.68 [1.13–2.48]). Likewise, the obesity-linked AA/AC genotypes of rs8050126 (*FTO*) was associated with T2D ($p=0.0051$, OR=1.31 [1.08–1.58]) as well as with LADA ($p=0.0052$, OR=1.97 [1.23–3.17]). The TT/TC genotype within the strongly T2D associated *TCF7L2* gene (rs7903146) were not associated with LADA ($p=0.14$, OR=1.35 [0.91–2.00]) but strongly with T2D ($p=4.8 \times 10^{-14}$, OR=1.97 [1.65–2.35]) in our study.

Conclusion: The genetic susceptibility to develop LADA is partly distinct from both T1D and T2D, and includes an insulin resistance associated gene. Killer cell immunoglobulin-like receptor genes confer susceptibility to type 1 diabetes in patients belonging to a 1-14 year age group and not in a 15-34 year age group

S.K. Sedimbi, C.B. Sanjeevi

Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden

Background: Natural Killer (NK) cells are potent modulators of innate (and adaptive) immune responses. Killer Ig-like receptors (KIR) are a group of activating and inhibitory receptors expressed on NK cells, which bind to specific motifs on Human Leukocyte Antigen (HLA) Class I molecules. The activation or inhibition of NK cell activity depends on the overall signal generated as a result of the dynamic balance between activating and inhibitory KIRs.

Aims: i) To test the KIR gene frequencies in Swedish children with type 1 diabetes (T1DM) and healthy controls and ii) To test whether presence (or absence) of certain KIR genes in combination with their putative HLA-C ligands (C1 and C2) confers susceptibility (or protection) to the disease.

Subjects and methods: A total of 350 consecutively diagnosed type 1 diabetes patients (of which 173 patients were in 1-14 year age group and 177 patients were in 15-34 year age group) and 293 healthy age and sex matched controls (0-14 years=152 and 15-34 years=141) were used for genotyping 16 KIR genes and HLA-C1 and C2 ligands using PCR-sequence specific primer (SSP) methodology. Statistical analyses were performed using Chi-square test and Fischer's exact test as applicable.

Results: i) 1-14 year age group: KIRs 2DL2 (OR=1.59; 95% CI=1.00–2.51; $P=0.04$), 2DL3 (OR=1.85; 95% CI=1.01–3.38; $P=0.04$), and 2DS2 (OR=1.68; 95% CI=1.06–2.66; $P=0.02$) are positively associated and 3DS1 (OR=0.47; 95% CI=0.30–0.74; $P=0.001$) is negatively associated with the disease in the 0-14 year age group. But we failed to see any of this association in patients in the 15-35 year age group. In 0-14 year age group, stratification analyses of KIR genes with their putative HLA-C ligands showed the combinations 2DL2+/HLA-C1- (OR=2.25; $P=0.02$); and 2DL3-/HLA-C1- (OR=2.17; $P=0.03$) were positively and 2DL3-/HLA-C1+ (OR=0.49; $P=0.02$); 2DS1-/HLA-C2+ (OR=0.60; $P=0.02$); 2DS2+/HLA-C1- (OR=0.56; $P=0.04$); 2DS2-/HLA-C1+ (OR=0.62; $P=0.03$) were negatively associated.

Conclusion: KIR genes are important in conferring susceptibility (and/or protection) to T1DM. Presence of HLA-C ligands (C1 and C2) confers protection to the disease when seen in association with the respective KIRs they bind to. Their absence, in the presence of the corresponding KIR genes confers susceptibility. From the functional perspective, presence of a ligand for an inhibitory KIR on the target cell delivers an inhibitory signal to the NK cell, leading to tolerance. Similar to the classical HLA association, age appears to be a very important factor in determining the role of KIR genes susceptibility to T1DM. The age group 1-14 years, being much more susceptible compared to that of 15-34 years.

Ctla-4 polymorphism and lymphocyte caspase-3 expression in Chilean children with type 1 diabetes (T1D)B. Angel¹, M. Arredondo², E. Codner³, E. Carrasco⁴, F. Dotta⁵, F. Pérez-Bravo¹¹Genetic Epidemiology Laboratory, INTA-University of Chile, Santiago,²Micronutrients, INTA-University of Chile, Santiago, Chile, ³Endocrinology,IDIMI-University of Chile, Santiago, ⁴Diabetes Unit, San Juan de DiosHospital-University of Chile, Santiago, ⁵Diabetes Unit. Department of

Internal Medicine, University of Siena, Italy

Background and aims: Cytotoxic T lymphocyte-associated antigen (CTLA-4) is a critical down-regulatory molecule expressed on T cells. Several polymorphism of the CTLA-4 gene has been associated with autoimmune diseases. Apoptosis events of β cells is the most important and final step in the development of autoimmune diabetes. The activation of induced cell death is the major event and caspase 3 represent the main protein for the apoptotic machinery. To characterize a genotype of CTLA4 in children with T1D and to correlate it with caspase 3 expression in peripheral mononuclear cells (PMCs) simulating “in vitro” the glucose effect on the Caspase 3 expression.

Materials and methods: CTLA-4 polymorphisms were determined by PCR in 260 T1D children and 255 controls. Caspase 3 expression was determined

by semiquantitative RT-PCR and Western Blot. The “in vitro” study included 11 T1D of recent diagnosis (first 15 days) and 11 controls. Caspase 3 mRNA expression by RT-PCR and their activity by colorimetric assay were analyzed.

Results: No differences in the genotypes frequencies were observed when comparing T1D (+49A/G: A/A:45; A/G:42; G/G:13%;) v/s controls (+49A/G: A/A:43; A/G:42; G/G:15%); $p=0.768$. A decreasing of mRNA/Casp3/ β -Actin expression was observed in T1D in the presence of glucose: 0.55 in basal and 0.24 at 14 mM and a slight diminution in the Casp3 activity: 1.0 in Basal and 0.9 at 14 mM in carriers of G allele and an increase of the mRNA/ β -Actin expression (0.4 in Basal and 0.83 to at 14 mM) in non carriers. Non significant changes in relation to the glucose stimulus were observed in control subject.

Conclusion: T1D's PMCs of recent diagnosis, carrying G allele in +49A/G polymorphisms of CTLA4, present an important decrease in the expression and activity of the major executioner of lymphocyte apoptosis in comparison to the non carriers.

Abnormal monocyte-related signatures in type 1 diabetes; a study of identical twins

R.D.G. Leslie¹, H. Beyan¹, H.A. Drexhage², H.J. De Witt²

¹Centre for Diabetes and Metabolic Medicine, Institute of Cell and Molecular Science, London, United Kingdom, ²Immunology, Erasmus MC, Rotterdam, Netherlands

Background and aims: Type 1 diabetes (T1DM) is probably due to an aggressive adaptive immune response but the innate immune system could be relevant since monocytes infiltrate the islets. We initially detected changes in T1DM monocytes including a cluster of altered genes expression profiles (unpublished).

Aim: Our present aim was to identify monocyte-related biomarkers in identical twin pairs discordant for T1DM (only one twin with diabetes) to determine and validate monocyte gene clusters which are diabetes-associated or associated with disease-susceptibility.

Materials and methods: We studied 14 identical twin pairs (all discordant for T1DM) 6 male; mean age of 37 years (range 17–53), mean disease duration 20.5 years (7–44) and 13 normal identical twin pairs, 7 male; mean age of 37 (23–55 years). Peripheral blood mononuclear cells (PBMC) were isolated using Ficoll. Monocytes were isolated from PBMC by MACS-CD14 separation. Real-time quantitative PCR was performed on extracted RNA for 14 candidate genes identified using Affymetrix plus appropriate controls including Able gene (housekeeping gene).

Results: Abnormal expression levels of 11 monocyte genes were validated, encompassing changes in monocyte pro-inflammatory signatures, MAP kinase pathway, cell adhesion/motility and immune regulation. Abnormal levels of gene expression were detected either in the diabetic twin alone (e.g. FABP5, MAPK6, CD9, CDC42, STX1A), or in both diabetic and non-diabetic twins (e.g. CCL2, CCL7, DHRS, HSP70, SDR, DHRS, PTPN7, EMP1) (all differences $p<0.02$); the latter having altered expression of a different gene set but gene expression levels all being strongly correlated between twins of a pair ($r>0.78$) and not altered in type 2 diabetes excluding a hyperglycaemic effect.

Conclusion: In summary, these results both identify and validate monocyte signatures of altered gene expression levels associated with T1DM which are either familial or disease specific, and in neither case associated with type 2 diabetes. Thus we identified both disease biomarkers as well as potential targets for therapeutic intervention.

¹Endocrinology, Hospital Universitario Insular de Gran Canaria, Las Palmas de Gran Canaria, Spain, ²Steno Diabetes Center, Gentofte, Denmark, ³Mathematics, Universidad de Las Palmas de Gran Canaria, Spain, ⁴Endocrinology, Hospital Clnico, Valencia, Spain, ⁵Endocrinology, Hospital Ni˜o Jess, Madrid, Spain, ⁶Endocrinology, Hospital de Cruces, Barakaldo, Spain, ⁷Paediatrics, Consorci Hospitalari Parc Taul, Sabadell, Spain, ⁸Paediatrics, Hospital Severo Ochoa, Madrid, Spain, ⁹Endocrinology, Hospital Arnau de Vilanova, Lleida, Spain, ¹⁰Endocrinology, Hospital Universitario de Canarias, Sta Cruz de Tenerife, Spain, ¹¹Endocrinology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, ¹²Paediatrics, Hospital Miguel Servet, Zaragoza, Spain

Background and aims: ET1DGN is the European branch of the Type 1 Diabetes Genetics Consortium (T1DGC), created to study the genetics and pathogenesis of type 1 diabetes. A total of 1232 affected sibpair (ASP) families have been included in Europe between 2004 and 2007. The aim of this study is to present the first results of the Spanish families.

Materials and methods: A total of 151 ASP families (610 members) have been included in Spain. Phenotypic and antibody information is available from most of the families and genetic information, from more than half of them. This includes HLA genotyping (118 families), a 6000 SNP genome scan ($N=85$) and SNP genotyping in genes previously described to be associated with type 1 diabetes ($N=70$). Association was analysed using multiple TDT-sib-TDT and linkage analysis was performed using non-parametric linkage (Merlin 1.1.1).

Results: Mean age of onset was 15.1 ± 8.7 (1–42) years, age at examination 30.7 ± 10.8 years, 18.8% of the affected siblings had associated autoimmune diseases, 57.3% had positive anti-GAD, 35.5% positive anti-IA2 and 24.8% were positive for both antibodies. High risk HLA alleles were present in 68.6% (DR3) and 48.6% (DR4) of the affected siblings, whereas 9.4% showed the low-risk allele DRB1*0701. Linkage analysis showed a predominant LOD of 6.4 ($p=2.84\cdot 10^{-8}$) on the short arm of chromosome 6, as well as LOD above 1 on chromosomes 2, 10, 17 and 21. The TDT-sib-TDT analysis of the genome scan data showed most significant association with markers on chromosomes 1 (rs1252133, unadjusted $p=7.25\cdot 10^{-4}$), 3 (rs1996818, $p=8.5\cdot 10^{-4}$), 15 (rs11433, $p=5.35\cdot 10^{-4}$) and 18 (rs635269, $p=1.61\cdot 10^{-4}$).

Of the genes previously described to be associated with type 1 diabetes, the following showed a non-corrected, significant ($p<0.05$) association with the disease in the Spanish families: *CEACAM21*, *CTLA4*, *CXCL12*, *IL2RA*, *IL4R*, *INS* and *VDR*.

Conclusion: Although HLA accounts for most of the genetic risk of type 1 diabetes also in Spanish ASP families, other genes seem to be play a role, too. Further stratification by HLA may clarify this point.

Background and aims: Type 1 diabetes (T1D) is a common, strongly heritable disease that most often manifests in childhood. Recent genome wide

association studies have revealed a number of new genes associated with the disease. We carried out a follow-up strategy to uncover additional novel T1D risk loci.

Materials and methods: We selected 1,192 independent single nucleotide polymorphisms (SNPs) with at least a nominally significant *P*-value (but excluding SNPs in the MHC region) from a combination of our data generated on 563 T1D probands and 1,146 controls plus 483 complete T1D family trios of the same ancestry, using the Illumina HumanHap550 SNP chip. We then genotyped these SNPs using the Illumina GoldenGate platform in an independent cohort of 939 nuclear T1D families from Montreal and the T1DGC. Subsequently we looked across all three cohorts plus the publicly available Wellcome Trust Case Control Consortium dataset for T1D to identify SNPs in loci that were both not previously described and nominally significant across all cohorts.

Results: We selected five loci for further investigation, which we queried in a T1D dataset from Toronto using an independent matched control dataset from Philadelphia both of which were genotyped on the HumanHap550K SNP chip. Two of the five loci were also significantly associated with T1D in this cohort and, interestingly, resided in genes that were biologically relevant to autoimmunity.

Conclusion: We have identified two novel loci that are associated with T1D across five different Caucasian cohorts. The identity of this loci will be presented.

The 3q21-region is showing moderate evidence for association with type 1 diabetes in three Finnish family datasets

A.-P. Laine¹, R. Veijola², O. Simell³, M. Knip^{4,5}, J. Ilonen¹

¹Immunogenetics laboratory, University of Turku, ²Department of Paediatrics, University of Oulu, ³Department of Paediatrics, University of Turku, ⁴Hospital for Children and Adolescents, University of Helsinki, ⁵Department of Paediatrics, University of Tampere, Finland

Background and aims: IDDM9-region on chromosome 3q has shown suggestive evidence for linkage to type 1 diabetes (T1D) in some but not all genome scans. In a previous study we have reported linkage to and association with the 3q21-region in Finnish datasets. LOD scores of 3.4 and 2.5 (markers D3S1589 and D3S3606 respectively) were found in a dataset of 121 Finnish T1D multiplex families. An association (transmission/disequilibrium test (TDT) *p*-value 0.0002) was found with a dataset of 384 Finnish T1D simplex families using marker AFM203wd10, located ~500kb downstream of the linked marker D3S1589. In an attempt to confirm the observed association, we have analyzed six SNP markers at a region spanning 518 kb around the AFM203wd10.

Materials and methods: The analyzed SNP markers rs777498, rs12485336, rs11718344, rs17693752 are located upstream of the AFM203wd10 and markers rs10755080 and rs7649075 downstream of the AFM203wd10. The respective distances between above-mentioned markers and AFM203wd10 in kilobases are -286, -118, -8.2, -1.4, +7 and +232. None of the marker alleles in any of the SNPs showed notable correlation with the AFM203wd10 alleles, *r*² was less than 0.5 for every marker interval. The SNP markers were genotyped in both the original simplex family dataset and in an additional, independent set of 330 Finnish simplex families and TDT analysis was performed using TDTPHASE program. The additional dataset was genotyped for the AFM203wd10 microsatellite and analyzed for TDT.

Results: In the original dataset the SNP markers showed increased transmission in TDT, (53%, 55%, 57%, 54%, 56%, 54% respectively towards downstream) but did not reach significance when tested individually and showed weaker association than the AFM203wd10 (64%). Haplotypes of the SNP markers did show association of the same magnitude as the AFM203wd10 which rules out genotyping error as the source of the original finding. In contrast to the original dataset, the additional Finnish dataset of 330 simplex families did not show significantly increased transmission in AFM203wd10 (53%) or in the SNPs (52%, 54%, 54%, 53%, 51%, 50% respectively towards downstream). SNP haplotypes upstream of the AFM203wd10 did show significantly increased transmission (strongest *p*-value 0.0005) and certain three-marker haplotypes in consecutive markers rs12485336, rs11718344 and rs17693752 showed significant association in both datasets (not corrected for multiple testing). The Finnish multiplex dataset of 121 families showed close

to nominal association in TDT when one sib in each family was used in the analysis (58%, *p*=0.07). The same allele as in the original simplex family dataset showed increased transmission, the combined association showed stronger significance than the original simplex families alone (61%, *p*=0.00007).

Conclusion: Although this initial follow-up study on the 3q21-region did not undoubtedly confirm or exclude the existence of a T1D locus at this region in the Finnish population, it provided enough proof to warrant a more definitive association study to be carried out in an expanded genomic region with an extensive SNP marker coverage.

Containment of the susceptibility region Iddm8 and sequencing of functional relevant candidate genes in the LEW.1AR1-iddm rat, an animal model of human type 1 diabetes

T. Arndt¹, H. Weiss², A. Jörns¹, S. Lenzen¹, E. Cuppen³, H.J. Hedrich⁴, D. Wedekind⁴

¹Hannover Medical School, Institute of Clinical Biochemistry, Germany, ²University of Rostock, Institute of Medical Biochemistry and Molecular Biology, Rostock, Germany, ³Hubrecht Institute, Functional genomics and bioinformatics, Utrecht, Netherlands, ⁴Hannover Medical School, Institute for Laboratory Animal Science, Germany

Background and aims: The LEW.1AR1-iddm rat is an animal model of human type 1 diabetes mellitus (T1DM) which arose through a spontaneous mutation within the MHC congenic inbred strain LEW.1AR1. Earlier genetic analyses using a (BN x LEW.1AR1-iddm) x LEW.1AR1-iddm backcross population (Diabetes incidence 6.5%) revealed three diabetes susceptibility loci: Iddm8 and Iddm9 (RNO1q45-54, RNO1p11-q11) as well as Iddm1 (RNO20p12 = MHCII region). Linkage analysis of a (PAR x LEW.1AR1-iddm) x LEW.1AR1-iddm backcross population (Diabetes incidence 13.5%) confirmed two susceptibility regions (Iddm1 und Iddm8). It was the aim of the study, (a) to narrow down the region Iddm8 using KASPar analysis, and (b) to sequence candidate genes in the region Iddm8 and Iddm9, to identify genes which are involved in T1DM pathogenesis.

Materials and methods: Fine mapping of the Iddm8 region was performed by SNP dependent KASPar (KBiosciences Allele Specific PCR) analysis to make use of both backcross populations. In parallel potential candidate genes were sequenced, which are also relevant for human T1DM and T2DM. Sequencing was performed with a 3730XL DNA (Applied Biosystems) sequencer and analysed using the PolyPhred program.

Results: With the aid of the SNP dependent KASPar method the identified susceptibility region Iddm8 could be reduced from 40 Mb to 3 Mb. Thereby a further containment of possible candidate genes could be achieved to reduce the length of the region for sequencing. Up to now 54 potential candidate genes were sequenced in total.

Additional sequencing showed that in the LEW.1AR1-iddm rat, genes which are mutated in other T1DM animal models, namely Ian5 (BB-DP rat) and clbl (KDP rat), are not affected. The AIRE gene (RNO 20), which is important for human T1DM pathogenesis, showed two SNPs in the coding region in comparison to the congenic strain LEW.1WR1.

Conclusion: Initially it was not possible to narrow down the susceptibility region Iddm8 on RNO1 of the LEW.1AR1-iddm rat using micro satellite markers. The KASPar method, however, offered a new possibility for fine mapping using single nucleotide polymorphisms (SNP). The smaller Iddm8 region contains further genes, which have been considered as functionally relevant candidate genes for human T1DM, such as Anxa1 (Annexin 1) and Pdcd11 (programmed cell death 11). It is also interesting that in the Iddm8 region some more genes could be identified, which are probably involved at the pathogenesis of human T2DM, such as HHEX (hematopoietically expressed homeobox) and TCF7L2 (transcription factor 7-like 2, T-cell specific). Thus, this approach provides the chance to identify the mutation responsible for T1DM development in the animal model.

Identification of a novel beta cell glucokinase (GCK) promoter mutation (-71G>C) which reduces promoter activity

D. Gasperikova¹, N.D. Tribble², J. Stanik^{1,3}, M. Huckova¹, N. Misovicova⁴, M. van de Bunt², L. Kuklisova¹, B. Barrow², L. Barak⁵, R. Dobransky⁶, E. Bereczkova⁷, K. Coldclough⁸, S. Ellard⁸, I. Klimes¹, A.L. Gloyn²
¹DIABGENE & Diabetes Laboratory, Institute of Experimental Endocrinology, Bratislava, Slovakia, ²Oxford Centre for Diabetes, Endocrinology & Metabolism, University of Oxford, United Kingdom, ³Children Diabetes Centre at 1st Pediatric Department, Comenius University School of Medicine, Bratislava, Slovakia, ⁴Clinical Genetics, Jesenius School of Medicine, Martin, Slovakia, ⁵Children Diabetes Center at 1st Pediatric Department, Comenius University School of Medicine, Bratislava, Slovakia, ⁶Diabetology Outpatient Department, Reimanus Hospital, Presov, Slovakia, ⁷District Hospital, Children Endocrinology Outpatient Department, Dunajska Streda, Slovakia, ⁸Institute of Biomedical & Clinical Sciences, Peninsula Medical School, Exeter, United Kingdom

Background and aims: Mutations in the gene encoding the β -cell enzyme glucokinase (GCK) cause maturity-onset diabetes of the young (MODY). Over 200 mutations have been identified in the coding region of the gene but no mutations to date have been found in the GCK promoter region. The aim of our study was to screen the GCK β -cell promoter region in 74 (68 SK + 6 UK) families with a phenotype suggesting a defect in glucokinase but with no abnormality of the GCK coding sequence.

Materials and methods: The β -cell GCK promoter was sequenced on an ABI 3130 and ABI 3700 respectively. The GCK promoter sequence (~1000bp upstream of the ATG translation initiation site) was examined for β -cell specific transcription factor binding sites using TRANSFAC. The effect of the novel mutation on GCK promoter activity was assessed using site directed mutagenesis and a luciferase expression system (normalized to control renilla expression) in INS-1 cells.

Results: A novel -71G>C mutation in the β -cell GCK promoter was identified in 6 unrelated families from Slovakia (n=5) and the UK (n=1). Family testing established that the mutation co-segregated with elevated fasting plasma glucose levels (>5.5mmol/l) in a total of 39 affected individuals. To determine the mechanism for this mutation, the human β -cell GCK promoter was examined for β -cell specific transcription factor binding sites. The novel -71G>C mutation maps directly to a potential transcriptional activator binding site for Sp1 and is only 4bp downstream of a USF2 site. The Pal-1 consensus binding site, which has been previously shown in rodents to be essential for β -cell GCK expression, is only 10bp away. The full length promoter (1031bp) was required for maximal activity. Site directed mutagenesis (-71G>C) in short (-430bp) and long (-1031bp) promoter sequences reduced promoter activity by 2 fold and 4 fold ($p=3.6 \times 10^{-6}$ and 1.9×10^{-6} respectively). Interestingly, the decrease in activity seen between these fragments was highly significant $p=3.4 \times 10^{-8}$ suggesting that this mutation potentially impacts on multiple regions.

Conclusion: We have identified a novel (-71G>C) mutation in the β -cell GCK promoter which co-segregates with elevated fasting glucose levels in 6 unrelated families. This mutation significantly reduces the gene expression *in vitro*. To ensure correct diagnosis of potential GCK-MODY cases analysis of the β -cell GCK promoter should be performed.

Variable clinical picture of mutations in the ABCC8 gene: can it be modified by the sensitivity to insulin or the islet-specific antibodies?

T. Klupa¹, I. Kowalska², K. Wyka³, A.-M. Patch⁴, J. Skupien¹, A. Noczynska⁵, S. Ellard⁴, A. Hattersley⁴, J. Sieradzki¹, W. Mlynarski³, M.T. Malecki¹
¹Department of Metabolic Diseases, Jagiellonian University, Krakow, Poland, ²Department of Endocrinology, Medical University of Bialystok, Poland, ³Department of Children's Diseases, Medical University of Lodz, Poland, ⁴Institute of Biomedical and Clinical Science, Peninsula Medical School, Exeter, United Kingdom, ⁵Department of Endocrinology, Medical University of Wroclaw, Poland

Background and aims: Mutations in the ABCC8 gene encoding the SUR1 subunits of the beta-cell KATP channel cause permanent neonatal diabetes

mellitus (PNDM). In addition, they may also result in other diabetic phenotypes. The aim of the study was to determine the contribution of ABCC8 gene to neonatal diabetes in Poland and to examine factors that may influence its clinical phenotype

Materials and methods: The Nationwide Registry of Neonatal Diabetes in Poland includes patients diagnosed before 6 months of age. ABCC8 gene mutations were detected by direct sequencing. We also performed the hyperinsulinemic euglycemic clamp before and after sulphonylurea therapy and tested for islet-specific antibodies in diabetic mutation carriers.

Results: We sequenced ABCC8 gene mutations in 16 Kir6.2 negative patients with neonatal diabetes, 14 permanent and 2 relapsed transient neonatal diabetes. We identified 4 diabetic probands (25% of all examined cases) with heterozygous missense mutations: F132V, R826W, V86A; and one compound heterozygote with two, N23H and R826W, mutations. Two mutations, F132V and V86A, occurred de novo in their carriers. In addition, a father of the R826W mutation carrier had adult onset diabetes. Three carriers of R826W and 2 carriers of N23H mutations were non-diabetic (range 24-63 yrs). There were striking differences in the clinical picture of SUR1 related diabetes: the carrier of two mutations, N23H and R286W, was controlled on diet alone (HbA1c 7.2%), while the F132V mutation carrier was on 47 units of insulin/day (HbA1c 11.7%). We performed the hyperinsulinemic euglycemic clamp in 3 diabetic subjects. Interestingly, we observed a variable degree of resistance to insulin: from moderate ($M=5.5$ and 5.6 mg/kg/min, respectively, in the two R826 mutation carriers) to severe ($M=2.6$ mg/kg/min in the F132V mutation carrier). In one R826 mutation carrier, a significant improvement in sensitivity to insulin was seen after the transfer to sulphonylurea (SU) with the M parameter increasing by >3.0 mg/kg/min. In his father, with the same R826W mutation, there was a moderate improvement in insulin sensitivity (M rose 1.1 mg/kg/min) and the daily insulin dose substantially reduced on SU, but could not be completely stopped. There was no response to SU treatment in the most insulin resistant F132V carrier of the mutation despite 6 months of high dose SUs (>1mg/kg of glibenclamide). Auto-antibodies were only present in one diabetic mutation carrier, V86A, although they did not seem to influence the clinical picture as she transferred off insulin to SU.

Conclusion: Mutations in SUR1 are the second commonest cause of PNDM in Poland. The clinical phenotype and treatment response of SUR1 diabetic mutation carriers is very heterogeneous. This appears to be modified by variable sensitivity to insulin and the presence of other variants in the gene. Although islet-specific antibodies are present in some mutation carriers, their role is uncertain.

Detection of the whole gene deletion mutation of the HNF1B gene in Japanese patients with MODY

N. Iwasaki¹, T. Yamamoto², A. Watanabe³, M. Tsurumi⁴, K. Asai⁴, K. Mizuno⁴, T. Shimada³, M. Ogata¹, M. Takizawa¹, Y. Iwamoto¹
¹Diabetes Center, Tokyo Women's Medical University, ²International Research and Educational Institute for Integrated Medical Science, Tokyo Women's Medical University, ³Division of Clinical Genetics, Nippon Medical School, ⁴First department of Internal Medicine, Nippon Medical School, Tokyo, Japan

Background and aims: Mutations in the HNF-1 β (HNF1B) gene are the cause of one form of maturity-onset diabetes of the young (MODY5). Genomic deletions of HNF1B have recently been shown to account for one third of mutations causing renal cysts and diabetes syndrome. We have screened our panel of MODY patients with diabetes and kidney disease for deletion of HNF1B.

Materials and methods: We studied 7 Japanese subjects with clinical diagnosis of MODY, and renal cysts or renal dysfunction without retinopathy. Direct sequencing showed no mutations in the coding region of HNF1B. We tested for complete and partial deletions of HNF1B by using quantitative multiplex PCR of short fluorescent fragments (QMPF) (Diabetes 2005, 3126). Then, we confirmed the deletion and determined its extent by comparative genome hybridization (CGH) using the Human Genome CGH micro-array 244A (Agilent, USA), which contains 243504 probes at a 6.4 kb interval, and with 8 probes in HNF1B.

Results: We found two subjects who were hemizygous for HNF1B by QMPF. The following CGH Micro-array revealed that the deleted region was spanning 1.3 Mb at 17q12 including HNF1B as well as TRIP3, AATF, ACACA, and LHX1. An exactly the same 1.3 Mb region, that encompassed by the segmental duplications those known to be hot spots for genomic rearrangements was deleted in both subjects. The clinical features of the two

patients were: patient 1 - non-obese male diagnosed with diabetes at 19 years of age, successfully treated with sulphonylureas, renal cysts, hyperuricemia, hepatic steatosis, hypercholesterolemia were pointed out. The ultrasonography revealed a pancreas with normal size. Father had diabetes; and patient 2 - a non-obese female presented with diabetic ketoacidosis at 24 years of age. The ultrasonography revealed renal cysts and a defect in the body and tail of the pancreas. The angiography disclosed the absence of a part of pancreatic artery indicating that this defect was caused by genetic malformation. The grand mother had diabetes.

Conclusion: We have identified two Japanese subjects with diabetes and renal cysts due to 1.3Mb deletion including *HNF1B* out of 7 subjects studied. The cases show various phenotype other than renal cysts and diabetes. This study indicates the importance of screening for the deletion of *HNF1B* in subjects with diabetes and kidney disease showing no mutations by routine screening of *HNF1B*.

⁵Pediatric Diabetes, Second University of Naples, Italy

Background and aims: Heterozygous mutations of insulin (INS) gene are found in patients with neonatal/infancy-onset diabetes. We previously demonstrated that INS gene mutations cause permanent diabetes by endoplasmic reticulum stress-induced apoptosis of the beta cells. Proband of the Italian series who carry insulin mutations show diabetes in isolation with onset between 1 to 6 months from birth. However, the affected parent of a familial case bearing the R65C (or R89C) mutation presented with diabetes at 4 years of age. Aim of this work was to screen the INS gene in patients referred to HSR Paediatric Diabetes Clinic in the period 2003-2006, who tested negative for T1D autoantibodies.

Materials and methods: We identified 9 patients with diabetes onset above 1 year of age, who were previously classified as patients with T1D on clinical ground, but tested negative for ICA, GAD, IA-A2, IAA autoantibodies at diagnosis and -later on - for zinc transporter 8 (ZnT8) autoantibodies.

Results: We screened the INS gene in 7 patients whose genomic DNA was available. We detected two INS gene mutations: the already described GB8S (or G32S) and the novel Signal-A23S. The GB8S mutant had diabetes onset at 2 y, 10 m of age with detectable C peptide at outset (0.49 ng/ml), and after 2 y (0.34 ng/ml); presently, his insulin dose is 0.5 U Kg⁻¹ d⁻¹. The individual with the Signal-A23S mutation presented with typical symptoms of diabetes (polyuria, polydipsia) when he was 6y 8m old (HbA1c= 11%). Insulin was started and continued for 6 months; during the following 2 years the patient went off/on insulin several times. Currently, he is on low insulin dose (0.2 U Kg⁻¹ d⁻¹). C-peptide measured 11 and 24 months after onset of hyperglycemia was 1.32 and 0.7 ng/ml, respectively. We have engineered the insulin mutations causing diabetes into a human insulin fluorescent reporter, human Ins-C-GFP, and characterized alterations in its maturation, trafficking, and secretion in live beta cells caused by the mutations.

Conclusion: We conclude that INS gene mutations can be found in children previously classified as T1D who tested negative for five T1D autoantibodies and with detectable levels of C-peptide long after diabetes diagnosis.

Searching for MODY-X

R.M. Roccasecca¹, A. Thompson¹, K. Stals², W. Bottomley¹, C. Cordina¹, S. Ellard², A. Hattersley², I. Barroso¹

¹Metabolic Disease Group, Wellcome Trust Sanger Institute, Cambridge,

²Institute of Biomedical and Clinical Sciences, Peninsula Medical School, Exeter, United Kingdom

Background and aims: Maturity Onset Diabetes of the Young is an autosomal dominant disease characterized by early onset of type 2 diabetes, usually before 25 years, caused principally by insulin secretion and action defects. So

far, mutations or chromosomal rearrangements in six genes, *GCK*, *IPF1*, *HNF1A*, *HNF4A*, *HNF1B* and *NEUROD1*, have been identified as responsible for the disease. Most studies have identified mutations in *HNF1A*, *GCK* and *HNF4A* as the most common causes of MODY although the prevalence of mutations in each gene varies across populations. In our study we investigated a cohort of MODY patients known not to have mutations in *HNF1A*, *GCK* and *HNF4A* to investigate the prevalence of coding mutations in the rarer genes associated with MODY: *IPF1*, *HNF1B* and *NEUROD1*. We also sequenced four additional candidate genes: *TCF7L2*, *NNT*, *PCIF1* and *TMEM27* to further investigate the possibility of these genes being involved in this disease.

Materials and methods: Genomic DNA from a cohort of 81 British patients diagnosed with MODY, and pre-screened for mutations in *HNF1A*, *GCK* and *HNF4A*, was PCR amplified using gene specific primers covering exons and splice junctions. PCR fragments were sequenced using Big Dye Terminator chemistry and mutations were confirmed on fresh genomic DNA aliquots. Sequence trace analysis was performed using Mutation Surveyor™ software.

Results: In this cohort we detected mutations in *HNF1B* in 5% of the patients, while the prevalence of mutations in *NEUROD1* and *IPF1* was 3% and 1%, respectively. We detected two previously described amino acid substitution polymorphisms in *TCF7L2* that were present in 14% of patients and three non-synonymous variants in *NNT* in a total of 11% of the patients. No coding variants were found in *PCIF1* and *TMEM27*.

Conclusion: In a cohort of 81 MODY patients without mutations in the most common MODY genes (*HNF1A*, *GCK*, *HNF4A*) approximately 9% of patients presented with mutations in *HNF1B* (5%), *NEUROD1* (3%) or *IPF1* (1%). This highlights the importance of screening for mutations in these genes, once mutations in the more commonly mutated genes has been excluded as the likely cause of MODY. Our study also demonstrated that in the remaining 91% of our patients (MODY X) mutations in *TCF7L2*, *NNT*, *PCIF1* and *TMEM27* do not account for the observed phenotype.

Prevalence of maturity onset diabetes of the young (MODY) in Sardinian overweight/obese children not selected according to family history for diabetes

M.G. Baroni¹, V.M. Cambuli^{1,2}, S. Romeo¹, T. Congiu¹, M. Incani¹, F. Sentinelli¹, S. Filetti², M.C. Musiu³, M.G. Cavallo⁴, E. Cossu¹, S. Loche³

¹Endocrinology and Metabolism, Department of Medical Sciences, University of Cagliari, Monserrato, ²Internal Medicine, Department of Clinical Sciences, University of Rome "La Sapienza", Rome, ³Paediatric Endocrine Unit, Regional Hospital for Microcitemia, Cagliari, ⁴Division of Endocrinology, Department of Clinical and Medical Therapy, University of Rome "La Sapienza", Rome, Italy

Background and aims: Childhood obesity is increasing worldwide. In children and adolescents, overweight can accelerate the clinical onset of any type of diabetes. In case of excess of body weight, it is advisable to screen children for impaired glucose regulation (IGR). Of the various causes of IGR in children and adolescents, maturity onset diabetes of the young (MODY) needs to be considered. MODY represents a proportion (2-5%) of the total cases of diabetes and it is characterized by an autosomal dominant mode of inheritance. The relative distribution of the different forms of MODY depends on the population investigated, although in all studies mutations in *GCK* and *HNF1A* are the two most prevalent, accounting for almost 80% of all cases in Caucasian populations. Nothing is known about the presence of MODY in Sardinian population, a region, together with Finland, with the highest prevalence of type 1 diabetes in the world. Aim of this study was to evaluate the prevalence of MODY in a cohort of overweight/obese children and adolescents affected by IGR (any subclasses: impaired fasting glycaemia, IFG; impaired glucose tolerance, IGT; diabetes mellitus, DM).

Populations and methods: We select subjects affected by IGR from a population of overweight/obese children and adolescents (age 4-18) consecutively screened by OGTT (1.75 g of glucose per kg, max 75 g; samples at baseline and after 120 minutes). We recorded metabolic measures (glycaemia, insulinaemia, lipids etc.) for phenotyping of the subjects and further stratification. Once excluded type 1 diabetes by the presence of auto-antibodies, the subjects were screened for the two most prevalent forms of MODY, searching for *GCK* (MODY2) and *HNF1A* (MODY3) mutations. This analysis was performed regardless of the presence of known diabetes in the families.

Results: 49 children with IGR were identified. Of these, 33 presented IFG (67.3%), 10 IGT (20.4%), 3 combined glucose intolerance (CGI, 6.1%), 3 diabetes (6.1%). In 5 hyperglycaemic children (2 IFG, 1 IGT, 2 DM) we found autoimmunity against beta-cells. In particular, in the 2 children with diabetes

both GADA and IA-2 were present. Once excluded this two cases with overt type 1 diabetes, we performed the genetic analysis in the other 47 children and adolescents: in 2 cases of IFG (4.25%) we found HNF-1 α mutations. One children (male, 12 years old, obese, pubertal) carried the Gly31Asp mutation on exon 1. The other children (male, 7 years old, obese, pre-pubertal) carried the Thr354Met mutation on exon 5. These mutations were confirmed in the mothers of both children. No hyperglycaemic children were positive for GCK mutations.

Conclusion: Our data shown that MODY could be present in children also in absence of a known family history for diabetes and in presence of a typical type 2 diabetes phenotype. In our population MODY3 was present in 4.25% of cases. Further research in obese and/or normal weight children will be useful to clarify the prevalence of MODY within IGR/DM subjects in the Sardinian population.

The second “de novo” activating glucokinase mutation (V452L) in a patient with developmental delay

A.L. Cuesta-Muñoz¹, T. Meissner², N. Cobo-Vuilleumier¹, M. Maringa³, M.A. García-Gimeno⁴, M.J. Castro-Santiago¹, J.C. Aledo¹, J. Weber⁵, P. Sanz⁶
¹Center for the Study of Pancreatic Beta-cell Diseases, IMABIS Foundation, Málaga, Spain, ²Department of General Pediatrics, University Children's Hospital Düsseldorf, Germany, ³Human Genetics Practice, Bonn, Germany, ⁴Institute of Biomedicine of Valencia, Consejo Superior de Investigaciones Científicas, Valencia, Spain, ⁵Integrigen, Bonn, Germany, ⁶Institute of Biomedicine of Valencia, Consejo Superior de Investigaciones Científica, Valencia, Spain

Background and aims: The glycolytic enzyme Glucokinase (GK) is considered the “glucose sensor” in the pancreatic β -cells since it regulates glucose stimulated insulin secretion. Activating mutations in the glucokinase gene (GCK) result in Monogenic Hyperinsulinism (HI-GCK).

Materials and methods: The child was the first offspring of healthy German parents and no consanguinity. Family history was negative for hyperinsulinism or diabetes. There was marked macrosomia of the newborn with a birth weight of 5860g and a length of 60 cm. At the third day of life the patient was admitted to the ICU of the local children hospital due to hypoglycemia and was treated with i.v. glucose. Hyperinsulinism suspected. At two weeks of age the i.v. glucose was stopped and changed to oral carbohydrates in addition to frequent feeding. The patient was finally discharged with diagnosis of “transient hyperinsulinism” without special diet or medication and with glucose concentrations of 2.6–3.3 mmol/l. At the age of 3 years he was sent to the neurology outpatient clinic because of speech delay and mental retardation. Glucose monitoring revealed persistence of low glucose concentrations (2.5–3.6 mmol/l) with low glucose levels particularly after the night fast.

Results: Genetic studies of the proband showed a novel activating mutation in GCK (V452L). Both, mother and father were negative for this mutation. Functional studies of V452L showed over 3 fold more affinity for glucose than that for Wild-type (2.5 vs. 7.6 mmol/l), and over 2.5 times more efficient (16.33 vs. 7.36 sec⁻¹ x mmol⁻¹ x l⁻¹). A fasting test revealed different insulin concentrations (0.2–6.7 mU/l) at 14, 16 and 18 hours of fasting without severe hypoglycaemia. After 12 hours glucose was 46mg/dl and at 18 h was 2.2 mmol/l (lowest glucose concentration). The OGTT revealed reactive hypoglycemia at 120 min (2.1 mmol/l). With diazoxide treatment the mean and the morning glucose concentration increased.

Conclusion: This is the third case of a “de novo” GCK activating mutation out of ten described so far (30%), and the second case of a patient with “de novo” HI-GCK activating with mental retardation. Therefore the high frequency of “de novo” GCK activating mutation along with the high risk of developing mental retardation means that any newborn with hypoglycemia not resolved in the first two weeks of life, should be tested for GCK mutations.

Structural changes in the repeated region of the carboxyl-ester lipase (CEL) gene and the development of diabetes

K. Fjeld^{1,2}, J. Torsvik^{1,2}, S. Johansson¹, J. Ek³, S. Flanagan⁴, A. Johansen³, H. Ræder⁵, O. Pedersen³, A.T. Hattersley⁴, T. Hansen³, A. Molven^{6,7}, P.R. Njølstad^{1,5}

¹Department of Clinical Medicine, University of Bergen, Norway, ²Centre for Medical Genetics and Molecular Medicine, Haukeland University Hospital, Bergen, Norway, ³Steno Diabetes Center, Gentofte, Denmark, ⁴Institute of Biomedical and Clinical Sciences, Peninsula Medical School, Exeter, United Kingdom, ⁵Department of Pediatrics, Haukeland University Hospital, Bergen, Norway, ⁶Gades Institute, University of Bergen, Norway, ⁷Department of Pathology, Haukeland University Hospital, Bergen, Norway

Background and aims: We have recently described a novel syndrome of exocrine and endocrine pancreatic dysfunction caused by mutations in a variable number of tandem repeats (VNTR) located in exon 11 of the carboxyl-ester lipase (CEL) gene. Sequencing of CEL has proven very challenging due to the repetitive nature of the GC-rich VNTR. The aims of this study were to develop a simple and robust method to search for mutations in the CEL VNTR and to use this method in the screening of diabetic subjects for CEL exon 11 sequence variations.

Materials and methods: We developed an assay which consisted of a multiplex PCR followed by DNA fragment analysis. The method could reveal insertions/deletions in the proximal repeats of the CEL VNTR and enabled simultaneous determination of the total number of repeats for each allele. A material of 241 diabetic MODY probands (95 from Denmark and 146 from UK), who had tested negative for mutations in the common MODY genes, were screened with the method. Mutation analyses were also performed by DNA sequencing in all Danish samples to assure consistency of results. Southern blotting was used to analyze suspected CEL gene rearrangements detected by the assay.

Results: We did not find any new cases with single-base deletions in the proximal repeats of the CEL VNTR, suggesting that such mutations will remain a rare cause of MODY. In the Danish MODY material, we identified one family with a VNTR consisting of only three repeats, whereas the normal number is 12–20. Further investigation of the family showed that five of seven individuals with the short VNTR had diabetes and one had impaired glucose tolerance. Family members with normal VNTR length were normoglycemic. There was no co-segregation between genotype and exocrine dysfunction in the family. In the total material, we observed six individuals who had three different VNTR lengths revealed by fragment analysis. This suggests that some individuals harbor three copies of the CEL VNTR. By sequencing and Southern blot analysis we confirmed the existence of an additional copy of the CEL VNTR in both affected subjects and in healthy controls. In addition, we found evidence that the duplication may occur in at least two different forms and that it may involve the neighboring CEL pseudogene.

Conclusion: Frame-shift mutations in the CEL VNTR seem to be a rare cause of MODY. Our data indicate that alleles with very few VNTR repeats may predispose to diabetes in some families. Interestingly, we also found evidence of novel rearranged CEL alleles, both in normal subjects and in diabetes patients, and we are currently performing further studies to pinpoint the exact structure, size and possible functional implication of the rearrangements.

Pancreatic exocrine dysfunction in diabetes: functional characterisation of the carboxyl-ester lipase gene

J. Torsvik^{1,2}, B.B. Johansson^{1,2}, S. Johansson^{1,2}, J. Saraste³, P.R. Njølstad^{1,4}, A. Molven^{5,6}

¹Department of Clinical Medicine, University of Bergen, ²Center for Medical Genetics and Molecular Medicine, Haukeland University Hospital, Bergen, ³Department of Biomedicine, University of Bergen, ⁴Department of Pediatrics, Haukeland University Hospital, ⁵Gade Institute, University of Bergen, ⁶Department of Pathology, Haukeland University Hospital, Bergen, Norway

Background and aims: We have described a novel syndrome of exocrine and endocrine pancreatic dysfunction caused by mutations in the carboxyl-ester lipase (CEL) gene. CEL is expressed mainly in the acinar tissue of the pan-

creas. The protein is secreted from the pancreas into the digestive tract where it plays a role in cholesterol and lipid-soluble vitamin ester hydrolysis and absorption. We identified mutations in the last exon of *CEL*, localized in a coding region consisting of a variable number of tandem repeats (VNTR). Both mutations were single base deletions that lead to a frameshift, predicting a new protein C-terminus. Patients with these mutations suffer from exocrine pancreatic dysfunction and diabetes with beta-cell failure. The pathogenic effect of the mutant *CEL* protein is unknown.

Materials and methods: The mutant and wild-type *CEL* genes were cloned in a mammalian expression vector and stably transfected into HEK293 cells. The recombinant proteins were studied using SDS-PAGE and Western blotting, and their subcellular distribution was analyzed by immunofluorescence.

Results: Both the normal and the mutant *CEL* proteins were secreted from the HEK293 cells into the growth medium at high levels. Real-time PCR experiments showed that the mRNA levels of the two transfected genes were nearly identical. In cells expressing wild-type *CEL*, the protein tended to co-localize with the endoplasmic reticulum (ER) and the Golgi compartment. However, in the cells expressing mutant *CEL*, the protein appeared to cluster in unidentified organelle-like structures in the cytoplasm and it also partly co-localized with the ER. One hypothesis is that the mutant protein follows a secretion route different from the classical ER to Golgi pathway used by wild type *CEL*. Experiments in which the protein synthesis is blocked by cycloheximide are ongoing to study whether the protein clusters are proteins that are marked for degradation or if they persist in the cytoplasm as a part of the secretion pathway of the protein.

Conclusion: Patients with a mutation in the VNTR of the *CEL*-gene suffer from diabetes and exocrine deficiency. The disease mechanism could involve impaired secretion or increased degradation of the protein. An alternative explanation is ER stress due to improper glycosylation as the wild type *CEL* protein is heavily O-glycosylated in the C-terminal end which is affected by the mutations.

Weight and glycaemic responses to 6 months Exenatide treatment in Alström syndrome subjects with type 2 diabetes

R.B. Paisey, D. Hodge, L. Bower

Diabetes, Torbay Hospital, Torquay, United Kingdom

Background and aims: Alström syndrome is a rare autosomal recessive syndrome associated with insulin resistant young onset type2 diabetes. Regular NHS sponsored clinics with Alström UK have allowed audit of antidiabetic therapy.

Materials and methods: Local Research and Ethics permission was obtained to study insulin and glucose responses to meals in 9 Alström subjects with intractable obesity and poor glycaemic control, despite varying combinations of Metformin and Glitazones. Three had also received insulin. Exenatide was added, oral agents continued and insulin reduced to twice daily long acting preparations, then withdrawn after 3 months if possible.

Results: Severe hyperinsulinaemia was confirmed in all cases (C peptide levels 2006–7614 pmol/l, one hour after a high carbohydrate breakfast). All had intractable obesity and poor glycaemic control (weight 89.8+/- 16.7Kg, BMI 34.2+/-3.5, and HbA1c 9.3+/- 1.6%). All agreed with the addition of Exenatide to oral hypoglycaemic agents and reducing insulin dosage in 3 cases. After 6 months of 10 micrograms BD subcutaneous Exenatide there were significant improvements in weight and glycaemic control (weight 84.0+/-13.9 Kg, $P<0.01$; HbA1c 7.9+/- 2.0%, $P=0.013$). The only significant adverse effect was nausea in 4 cases. Insulin was successfully withdrawn in two cases.

Conclusion: Significant weight reductions and improvement in glycaemic control were sustained for 6 months by the addition of Exenatide treatment in 9 type 2 diabetic Alström subjects with proven hyperinsulinism.

The role of genetic variation in the cannabinoid type 1 receptor gene (*CB1R*) in the pathophysiology of human obesity

D. Schleinitz¹, Y. Böttcher², S. Carmienke², A. Tönjes², J. Berndt¹,

N. Klötting², K. Ruschke², G.H. Scholz², M. Blüher², M. Stummvoll², P. Kovacs¹

¹Interdisciplinary Center for Clinical Research, University of Leipzig,

²Medical Department III, University of Leipzig, ³Medical Department I, Hospital St. Elisabeth, Leipzig, Germany

Background and aims: The endocannabinoid system has been suspected to contribute to the association of visceral fat accumulation with metabolic diseases. Our recent findings suggest that abdominal fat accumulation is a critical correlate of the dysregulation of the peripheral endocannabinoid system in human obesity. Therefore, the cannabinoid type 1 receptor gene (*CB1R*) was investigated as a plausible obesity candidate gene by testing whether genetic variation within the *CB1R* might affect obesity and pathophysiologically relevant traits.

Materials and methods: The *CB1R* was sequenced (exons, exon-intron boundaries, 5' and 3' UTRs) in DNA samples from 48 non-related Caucasian subjects to identify genetic variants. Eight variants were identified, 4 of which were novel. Seven variants including HapMap (www.hapmap.org) tagging single nucleotide polymorphisms (SNPs) and representing their linkage disequilibrium groups were genotyped for subsequent association studies in 2 independent cohorts with detailed metabolic testing: German Caucasians (N=1100; mean age 50±14 years, mean BMI 29.3±5.7 kg/m²) and an isolated population of Sorbs from Germany (N=933; mean age 48±16 years, mean BMI 27.0±4.9 kg/m²), totalling 2033 subjects.

Results: In a case control study including a subgroup of 304 lean (BMI<25kg/m²) vs. 307 obese (BMI>30kg/m²) subjects from the German Caucasian cohort, none of the SNPs was associated with obesity. However, in the entire study cohort of German Caucasians, several SNPs (rs806368, rs806369, rs806370, rs12720071) were significantly associated with obesity-related quantitative traits (% body fat, serum leptin, fasting plasma insulin) (all $P<0.05$ after adjusting for age, sex and body mass index-BMI). Furthermore, in the isolated population of Sorbs, rs806368 was significantly associated with obesity in a case-control study including a subgroup of 344 obese and 211 lean Sorbs (adjusted $P<0.05$). Consistent with this, the rs806368 also showed association with BMI and fasting plasma glucose (all adjusted $P<0.05$).

Conclusion: Although modest, the association of *CB1R* genetic variants with obesity and pathophysiologically relevant traits in 2 independent populations indicates its potential role in the pathophysiology of human obesity. Since CB1 system is a known target for obesity treatment, our data provoke further studies to reveal pharmacogenetic aspects of the *CB1R* genetic variation.

Variation in the transcription factor 7-like 2 (TCF7L2) does not play a significant role in conferring type 2 diabetes risk in Japanese Americans

D. Gable¹, B. Pierce², P. Talmud³, K. Lee³, S. Humphries³, M. Austin²

¹Department of Diabetes and Endocrinology, St Mary's Hospital, London,

United Kingdom, ²Department of Epidemiology and Institute for Public Health Genetics, School of Public Health and Community Medicine, Seattle, United States, ³Centre for Cardiovascular Genetics, University College London, United Kingdom

Background and aims: Specific alleles of a tetranucleotide repeat (DG10S478) in the TCF7L2 gene were originally found to be associated with type 2 diabetes in samples from Iceland, Denmark and the USA, explaining a high proportion of the cases (Genotype population attributable risk 21%). This finding has since been replicated in Indian Asians and Black Afro-Caribbeans. This study aimed to estimate the impact of this variant in a sample of Japanese ancestry.

Materials and methods: We determined DG10S478 genotype in a sample of 609 Japanese American Family Study [JAFS] participants. JAFS was designed to investigate risk factors for coronary heart disease, diabetes, and the insulin resistance syndrome in Japanese American families. The Megabace (Amersham Biosciences, UK) genotyping program was used to determine purified (Ampure magnetic bead system [Agencourt MA, USA]) PCR product length.

Results: The expected four alleles were seen but frequencies were significantly different to those reported in caucasian studies, the common allele being +8 rather than +0. The frequency of the previously identified risk allele [not +0] was not different between those with and without type 2 diabetes. In the parental generation, compared to [+0], the [not+0] allele was associated with an odds ratio of 2.39 [0.30–18.68: $p=0.73$] for type 2 diabetes. By contrast, compared to the most common allele in this Japanese American sample, [+8] the hazard ratio associated with the combined rare alleles [not+8] was 0.82 [0.35–1.93: $p=0.21$]. The frequency of the combination, “any allele other than the common allele”, is much lower in Japanese Americans (0.06[0.03–0.05]) than that reported in caucasian studies (Range 0.24–0.34)[2;5]. A genotype population attributable fraction based on this odds ratio for the combined rare allele [Not +8] in this Japanese American sample is only 1.0%.

Conclusion: Although, the previously identified risk allele [not+0] and the rare alleles of this Japanese American sample, [not+8] may be associated with differences in T2DM risk, they have a much lower frequency in this ethnic group. The sequence variants [rs12255372, C>T; rs7903146G>T] that mark the risk haplotype in Caucasians and Indian Asians are also much rarer in samples of Japanese ancestry. This means that variation in TCF7L2 is unlikely to contribute, to the same magnitude, to differences in genetic risk of T2DM in a population of Japanese Ancestry.

Fine-mapping type 2 diabetes causal variants on chromosome 9p21 in 2000 UK cases and 3000 unselected controls

A. Morris¹, I. Prokopenko², P. Akan³, H. Lango⁴, E. Zeggini², T.M. Frayling⁴, P. Deloukas³, A.T. Hattersley⁴, M.I. McCarthy²

¹Genetic Epidemiology, Wellcome Trust Centre for Human Genetics, Oxford, United Kingdom, ²Type 2 Diabetes Group, Wellcome Trust Centre for Human Genetics, Oxford, United Kingdom, ³Genotyping Group, Wellcome Trust Sanger Institute, Hinxton, United Kingdom, ⁴University of Exeter, United Kingdom

Background and aims: One of the most interesting regions to emerge from the recent genome wide association scans for type 2 diabetes (T2D) lies on chromosome 9p21. The region is devoid of annotated genes, but is ~100kb from *CDKN2A* and *2B*, and contains at least two independent signals for T2D, and one for coronary artery disease. The stronger signal of association with T2D ($p<10^{-7}$ in meta-analysis) mapped to a ~10kb interval flanked by two recombination hotspots. Multi-locus analysis of this region revealed a two-SNP haplotype (rs10811661 and rs10757283) that is more strongly associated with T2D ($p=5.8\times 10^{-8}$) than either SNP alone. This suggests that these polymorphisms may tag a rarer risk haplotype which harbours a causative allele, or that there may be multiple causal variants in the region. Our aim is to dissect the haplotype association and fine-map causal variants within the region.

Materials and methods: To address this hypothesis, we have sequenced the ~10kb region flanking the associated two-SNP haplotype in a reference panel of 96 samples: 16 CEPH individuals and 80 T2D cases, 40 of them carrying the two high-risk alleles at rs10811661 and rs10757283. A total of 30 SNPs were identified, 5 of which are not present in Phase II HapMap. Haplotypes were reconstructed in the reference panel and subsequently used to impute genotypes at all 30 SNPs in the entire case-control sample. The GENEPM algorithm was then used to jointly test for T2D association with all SNPs across the region by clustering haplotypes according to their similarity in terms of allelic-makeup and risk of carrying causal variants.

Results: There is overwhelming evidence of T2D association (\log_{10} Bayes' factor of 8.52), with haplotypes grouped into three distinct risk classes: high-risk haplotypes (26% frequency, posterior mean odds ratio of carrying causal variants of 20.6), low-risk haplotypes (15% frequency, posterior mean odds ratio of 0.60), and neutral haplotypes (59% frequency). The three clusters are separated by two sets of SNPs in the region that are not in linkage disequilibrium with each other, but that tag rs10811661 and rs10757283, respectively.

Conclusion: Our results demonstrate that T2D risk in this region is most likely to be due to (at least) two independent causative mutations, although further work is required to determine which, if any, of the SNPs discovered by sequencing are functional.

CHOP T/C and C/T haplotypes contribute to early-onset type 2 diabetes in Italians

C. Gragnoli^{1,2}, F. Chiaramonte³

¹Lab. of Molecular Genetics of Complex & Monogenic Disorders, Penn State University, Medicine & Physiology, Hershey, United States, ²Center for Biotechnology & Dept of Biology, Temple University, Sharro Institute for Cancer Research & Molec. Med, Philadelphia, United States, ³Diabetology Unit, Santo Spirito Hospital, Rome, Italy

Type 2 diabetes (T2D) is characterized by impaired insulin secretion, insulin insensitivity and decreased beta cell mass. Multiple genes contribute to T2D. The chromosome 12q13.1 region is in linkage to T2D in different populations, including our Italians dataset. *CHOP* is a candidate gene for the linkage, as it is located in the chromosome 12q13.1 region, and may contribute to T2D by increasing beta cell apoptosis susceptibility and by impairing insulin sensitivity. Our goal was to identify any potential *CHOP* gene variants contributing to T2D in our Italian early-onset T2D families, which show linkage to the *CHOP* region. We directly sequenced the *CHOP* gene in 28 Italian probands of the linked T2D families and in 115 control subjects. We performed genotype and haplotype association tests with T2D of the identified SNPs. We performed model-free and parametric association haplotype tests with T2D. We identified three SNPs (5'UTR-c.279T>C, 5'UTR-c.120A>G and +nt30C>T (F10F) in *CHOP*. These SNPs are in LD. The association test showed an association trend with T2D of the TT (F10F) and AG (-c.120A>G) genotypes. The haplotype association test resulted significant for the haplotypes T/C (frequency=0.33) and C/T (frequency=0.01) (at 5'UTR-c.279T>C and +nt30C>T, respectively) under non-parametric analysis (p -value=0.000), the recessive model (p -value=0.0000) and the additive model (p -value=0.0014). Our data show that *CHOP* described haplotypes T/C and C/T, as a single additive and as a homozygous variant, contribute significantly to T2D in our Italian early-onset group. We conclude that the *CHOP* T/C and C/T haplotype contributes to our T2D linkage signal on chromosome 12q13.1

Genetic risk of development of posttransplantation diabetes mellitus (PTDM) in renal allograft recipients

E. Kang¹, M. Kim², H. Kim³, C. Nam⁴, C. Ahn¹, B. Cha¹, S. Kim², H. Lee¹

¹Internal Medicine, Yonsei University College of Medicine, Seoul, ²Surgery, Yonsei University College of Medicine, Seoul, ³Internal Medicine, Kwandong University College of Medicine, Gangneung, ⁴Preventive Medicine and Public Health, Yonsei University College of Medicine, Seoul, Republic of Korea

Background and aims: Posttransplantation diabetes mellitus (PTDM) is a major metabolic complication in renal transplant recipients. Recent genome wide association studies have revealed several genes associated with type 2 diabetes in Caucasian populations. We examined the association of 13 single nucleotide polymorphisms (SNPs) within 6 genes in renal allograft recipient cohort.

Materials and methods: 624 kidney recipients transplantation from 1989 to 2007, without a history of diabetes, and with a pretransplant fasting plasma glucose < 126 mg/dL were Included in the study. We analyzed 13 SNPs (rs4402960 in *IGF2BP2*, rs10811661 in *CDKN2A/B*, rs1111875, rs7923837, rs5015480 in *HHEX*, rs13266634 in *SLC30A8*, rs11196205, rs4506565, rs12243326, rs7903146, rs12255372, rs7901695 in *TCF7L2*, and rs734312 in *WFS1*) in 174 patients with PTDM and 450 patients with non-PTDM by using TaqMan real-time PCR.

Results: Among 13 SNPs examined, 5 loci were significantly associated with PTDM (rs1111875 in *HHEX*, $p<0.001$; rs7923837 in *HHEX*, $p=0.009$; rs5015480 in *HHEX*, $p=0.005$; rs13266634 in *SLC30A8*, $p=0.007$; rs7903146 in *TCF7L2*, $p=0.029$). Four SNPs remain significant after adjustment for age, gender, body weight gain, and type of immunosuppressant (rs1111875 in *HHEX*, hazard ratio (HR) =1.35, $p=0.006$; rs5015480 in *HHEX*, HR=1.13, $p=0.026$; rs13266634 in *SLC30A8*, HR=1.32, $p=0.013$; rs7903146 in *TCF7L2*, HR=1.45, $p=0.039$). Rs4402960 in *IGF2BP2*, rs10811661 in *CDKN2A/B*, and rs734312 in *WFS1* were not associated with PTDM ($p=0.075$, $p=0.115$, $p=0.810$ respectively).

Conclusion: These data provide evidence that the *SLC30A8*, *HHEX*, *TCF7L2* genetic variations are associated with PTDM and rs1111875 in *HHEX* was the most powerful genetic predictor for PTDM development in renal allograft recipients.

Analyses of *S100B* rs2300403 T/C contribution to T2D in a large population based-study - the HUNT studyP.M. Thorsby^{1,2}, J.-C. Lambert³, K. Midtthjell⁴, N. Gjerlaugsen¹, J. Holmen⁴, K.I. Birkeland^{5,2}, A. Meirhaeghe³¹Aker University Hospital, Hormone Laboratory, Oslo, Norway, ²Aker University Hospital, Aker- Ullevål Diabetes Research Centre, Oslo, Norway, ³Institut Pasteur de Lille, INSERM U744, Lille, France, ⁴Norwegian University of Science and Technology, HUNT Research Centre, Verdal, Norway, ⁵Aker University Hospital, Department of Endocrinology, Oslo, Norway

Aims: The *S100B* gene, a glial-derived protein, is associated with beta-amyloid and phospho-tau accumulation and Alzheimer's disease. It also influences β -cell destruction. We wanted to study whether the polymorphism rs2300403 in *S100B*, shown to be associated with the risk of Alzheimer's disease, could be associated with type 2 diabetes or related clinical parameters.

Methods: 65,905 individuals above 20 years of age participated in a health survey in Nord-Trøndelag county in Norway (HUNT 2) in 1995–97. We studied a population-based randomly selected group of 869 individuals with self-reported diabetes or non-fasting serum glucose above 11.1 mmol/l, and 2,080 non-diabetic control subjects with serum glucose below 5.5 mmol/l. The study was powered to detect differences in allele frequencies as low as 5 %. The *S100B* rs2300403 T/C polymorphism was studied (TaqMan® SNP genotyping assays in a two color real-time PCR), and traditional clinical risk factors were investigated cross-sectionally.

Results: The cases were slightly older than the controls (66.8 \pm 13.7 vs. 65.6 \pm 14.5 years, $p=0.031$). The clinical characteristics of cases and controls from HUNT 2 are displayed in the table below.

	Type 2 diabetes	Control subjects	p
Gender (female/male) *	430/439	1056/1024	ns
BMI (kg/m ²)	29.1 (5.0)	26.4 (3.9)	<0.001
Waist (cm)	96.2 (12.5)	87.9 (11.2)	<0.001
W/H ratio	0.90 (0.08)	0.86 (0.08)	<0.001
SBP (mm Hg)	152.8 (25.5)	144.8 (24.2)	<0.001
DBP (mm Hg)	83.8 (13.7)	82.3 (12.7)	0.004
S-Cholesterol (mmol/l)	6.1 (1.3)	6.3 (1.3)	0.006
S-HDL (mmol/l)	1.2 (0.4)	1.4 (0.4)	<0.001
S-TG (mmol/l)	2.5 (1.8)	1.7 (0.9)	<0.001

The allele frequencies of the *S100B* rs2300403 polymorphism was 0.69 for the T allele and 0.31 for the C allele. There was no difference in frequencies between T2D and controls ($\chi^2=0.79$), even when testing cases against the oldest third of the controls (age > 74 years, $\chi^2=0.86$). The T allele was significantly associated with increased glucose in the control group compared with CC subjects (4.99 (0.42) mmol/l vs 4.91 (0.48), respectively, $p=0.014$). No other clinical parameter (SBP, DBP, BMI, W/H ratio, Cholesterol, HDL or TG) showed association with this polymorphism.

Conclusion: The *S100B* rs2300403 polymorphism was not associated with T2D but it might influence glucose metabolism.

Impact of transcription-factor 7-like 2 (*TCF7L2*) gene-variants on the response to anti-hyperglycaemic treatment in non-obese patients with type 2 diabetesS.S. Lund¹, L. Tarnow¹, C.D.A. Stehouwer², C.G. Schalkwijk^{3,2}, M. Frandsen¹, U.M. Smidt¹, T. Hansen¹, O. Pedersen¹, H.-H. Parving⁴, A.A. Vaag¹¹Steno Diabetes Center, Gentofte, Denmark, ²Department of Internal Medicine, University Hospital Maastricht, Netherlands, ³Department of Clinical Chemistry, University Medical Centre, Amsterdam, Netherlands, ⁴Department of Medical Endocrinology, Rigshospitalet, Copenhagen, Denmark

Background and aims: Common *TCF7L2* gene-variants have been associated with type-2-diabetes (T2DM) (rs7903146 and rs12255372) and obesity (rs10885406). In non-obese T2DM-patients, we studied the impact of *TCF7L2* gene-variants on anti-hyperglycaemic (HaemoglobinA_{1c} (HbA_{1c})) and

anti-inflammatory (high-sensitivity C-reactive-protein (hsCRP)) efficacy of metformin or repaglinide targeting insulin-resistance and insulin-secretion, respectively.

Materials and methods: Randomized, double-masked, 2 x 4 months cross-over-study of metformin 1g twice-daily versus repaglinide 2 mg thrice-daily in 96 non-obese (BMI ≤ 27 kg/m²) insulin-naïve Caucasian T2DM-patients (rs10885406: AA: n=17; AG: n=60; GG: n=19; rs7903146: TT: n=8; TC: n=58; CC: n=30; rs12255372: GG: n=36; GT: n=55; TT: n=5).

Results: Compared with AA-homozygotes, rs10885406 G-allele carriers had lower HbA_{1c} during metformin treatment (Mean [95%CI] HbA_{1c}-difference during metformin: G-allele carriers versus AA-homozygotes: -0.52% [-0.97; -0.06], $p=0.026$). In rs10885406 G-allele carriers, rs12255372 T-allele carriers and rs7903146 TT-homozygotes, hsCRP levels were lower during metformin versus repaglinide treatments (Mean [95%CI] relative hsCRP difference metformin versus repaglinide, rs10885406 G-allele-carriers: -26% [-42; -4]; $p=0.024$; rs12255372 T-allele carriers: -31% [-49; -6]; $p=0.017$; and rs7903146 TT-homozygotes: -58% [-81; -7]; $p=0.033$). Compared with AA-homozygotes, rs10885406 G-allele carriers had increased hsCRP levels during repaglinide treatment (Mean [95%CI] relative hsCRP difference during repaglinide, rs10885406 G-allele carriers versus AA-homozygotes: 76% [9; 185], $p=0.021$). Treatment-by-*TCF7L2*-genotype interactions were significant for hsCRP (rs10885406: $p=0.029$; rs12255372: $p=0.046$; and rs7903146: $p=0.027$), but not for HbA_{1c}.

Conclusion: In non-obese T2DM-patients, common *TCF7L2* gene-variants might influence anti-hyperglycaemic treatments responses. Metformin may have improved glycaemic and/or anti-inflammatory effects in rs10885406 G-allele carriers, rs12255372 T-allele carriers or rs7903146 TT-homozygotes, whereas repaglinide may have improved anti-inflammatory effects in rs10885406 AA-homozygotes.

Protective role of the rare genetic variant of the hypoxia inducible factor-1 alpha (HIF1 α) in type 2 and type 1 diabetesG. Nagy¹, R. Nagy², A. Székely³, N. Németh³, M. Sasvári-Székely², A. Somigyi¹¹II. Department of Internal Medicine, Semmelweis University, ²Department of Medical Chemistry, Molecular Biology and Pathobiochemistry, Semmelweis University, ³Department of Psychiatry, Eötvös Loránd University, Budapest, Hungary

Background: Hypoxia inducible factor-1 alpha (HIF1 α) is a transcription factor known to increase the synthesis of the vascular endothelial growth factor (VEGF) under hypoxic conditions. By influencing VEGF levels, HIF1 α is thought to play an important role in neo-vascularisation, embryonic pancreas as beta-cell mass development, and beta cell function. A genetic association analysis of the HIF1 α gene polymorphism performed on a Japanese sample raised the possibility that the P582S (A C>T change) functional polymorphism found in the coding region HIF1 α gene could be a protective factor against type 2 diabetes mellitus (T2DM).

Aims: Distribution of different genetic variants may significantly vary between different populations. Thus our aim was to determine the frequency of the P582S (C>T) mutation in a control (K), a T2DM and a type 1 diabetic (T1DM) sample in a Caucasian (Hungarian) sample.

Materials and methods: 367 T2DM and 71 T1DM and 341 sex matched K subjects were recruited. Using a non-invasive sampling technique, buccal cells were collected for DNA isolation. Genotyping was performed by real time PCR using TaqMan probes.

Results: Frequency of the C allele was more pronounced in both T1DM (90.8%) and T2DM (90.9%) as compared to controls (86.8%). Statistical analysis of allele-wise distribution in the three groups yielded significant results: $\chi^2(2)=6.515$, $p=0.038$. The CC genotype was more frequent in both patient groups (81.7% in T1DM and 82.3 in T2DM) than in the control group (75.7%). The CT genotype was less frequent in the patient groups (18.3% in T1DM and 17.2 in T2DM) as compared to the 22.3% in controls. The TT genotype was extremely rare in the population (0.0% in T1DM, 0.5% in T2DM and 2% in controls) therefore the genotypes were grouped as T absent (CC) and T present (CT and TT) for genotype-wise statistical analysis. Frequency of the T absent and T present groups were compared in the patient (including T1DM and T2DM) and control groups. The T absent genotype was significantly more frequent in the patient group (82.2%) as compared to the controls (75.7%) $\chi^2(1)=4.989$, $p=0.026$.

Conclusion: Genotype and allele frequency analysis confirmed the possible protective role of the HIF1 α T allele against T2DM in a Caucasian population. Allele frequency analysis also suggested that the T allele might also be a protective factor in T1DM. Our results confirm the possible role of the HIF1 α gene in the pathomechanism of diabetes.

University, Villejuif, France, ⁶Department of Epidemiology and Public

Health, Imperial College London, United Kingdom

Background and aims: Non-diabetic individuals with fasting plasma glucose (FPG) levels at the high end of the normal range have a higher risk of cardiovascular mortality.

Materials and methods: To identify genetic determinants that contribute to inter-individual variation in FPG, we first tested 392,935 Single Nucleotide Polymorphisms (SNPs) in 654 normoglycemic subjects for association with FPG.

Results: We replicated the most strongly associated SNP (rs560887, $p=4\times 10^{-7}$) in an additional 9,353 subjects. SNP rs560887 maps to intron 3 of the *G6PC2* (glucose-6-phosphatase catalytic subunit-related protein 2) gene which is selectively expressed in pancreatic islets (also known as IGRP, an auto antigen in T1D). This SNP is associated with FPG ($\beta=-0.06$ mmol/l per A-allele, combined $p=4\times 10^{-23}$) and with pancreatic beta-cell function (Homa-B model; combined $p=3\times 10^{-13}$) in three European cohorts, although it is not associated with T2D risk. However, rs560887 A allele carriers have a lower risk of developing $FPG\geq 6.1$ mmol/l over a 9-year follow-up period (Hazard ratio=0.83, $p=0.009$) suggesting that *G6PC2/IGRP* may regulate FPG by modulating the set-point for glucose-stimulated insulin secretion in beta-cells. Interaction analysis of rs560887 with the glucokinase regulatory (*GCKR*) variant rs1260326-P446L and the glucokinase (*GCK*) variant rs1799884/-30G/A in the D.E.S.I.R cohort showed an additive effect of the three SNPs on FPG ($p=5\times 10^{-21}$). Individuals carrying more than four alleles associated with low FPG (10.7% of the D.E.S.I.R population), show a mean 0.24 mmol/l (4.5%) decrease of FPG compared to subjects carrying only one allele.

Conclusion: In conclusion we identified the *G6PC2/IGRP* gene as a major regulator of glucose levels which supports further the role of various components of the glucose phosphorylation pathway in glucose homeostasis

Role of TCF7L2 and HHEX/IDE risk alleles in the pathophysiological and clinical phenotype of newly diagnosed type 2 diabetic patients

S. Bonetti¹, E. Trabetti², M. Trombetta¹, G. Malerba², L. Boselli¹,

M. Muggeo¹, P. Pignatti², E. Bonora¹, R.C. Bonadonna¹

¹Department of Biomedical and Surgical Sciences, ²Department of Mother, Child, Genetics, University of Verona School of Medicine, Verona, Italy

Background: Several SNP variants which carry an increased risk for type 2 diabetes (T2DM) have been identified by recent GWA studies. Among them, the risk alleles T of rs7903146 and G of rs1111875 are related to TCF7L2 and HHEX genes, respectively, and these, in turn, are both involved in the Wnt pathway which plays a role in pancreas organogenesis. Some studies have reported a role of these risk alleles in determining beta-cell function (β F) in nondiabetic people.

Aims: We tried to assess the role played by rs7903146 and rs1111875 in the pathophysiological and clinical phenotype of patients with newly diagnosed T2DM.

Research methods: In 345 drug-naïve GAD-antibody negative patients with newly diagnosed T2DM (age: 58 ± 0.5 yrs; BMI: 30.4 ± 0.3 kg/m²; HbA1c: $6.9\pm 0.1\%$; mean \pm SEM) we performed an OGTT for β F and a standard euglycemic insulin clamp to assess insulin sensitivity (SI) (M value; 605 ± 19 μ mol min⁻¹m⁻² BSA), on separate days. OGTT plasma glucose (G) and C-peptide concentration curves were analyzed by state-of-art mathematical modeling to quantify basal insulin secretion rate (B-ISR: 1.06 ± 0.02 U hr⁻¹m⁻² BSA), and the sensitivity of β -cells to both the rate of increase of G (derivative or dynamic control; 583 ± 34 [pmol m⁻²] per [mM/min]) and to G concentration (proportional or static control; 51.3 ± 2.6 [pmol min⁻¹m⁻² BSA] per [mmol/l]). Rs7903146 and rs1111875 were genotyped and found in H-W equilibrium.

Results: The T allele of rs7903146 in homozygosity was associated to significant reductions in B-ISR (C/C, $n=123$: 1.12 ± 0.04 U hr⁻¹m⁻² BSA; C/T, $n=164$: 1.06 ± 0.03 ; T/T, $n=59$: 0.95 ± 0.04 ; $p<0.05$ by MANOVA) and in fasting triglycerides (C/C: 1.8 ± 0.1 mmol/l; C/T: 1.8 ± 0.1 ; T/T: 1.3 ± 0.1 ; $p<0.05$ by MANOVA). Rs1111875 genotype showed significant associations ($p<0.05$ by MANOVA) with waist circumference and SI, and suggestive trends for β F, but all these associations disappeared when covariates were taken into account.

Conclusion: In newly diagnosed T2DM patients: 1. rs7903146 risk allele T of TCF7L2 is associated with reduced basal insulinization, but with less burden of atherogenic dyslipidemia; 2. definition of a role, if any, of rs1111875 genetic variability in determining the pathophysiologic phenotype requires more extensive and detailed studies.

University of London, United Kingdom

Background and aims: The fetal insulin hypothesis proposed that the association between low birth weight and type 2 diabetes (T2D) could be explained by T2D risk alleles in the fetus reducing insulin-mediated fetal

growth. This has been supported by epidemiological data but there has been no direct molecular genetic support. Type 2 genes may also increase birth weight by increasing maternal glycaemia. Recent genome-wide association studies have identified novel T2D risk variants but their role in fetal growth is not known.

Materials and methods: We examined five recently identified T2D loci (*CDKAL1*, *CDKN2A/B*, *HHEX-IDE*, *IGF2BP2* and *SLC30A8*) for their impact on fetal growth, either through fetal genotype or maternal genotype, or a combination. We used data from 7986 mothers and 19200 offspring from four studies of white Europeans.

Results: We found strong evidence that fetal *CDKAL1* and *HHEX-IDE* T2D risk genotypes influence birth weight. Each fetal copy of the *CDKAL1* and *HHEX-IDE* T2D risk alleles reduced birth weight by 21g (95%CI: 11–31g; $P=2\times 10^{-5}$) and 14g (95%CI: 4–23g; $P=0.004$), respectively. Adjustment for maternal genotype ($n=5,712$), resulted in an increase in effect size (*CDKAL1*: birth weight reduced by 36g [16–56g]; $P=0.0005$. *HHEX-IDE*: 29g [10–48g]; $P=0.003$), consistent with an opposing effect of maternal genotype on birth weight. There were no associations between the other variants and fetal growth ($P>0.05$).

Conclusion: Our data provide the first direct evidence for the fetal insulin hypothesis by showing that common T2D risk alleles in *CDKAL1* and *HHEX-IDE* can reduce birth weight through a predominant effect of fetal genotype. This contrasts with the predominantly maternal effect of *TCF7L2* and suggests that T2D risk loci have heterogeneous effects on fetal insulin secretion.

Extended analysis of genome-wide scans provides clues about novel common and rare susceptibility loci for type 2 diabetes

E. Zeggini¹, R. Lawrence¹, A.T. Hattersley², T.M. Frayling², the Wellcome Trust Case Control Consortium, K.S. Elliott¹, M.I. McCarthy¹

¹WTCHG, University of Oxford, United Kingdom, ²Institute of Biomedical and Clinical Science, Peninsula Medical School, Exeter, United Kingdom

Background and aims: Multiple new type 2 diabetes (T2D) susceptibility loci have been identified through genome-wide association (GWA) scans, but established associations account for only a small proportion of the genetic component of the disease. The established T2D loci *PPARG*, *KCNJ11*, *TCF7L2*, *HHEX/IDE*, *CDKN2A/B*, *CDKAL1*, *FTO*, *SLC30A8*, *IGF2BP2*, *TCF2* and *WFS1* have a cumulative sibling recurrence risk ratio (lambda-s) of 1.06. In European populations, the overall lambda-s for T2D has been estimated to be approximately 3. We have carried out a meta-analysis of 3 T2D GWA scans across 10,128 individuals of European descent and ~2.2 million SNPs (directly genotyped and imputed). Through replication testing in an independent set of samples (effective sample size of up to 53,975) we have detected at least six new loci with robust evidence for association ($p<5\times 10^{-8}$), and modest effect sizes (largest allelic odds ratio was 1.15).

Materials and methods: On the basis of replication sample allele frequencies and effect sizes, we calculated the individual lambda-s values for these novel loci to investigate the proportion of the genetic component of T2D that they explain. To assess the role of rare variants in T2D susceptibility, we have used a super-locus approach (explained below) to analyse markers with frequency <0.05 from the Wellcome Trust Case Control Consortium T2D GWA scan. To do this, we looked across all gene regions genome-wide (defined as 50kb either side of the gene transcriptional start and end sites). For each gene, we constructed a 2x2 table of the number of cases carrying at least one and the number of cases not carrying any rare variant minor alleles in the region, versus the number of controls carrying at least one or not carrying any rare variant alleles in the region. We tested for differences in the frequency with which cases carry at least one rare variant allele versus controls by the chi-squared test (or Fisher's exact test where required).

Results: The individual lambda-s values for the novel loci detected through meta-analysis are: 1.001 for *JAZF1*, 1.002 for *CDC123/CAMK1D*, 1.001 for *TSPAN8/LGR5*, 1.002 for *THADA*, 1.002 for *ADAMTS9* and 1.001 for *NOTCH2*. Together with the previously established 11 loci, their cumulative lambda-s is 1.07, assuming a log-additive model. Using the rare variant super-locus approach in the WTCCC data, we detected several loci with promising evidence for association ($p<0.00001$), for example within the *LOC391845* (1.4% of cases with at least one rare allele v. 0.2% of controls, $p=4\times 10^{-6}$) gene. They are being followed up by large-scale replication and deep resequencing studies.

Conclusion: The lambda-s values indicate that the known susceptibility variants account for only a small proportion of observed familial aggregation. Part of the explanation may relate to the fact that the variants causal for the observed associations have yet to be defined. However, it is also probable that there are many novel loci to be found, and that studies of the role of rare variants may prove a powerful approach for their discovery.

Background and aims: Dense-mapping (5290 SNPs) of the well-replicated chr1q type 2 diabetes (T2D) linkage region (147.0–169.7Mb) identified two promising association signals in samples of European descent. The first resides within the *NOS1AP* (*CAPON*) gene (e.g. rs7538490, OR 1.53 [95%CI 1.28–1.81], $p=1.2\times 10^{-6}$), and the second within an extensive linkage disequilibrium (LD) block that includes the *ASH1L* and *PKLR* genes (e.g. rs11264372, OR 1.35 [1.17–1.56], $p=5.1\times 10^{-5}$). The aim of this study was to explore these putative associations in further samples.

Materials and methods: We first examined genome-wide association data from the Wellcome Trust Case Control Consortium (WTCCC) T2D sample containing 1495 T2D cases (independent of those already typed by the 1q consortium) and 2938 controls of UK origin. We also genotyped rs7538490 in 2 further independent sets containing 2955 T2D cases and 3336 controls from the UK. We typed rs11264371 ($r^2=1.0$ with rs11264372) in 3441 T2D cases and 5334 controls.

Results: We found no evidence of association within the independent WTCCC sample for the *NOS1AP* signal (rs7538490, OR 0.98 [0.88–1.09] or the *ASH1L/PKLR* region (rs11264371, 1.04 [0.93–1.18]). The extended replication efforts in additional UK case-control sets also failed to demonstrate any detectable effect at either SNP. Meta-analysis of the combined replication sample showed no association at these two loci: rs7538490 OR 1.01 [0.95–1.08] for total 4934 T2D cases and 6789 controls; rs11264371 OR 1.03 [0.97–1.10] for 4351 T2D cases and 6100 controls.

Conclusion: Notwithstanding differences in ascertainment between the highly-selected cases used for the original high density association screen and those used for replication, we conclude that no convincing role in T2D susceptibility was observed for these SNPs in *NOS1AP* and around *ASH1L/PKLR* region. All in all, dense association mapping across the region, in large, well-powered samples has failed to identify common SNP variants that may be contributing to the replicated linkage signal. We are now testing the hypothesis that structural variants, and low frequency, intermediate penetrance SNPs may be causal for the observed linkage.

Studies of genome-wide association data support a genetic overlap between type 2 diabetes and prostate cancer

K.S. Elliott¹, E. Zeggini¹, N. Rayner¹, C. Groves^{1,2}, T. Frayling³, A. Hattersley³, Diabetes Genetics Replication and Meta-analysis (DIAGRAM) Consortium, M.I. McCarthy²

¹Wellcome Trust Centre for Human Genetics, University of Oxford, United Kingdom, ²Oxford Centre for Diabetes, Endocrinology and Metabolism, University of Oxford, United Kingdom, ³Institute of Biomedical and Clinical Science, Peninsular Medical School, Exeter, United Kingdom

Background and aims: Recent genome-wide association (GWA) studies have identified and confirmed many type 2 diabetes (T2D) susceptibility

genes. Several of these T2D loci (*PPARG*, *TCF7L2*, *CDKN2A*, *HHEX* and *IGF2BP2*) as well as some genes causal for monogenic diabetes have known roles in cancer pathogenesis. Association of T2D and prostate cancer at alternate alleles of the same variant in the *HNF1B* gene support a shared genetic aetiology between the two diseases. This is further supported by recent publications showing association with T2D and prostate cancer at separate unlinked variants in the *JAZF1* gene.

Materials and methods: To formally assess this genetic relationship we compared meta-analysed T2D GWA data from the Diabetes Genetics Replication And Meta-analysis (DIAGRAM) Consortium with publicly available GWA prostate cancer data from the Cancer Genetics Markers of Susceptibility (CGEMS) project. For SNPs where there was data available for both diseases ($n=393,763$), we looked SNP-by-SNP at the distribution of p -values above and below $p=0.01$ for T2D and prostate cancer. Second, we adopted a more targeted approach by looking for T2D and prostate cancer signals (defined by $p<0.001$) in gene regions containing confirmed T2D and prostate cancer variants.

Results: When we looked SNP-by-SNP, genome-wide, for evidence of association signals (defined by $p<0.01$) shared between T2D and prostate cancer, we found 73 instances representing 42 independent signals compared to an expectation of 8.3 independent signals under the null (binomial test $p<10^{-6}$). Of these 42 signals, 22 showed discordant and 20 showed concordant directions of association between the two diseases. When we focussed attention on regions already known to be implicated in disease risk (to improve power), we found a strong over-representation of prostate cancer association signals (defined by $p<0.001$) in the 17 regions known to harbour T2D susceptibility variants compared to all other autosomal genes for which data was available ($n=18,719$) (chi-squared test $p=3\times 10^{-8}$): in all, six of these regions (*CDKAL1*, *NOTCH2*, *CAMK1D*, *JAZF1*, *HNF1B* and *KCNJ11*) contained such a prostate cancer signal. In the reciprocal analysis, there were just the two known T2D signals (*HNF1B* and *JAZF1*) (defined by $p<0.001$) in the 10 confirmed prostate cancer gene regions (chi-squared test $p=0.102$). Since there is a greater chance of finding signals in large gene regions, we tested the relationship between confirmed disease genes and gene region size and found that the mean of confirmed disease gene region sizes fell between the 15th and 85th quantiles of 10,000 random permutations.

Conclusion: The non-random co-localisation of T2D and prostate cancer signals at the genome-wide level indicates undefined overlaps in aetiological mechanisms. When false positive associations are reduced by studying gene regions harbouring confirmed T2D or prostate cancer disease variants, the over-representation of prostate cancer signals in T2D gene regions strengthens the evidence of an overlapping genetic basis for T2D and prostate cancer.

The role of confirmed type 2 diabetes risk alleles on age-of-diagnosis in a Norwegian population based sample: the HUNT Study

S. Johansson¹, J.K. Hertel¹, K. Midthjell², A. Molven¹, P.R. Njølstad¹

¹Department of Clinical Medicine, University of Bergen, ²Department of Public Health and General Practise, Norwegian University of Science and Technology, Verdal, Norway

Background and aims: We and others have recently shown that the novel associated SNPs of the first wave of type 2 diabetes (T2D) whole-genome association scans are consistently replicated in many populations and under different study designs. It could be speculated that these risk alleles are associated with younger onset of diabetes due to a higher genetic load. Here, we explore the relationship between age-of-diagnosis and confirmed risk-associated SNPs close to the genes *IGFBP2*, *CDKAL1*, *SLC30A8*, *CDKN2B*, *HHEX* and *FTO*.

Materials and methods: 1449 patients with T2D and 1551 controls from the population-based HUNT-study in Norway were analysed for the six most consistently associated SNPs near *IGFBP2*, *CDKAL1*, *SLC30A8*, *CDKN2B*, *HHEX* and *FTO*. Logistic regression was used to compare the allele distribution between cases diagnosed at 35–59 years, cases diagnosed at the age of 60 and above, and all controls. Age-of-diagnosis was also studied as a quantitative trait. All analyses included BMI and gender as covariates.

Results: The risk allele at *HHEX* was associated with younger age of diagnosis ($p=0.06$), with a similar but weaker trend at *CDKN2B* and *FTO*. SNPs close to *CDKAL1* and *SLC30A8* were not differentially distributed in the two age groups. Interestingly, the *IGFBP2* risk allele at SNP rs4402960 may be associated with older age of diagnosis ($p=0.08$).

Conclusion: For three of the examined SNPs, our results are in line with the hypothesis of a higher genetic load in cases with younger onset of diabetes. However, our data on *IGFBP2* suggest that certain risk alleles may be more pronounced in cases with late-onset diabetes.

Genetic analysis of “European” type 2 diabetes SNPs from whole genome association studies in African Americans

D.W. Bowden¹, J.P. Lewis¹, N.D. Allred¹, C.D. Langefeldt², J. Divers², B.I. Freedman³

¹Center for Human Genomics, ²Public Health Sciences, ³Internal Medicine, Wake Forest University School of Medicine, Winston-Salem, United States

Several whole genome association (WGA) studies have identified type 2 diabetes mellitus (T2DM) susceptibility genes in European-derived populations. Little investigation of these loci has been reported in other ethnic groups, specifically African Americans (AAs). Differences exist between these populations for T2DM risk, suggesting they may not share identical genetic risk factors. Our objective was to examine the influence of T2DM genes identified in WGA studies in a large AA case-control population. SNPs in 12 loci (e.g. *TCF7L2*, *IDE/KIF11/HHEX*, *SLC30A8*, *CDKAL1*, *PKN2*, *IGF2BP2*, *FLJ39370*, and *EXT2/ALX4*) associated with T2DM in European-derived populations were genotyped in 993 T2DM AA cases and 1054 AA controls. In addition, 68 ancestry-informative markers (AIMs) were genotyped to account for the impact of admixture on association results. While power to detect association differed based on allele frequency and reported odds ratios, power analyses suggested evidence for association would be observed in 4–5 loci. With the exception of *TCF7L2*, little evidence of association with T2DM in AAs was observed. One *TCF7L2* SNP (rs7903146) showed compelling evidence of association with T2DM [admixture adjusted $P=1.59\times 10^{-6}$, additive model, OR=1.37 (1.31–1.43)]. The only other SNP with nominal evidence of association after admixture adjustment was the intragenic SNP rs9300039 [$P=0.029$, dominant model, OR=1.48 (1.28–1.71)]. Interestingly, 4 of the SNPs are monomorphic in the Yoruba population of the HAPMAP project with only the “risk” allele from the populations of European descent observed. We conclude that, except for *TCF7L2*, “European” T2DM variants do not significantly contribute to inter-individual susceptibility to T2DM in AAs. Consequently, genes contributing to T2DM in AAs and other peoples of African origin may, in part, be different from those in European-derived populations. The high frequency of risk alleles in several of these genes may, however, contribute to the increased prevalence of T2DM in AAs.

HNF4 α directs histone methylation to silence PED/PEA-15 expression in human hepatocytes

R. Teperino, R. Valentino, M. Ciccarelli, A. Perfetti, A.T. Alberobello, F. Giacco, R. Buonomo, P. Formisano, F. Beguinot, P. Ungaro
Dipartimento di Biologia e Patologia Cellulare e Molecolare & IEOS-CNR, Università Di Napoli, Italy

Background and aims: PED/PEA-15 is a gene commonly overexpressed in tissues from type 2 diabetic individuals and healthy subjects at high risk of developing diabetes (such as first degree relatives). Indeed, overexpression of the PED/PEA-15 gene in mice, impairs glucose tolerance and leads to diabetes in conjunction with high-fat diet treatment. The Hepatocyte Nuclear Factor 4 α (HNF-4 α) is a liver-enriched nuclear receptor involved in the control of glucose homeostasis. Point mutations in HNF-4 α impair liver and pancreatic regulation of glucose homeostasis and cause Maturity Onset Diabetes of the Young Type 1 (MODY 1). More recently, genetic and biochemical evidences indicate that HNF-4 α may also play a role in the development of Type 2 Diabetes.

Recent evidences in our lab, indicate that HNF-4 α inhibits PED/PEA-15 expression in liver by binding its responsive element on PED/PEA-15 promoter. The aim of our work is to understand the molecular mechanism by which HNF-4 α exerts its action on PED/PEA-15 expression and test the hypothesis that HNF-4 α might induce a packaging of chromatin in the region of PED/PEA-15 promoter.

Materials and methods: Hela and HepG2 cells are used in this study. A bioinformatic analysis has been performed using the software RECON to map potential nucleosomes on the core-promoter of PED/PEA-15, and Micrococcal Nuclease (MNase) Protection Assay has been used to further confirm “in silico” data. Chromatin Immunoprecipitation (ChIP) and ReChIP Assays have been performed to identify histone marks and histone-associated proteins.

Results: Our work show the fundamental role of HNF-4 α in directing nucleosome assembly and histone methylation to maintain PED/PEA-15 gene repression in HepG2 cells. This data has been further confirmed in Hela cells overexpressing HNF-4 α (Hela-HNF). Indeed, both in Hela-HNF and HepG2 cells HNF-4 α expression promotes the assembly of histone deacetylase (HDAC), as well as histone methyl transferase (HMT) complexes on the PED/PEA-15 promoter and leads to the di-methylation of Lysine 9 on histone H3. Furthermore, HNF-4 α interacts with and recruits SMRT (Silencing Mediator of Retinoic Acid and Thyroid Hormone Receptor) corepressor to PED/PEA-15 promoter leading the associated chromatin to condense. These modifications are barely undetectable in both Hela and HepG2 cells transfected with a HNF-4 α specific shRNA plasmid where HNF-4 α is expressed at low levels.

Conclusion: These results suggest that HNF-4 α functions as a scaffold protein for both histone deacetylase and histone methyl transferase activities to inhibit PED/PEA-15 transcription, thus representing a new potential molecular tool to target PED/PEA-15 expression. Further *in vivo* studies should be done to determine whether HNF-4 α may act via chromatin remodeling even *in vivo* and whether alterations of this mechanism might play a role in the overexpression of PED/PEA-15 gene observed in type 2 diabetic patients and their healthy first degree relatives.

PGC-1 α and PGC-1 β are related to markers for fibre type composition in human skeletal muscle

A.H. Olsson¹, T. Rönn¹, A. Vaag², L. Groop¹, P. Poulsen², C. Ling¹

¹Clinical Sciences, Diabetes and Endocrinology, Lund University, Malmö, Sweden, ²Steno Diabetes Center, Gentofte, Denmark

Background and aims: Human skeletal muscle contains three major fibre types distinguished by their myosin heavy chain (MHC) isoforms. The mitochondria content and oxidative capacity is the highest in slow oxidative type I fibres, lower in fast oxidative type IIa fibres, and lowest in fast glycolytic type IIx/d fibres. The amount of oxidative type I fibres is reduced and glycolytic type IIx/d fibres is increased in muscle from patients with type 2 diabetes (T2D) and subjects with a family history of T2D. The transcriptional co-acti-

vators PGC-1 α and PGC-1 β are both implicated in the formation of oxidative fibres in skeletal muscle and are down-regulated in diabetic muscle. The aim of the present study was to investigate factors influencing the expression of markers for fibre type composition in human skeletal muscle of twins.

Materials and methods: mRNA expression of three fibre type markers; MHC7 (slow oxidative), MHCIIa (fast oxidative) and MHCIIx/d (fast glycolytic), were analysed in muscle biopsies from young (n=102) and elderly (n=81) non-diabetic twins and related to the level of PGC-1 α and PGC-1 β mRNA. Single nucleotide polymorphisms (SNPs) in the three MHC gene regions (10 SNPs in MHC7, 5 SNPs in MHCIIa and 5 SNPs in MHCIIx/d) were genotyped and related to gene expression.

Results: While MHCIIa mRNA expression was reduced in skeletal muscle from elderly compared with young twins (1.07 ± 0.07 versus 1.50 ± 0.07 ; $p < 0.001$), the expression of MHC7 and MHCIIx/d did not change with age. Regression analysis showed that PGC-1 α was positively related to the expression of all three fibre type markers in human muscle ($p < 0.01$). However, PGC-1 β was positively related to MHCIIa and negatively related to MHCIIx/d expression ($p < 0.05$). One SNP, rs17794387, showed a nominal association to MHC7 expression ($p < 0.05$) and another SNP, rs3764851, to MHCIIx/d expression ($p = 0.014$) in muscle of twins. The level of MHC7 was positively related to $\dot{V}O_2\text{max}$ ($p = 0.009$) and MHCIIa expression was positively related to insulin-stimulated glucose uptake ($p = 0.008$). Furthermore, MHCIIx/d mRNA expression was negatively related to both insulin-stimulated glucose uptake ($p = 0.04$) and $\dot{V}O_2\text{max}$ ($p < 0.0001$).

Conclusion: Age and PGC-1 α and β , are associated with the expression level of markers for fibre type composition in human skeletal muscle. Furthermore, these fibre type markers are related to $\dot{V}O_2\text{max}$ and insulin-stimulated glucose uptake.

Association of APLN (Encoding Apelin) variants with type 2 diabetes in Chinese Han population

C. Wang, R. Zhang, C. Hu, X. Ma, W. Jia, K. Xiang

Endocrinology & Metabolism, Shanghai Jiaotong University affiliated No.6 People Hospital, Shanghai Diabetes Institute, Shanghai, China

Background and aims: Adipocyte-derived cytokines have been recognized to be involved in body fat distribution, insulin sensitivity and contribute to the etiology of type 2 diabetes, obesity, and metabolic syndrome. Recent studies showed that apelin is one of the newly adipokines that is highly expressed in white adipose tissue. Apelin expression was up-regulated in obese mice with hyperinsulinemia, and the plasma apelin level was dramatically high in obese subjects and diabetic patients. Thus, we hypothesized that genetic variants in the APLN gene (encoding apelin) may associated with susceptibility to type 2 diabetes.

Materials and methods: The APLN gene is located on chromosome Xq25-q26.3. We examined the relationship between APLN variation and type 2 diabetes (selecting four tagging SNPs capturing > 80% common variation) in a total of 3,700 Chinese Han subjects (1,892 hospital cases [age 61.2 ± 12.6 years, 52.2% male] and 1,808 community-based control subjects with normal glucose regulation [age 57.3 ± 12.3 years, 41.4% male]) using Sequenom MassARRAY system. Association was measured using either χ^2 or Fisher's exact test. Furthermore, cases and controls were stratified by gender respectively and association was measured for each group.

Results: After quality control steps, allele and genotype (in females) frequencies of three SNPs (rs3115759, rs2235307 and rs2281068) were compared in 1,775 type 2 diabetes cases and 1,807 control subjects. None of the SNPs showed an association with type 2 diabetes (rs3115759: G allele 32.3% in case, 32.2% in controls, $P = 0.95$; rs2235307: T allele 18.9% in cases, 18.6% in controls, $P = 0.83$; rs2281068: T allele 32.5% in cases, 31.8% in controls, $P = 0.59$). Similarly, no evidence showed association of APLN variants with type 2 diabetes in both female and male groups.

Conclusion: Although apelin presents itself as a good candidate for contributing to type 2 diabetes susceptibility, this study has failed to find an association between SNPs in the APLN gene region and type 2 diabetes in Chinese. Supported by: Major Project of National Natural Science Foundation of China and National Basic Research Program of China

Effect of adiponectin gene polymorphisms on circulating total and high-molecular weight adiponectin and insulin resistance in non-diabetic Greek womenL. Melistas¹, C.S. Mantzoros², M. Kontogianni¹, J.M. Ordovas³, N. Yiannakouris¹¹Nutrition-Dietetics, Harokopio University of Athens, Athens, Greece,²Division of Endocrinology, Beth Israel Deaconess Medical Center,Harvard Medical School, Boston, United States, ³Nutrition and Genomics Laboratory, JM-USDA–HNRCA at Tufts University, Boston, United States

Background and aims: Adiponectin is an adipokine that modulates insulin sensitivity and whose low circulating concentration is associated with insulin resistance. Recent studies have demonstrated that the high-molecular weight (HMW) multimer of adiponectin is the active form of the hormone. In the present study, we assessed whether adiponectin gene variants contribute to circulating total and HMW adiponectin, insulin resistance (IR), or cardiovascular disease risk factors in a healthy Greek women population.

Materials and methods: A total of 349 Greek non-diabetic women (mean age: 47.0 ± 12.1 y, mean BMI: 29.5 ± 5.6 kg/m²) were genotyped for two single nucleotide polymorphisms (SNPs) in the adiponectin gene [45T>G (rs2241766) and 276G>T (rs1501299)]. Body composition was assessed in all subjects with dual X-ray absorptiometry (DXA) and fasting plasma glucose, lipid, lipoprotein and apolipoprotein (apo) B and A1 levels were determined. Plasma insulin and adiponectin concentrations were measured by RIA. Plasma levels of HMW adiponectin were determined in a subgroup of study participants (n=211) by ELISA. IR was estimated with the homeostasis model assessment (HOMA). Polymorphisms were genotyped with TaqMan SNP allelic discrimination.

Results: Multiple regression analysis showed that total and HMW adiponectin were significantly negatively correlated with BMI, body fat, waist circumference, waist-to-hip ratio, fasting triglyceride, insulin levels, as well as HOMA-IR, and positively with HDL cholesterol and apoA1 levels (all $P < 0.001$). Total and HMW adiponectin concentrations were not significantly different across genotypes for the two SNPs. In addition, no association was found between the two SNPs and BMI, body composition variables and plasma lipid levels. However, in multivariate analysis controlling for potential confounders SNP 276G>T was associated with higher fasting insulin levels ($P=0.01$) and HOMA-IR index ($P=0.009$), and SNP 45T>G exhibited a tendency towards association with lower insulin levels and HOMA-IR ($P=0.05$ and $P=0.07$, respectively). To analyze the possible interaction between body fat and the adiponectin gene SNPs on insulin resistance the study group was divided into two subgroups according to the percentage of body fat (below or above the median of 41.0%). We found that in the highest body fat group (>41%) carriers of the minor +45G and +276T alleles had lower (2.63 ± 1.42 vs. 2.11 ± 1.19 ; $P=0.005$) and higher (2.24 ± 1.10 vs. 2.84 ± 1.60 ; $P=0.002$) HOMA-IR, respectively, whereas no significant differences were observed among leaner individuals (P for interaction <0.05). Haplotype analysis revealed that subjects homozygous for the 45T/276G haplotype had lower total adiponectin levels than did non-carriers of this haplotype (13.71 ± 7.12 vs. 16.40 ± 6.68 µg/ml; $P=0.05$).

Conclusion: The current study shows that SNPs 45T>G and 276G>T in the adiponectin gene are significantly associated with insulin resistance in non-diabetic Greek women with high body fat levels. However, no association was found between these two SNPs and body composition parameters, lipid profile, or with circulating total and HMW adiponectin concentrations.

A Mendelian randomisation study provides initial evidence that sex hormone binding globulin (SHBG) levels alter type 2 diabetes riskJ.R.B. Perry¹, D. Melzer², M. Maggio³, D. Hernandez⁴, A. Singleton⁴, L. Ferrucci⁵, C. Palmer⁶, A. Bennett⁷, A. Ruokonen⁸, V. Panicker⁹, M.-R. Jarvelin¹⁰, A. Hattersley¹, M. McCarthy⁷, T. Frayling¹

¹Genetics of Complex Traits, Peninsula Medical School, Exeter, United Kingdom, ²Epidemiology and Public Health, Peninsula Medical School, Exeter, United Kingdom, ³National Institutes of Health, National Institute on Aging, Baltimore, United States, ⁴Laboratory of Neurogenetics, National Institute of Aging, Bethesda, United States, ⁵Longitudinal Studies Section, National Institute on Aging, Baltimore, United States, ⁶Biomedical Research Centre, University of Dundee, United Kingdom, ⁷Oxford Centre for Diabetes, Endocrinology and Metabolism, University of Oxford, Oxford, United Kingdom, ⁸Public Health Science and General Practice, University of Oulu, Finland, ⁹Henry Wellcome Laboratories for Integrative Neuroscience and Endocrinology, University of Bristol, United Kingdom, ¹⁰Public Health and Primary Care, Imperial College London, London, United Kingdom

Background and aims: Sex hormone binding globulin (SHBG) levels are inversely correlated with type 2 diabetes and insulin resistance but the causal direction of this association is not known. SHBG levels may be altered because they influence type 2 diabetes risk or because they are secondary to disease processes. Genetics can help dissect the causal direction of this association using a Mendelian Randomization approach. If gene variants that increase SHBG levels also decrease type 2 diabetes risk this provides evidence of a protective role of SHBG.

Materials and methods: We performed a genome wide association study for SHBG levels using 1200 individuals from the population based InCHIANTI study. Two studies with SHBG levels measured, the WATTS study (n=546) and Northern Finland 1966 Birth Cohort (N=4044), were used to replicate findings. We tested the association of variants altering SHBG levels with type 2 diabetes using inverse-variance weighted meta-analysis of a type 2 diabetes case control study of 12,643 UK individuals.

Results: In the InCHIANTI study, a one standard deviation (SD) increase in SHBG levels is correlated with type 2 diabetes: odds ratio: 0.73 (0.59–0.89), $p=0.002$. We identified a variant (rs1799941) near the SHBG gene associated with a per allele difference of 0.21 SDs in SHBG levels ($p=3 \times 10^{-5}$) in the InCHIANTI population. The association replicated ($p=1.4 \times 10^{-12}$) and meta-analysis of all three studies provided very strong evidence of association ($p=1.8 \times 10^{-16}$). In InCHIANTI the SNP was also associated with free testosterone levels ($p=0.01$) and ratio of total testosterone/SHBG ($p=0.003$) in males but not females. The SHBG allele associated with increasing SHBG levels was associated with a reduced risk of type 2 diabetes with an odds ratio of 0.90 (95% CIs: 0.85–0.96, $p=0.0009$). This is consistent with the expected effect given the rs1799941-SHBG and SHBG-T2D correlations. There was a trend towards this association being stronger in males 0.88 (95% CIs: 0.81–0.95, $p=0.002$, N=6747) than females 0.94 (95% CIs: 0.86–1.02, $p=0.16$, N=5896) but this difference was not significant.

Conclusion: Although additional data is needed to confirm the association our study suggests that SHBG is causally influencing the risk of type 2 diabetes.

Impact of the transcription factor 7like 2 polymorphism (TCF7L2) on insulin secretion and action before and after physical inactivityA.C. Alibegovic¹, L. Hojbjerg², M.P. Sonne², O. Pedersen³, T. Hansen³, B. Stallknecht², F. Dela², A. Vaag¹

¹810, Steno Diabetes Center, Gentofte, Denmark, ²4, University of Copenhagen, Copenhagen, Denmark, ³521, Steno Diabetes Center, Gentofte, Denmark

Background and aims: Physical inactivity is a risk factor for type 2 diabetes (T2D). However, little is known about the extent to which physical inactivity is more harmful to some persons than to others. Common genetic variants encoding the TCF7L2 polymorphism have been associated with impaired beta-cell function and T2D. The purpose of this study was to examine whether the diabetes risk TCF7L2 rs-7903146 T-allele modulates changes in insulin secretion and whole body insulin sensitivity following ten days of bed rest (BR).

Materials and methods: 38 healthy young Caucasian men completed the study. Subjects were recruited from a cohort of young men with low (LBW) and normal birth weight (< 10 and between 50–90 percentiles, respectively). 21 subjects were carriers of the T2D risk T allele (combined CT and TT alleles) and 17 subjects were low risk CC homozygous. No impact of - or association between - birth weight and genotype were observed, and number of LBW subjects were 10 in the CC and 11 in CT/TT group, respectively. Insulin secretion and insulin action was studied before and after ten days of BR by intra venous glucose tolerance tests combined with euglycemic hyperinsulinemic clamps (3 hours, insulin infusion rate 80mU/m²/min). The TCF7L2 rs7903146 was genotyped using allelic discrimination performed with an ABI 7900 system (KBioscience, Herts, UK). The genotyping success rate was 98% and among 38 replicate samples no mismatches were observed. The genotype distribution obeyed Hardy-Weinberg equilibrium.

Results: No significant differences in BMI, waist-hip ratio, age, fasting plasma insulin or insulin action were observed in the two groups prior to BR. However, first phase insulin secretion (FPIS) and FPIS disposition index (FPIS x M-value; FPIS-Di) were significantly lower in CT/TT group: 1559 ± 290 vs. 2122 ± 355 pmol/L/min ($P < 0.05$) and 21929 ± 4462 vs. 30409 ± 5386 mg glucose/kg lean body mass (LBM) ($P < 0.05$) compared to CC group prior BR. After BR, CT/TT group demonstrated significantly lower FP insulin levels 29 ± 2 vs. 47 ± 7 pmol/L ($P < 0.05$) as well as FPIS 2108 ± 299 vs. 3503 ± 405 pmol/L/min ($P < 0.001$), and FPIS-Di 23963 ± 3720 vs. 34289 ± 4574 mg glucose/kg LBM ($P < 0.05$) compared with CC group. The increment in FPIS in response to BR was significantly lower in CT/TT group compared with CC group 555 ± 121 vs. 1381 ± 396 pmol/L/min ($P < 0.05$). Although insulin action decreased in all subjects in response to BR, CT/TT group tended to be more insulin sensitive after BR as compared with CC group as determined by Homeostasis-Model-Assessment (HOMA) index, 6.1 ± 0.6 vs. 9.6 ± 1.4 ($P < 0.05$), and to some extent clamp M-value 11 ± 0.4 vs. 10 ± 0.6 mg glucose/kg LBM/min ($P > 0.05$).

Conclusion: Young healthy carriers of the diabetes risk TCF7L2 rs-7903146 T-allele exhibit a diminished compensatory increase in first phase insulin secretion during 10 days of BR indicating a greater vulnerability to physical inactivity.

Human natriuretic peptides genes are strongly associated with the risk for hyperglycaemia in a French population: the D.E.S.I.R. study
S. Maimaitiming^{1,2}, R. Roussel^{1,2}, F. Fumeron^{1,2}, N. Emery², G. Velho¹, K. Mohammadi^{1,2}, N. Munoz¹, B. Balkau^{3,4}, J. Tichet⁵, M. Marre^{1,2}

¹Faculty of Medicine Xavier Bichat, INSERM U 695, Paris, France, ²Faculty of Medicine Xavier Bichat, University Denis Diderot, Paris, France,

³INSERM, U780-IFR69, Villejuif, France, ⁴Faculty of Medicine, University Paris-Sud, Orsay, France, ⁵Institut Régional Pour la santé, IRSA, La Riche, France

Background and aims: Natriuretic peptides induce lipolysis and may play a role in metabolic diseases. We studied the associations of several polymorphisms and haplotypes of the very close ANP and BNP genes (chr.1p36.2) with type 2 diabetes and impaired fasting glucose (T2D/IFG) in the DESIR study, a general population based cohort with a 9 year follow-up.

Materials and methods: 5,212 subjects were included. Four Hapmap selected tag-SNPs (3 in BNP gene, rs198381/rs198389/rs198388 and 1 in ANP gene, rs5065) were genotyped (Taqman). Plasma BNP levels were measured in a random sample of 369 subjects (IRMA). We tested the association between the genetic variations and the metabolic parameters with ANOVA and ANCOVA, the impact of genetic variations and the incidence of T2D/IFG (566 new cases) with logistic regression and haplotype analysis with THESIAS program. When appropriate, tests were adjusted for sex, age and BMI.

Results: Subjects with rs198381 CC genotype had higher fasting glucose levels (TT 5.35 ± 0.01 mmol/l, TC 5.38 ± 0.02 and CC 5.57 ± 0.08, $p = 0.005$), insulinemia (TT 47.1 ± 0.4 pmol/l, TC 46.5 ± 0.8 and CC 54.2 ± 2.6, $p = 0.001$) and HOMA-IR (TT 1.67 ± 0.02, TC 1.65 ± 0.03 and CC 2.05 ± 0.11, $p = 0.0001$). The minor allele of rs198381, rs198388 and rs5065 were associated with higher prevalence (co-dominant model: OR=1.31, $p = 0.0004$; OR=1.18, $p = 0.004$ and OR=1.29, $p = 0.0003$, respectively) and incidence (OR=1.22, $p = 0.02$; OR=1.18, $p = 0.04$ and OR=1.20, $p = 0.03$, respectively) of T2D/IFG. Six haplotypes described 98% of genetic variation. Compared to TTGT, the most frequent haplotype (55% frequency), CCAT, TCAC and TTAC were associated with a higher risk of T2D/IFG (OR=1.86, $p = 0.00001$; OR=1.66, $p = 0.01$ and OR=2.22, $p = 0.0001$, respectively). The rs198381 C allele was associated with higher BNP concentrations (TT 5.44 ± 0.45 pg/ml, TC 6.94 ±

0.92 and CC 8.36 ± 1.28, $p = 0.03$). The haplotype CCAC had higher plasma BNP concentrations ($p = 0.04$) compared to TTGT. In order to replicate this association, we selected the normoglycemic subjects from the DESIR study as controls ($n = 3,065$) and the T2D subjects from a cardiovascular trial in diabetes, the DIABHYCAR study ($n = 3,160$) as cases. The rare alleles of rs198388 and rs5065 were associated with higher risk of T2D (OR=1.19, $p = 0.01$ and OR=1.44, $p = 0.005$, respectively). Haplotype analysis confirmed this association. The haplotypes TCAC and TTAC were associated with a higher risk of T2D (OR=1.71, $p = 0.02$ and OR=2.52, $p = 0.0002$, respectively).

Conclusion: These results suggest a role of natriuretic peptides genes in the pathophysiology of T2D, possibly through BNP circulating levels and insulin resistance.

Genetic variation in ATP5O is associated with mRNA expression in human skeletal muscle and *in vivo* glucose uptake

T.S. Rönn¹, P. Poulsen², L. Groop¹, A. Vaag², C. Ling¹

¹Diabetes and Endocrinology, Clinical Sciences, Lund University, Malmö, Sweden, ²Steno Diabetes Center, Gentofte, Denmark

Background and aims: Impaired oxidative capacity of the mitochondria in skeletal muscle has been suggested to contribute to insulin resistance and type 2 diabetes (T2D). Furthermore, mRNA expression of genes involved in oxidative phosphorylation, including the nuclear encoded ATP5O, is reduced in skeletal muscle from patients with T2D. However, the cause of this reduction in ATP5O mRNA level remains unknown. ATP5O is located in the stalk of the ATP synthase complex connecting the catalytic core and the membrane proton channel, thereby influencing conformational changes and proton conductance. We aimed to investigate 1) mechanisms regulating ATP5O expression in skeletal muscle and the association to *in vivo* measures of glucose metabolism, and 2) association between ATP5O single nucleotide polymorphisms (SNPs) and risk of T2D.

Materials and methods: ATP5O mRNA expression was analysed in skeletal muscle biopsies from young ($n = 86$) and elderly ($n = 68$) non-diabetic twins taken before and after a hyperinsulinaemic euglycaemic clamp. 11 SNPs from the ATP5O locus were genotyped in the twins and in a T2D case control cohort ($n = 1466$). DNA methylation of one region of the ATP5O promoter was analysed in a subset of twins (11 young and 11 elderly) using bisulfite sequencing.

Results: The mRNA level of ATP5O in skeletal muscle was reduced in elderly compared with young twins, both in the basal (0.19 ± 0.01 versus 0.28 ± 0.01 ; $P < 0.0005$) and insulin-stimulated (0.21 ± 0.01 versus 0.30 ± 0.01 ; $P < 0.0005$) state. Two SNPs influenced the expression of ATP5O of the young twins (rs12482697: T/T ($n = 65$) 0.30 ± 0.010 versus T/G ($n = 16$) 0.25 ± 0.012 ; $P = 0.02$ and rs11088262: A/A ($n = 70$) 0.31 ± 0.012 versus A/G ($n = 16$) 0.25 ± 0.011 ; $P = 0.004$) during the clamp. A multivariate regression analysis showed that ATP5O expression in skeletal muscle was positively related to insulin-stimulated PGC-1 α expression ($P < 0.0001$) and inversely related to age ($P < 0.0001$) and female sex ($P < 0.003$). The degree of DNA methylation around the transcription start of ATP5O was low - and similar - in young ($0.14\% \pm 0.07$) and elderly ($0.73\% \pm 0.03$) twins, and ATP5O DNA methylation was not associated to mRNA expression ($r = 0.24$; $P = 0.32$). The mRNA level of ATP5O in young and elderly twins ($n = 155$) was positively related to insulin stimulated glucose uptake (regression coefficient = 6.6; $P = 0.02$). In addition, the 2 SNPs influencing the expression level of ATP5O in skeletal muscle of the young twins were also associated with glucose uptake (rs12482697: T/T ($n = 79$) 12.1 ± 0.36 versus T/G ($n = 18$) 9.8 ± 0.75 ; $P = 0.005$ and rs11088262: A/A ($n = 85$) 12.2 ± 0.4 versus A/G ($n = 18$) 9.8 ± 0.5 ; $P = 0.002$, respectively). We could not detect any association between SNPs in the ATP5O region and T2D.

Conclusion: ATP5O mRNA expression in human skeletal muscle is regulated by age, common polymorphisms, and PGC-1 α expression, and is associated to peripheral insulin sensitivity.

Decreased insulin secretion and increased risk of type 2 diabetes associated with allelic variations of the WFS1 gene encoding wolframin. The DESIR prospective study

N. Cheurfa¹, G.M. Brenner¹, D.A.F. Ferrarezi¹, A.F. Reis², J. Tichet³, B. Balkau⁴, F. Fumeron^{1,5}, M. Marre^{1,5}, G. Velho¹

¹Unité 695, INSERM, Paris, France, ²Laboratory of Molecular Endocrinology, Federal University of Sao Paulo, Brazil, ³IRSA, Institut Inter Régional pour la Santé, La Riche, France, ⁴Unité 780 - IFR69, INSERM, Villejuif, France, ⁵Faculté de Médecine Xavier Bichat, Université Denis Diderot, Paris, France

Background and aims: Mutations in the gene encoding wolframin (WFS1), an endoplasmic reticulum membrane protein, are responsible for Wolfram syndrome, a rare, recessive disorder characterised by diabetes mellitus, optic atrophy and other neurological and endocrinological abnormalities. Recently, common variants of WFS1 were shown to be associated with type 2 diabetes in cross-sectional studies. In the present study, we investigated associations of allelic variations in the WFS1 gene with insulin secretion, insulin sensitivity and the risk for type 2 diabetes in a 9 year prospective study.

Materials and methods: We studied 3962 unrelated French subjects from the general population who completed the 9 year protocol of the prospective DESIR study. Prevalence of impaired fasting glucose (IFG) and diabetes mellitus (DM) at baseline was 6.7% (n=264) and 3.4% (n=134), respectively. During follow-up, 296 new cases of IFG and 203 new cases of DM were detected. Additional cross-sectional analyses were performed with 2980 French Caucasian type 2 diabetic patients from the DIABHYCAR cohort. Two SNPs were genotyped using Assay by Design kits from Applied Biosystems: rs7672995 (G>C, R228R, exon 6) and rs734312 (A>G, H611R, exon 8). All statistics were adjusted for sex, age and BMI.

Results: Cox proportional hazards survival regression analyses showed an association of the major G-allele of R228R variant (exon 6) with the incidence of DM (hazard ratio of 1.43, 95% C.I. 1.09–1.48, $p=0.008$ for a recessive model) or the combined incidence of IFG and DM (hazard ratio of 1.13, 95% C.I. 1.01–1.28, $p=0.05$) in the follow-up of DESIR. An association was also observed with the total prevalence of IFG/DM at the end of the study (baseline plus incident cases) assessed by logistic regression analyses (odds ratio of 1.35, 95% C.I. 1.03–1.78, $p=0.03$ for a recessive model). Insulin secretion assessed at baseline in normoglycaemic subjects who developed IFG or DM during the study was decreased in carriers of the at risk G-allele: HOMA%B $68\pm 30\%$ (GG), $71\pm 31\%$ (GC) and $74\pm 30\%$ (CC; $m\pm SD$; $p=0.02$ for log-transformed data). Insulin sensitivity (HOMA%S) was not different in carriers of the three genotypes. Similarly, the major A-allele of the H611R variant (exon 8) was associated with decreased insulin secretion at baseline and increased risk of DM (incidence and total prevalence). Cross-sectional analyses of combined DESIR and DIABHYCAR cohorts confirmed the at risk effect on diabetes of R228R G-allele (odds ratio of 1.38, 95% C.I. 1.12–1.68, $p=0.002$), H611R A-allele (odds ratio of 1.25, 95% C.I. 1.06–1.46, $p=0.007$) and the G/A haplotype (frequency of 0.532 vs. 0.563 in normoglycaemic and diabetic subjects; odds ratio of 1.18, 95% C.I. 1.05–1.29, $p=0.008$).

Conclusion: Allelic variations in the WFS1 gene modulated insulin secretion in normoglycaemic subjects at risk of developing type 2 diabetes, and increased the risk of type 2 diabetes in a 9 year prospective study. In our study, the most frequent haplotype in French Caucasians at the haplotype block containing the WFS1 gene was associated with increased risk of diabetes.

314

Relative importance of early insulin response and insulin sensitivity, corrected for measurement errors, on type 2 diabetes and HbA_{1c}. Cross-sectional and 12 year follow-up studies

L.G.T. Berglund^{1,2}, C. Berne³, K. Svärdsudd⁴, H. Garmo¹, B. Zethelius²

¹Uppsala Clinical Research Center, ²Uppsala University, Department of Public Health/Geriatrics, ³Uppsala University, Department of Medical Sciences, ⁴Uppsala University, Department of Public Health/Family Medicine and Clinical Epidemiology, Sweden

Background and aims: In epidemiological studies the effects of impairments of insulin sensitivity and early insulin response on progression to type 2 dia-

betes have not been independent of each other and the effect of the former variable has been considered the largest in bivariate models. Our hypothesis was that the effect of early insulin response has been underestimated due to low reliability.

Materials and methods: We used data from 1130 men in a population-based study and a reliability study where 17 men made a replicate measurement 4 to 6 weeks after the first measurement. The relations between response variables fasting and 2 hour glucose from an oral glucose tolerance test (OGTT) at baseline (age 70), fasting glucose and HbA_{1c} at a seven and twelve years follow-up, prevalent type 2 diabetes at baseline and incident type 2 diabetes over seven and twelve years of follow-up, and the predictors insulin sensitivity index (M/I) from an euglycaemic insulin clamp, and early insulin response at an OGTT, were estimated using linear and logistic regression models, when measurement errors of both predictors were taken into account. Confidence intervals for the effects of the predictors and their difference were assessed with the bootstrap method.

Results: The effects of insulin sensitivity index and early insulin response at age 70 on fasting glucose at age 82 were strengthened by 6.1 % and 24.5 % ($p=0.13$), respectively, and on HbA_{1c} at age 82 the effects were strengthened by 1.1 % and 30.4 % ($p<0.001$), respectively, when corrected for measurement errors. In the corrected models the greater strengthening of early insulin response made the effects of insulin sensitivity index and early insulin response on the response variables to be essentially similar for fasting glucose but for HbA_{1c} the relative importance of early insulin response was found to be higher as compared to insulin sensitivity index ($p=0.03$). Results were similar for the other response variables.

Conclusion: The results imply that the etiological effect of early insulin response has been underestimated to a greater extent due to low reliability as compared to insulin sensitivity. Our results suggest that reliability should be considered for the design of intervention studies and preventive studies.

315

SLC2A2 gene polymorphisms and human beta cell function

S. Del Guerra¹, R. Lupi¹, M. Bugliani¹, S. Torri¹, M. Galli¹, V. D'Aleo¹, S. Del Prato¹, S. Del Prato¹, U. Boggi², F. Filippini², P. Marchetti¹

¹Endocrinology and Metabolism - Metabolic Unit, University of Pisa,

²Department of Oncology, Transplantation and Advanced Technologies in Medicine, University of Pisa, Italy

Background and aims: An association between single nucleotide polymorphisms (SNPs) in SLC2A2, the gene encoding glucose transporter 2 (GLUT2), and type 2 diabetes has been reported.

Materials and methods: To evaluate some features of islets (HI) from subjects with the rs5393 and/or rs5394 SNPs, we prepared HI from the pancreas of non-diabetic (ND) and type 2 diabetic (T2D) organ donors, matched for age and body mass index. HI were isolated by collagenase digestion and density gradient purification; SNPs were identified by the TaqMan Allelic Discrimination Assay (Applied Biosystem); insulin secretion was measured in response to acute (45 min) exposure to 3.3 and 16.7 mmol/l glucose; SLC2A2 mRNA expression was assessed by quantitative RT-PCR.

Results: Subjects carrying the rs5393 or rs5394 polymorphism were respectively 50 and 20% in ND, and 40 and 45% in T2D. Both polymorphisms were present in 5 and 30% of ND and T2D respectively ($p=0.05$ by the chi-square test). Glucose-stimulated (16.7 mmol/l) insulin release (GSIR) was lower in T2D than ND (0.045 ± 0.022 vs 0.168 ± 0.112 μU /islet/min, $p<0.01$), which was accompanied by reduced stimulation index (SI, 1.54 ± 0.62 vs 3.77 ± 1.95 , $p<0.01$). Both in ND and T2DM, GSIR was ~ 40% lower when the rs5394 SNP was present, either alone or in combination with rs5393. This led to a statistically ($p<0.05$) higher percentage of patients with SI below the median value in the presence of rs5394 (76.9%) than in its absence (22.7%). The presence of the rs5393/5394 polymorphisms was in addition associated with a ~ 40% reduction of GLUT2 gene mRNA expression.

Conclusion: The combined presence of rs5393/5394 polymorphisms of GLUT2 gene was more frequent in T2D than ND in the present series; rs5394 appeared to be associated with decreased glucose stimulated insulin release; the SLC2A2 gene polymorphisms were accompanied by a ~ 40% reduction of SLC2A2 mRNA.

316

CDKAL1 is associated with increased risk for type 2 diabetes and beta cell dysfunction: joint analyses of the Singapore National Health Survey 1998 and the Singapore Diabetes Cohort StudyD.P.K. Ng¹, M. Tan², S. Ye¹, S. Nurbaya¹, D. Koh¹, W. Kon³, H. Leong⁴, E. Tai²¹Community, Occupational and Family Medicine, National University of Singapore, ²Endocrinology, Singapore General Hospital, ³Endocrinology, Tan Tock Seng Hospital, Singapore, ⁴Clinical Services, National Healthcare Group Polyclinics, Singapore

Background and aims: Genetic variation at the cyclin-dependent kinase 5 regulatory subunit-associated protein 1-like 1 (*CDKAL1*) locus on 6p22.3 has been associated with increased risk for type 2 diabetes mellitus (T2DM) and beta-cell dysfunction in a number of studies on Caucasians. However, its relevance in Asians is much less established.

Materials and methods: We examined the association between the *CDKAL1* rs7756992 SNP with T2DM using a case-control study design. A total of 2098 T2DM cases (1514 Chinese, 353 Malay and 231 Asian Indian) were from the primary care-based Singapore Diabetes Cohort Study (SDCS) while 2764 controls (1965 Chinese, 442 Malay and 339 Asian Indians) were subjects with normal glucose tolerance (NGT) that formed part of the population-based Singapore National Health Survey 1998 (NHS98) collection. The association between rs7756992 and diabetes-related traits including HOMA beta-cell function was analyzed using data from 2817 Chinese, 774 Malays and 583 Asian Indian subjects from the NHS98, irrespective of their level of glucose tolerance.

Results: The G allele of rs7756992 was strongly associated with T2DM in Chinese (OR = 1.24, 95%CI = 1.12–1.38, $P < 0.001$), with nominal significance among Malays (OR = 1.28, 95%CI = 1.03–1.58, $P = 0.023$) and Asian Indians (OR = 1.37, 95%CI = 1.03–1.81, $p = 0.033$) under an additive model of inheritance. These genetic associations were independent of gender and body mass index. The G risk allele was also associated with lower values for HOMA beta-cell function after adjustment for gender, age and HOMA insulin resistance among Chinese subjects ($P = 0.037$) but not in the more limited collections of Malays and Asian Indians.

Conclusion: *CDKAL1* and its related pathways are likely to be important in the pathogenesis of T2DM across diverse Asian ethnic groups.

317

eNOS D298D variant is associated to reduced first phase of insulin secretion in first degree relatives of type 2 diabetic subjectsR. D'Alfonso¹, S. Rizza¹, M. Cardellini¹, S. Frontoni¹, M.L. Hribal², M.A. Marini¹, G. Sesti², R. Lauro¹, M. Federici¹¹Internal Medicine, University of Rome Tor Vergata, Italy, ²Clinical and Experimental Sciences, University of Catanzaro Magna Graecia, Italy

Background and aims: Type 2 diabetes mellitus is characterized by impaired insulin secretion and reduced insulin action. Cellular studies and animal models suggested that endothelial nitric oxide synthase (eNOS) plays a role in insulin action. We and others observed that eNOS D298D variant is associated to insulin resistance in first degree relatives of type 2 diabetes subjects (FDRs). However, FDRs are also characterized by impaired insulin secretion in the first phase. eNOS plays a major role in regulating micro- and macrovascular function and architecture. Recently it has been suggested that that in the ZDF rat model of type 2 diabetes, an inability of the islet to maintain vascular integrity may contribute to beta-cell failure, while in the Otsuka-Long-Evans-Tokushima fatty rat, islet degeneration leading to diabetes is associated with loss of capillary number within the islet. Because of the pivotal role of eNOS in regulating vascular function we investigated if the D298D eNOS variant, which was shown to impair eNOS function, might be associated to defective beta cell function.

Materials and methods: We investigated eNOS D298 variant in 296 offspring of diabetics parents (T2DM) (109 women, 187 men), 122 diabetics patients (59 women, 63 men) all with BMI < 35 and age < 75 years and 38 (20 women, 18 men) normal glucose tolerant subjects. All subjects were investigated with fasting glucose and insulin levels, lipid parameters, anthropometric and blood pressure values. All FDRs were subjected to euglycemic hyperinsulinemic clamp and oral glucose tolerance test (OGTT). Control subjects have no family history of diabetes. First-phase and second-phase insulin secretion were determined using validated indexes previously proposed by Stumvoll. E298D

polymorphism was studied with polymerase chain reaction (PCR) amplification followed by enzymatic digestion with *MboI*. All statistical analyses were performed using the SPSS software program.

Results: Among FDRs 46.7% were homozygous for the wild-type E298 eNOS, 30.7% were heterozygous and 22.6% homozygous for D298 eNOS allele. Among DM2 subjects 46.3% were homozygous for the wild-type E298 eNOS, 25.3% were heterozygous and 28.4% homozygous for D298 eNOS allele. Among control subjects 57.9% were homozygous for the wild-type E298 eNOS, 34.2% were heterozygous and 7.9% homozygous for D298 eNOS allele. No significant differences were observed among carriers of the 3 genotypes for age, sex, BMI and body composition. In FDRs, multivariate analysis corrected for age, sex and BMI revealed that the presence of the eNOS D298 variant was associated to slightly but significant reduced first phase of insulin secretion as estimated by the Stumvoll index ($p < 0.001$). In DM2 logistic regression analysis corrected for age, sex and BMI revealed that homozygosity for D298 compared to wild-type E298 eNOS was significantly associated to secondary failure ($p < 0.039$).

Conclusion: Our preliminary study suggest that the presence of the D298 eNOS variant may impair beta cell function. Further studies in larger cohorts are necessary to establish a role for this variant in regulation of insulin secretion

318

The concurrent presence of risk alleles for TCF7L2 and HHEX/IDE potentiates the insulin secretory defect in subjects at high risk of diabetes. The GENFIEV StudyC. Bianchi¹, R. Miccoli¹, N. Pulizzi¹, R. Bonadonna², M. Trombetta², F. Giorgino³, S. Frontoni⁴, F. Cavalot⁵, G. Cavallo⁶, E. Faloia⁷, G. Marchesini⁸, F. Leonetti⁹, A. Consoli¹⁰, L. Groop¹¹, S. Del Prato¹¹Department of Endocrinology and Metabolism, University of Pisa, Italy,²Department of Endocrinology and Metabolism, University of Verona, Italy,³Department of Endocrinology and Metabolism, University of Bari, Italy,⁴Department of Internal Medicine, University Tor Vergata, Roma, Italy,⁵Department of Clinical Biological Sciences, University of Turin, Italy,⁶Department of Endocrinology and Metabolism, University La Sapienza, Rome, Italy,⁷Division of Endocrinology, Polytechnic University of Marche, Ancona, Italy,⁸Diabetology, University of Bologna, Italy,⁹Department of Clinical Sciences, University La Sapienza, Rome, Italy,¹⁰Department of Medicine and Aging Sciences, University of Chieti, Italy,¹¹Department of Clinical Sciences, University of Malmö, Malmö, Sweden

Background and aims: Recently, genetic variants at the transcription factor 7-like 2 gene (*TCF7L2*) locus have been found to confer greater risk for developing diabetes. Moreover, statistically significant association with impaired insulin secretion but not with impaired insulin action has been found. Similar effects has been reported for the *HHEX/IDE* (hematopoietically expressed homeobox, insulin degrading enzyme) gene so that the possibility exists for gene-to-gene interaction that may enhance beta-cell dysfunction and risk of developing Type 2 diabetes (T2DM).

Materials and methods: The GENFIEV (Genetics, Physiopathology and Evolution of Type 2 diabetes) study is a multicenter Italian trial designed to identify and characterize subjects at risk of T2DM. A total of 488 non-diabetic subjects have been identified (41% men/59% women; age 49±11 years; BMI 29±5 Kg/m²) within the GENFIEV cohort in whom rs7903146 of *TCF7L2* and rs1111875 of *HHEX/IDE* SNPs have been genotyped. Effects of these genotypes on measures of insulin sensitivity (1/basal insulin) and insulin secretion have been then assessed. Beta-cell function was estimated by minimal model analysis of plasma glucose and C-peptide response to a 2-hr 75-g OGTT. This analysis allows quantification of fasting insulin secretion (B-IS), beta-cell sensitivity at glucose incremental rate, i.e. derivative control (S-CD; pmol.m⁻² BSA per mM.min⁻¹), and glucose - proportional control (S-CP), i.e. the curve of insulin secretion in response to glucose 4.0, 5.5, 8.0 e 11 mM (CP; pmol.min⁻¹.m⁻² BSA per mM).

Results: Subjects homozygous for the T allele of *TCF7L2*, but not for the G allele of *HHEX/IDE*, had higher 1/fasting insulin value (ANOVA: $p = 0.05$) but significantly lower B-IS (Kruskal-Wallis Test $p = 0.001$) and C-CD ($p = 0.002$) as compared to CC or CT subjects. S-CP, reflecting second-phase insulin secretion, was more impaired in TT subjects than in carriers of the CT e CC alleles of *TCF7L2* (ANOVA for repeated measures, $p < 0.05$) as well as than in the GG alleles of the *HHEX/IDE* gene (ANOVA, $p < 0.006$). Based on relatively high frequency of risk alleles for both *TCF7L2* (65%) and *HHEX/IDE* (85%) genes, we evaluated whether the two genes could exert a combination effect. Both B-IS and S-CD significantly and progressively lowered with the increase

in the number of risk alleles (no risk alleles: 109 (IQR, 47) and 1229 (1120); 1 risk allele: 98 (53) and 1224 (1120); 2 risk alleles: 97 (63) and 1406 (1323); 3 risk alleles: 95 (52) and 1013 (857); 4 risk alleles: 69 (39) and 954 (928); $p < 0.01$), while S-CP reduction did not reach the statistical significance.

Conclusion: This preliminary analysis of the genotype and phenotype of non-diabetic subjects from the GENFIEV cohort indicates that *TCF7L2* has more pronounced effect on beta-cell function than *HHEX/IDE* but it also suggests that interaction of *TCF7L2* with *HHEX/IDE* has an additive effect, resulting in further impairment of beta-cell function.

319

Common genetic variation within the *NR4A3* locus associates with beta cell function in non-diabetic Germans

H. Staiger, F. Machicao, N. Stefan, A. Fritsche, H.-U. Häring
Internal Medicine IV, Medical Clinic, University Hospital Tübingen, Germany

Background and aims: Nor-1 (neuron-derived orphan receptor 1), nuclear receptor-related protein (Nurr) 77, and Nurr-1 constitute the NR4A family of orphan nuclear receptors which were recently found to regulate hepatic glucose production, insulin signalling in adipocytes, and oxidative metabolism in skeletal muscle. In this study, we assessed whether common genetic variation within the *NR4A3* locus, encoding Nor-1, contributes to the development of prediabetic phenotypes, such as glucose intolerance, insulin resistance, or beta-cell dysfunction.

Materials and methods: We genotyped 1495 non-diabetic subjects from Southern Germany for the five tagging single nucleotide polymorphisms (SNPs) rs7047636, rs1526267, rs2416879, rs12686676, and rs10819699 (minor allele frequencies ≥ 0.05) covering 100% of genetic variation within the *NR4A3* locus ($D' = 1.0$, $r^2 \geq 0.9$) and assessed their association with metabolic data derived from the fasting state, an OGTT, and a hyperinsulinemic-euglycemic clamp (subgroup, $N = 506$).

Results: All five SNPs were in Hardy-Weinberg equilibrium ($p \geq 0.7$, all; χ^2 -test). The minor allele of rs7047636 was associated with elevated plasma glucose levels at 120min of OGTT ($p = 0.007$; dominant model; t-test). The minor allele of rs1526267 was associated with a higher BMI and reduced clamp-derived insulin sensitivity ($p = 0.01$, both; dominant model; t-test). Most convincingly however, the minor alleles of three SNPs, i.e., rs1526267, rs12686676, and rs10819699, were consistently associated with higher insulin release as derived from the insulinogenic index and the $AUC_{\text{C-peptide}}/AUC_{\text{glucose}}$ ratio ($p < 0.05$, all; dominant model; t-test).

Conclusion: Common genetic variation within the *NR4A3* locus determines insulin secretion. Thus, *NR4A3* represents a novel candidate gene for beta-cell dysfunction and type 2 diabetes mellitus.

Background and aims: Recent genome-wide association (GWA) studies have identified at least 6 novel type 2 diabetes susceptibility gene regions. We assessed the effect of these regions on insulin secretion and insulin sensitivity index as determined by a hyperglycaemic clamp.

Materials and methods: Gene variants in *HHEX/IDE*, *CDKAL1*, *SLC30A8*, *IGF2BP2* and *CDKN2A/CDKN2B* were genotyped in a cohort of 146 normal glucose tolerant (NGT) and 126 impaired glucose tolerant (IGT) subjects from the Netherlands and Germany, who all underwent a hyperglycaemic clamp at 10 mmol/l glucose.

Results: Variants in *CDKAL1* and *IGF2BP2* are associated with reductions in first phase insulin secretion (34% and 28% resp., $P < 0.01$) and disposition index ($p < 0.02$). No effect of these variants on second phase insulin secretion was shown in our cohorts. For the gene regions near *HHEX/IDE*, *SLC30A8* and *CDKN2A/CDKN2B* we do not find associations with altered insulin se-

cretion (Figure 1). Furthermore, the gene variants were not associated with insulin sensitivity indexes.

Conclusion: Our data show that gene variants in *CDKAL1* and *IGF2BP2* attenuate the first phase of glucose stimulated insulin secretion, but show no effect on the second phase of insulin secretion. Our results based on hyperglycaemic clamps provide further insight into the pathogenic mechanism behind the association of these gene variants with type 2 diabetes.

Pro72Arg polymorphism of TP53 affects insulin sensitivity in diabetic subjects

R. Testa¹, A.R. Bonfigli¹, C. Sirolla², M. Marra¹, L. Spazzafumo², M. Boemi¹, F. Olivieri³, S. Salvioli⁴, C. Franceschi⁴, I. Testa¹

¹Diabetology Unit, IRCCS-INRCA, Ancona, ²Centre of Epidemiology and Biostatistics, IRCCS-INRCA, Ancona, ³Faculty of Medicine, Polytechnic University of Marche, Ancona, Italy, ⁴Department of Experimental Pathology, University of Bologna, Italy

Background and aims: It has recently been demonstrated that p53 regulates genes implicated in energy generating metabolic pathways, suggesting its possible involvement in diabetes. The aim of this study was to evaluate whether Pro72Arg polymorphism of TP53 is associated with metabolic parameters and insulin resistance in diabetic subjects.

Materials and methods: The study design was cross-sectional and observational. We studied 303 type 2 diabetic patients (mean age±SD, 65.2±8.6 years, 180 men and 123 women) and 328 non diabetic control subjects (mean age±SD, 65.6±8.1 years, 190 men and 138 women) matched for age and sex.

Results: The frequencies of the different genotypes were: 183 (55.8%) Arg/Arg, 121 (36.9%) Arg/Pro and 24 (7.3%) Pro/Pro genotypes in the non diabetic group and 169 (55.8%) Arg/Arg, 109 (35.9%) Arg/Pro and 25 (8.3%) Pro/Pro genotypes in the diabetic group. This genotype distribution was not different between diabetic and non diabetic subjects ($\chi^2=0.24$; $P=0.88$). The 2-way analysis of variance highlights that the increase in fasting glucose plasma levels in diabetic subjects was due to the effect of diabetes ($F=313.11$, $P<0.01$) whereas no p53 genotype ($F=0.25$; $P=0.77$) and p53 genotype-diabetes interaction effects ($F=0.25$; $P=0.77$) were found. Equally, no p53 genotype or genotype-diabetes interaction effects were detected for BMI, waist and HbA1c. Significant genotype-diabetes effect on HOMA index was found ($F=4.25$; $P=0.01$). In diabetic patients, Pro/Pro subjects showed significant lower levels of HOMA with respect to Arg/Arg and Arg/Pro carriers ($F=4.73$, $P=0.03$ and $F=8.05$, $P<0.01$, respectively). Noteworthy, no difference between diabetic and non diabetic Pro/Pro carriers was found ($F=0.75$; $P=0.38$). Significant p53 genotype-diabetes interaction effects were found on the levels of fasting insulin, HDL cholesterol and triglycerides. In particular, these variables showed a genotype-dependent trend in accordance with the variation of insulin resistance.

Conclusion: Our results indicate for the first time that this polymorphism may affect insulin sensitivity in diabetic subjects. The key results of our approach are the following: 1) in diabetic subjects, the Pro/Pro genotype is associated with lower values of HOMA index with respect to Arg carriers; 2) HOMA index values are similar for diabetic and non-diabetic Pro/Pro subjects. These findings could open a new field of research in the complex metabolic network regulated by p53.

The DGAT2 gene is a candidate for dissociation between fatty liver and insulin resistance in humans

K. Kantartzis¹, F. Machicao¹, J. Machann², F. Schick², A. Fritsche¹, H.-U. Häring¹, N. Stefan¹

¹Department of Internal Medicine IV, ²Section on Experimental Radiology, University of Tübingen, Germany

Background and aims: The enzyme acyl-CoA:diacylglycerol acyltransferase (DGAT) catalyzes the final step of triglyceride synthesis. Mice overexpressing hepatic DGAT2, the isoform predominantly expressed in the liver, developed fatty liver, but not insulin resistance, under a high-fat diet. In the present study we hypothesized that human DGAT2 may have a similar function, and investigated whether common single nucleotide polymorphisms (SNPs) in DGAT2 contribute to dissociation between fatty liver and insulin resistance in humans.

Materials and methods: The SNPs rs10899116 C>T and rs1944438 C>T in DGAT2, which had a minor allele frequency of >0.05 and covered 100% of the alleles with a D' of 1 were genotyped in 187 individuals at risk for type 2 diabetes who participated in a lifestyle intervention program with diet modification and increase in physical activity. Total body fat and visceral fat were

determined by magnetic resonance (MR) tomography and liver fat and intramyocellular fat by ¹H-MR spectroscopy. Insulin sensitivity was estimated from the oral glucose tolerance test (OGTT) and in a subgroup measured by the euglycemic hyperinsulinemic clamp.

Results: After 9 months of intervention total body fat, visceral fat and intramyocellular fat significantly decreased (all $p>0.22$). Liver fat also decreased (-33%, $p<0.0001$) and insulin sensitivity increased (OGTT, 13.5%, $p<0.0001$; clamp, 13%, $p=0.04$). There was an inverse correlation of change in liver fat with change in insulin sensitivity (OGTT, $r=-0.31$, $p<0.0001$; clamp, $r=-0.32$, $p=0.03$). Carriers of the minor T allele of the SNP rs1944438 had less decrease in liver fat (T/T, -24±5%; C/T, -17±10) compared to C/C homozygotes (-39±7%, $p=0.008$). In contrast, the SNP was not associated with change in insulin sensitivity (OGTT, $p=0.79$; clamp, $p=0.53$). Likewise, subjects with fatty liver ($n=54$) carrying the minor T allele of SNP rs1944438 had less decrease in liver fat compared to C/C homozygotes ($p=0.02$), but displayed similar change in insulin sensitivity calculated from the OGTT ($p=0.52$).

Conclusion: These data suggest that DGAT2 mediates dissociation between fatty liver and insulin resistance in humans. This finding may be of clinical relevance in the prevention and treatment of insulin resistance and type 2 diabetes in subjects with fatty liver.

Insulin secretion and insulin sensitivity in first degree relatives of subjects with impaired glucose regulation

S.M. Shefin¹, R.M. Hafizur², N.M. Islam², M.M. Hossain², Z.A. Latif¹, S. Akter², Q. Nahar², S. Islam², K. Hasan², M.O. Faruque², L. Ali²

¹Endocrinology and Diabetology, ²Dept Biochemistry & Cell Biology, BIRDEM, Dhaka, Bangladesh

Background and aims: First degree relatives of T2 DM subjects are at increased risk for the disease, but no studies exist on the first degree relatives of subjects with impaired glucose regulation (IGR). There are also substantial genetic heterogeneity regarding the pathophysiology of diabetes and thus the basic defects of the disorder should be investigated in different populations. Present study was aimed to investigate the insulin secretory capacity and insulin sensitivity of the first degree relatives of the Bangladeshi IGR subjects.

Subjects and methods: Forty one first degree relatives of 14 IFG cases (RIFG), 116 first degree relatives of 36 IGT cases (RIGT), 76 first degree relatives of 20 combined IFG-IGT cases (RIFG-IGT) and 20 age-matched healthy controls were recruited. Serum glucose was measured by glucose-oxidase method, lipid profile by enzymatic-colorimetric method and serum insulin by ELISA. Insulin secretory capacity (HOMA % B) and insulin sensitivity (HOMA % S) were calculated by fasting serum glucose and fasting serum insulin.

Results: BMI ($M\pm SD$, kg/m²; Control, 22±2; RIFG, 24±5; RIGT, 22±4; RIFG-IGT, 23±4) was significantly higher in RIFG and RIFG-IGT subjects compared to Controls. Fasting serum glucose (FG; mmol/l; Controls, 4.8±0.4; RIFG, 5.4±0.8; RIGT, 5.8±2.2; RIFG-IGT, 5.9±1.4) was significantly higher in RIFG and RIFG-IGT ($p=0.0001$) compared to Controls. RIGR groups had significantly ($p=0.0001$) higher postprandial serum glucose (Controls, 5.4±1.0; RIFG, 7.1±2.7; RIGT, 8.2±5.1; RIFG-IGT, 8.3±4.9) compared to Controls. Dyslipidemia was evident in RIGR subjects compared to Controls although the values were within the normal range. HOMA % B [Median (range); Controls, 101 (62-159); RIFG, 79 (23-185); RIGT, 76 (16-201); RIFG-IGT, 78 (13-152)] was significantly lower among the RIFG, RIGT and RIFG-IGT subjects compared to Controls. HOMA % S [Controls, 115 (74-268); RIFG, 85(35-251); RIGT, 112 (13-288); RIFG-IGT, 84(21-288)] value in RIFG-IGT subjects were significantly lower compared to Controls. When RIGR subjects were categorized using the BMI cut-off point standardized for Bangladeshi population, all the three RIGR groups with BMI values >23 have shown significantly less insulin sensitivity compared to their counterparts with BMI <23. In bivariate correlation (Spearman) analysis it was found that HOMA % S was negatively ($p<0.01$) and HOMA % B was positively ($p<0.001$) correlated with BMI, waist circumference and percent body fat in all the three RIGR groups. On logistic regression analysis with pooled data from all the RIGR subjects a significant positive association of the prediabetic-relative state with HOMA %B and a significant negative association of the same state with HOMA %S was found even when the effects of other confounding/covariates were adjusted. Multiple regression revealed that HOMA %B in IGR is associated with BMI and WHR, and HOMA %S in these subjects is associated with BMI and percent body fat contents when the effects of other confounding factors are adjusted.

Conclusion: a) β -cell secretory dysfunction seem to have a genetic origin in all groups of IGR in Bangladeshi population, b) the genesis of the various

phenotypes of IGR results from a complex interaction between the primary defect in insulin secretion and other primary or secondary factors contributing to insulin resistance.

The frequent *UCP2* -866G>A protects against insulin resistance in Danes: large-scale studies of obesity and related metabolic traits

L. Wegner¹, G. Andersen¹, L.T. Dalgaard², S. Anthonsen^{1,2}, T. Nielsen¹, N. Grarup¹, K. Borch-Johnsen^{1,2}, T. Jørgensen³, A. Sandbæk⁴, T. Lauritzen⁵, T. Hansen¹, J. Holmkvist¹, O. Pedersen^{2,4}

¹Steno Diabetes Center, Gentofte, ²Department of Science, Systems and Models, Roskilde University, ³Research Centre for Prevention and Health, Glostrup University Hospital, ⁴Faculty of Health Science, University of Aarhus, ⁵Department of General Practice, University of Aarhus, Denmark

Background and aims: Uncoupling protein-2 (UCP2) is a mitochondrial transporter that uncouples oxidative phosphorylation via proton leakage from the inner mitochondrial membrane. It is involved in the regulation of reactive oxygen species production and energy metabolism and is ubiquitously expressed. The frequent rs659366 in the *UCP2* promoter has been extensively studied across different populations; however, the results have not been consistent. The A-allele of rs659366 has been shown to associate with reduced risk of obesity among white Europeans, with reduced and increased risk of type 2 diabetes (T2D), and quantitative metabolic traits. The aim of this study was to investigate if the A-allele of rs659366 is associated with T2D, obesity, or quantitative metabolic traits in large-scale studies of Danes.

Materials and methods: The *UCP2* rs659366 was genotyped in 13,588 Danes involving the population-based Inter99 cohort of middle-aged people ($n=6,051$), the ADDITON study ($n=7,220$), and a population-based sample of young healthy subjects ($n=317$) using Taqman allelic discrimination.

Results: No association of rs659366 with obesity or T2D was observed; however, in studies of 6,051 individuals of the Inter99 cohort A-allele carriers had impaired insulin release (fasting [$p=0.002$] and 120-min post-OGTT [$p=0.02$]) and lower fasting glycaemia ($p=0.02$). Furthermore, young healthy A-allele carriers were less insulin-resistant (HOMA-IR, $p=0.0007$), and more insulin-sensitive ($p=0.02$).

Conclusion: The A-allele of rs659366 is not associated with obesity or T2D in Danes; however, middle-aged A-allele carriers have impaired glucose-stimulated insulin release combined with increased insulin sensitivity.

The *TRIB3* R84 variant is associated to selective insulin resistance in human umbilical vein endothelial cells *in vitro* and early atherosclerosis *in vivo*

M.L. Hribal¹, G. Formoso², F. Andreozzi¹, S. Di Silvestre³, S. Prudente⁴, M.A. Marini⁵, A. Pandolfi³, V. Trischitta^{6,4}, G. Sesti¹, A. Consoli²

¹Dept of Experimental and Clinical Medicine, University of Magna Graecia, Catanzaro, ²DMSI, CeSI Institute, G. d'Annunzio University, Chieti, ³Dept of Biomedical Sciences, CeSI Institute, G. d'Annunzio University, Chieti, ⁴CSS Mendel Institute, Rome, CSS Scientific Institute, San Giovanni Rotondo (FG), ⁵Dept of Internal Medicine, University of Tor Vergata, Rome, ⁶Dept of Clinical Sciences, Sapienza University, Rome, Italy

Background and aims: It has been proposed that PI3Kinase dependent insulin signaling pathway exerts a tonic inhibition on the MAPK dependent insulin pathway controlling, among others, potentially atherogenic insulin effects such as leukocyte adhesion molecules expression. Thus, impairment of PI3K pathway might enhance insulin atherogenic effects. An inhibitor of insulin action, *TRIB3*, was identified that affects insulin action by binding to and inhibiting phosphorylation of Akt, a cardinal enzyme downstream of PI3K in the insulin signaling pathway. We recently described a Q84R gain-of-function polymorphism of *TRIB3* with the R84 variant being associated with insulin resistance and an earlier age at myocardial infarction. In the present study we test the hypothesis that polymorphisms associated with a loss of function in the PI3Kinase insulin pathway are correlated with upregulation of signalling pathways leading to insulin atherogenic effects.

Material and methods: We investigated insulin signaling and leukocyte adhesion molecules expression in cultured human endothelial cells (HUVECs) naturally carrying the three *TRIB3* genotypes (Q84Q, Q84R, R84R).

Results: In both Q84R and R84R HUVECs, the amount of *TRIB3* co-immunoprecipitated with Akt was greater than in Q84Q cells with a ~50% impairment in insulin-stimulated activation of both Akt and eNOS. In Q84Q cells, phosphorylation of ERK1/2, members of the MAPK family, was low in the basal state, and responsive to insulin. By contrast, in Q84R and R84R cells, ERK1/2 were maximally phosphorylated in the basal state without further increase in response to insulin. Moreover, in Q84Q the expression of VCAM-1, ICAM-1 and E-Selectin was induced by long term insulin stimulation. On the other hand, in Q84R and R84R cells, adhesion molecules expression was maximal in the basal state and not responsive to insulin. Both Q84R and R84R cells were not responsive to insulin-stimulated NO production. To determine whether the R84 variant was associated with early manifestation of atherosclerosis, carotid intima-media thickness (IMT) was measured by ultrasonography in 173 nondiabetic offspring of type 2 diabetics. IMT was increased in Q84R and R84R compared with Q84Q subjects ($P=0.02$).

Conclusion: The *TRIB3* R84 variant selectively impairs the vasodilatory action of insulin while enhancing MAPK activity and adhesion molecules expression. This data reinforce the hypothesis that insulin resistance, selectively affecting the PI3K pathway, might contribute to the pathogenesis of macrovascular complications of diabetes.

ENPP1 as an insulin resistance gene

J.C. Florez^{1,2}, E.S. Stoleran^{1,2}, A.F. Moore^{1,2}, A.K. Manning³, J.B. McAttee^{1,2}, J. Dupuis³, C.S. Fox³, L.A. Cupples³, K.A. Jablonski⁴, R.F. Arakaki⁴, B.J. Goldstein⁴, S.E. Kahn⁴, A.E. Kitabchi⁴, W.C. Knowler⁴, J.B. Meigs^{5,3}

¹Center for Human Genetic Research and Diabetes Unit, Massachusetts General Hospital, Boston, ²Program in Medical and Population Genetics, Broad Institute of Harvard and MIT, Cambridge, ³Glycemic Group, Framingham Heart Study, Framingham, ⁴Research Group, Diabetes Prevention Program, Rockville, ⁵General Medicine Division, Massachusetts General Hospital, Boston, United States

Background and aims: Functional studies suggest that the non-synonymous K121Q polymorphism (rs1044498) in the ectoenzyme nucleotide pyrophosphate phosphodiesterase *ENPP1* may confer susceptibility to insulin resistance; genetic evidence quantifying its effect on type 2 diabetes, however, has been conflicting. In a comprehensive meta-analysis of 23 European population studies we recently demonstrated a modest increase in risk of type 2 diabetes for QQ homozygotes (combined odds ratio [OR] 1.38, 95% CI 1.10–1.74, $P=0.005$). This risk was modified by BMI, with a higher OR in studies in which the mean BMI of controls was lower. We therefore sought to 1) assess the effect of *ENPP1* K121Q on quantitative glycemic traits; 2) fine-map the association signal, to establish whether it indeed stems from K121Q and not from another variant in the region; 3) verify its interaction with obesity; 4) examine its ability to predict diabetes onset prospectively; and 5) explore its impact on diabetes preventive strategies.

Materials and methods: We characterized the haplotype structure of *ENPP1* and selected 39 tag SNPs that captured 96% of common variation in the region (minor allele frequency $\geq 5\%$) with an $r^2 \geq 0.80$. We genotyped these SNPs in 2,511 Framingham Heart Study (FHS) participants and used age-sex-adjusted linear mixed effects models to test for association with quantitative metabolic traits and their interaction with BMI. We then genotyped *ENPP1* K121Q in 3,548 participants in the Diabetes Prevention Program (DPP), in which lifestyle modification and metformin were compared to placebo, and performed Cox regression analyses using genotype, intervention, and interactions as predictors of diabetes incidence.

Results: In the FHS, the Q allele was associated with increased fasting plasma glucose (FPG), hemoglobin A_{1c}, fasting insulin, and insulin resistance by homeostasis model assessment (HOMA-IR; all $P=0.01$ – 0.006). Linear mixed effect models indicated that the effects of all detected associations could be driven by K121Q. We found no association of K121Q with obesity, but interaction models suggested that the effect of the Q allele on FPG and HOMA-IR was stronger in those with a higher BMI ($P=0.008$ and 0.01 for interaction, respectively). There was no association of *ENPP1* K121Q with diabetes incidence in FHS based on a limited sample of 241 cases. In the DPP, there was a nominally significant interaction between genotype at K121Q and intervention under a dominant genetic model ($P=0.03$). In the placebo arm ($n=996$),

Q allele carriers were more likely to develop diabetes than KK homozygotes (hazard ratio 1.38, 95% CI 1.08–1.76, $P=0.009$). Metformin and lifestyle modification eliminated this increased risk.

Conclusion: The *ENPP1* Q121 variant appears to increase risk of type 2 diabetes and is associated with hyperglycemia and insulin resistance in whites, an effect which seems to be modulated by BMI. The risk of diabetes ascribed to this polymorphism may be eliminated by preventive interventions.

Enhanced insulin sensitivity in obese patients with a rare cancer predisposition syndrome (Cowden Syndrome) due to *PTEN* mutations: further evidence for the Yin-Yang hypothesis

A. Pal¹, T.M. Barber¹, L. McCulloch¹, R. Smith¹, B.A. Barrow¹, L. Walker², A.L. Gloy¹

¹Oxford Centre for Diabetes, Endocrinology and Metabolism, University of Oxford, ²Clinical Genetics, Churchill Hospital, Oxford, United Kingdom

Background and aims: One emerging theme from genome-wide scans for association in Type 2 diabetes (T2DM) is the frequency with which novel signals map to genes involved in cell cycle regulation. Moreover, recent studies have demonstrated that common genetic variants predisposing to cancer protect against T2DM; variants in *HNF1B* have been shown to predispose to prostate cancer and also confer protection against T2DM. This yin-yang effect, whereby genetic variations at certain loci have divergent effects on cancer predisposition and the development of T2DM, is accruing substantiation. Cowden syndrome is a rare cancer predisposition syndrome (prevalence of 1 in 200 000) caused by mutations in the phosphatase and tensin homolog tumour suppressor gene (*PTEN*). *PTEN* is a lipid phosphatase which metabolises phosphatidylinositol phospholipid-4,-5-bisphosphate (PtdIns)-3,4,5-triphosphate (PIP₃) to PtdIns-4,-5-bisphosphate and consequently reverses a step in PI₃-kinase signalling (a key pathway in insulin action). *PTEN* is expressed in pancreatic beta-cell, liver, muscle and adipose tissue. Studies in mice have shown that *PTEN* haploinsufficiency promotes insulin sensitivity, and that beta-cell specific knockout mice have increased beta-cell mass and hypoglycaemia. We hypothesised that *PTEN* haploinsufficient patients with Cowden syndrome could have enhanced insulin sensitivity and beta-cell function.

Materials and methods: To test our hypothesis we recruited patients with Cowden syndrome ($n=7$) and age, BMI and gender-matched controls ($n=7$). Subjects underwent an oral glucose tolerance test (75g) and blood samples were analysed for plasma glucose and serum insulin at baseline (fasting) and at +30 minutes post-oral glucose load. Insulin sensitivity and beta-cell function were assessed with the homeostasis model of insulin resistance (HOMA2 IR) and disposition index (DI) respectively. Paired t-test analyses were implemented in SPSS.

Results: Results are shown as geometric mean [SD range]; Cowden syndrome patients vs controls. Patients with Cowden syndrome and control subjects were well-matched for gender ($P=1.0$), age (36.5 [25.8, 51.6] vs 36.8 [26.5, 51.0], $P=0.88$) and BMI (32.6 kg/m² [25.8, 41.3] vs 32.9 kg/m² [26.6, 40.6], $P=0.79$). Patients with Cowden syndrome have greater insulin sensitivity (HOMA2 IR 0.51 [0.19, 1.38] vs 1.35 [0.67, 2.69], $P=0.028$) and although not statistically significant there was a tendency for improved beta-cell function (DI 136.2 [65.9, 281.2] vs 75.5 [29.6, 192.5], $P=0.29$) compared to matched controls.

Conclusion: Our data support the hypothesis that in humans, a manifestation of *PTEN* haploinsufficiency is improved insulin sensitivity and beta-cell function. These data suggest that the beneficial effects of loss of *PTEN* are most marked in tissues of insulin action rather than in improved beta-cell function *per se*. Understanding the role of *PTEN* in insulin secretion/action is not only of biological importance but will also clarify the potential for adverse oncogenic events related to manipulation of these pathways to treat diabetes.

Impact of *WFS1* polymorphisms on pre-diabetic phenotypes in a population-based sample of middle-aged people with normal and abnormal glucose regulation

T.W. Boesgaard¹, T. Sparso¹, G. Andersen¹, T. Jørgensen², K. Borch-Johnsen^{1,2}, A. Sandbæk⁴, T. Lauritzen⁴, J. Vasson⁵, M.A. Permutt⁵, B. Glaser⁶, S. Madsbad⁷, O. Pedersen^{1,8}, T. Hansen¹

¹Steno Diabetes Center, Gentofte, Denmark, ²Research Centre for Prevention and Health, Glostrup University Hospital, Denmark, ³Epidemiology, Steno Diabetes Center, Gentofte, Denmark, ⁴Department of General Practice, University of Aarhus, Denmark, ⁵Metabolism and Lipid Research Division, Washington University School of Medicine, Saint Louis, WA, United States, ⁶Hadassah-Hebrew, University Medical Centre, Jerusalem, Israel, ⁷Department of Endocrinology, Hvidovre University Hospital, Denmark, ⁸Faculty of Health Science, University of Aarhus, Denmark

Background and aims: variants in *WFS1* have been shown to associate with type 2 diabetes. We aimed to examine metabolic risk phenotypes of *WFS1* variants in glucose-tolerant people and in individuals with abnormal glucose regulation.

Materials and methods: The type 2 diabetes-associated *WFS1* variant rs734312 (His611Arg) was genotyped in the population-based Inter99 cohort involving 4,568 glucose-tolerant individuals and 1,471 individuals with treatment-naïve abnormal glucose regulation, and in additional 3,733 treated type 2 diabetic patients from Steno Diabetes Center and the ADDITION study using TaqMan[®] allelic discrimination.

Results: The *WFS1* rs734312 A-allele showed a borderline significant association with type 2 diabetes with a relative risk consistent with previous reports. In individuals with abnormal glucose regulation the rs734312 A-allele was in an allele-dependent manner associated with a decrease in insulinogenic index ($p=0.03$) and a decreased 30-min serum-insulin level ($p=0.05$) after an oral glucose load while, curiously, in glucose-tolerant individuals the same allele was associated with increased fasting serum-insulin ($p=0.02$) and insulin resistance assessed by HOMA-IR ($p=0.03$), see table. We also examined for interaction with glucose tolerance status applying a linear model with glucose tolerance status as an interaction term. In this analysis we demonstrated a significant association with traits related to β -cell function (30-min serum-insulin, $p=0.009$, and insulinogenic index, $p=0.003$).

Table Anthropometric and metabolic characteristics of 5,384 treatment-naïve Danish individuals from the Inter99 cohort stratified according to *WFS1* rs734312 genotype and glucose tolerance status

Data are means \pm standard deviation. All analyses were made using a genetic additive model

Conclusion: Type 2 diabetes-associated risk alleles of *WFS1* are associated with estimates of a decreased pancreatic β -cell function among middle-aged individuals with abnormal glucose regulation.

Normal glucose-tolerance (NGT)

CDKN2A/B polymorphism is associated with susceptibility to type 2 diabetes, but not with the gene expression in the adipose tissues in the Japanese

S. Omori^{1,2}, Y. Tanaka², H. Maegawa³, A. Kashiwagi³, R. Kawamori⁴, K. Kaku⁵, Y. Nakamura⁶, S. Maeda¹

¹Laboratory for Endocrinology and Metabolism, Center for Genomic Medicine, RIKEN, Yokohama, ²Department of Internal Medicine, Division of Metabolism and Endocrinology, St. Marianna University School of Medicine, Kawasaki, ³Department of Medicine, Shiga University of Medical Science, Otsu, ⁴Department of Medicine, Metabolism and Endocrinology, School of Medicine, Juntendo University, Tokyo, ⁵Division of Endocrinology and Metabolism, Department of Internal Medicine, Kawasaki Medical School, Kurashiki, ⁶Laboratory of Molecular Medicine, Human Genome Center, Institute of Medical Science, University of Tokyo, Japan

Background and aims: Recently, genome-wide association studies were conducted by European and American groups, and several candidate loci were identified in populations of European descent. The aim of the present study is to further investigate the involvement of these polymorphisms in conferring susceptibility to type 2 diabetes across different ethnicities.

Materials and methods: We examined the association of 14 SNPs within 11 candidate loci (rs4402960 in *IGF2BP2*, rs10811661 in *CDKN2A/B*, rs1111875 and rs7923837 in *HHEX*, rs13266634 in *SLC30A8*, rs1113132 and rs11037909 in *EXT2*, rs9939609 and rs8050136 in *FTO*, rs7756992 in *CDKAL1*, rs1801282 in *PPARG* Pro12Ara, rs5219 in *KCNJ11* Glu23Lys, rs7480010 in *LOC387761*, and rs9300039 in *ch11*) with type 2 diabetes in a Japanese population. We analyzed these SNPs in 1,630 Japanese subjects with type 2 diabetes and in

1,064 control subjects by using an invader assay or a TaqMan assay. In addition, we investigated the correlation between *CDKN2A/B* polymorphism and its expression in the adipose tissues by using real-time RT-PCR.

Results: Among the 11 loci examined, 6 loci were significantly associated with type 2 diabetes in our population by a logistic regression analysis ($p < 0.05$ after adjusting age, gender, BMI), similar to previously reported results. We also identified an interactive effect of these 6 loci (table 1). In this population, the remaining 5 loci were not significantly associated with type 2 diabetes. In addition, we identified that the *CDKN2B* is preferentially expressed in the subcutaneous adipose rather than visceral adipose (Subcutaneous: 4.78 [95% CI 3.00 - 7.60] vs. Visceral: 0.07 [95% CI 0.05 - 0.10], geometric mean of arbitrary unit), whereas the expression of *CDKN2A* could not be detected in the adipose tissues. The *CDKN2B* expressions in the adipose tissues, however, did not differ according to the *CDKN2A/B* genotypes (rs10811661).

Conclusion: We have identified 6 of the 11 loci that were identified by genome-wide association studies in European descent. These loci are considered strong candidates for type 2 diabetes susceptibility across different ethnicities, although further studies are required to elucidate precise mechanisms underlying the contribution of these genes and gene polymorphisms to conferring susceptibility to type 2 diabetes.

Autoantibody responses to zinc transporter 8 in children at risk for type 1 diabetes

P. Achenbach¹, U. Landherr¹, K. Koczwara¹, V. Lampasona², S. Krause¹, A.G. Ziegler^{1,3}, E. Bonifacio⁴

¹Institut für Diabetesforschung, Munich, Germany, ²Dept. of Laboratory Medicine, Istituto Scientifico San Raffaele, Milan, Italy, ³Klinikum Schwabing, Städt. Klinikum München GmbH, Munich, Germany, ⁴Center for Regenerative Therapies – Dresden, University of Technology, Germany

Background and aims: Zinc transporter 8 (ZnT8) has recently been identified as a major target antigen in the autoimmune pathogenesis of type 1 diabetes (T1DM). The aim of this study was to determine the cumulative prevalence of autoantibodies to ZnT8 in relation to other islet autoantibodies in at risk children who have been prospectively followed from birth.

Materials and methods: Antibody binding to ZnT8 was determined in sera of 1777 children, including 144 children who developed autoantibodies to insulin, GAD and/or IA-2 (78 with multiple antibodies) and 42 who progressed to T1DM, using Protein A-based radiobinding assays and 35-S labelled in vitro transcribed/translated human recombinant ZnT8 constructs. All children were screened for autoantibodies to a C-terminal (aa 268–369) portion of the A325-arginine-isoform of ZnT8 (ZnT8-C-Abs). Autoantibodies to the N-terminal (aa 1–74) portion of ZnT8 (ZnT8-N-Abs) were tested in all ZnT8-C-Abs positive children and in HLA DR3 and DR4-matched ZnT8-C-Abs negative children. In addition, islet autoantibody and/or ZnT8-Abs positive children were tested for antibody binding to C-terminal constructs of the A325-tryptophan- and A325-glutamine-isoforms of ZnT8.

Results: Persistent ZnT8-C-Abs were detected in 53 children. This included 47 of 78 with multiple other islet antibodies, 2 of 35 with IAA only, 2 of 35 with GADA only, and 2 with no other islet antibodies. ZnT8-C-Abs developed at a median age of 3.2 years (IQR 2.1–5.3). The cumulative risk for developing ZnT8-C-Abs was 3.2% by age 8 years and 4.3% by age 11 years. ZnT8-C-Abs preceded autoantibodies to insulin, GAD and/or IA-2 in 3 children. ZnT8-N-Abs were often transient; at least one ZnT8-N-Abs positive sample was found in 11 children with ZnT8-C-Abs positive, 2 children who were ZnT8-C-Abs negative/islet autoantibody positive, and 8 of 633 (1.6%) autoantibody negative children.

Seven of the islet autoantibody positive children were positive for antibodies against the ZnT8 A325-tryptophan- and/or A325-glutamine-isoforms but had no antibodies against the ZnT8 A325-arginine-isoform; 4 of these 7 developed diabetes. There were heterogeneous antibody binding patterns among the ZnT8-C-Abs positive children with the majority of subjects responding equally well to all three isoforms, but some children showed an increased and few an exclusive binding to one or two of the ZnT8 isoforms. Follow-up over time revealed that these binding patterns could change suggesting epitope changes.

Thirty-one of the 60 ZnT8-Abs positive children (51.7%) progressed to diabetes. The 10-year cumulative risk from the time of appearance of ZnT8-Abs was 60% (95% CI, 46–74).

Conclusion: Autoantibodies to ZnT8 can appear early in the pathogenesis of childhood T1DM and they are associated with high diabetes risk. Screening for ZnT8-Abs should consider differences in antibody binding to different ZnT8-isoforms.

Transplantation of adipose tissue and feeding of high fat diet protect BB rats from type 1 diabetes development

I. Klötting¹, B. Wilke¹, N. Klötting^{1,2}

¹Laboratory Animal Science, University of Greifswald, Karlsburg,

²Department of Internal Medicine III, University of Leipzig, Germany

Background and aims: We breed type 1 diabetic BB rats since more than 25 years. Several days before BB rats become diabetic their body seems to be flabby which may be attributed to loss of subcutaneous fat. This observation prompted us to search for possibilities to avoid the loss of adipose tissue. We have chosen two different ways: transplantation of adipose tissue and feeding of high fat diet to protect BB rats from type 1 diabetes.

Materials and methods: For transplantation study we used 9 complete littermates of BB rats (53M:55F) which were subcutaneously grafted with 1 or 2 g

visceral adipose tissue of sex and MHC matched congenic, but non-diabetic BB rat strains at an age of 4 weeks. Sham operated and untreated BB rats (20M:21F) served as controls. For the diet study 8 breeding pairs were fed a high fat diet (Ssniff R-Z + 10% tallow, Soest, Germany). The progeny of these breeding pairs (n=55) was also given this diet up to an age of 30 weeks. 42 BB rats fed the normal rat diet (Ssniff R-Z) under pregnancy and during the observation period served as controls. All BB rats were observed for diabetes occurrence up to an age of 30 weeks. The diabetes frequency was compared with the Chi-square test.

Results: From the fat grafted animals in total 36 out of 53 male BB rats (68%) and 27 out of 55 female BB rats (49%) developed type 1 diabetes. In the control group 17 out of 20 male (85%) and 20 out of 21 female BB rats (95%) became diabetic. Therefore, significantly more grafted males than females developed diabetes up to an age of 30 weeks ($p=0.0002$). In contrast to the transplantation study, the BB rats fed with high fat diet significantly more females than males were diabetic in comparison with normal fed BB controls (M 17/25, 68% vs. 23/23, 100% $p=0.003$; F 23/30, 76% vs. 17/19, 89% $p=0.23$). The age at onset of diabetes and the level of hyperglycaemia were largely comparable between study and control groups.

Conclusion: Both adipose tissue transplantation and high fat diet protect BB rats from type 1 diabetes development in a sex specific manner. The manipulations may influence fat accumulation and/or fat metabolism which prevent type 1 diabetes development in BB rats. This idea is supported by the finding that a mutation in the leptin receptor of NOD mice suppresses type 1 diabetes progression.

An increase in C-reactive protein often precedes and predicts clinical onset of type 1 diabetes in GAD-antibody positive relatives

J. De Grijse¹, P. Couck², I. Truyen¹, I. Weets¹, I. Vermeulen¹, F. van Genderen¹, E. Vekens¹, K. Decocchez¹, J. Ruige³, C. Van Schravendijk¹, B. Keymeulen¹, D. Pipeleers¹, F. Goris^{1,2}

¹Diabetes Research Center, Brussels Free University, ²Department of Clinical Chemistry and Radioimmunology, University Hospital Brussels Free University, ³Department of Internal Medicine, University Hospital Ghent, Belgium

Background and aims: Type 1 diabetes is a chronic inflammatory disease, characterized by insulinitis, but the frequency and intensity of this process in human prediabetes is unknown. In view of previous contradictory reports we reevaluated whether circulating levels of C-reactive protein (CRP) – an established marker of inflammation – may contribute to the prediction of type 1 diabetes in a registry-based, representative and fully characterized group of first degree relatives of known patients.

Materials and methods: Random CRP levels were measured at baseline and during yearly follow-up in 211 persistently islet antibody-positive (Ab⁺) first degree relatives (37 with prediabetes) of type 1 diabetic patients and in 211 age- and sex-matched persistently antibody-negative relatives (median age 14.0 ± 8.8 yr) with known *HLA-DQ* genotype (no prediabetes) followed for 81 (59–90) months and recruited by the Belgian Diabetes Registry (BDR). Serum CRP levels were measured centrally by immunoturbidimetry using Vitros high sensitivity CRP reagents on a Vitros 5,1 FS analyser (Ortho-Clinical Diagnostics, Rochester, NY, USA)

Results: Baseline CRP levels were positively correlated with female sex ($p < 0.001$), age- and sex-adjusted BMI ($p < 0.001$) and presence of GAD antibodies (GADA) ($p = 0.030$), but not with clinical outcome or overall antibody status. However, CRP levels increased more within 2 years prior to clinical onset in prediabetes (median [interquartile range] of CRP change: $0.61 [0.11 - 1.49]$ mg/L) than in individually age- and sex-matched non-diabetic relatives with or without antibodies followed equally long ($p < 0.001$). In survival analysis, an increase in CRP within one year after study entry (median [interquartile range]: $0.35 [0.15 - 1.76]$ mg/L) was associated with progression to diabetes ($p = 0.02$ versus relatives without increasing CRP levels). This association was restricted to the subgroup of persistently GADA⁺ relatives ($n = 150$; $p < 0.001$ versus GADA⁺ relatives without CRP increase) (see figure). Multivariate Cox regression analysis confirmed CRP increase as an independent predictor of diabetes (Hazard Ratio [95% CI]: $2.8 [1.3 - 6.1]$; $p = 0.01$) besides presence of IA-2A ($p < 0.001$) and *HLA-DQ2/DQ8* ($p = 0.002$) in the GADA⁺ subgroup.

Conclusion: CRP levels often increase before clinical onset of diabetes in GADA⁺ relatives reflecting an inflammatory state and contributing to disease prediction.

A platform for the identification and validation of beta cell specific membrane biomarkers

D. Flamez¹, A. Berton², I. Roland², B. Kutlu³, N. Goodman³, M.-C. Beckers⁴, D. Maréchal⁴, S. Goldman⁵, C. Van Huffel⁶, I. Salmon², D.L. Eizirik¹

¹Laboratory of Experimental Medicine, Brussels, Belgium, ²Laboratory of Pathology, Brussels, Belgium, ³ISB, Institute of Systems Biology, Seattle, United States, ⁴Eurogentec SA, Namur, Belgium, ⁵Laboratory of Nuclear Medicine, Brussels, Belgium, ⁶Keymarker SA, Namur, Belgium

Background and aims: The natural history of Type 1 diabetes is currently unknown. Onset of hyperglycemia is believed to occur when > 80% of the beta cell mass is destroyed. Detecting progressive beta cell loss and/or regeneration in pre-clinical or recent onset T1D would allow a better understanding of the natural history of diabetes and validate clinical trials to prevent the disease. The challenge for beta cell mass quantification is that islets are small micro-organs scattered in the pancreas, and none of the proposed beta cell markers are sufficiently specific for imaging. Our aim is to identify novel beta cell specific membrane proteins that can be used as biomarkers for imaging beta cell mass, purification of beta cells or for drug targeting specifically to beta cells.

Materials and methods: Bioinformatic analysis was performed on Massively Parallel Signature Sequencing (MPSS) datasets of two human pancreatic islet samples and on Affymetrix Gene Chip Rat 230.2 array datasets of purified rat beta and alpha cells using the programs TMHMM and Ingenuity Pathway Analysis (IPA). Antibodies against beta cell specific membrane proteins were tested by immunohistochemistry (IHC) on human pancreatic tissue and by Western Blotting (WB) on mouse and rat tissues and on INS-1E and AR42J cells. The sensitivity and specificity of the best candidates will be analysed using multi-tissue human and rat tissue arrays.

Results: We compared MPSS datasets obtained in human islets with publicly available MPSS data obtained in 32 human tissues and selected 848 unique islet specific genes. Using TMHMM and IPA 114, membrane proteins were selected. Genes were then classified as beta cell- or non-beta cell- specific by comparative analysis of Affymetrix microarray data obtained in primary rat beta and alpha cells. Membrane proteins that were highly changed after treatment with the cytokines IL1 β and IFN γ were removed from the list. We retained 44 membrane proteins that are highly enriched in beta cells. After comparison with the expression in the β -Cell Gene Atlas, 12 candidates were retained as potential beta-cell biomarkers. Specific antibodies for 7 of these membrane proteins were purchased or prepared and studied in IHC and in WB studies. Membrane and islet cell localisation was confirmed for all candidates tested. Three candidates showed low expression levels while two candidates had background staining in ductal cells. Four candidates are currently being tested in the human tissue array.

Conclusion: Using a systems biology approach we selected 12 membrane proteins that are highly enriched in pancreatic beta cells. Seven membrane proteins were validated with antibodies specifically directed against the candidate biomarkers. All seven were confirmed to be islet specific membrane proteins validating the present systems biology approach.

Method for high-throughput screening of HLA-B*39 allele to be used in the assessment of genetic risk for type 1 diabetes

M. Kiviniemi¹, A.-P. Laine¹, Z. Gombos¹, R. Hermann¹, M. Knip², J. Nurmi³, T. Lövgren⁴, J. Ilonen¹, the Finnish Pediatric Diabetes Registry
¹Immunogenetics Laboratory, University of Turku, ²The Hospital for Children and Adolescents, University of Helsinki, ³Abacus Diagnostica Ltd., Turku, ⁴Department of Biotechnology, University of Turku, Finland

Background and aims: An independent effect of HLA-B*39 allele for risk of type 1 diabetes has been established. In the Finnish population the effect of this allele is seen in HLA-DRB1*0404-DQB1*0302 haplotypes, the risk conferred by the haplotype is dependent on the presence of B*39 allele in linkage with mentioned class II alleles. A high-throughput assay is needed to exploit this information in genetic screening for natural history and prevention studies and for this purpose an assay for the detection of B*39 allele was developed and the effect of B*39 on the risk conferred by DRB1*0404-DQB1*0302 confirmed in an expanded series of nuclear families with a diabetic child.

Materials and methods: The developed assay was used to screen for the presence of HLA-B*39 allele in 907 Finnish nuclear families with a diabetic child. The assay uses whole blood dried on a sample collection card as sample material, and is based on an allele-specific PCR amplifying only the HLA-B*39 allele, followed by detection of the PCR-products by plate hybridization utilizing lanthanide-labelled probes. The chi-square function of the Epistat software was used in the statistical calculations.

Results: The developed assay was validated by screening 153 previously genotyped samples, and the results were fully concordant when compared to a formerly used standard gel detection of specifically amplified products. Since the results of the new test are produced as numbers they are easily calculated and interpreted by a computer program and integrated to databases. The effect of B*39 allele on the risk of type 1 diabetes conferred by HLA-DRB1*0404-DQB1*0302 haplotype was confirmed in 907 Finnish nuclear families with a diabetic child where affected family-based artificial controls (AFBAC) controls were formed from non-transmitted haplotypes of healthy parents. The odds ratio (OR) for subjects with DRB1*0404-DQB1*0302-B*39 was 8.53 (3.92-19.34) compared to 2.27 (1.54-3.34) for DRB1*0404-DQB1*0302-non-B*39. For comparison the OR for DRB1*0401-DQB1*0302 was 7.58 (5.93-9.70), and for DRB1*0404-DQB1*0302 without regarding B*39 3.47 (2.47-4.88).

Conclusion: The developed HLA-B*39 screening method proved to be robust, simple and fast and well suited for large-scale screening and amenable to automation. The considerably greater predisposing effect of the HLA-DRB1*0404-DQB1*0302-B*39 haplotype compared to that of the HLA-DRB1*0404-DQB1*0302-non-B*39 haplotype was confirmed in the study. Thus the integration of the developed method into the current screening system will increase the specificity of type 1 diabetes risk estimation.

335

First international proficiency testing of novel autoantibodies against Zn Transporter-8 and IA-2beta - Results of the Diabetes Antibody Standardisation Program

M. Schlosser¹, P.W. Mueller², P. Achenbach³, P.J. Bingley⁴

¹Medical Biochemistry and Molecular Biology, University of Greifswald, Karlsburg, Germany, ²Diabetes and Molecular Risk Assessment, Centers of Disease Control and Prevention, Atlanta, United States, ³Institut für Diabetesforschung, TU Munich, Germany, ⁴Clinical Science at North Bristol, University of Bristol, United Kingdom

Background and aims: The Diabetes Antibody Standardization Program (DASP) is a collaboration between the Immunology of Diabetes Society and US Centers for Disease Control and Prevention, set up to evaluate and improve assays for diabetes-associated autoantibodies. Autoantibodies to the novel islet antigens, ZnT8 and IA-2 β , have been associated with type 1 diabetes but their role in predictive strategies has yet to be defined. The DASP 2007 workshop set out to assess the sensitivity/specificity and concordance of assays for ZnT8 and IA-2 β antibodies (Ab) in laboratories throughout the world, and to examine associations with established islet antibody markers.

Materials and methods: Eighteen laboratories from 8 countries received coded sera from 49 patients with newly diagnosed T1DM (median age 17 years, range 5-32) and 100 controls (median age 20 years) with ZnT8 and IA-2 β clones (donated by J Hutton, Denver and V Lampasona, Milan), and positive and negative reference standards. All labs performed in-house radiobinding

assays (serum volume 2–10 µl) using ^{35}S -labelled in vitro transcribed/translated human recombinant ZnT8 (16 labs) and IA-2 β (13 labs). Lab-reported results were recalculated after adjustment to the positive/negative standards (using an index for ZnT8 and multiple point standard curve for IA-2 β). Results were analyzed using receiver operator characteristic (ROC) curves. The sensitivity was adjusted to 95% specificity (AS_{95}) in controls.

Results: For ZnT8 Ab, the median lab-reported sensitivity was 51% (interquartile range (IQR) 44–56%), and specificity 98% (IQR 97–98%). ROC curve analysis showed significant differences between patients and control subjects in 15/16 assays ($p=0.021$ to $p<0.0001$). The median AUC of all assays was 0.71 (IQR 0.68–0.74) with AS_{95} 54% (IQR 47–59%). Samples from 22 patients were reported positive in 12 of 16 assays, and 26 were reported positive in 8 assays. Interlaboratory concordance based on the ZnT8 Ab index was high ($r^2=0.999$; $p<0.0001$). For IA-2 β Ab, the median lab-reported sensitivity was 45% (IQR 43–50%), and specificity 98%. In all labs, ROC curve analysis showed significant differences between patients and control subjects ($p=0.004$ to $p<0.0001$). The median AUC was 0.71 (IQR 0.68–0.74) with AS_{95} 53% (IQR 48–54%). 21 patient samples were reported positive in 11 of 12 assays, and 26 were reported positive in 6 assays. Interlaboratory concordance based on the common IA-2 β units derived from the standard curve was high ($r^2=1.0$; $p<0.0001$). In all labs, IA-2 β -Ab levels significantly correlated with autoantibodies to IA-2 ($r_s=0.685$ to 0.87 ; $p<0.0001$).

Conclusion: The DASP evaluation of these novel autoantibodies demonstrated remarkable consistency in sensitivity and specificity with high levels of concordance between participating labs for both ZnT8 and IA-2 β Ab, and confirmed their validity as diabetes-associated markers. ZnT8 and IA-2 β Ab assays perform well and are suitable for general implementation in the classification and prediction of T1DM. The DASP workshop model provides a powerful resource for rapid, comprehensive evaluation of novel autoantibody markers.

Genetic predictors of islet autoimmunity in early childhood. The Diabetes Autoimmunity Study in the Young (DAISY)

M.J. Rewers, J. Norris, G. Eisenbarth, K. Barriga, A. Steck, J. Hutton, W. Zhang
Barbara Davis Center for Childhood Diabetes, University of Colorado, Denver, United States

Background and aims: While multiple markers of genetic susceptibility for type 1 diabetes (T1D) are being reported from linkage and association studies, little is known concerning their independent predictive value on a population basis.

Materials and methods: DAISY is following from birth to development of islet autoimmunity (IA) and T1D 2449 high-risk children who have a high-risk HLA-DR,DQ genotype or are first-degree relatives of someone with T1D. Blood is drawn for the detection of autoantibodies to insulin, GAD65, IA-2 and ZnT8 at 9 and 15 months and annually thereafter. IA is defined as positivity for at least one of the 4 autoantibodies on two or more consecutive visits. By mean age of 7.0 ± 4.4 years, 163 children have developed IA and, of those, 53 have developed diabetes. Parametric models with Weibull distribution and Cox proportional hazards models were used to examine genetic predictors of IA and diabetes, respectively.

Results: By age 12 yr, the cumulative risk (95%CI) of IA was 36% (19–56%), 11% (3–35%), and 14% (8–25%) in, respectively, relatives with HLA-DR3/4, DQ8, all other relatives, and general population children with HLA-DR3/4, DQ8. The risk of T1D by age 12 in these groups was, respectively 24% (15–37%), 4% (3–7%), and 1% (0.4–3%). The HLA-DR,DQ genotype and, to a much lesser extent the PTPN22 and INS genotypes predicted development of IA and T1D.

Conclusion: These genotype first prospective population data including IA defined using ZnT8 as well as the classical islet autoantibodies confirms the dominant effect of genetic susceptibility conferred by the HLA-DR,DQ genotypes on the risk of IA and T1D in early childhood.

Multivariate analysis of predictors of IA and diabetes, controlling for gender, race, and family his

Covariates	HR for IA (95% CI)	HR for T1D (95% CI)
HLA-DR3/4, DQ8	3.2 (2.3–4.6)	8.1 (4.5–14.6)

The evaluation of immunological parameters, beta cell function and insulin resistance in first degree relatives of the patients with autoimmune diabetes

K. Siewko, M. Szelachowska, A. Nikolajuk, M. Gorska
Department of Endocrinology, Diabetology and Internal Medicine, Medical University, Białystok, Poland

Background and aims: The presence of immunological and/or metabolic markers in the blood of people predisposed to autoimmune diabetes increases the risk of clinical onset of diabetes. Insulin resistance in type 1 diabetes has aroused a great interest recently. The aim of the study was the evaluation of the first phase of insulin secretion, C-peptide concentration, HOMA%B index, as well as insulin resistance, measured by HOMA-IR, in relation to the occurrence of antibodies against pancreatic islets (GADA, IAA, and anti-IA2).

Materials and methods: The study was conducted in 90 I 0 relatives of the patients with type 1 diabetes (60 adults and 30 children), aged 9–65 years (mean age 27.1 ± 15.5), mean BMI 24.6 ± 4.95 kg/m 2 . Fasting C-peptide concentration was determined using ELISA method, insulin concentration during the intravenous glucose load test (0, 1, 3, 5 min) - by EASIA method, and GADA, IAA, and anti-IA2 titres - by RIA method. HOMA-IR and HOMA%B indices were calculated using computer calculator from the Website Oxford Centre for Diabetes, Endocrinology and Metabolism.

Results: The presence of a positive titre of at least one of the antibodies was found in 28 patients (31.11%). The highest percentage concerned IAA (22.22%). None of the persons had C-peptide concentration below normal range, however 22 people (24.44%) showed its increased values. Significantly higher insulin concentration at 0 min ($7.71 \mu\text{IU/ml} \pm 4.29$ vs $5.27 \mu\text{IU/ml} \pm 2.32$ $p<0.002$) and significantly lower concentrations at 1 min ($46.22 \mu\text{IU/ml} \pm 33.46$ vs $64.34 \mu\text{IU/ml} \pm 34.06$ $p<0.008$) and at 3 min ($45.9 \mu\text{IU/ml} \pm 30.69$ vs $59.7 \mu\text{IU/ml} \pm 24.86$ $p<0.005$) were observed during intravenous test of glucose load in the group of the relatives as compared to the control group. The highest fasting insulin values were observed in the group of relatives with positive IAA titres. Significantly higher HOMA-IR (1.16 ± 0.63 vs 0.79 ± 0.34 , $p<0.002$) and significantly lower HOMA%B index (92.84 ± 29.39 vs 114.0 ± 47.06 , $p<0.015$) were found in the study group as compared to the controls. Positive correlations between IAA and C-peptide concentration ($r=0.282$, $p<0.002$), IAA and HOMA-IR ($r=0.287$, $p<0.002$) and a negative correlation between IAA and HOMA%B ($r=-0.226$, $p<0.015$) were observed.

Conclusion: The increased concentrations of fasting C-peptide and insulin, with decreased beta cell function, can be referred to compensatory increase in secretory capacity of beta cells in the group of I 0 relatives. Higher concentrations of fasting C-peptide and insulin levels, as well as increased HOMA-IR may suggest insulin resistance in these people. The presence of significant correlations between IAA and HOMA-IR and HOMA%B may indicate that these I 0 relatives are at higher risk of the development of autoimmune diabetes mellitus.

338

Relationship of insulin resistance to islet autoimmunity in children

C. Winkler¹, M. Zwilling¹, A.-G. Ziegler^{1,2}
¹Institut für Diabetesforschung, Munich, ²Städt. Klinikum München GmbH, Klinikum Schwabing, Munich, Germany

Background and aims: It has been suggested that metabolic demand and insulin resistance play a role in the development of T1D, including the onset of autoimmunity. The aim of the present study was to determine whether islet autoimmunity is associated with insulin resistance.

Materials and methods: The analysis included 779 children from the German BABYDIAB study, a prospective observational study that followed newborn offspring of mothers or fathers with T1D from birth to 17 years of age. Insulin resistance was estimated by homeostasis model assessment of insulin resistance (HOMA-IR) in 25 children at age of 5 years, in 484 children at age of 8 years, in 344 children at age of 11 years, in 85 children at age of 14 years and in 6 children at age of 17 years; 159 children had more than one HOMA-IR measurement. Of the 779 children, 86 had at least one persistent islet autoantibody, median age at first islet autoantibody appearance was 5.03 (IQR, 2.12–8.10); and 15 children developed T1D, median age at diagnosis was 9.36 (IQR, 7.71–10.78).

Results: Median HOMA-IR at 5, 8, 11, and 14 years were 0.32 (IQR, 0.23–0.76), 0.76 (IQR, 0.49–1.17), 1.17 (IQR, 0.8–1.75), and 1.7 (IQR, 1.07–2.42),

respectively. In a general linear model, increased HOMA-IR was associated with female gender ($P < 10^{-10}$), older age ($P = 4 \times 10^{-7}$) and increased BMI ($P < 10^{-10}$). Children with islet antibodies had in tendency lower HOMA-IR than children who were islet autoantibody negative, but this was not significant ($P = 0.11$) after correction for age of measurements, BMI and gender. Moreover, islet autoantibody positive children did not have increased BMI. Although relatively few children progressed to diabetes, an increased HOMA-IR was not associated with a faster progression rate in the antibody positive children, but rather was associated with a reduced diabetes risk ($P = 0.04$). Only 5 of 15 children who developed diabetes had HOMA-IR above the median for the respective age in the last measurement prior to diabetes onset.

Conclusion: Islet autoantibody positive children are not insulin resistant soon after sero-conversion and during follow-up. These results are inconsistent with the notion that insulin resistance is a risk factor for islet autoimmunity.

Factors associated with glucose intolerance in patients with chronic hepatitis B or chronic hepatitis C

A.N. Mavrogiannaki, B.G. Karamanos, E.K. Manesis, J.S. Koskinas, G.V. Papatheodoridis, A.C. Thanopoulou, M.M. Noutsou, A.J. Kofinis, A.J. Archimandritis

Diabetes Center, 2nd Academic Department of Internal Medicine, Athens, Greece

Background and aims: The comparison of the prevalence of glucose intolerance between patients with chronic hepatitis B (CHB) and C (CHC) is mostly based on abnormal fasting glucose or known diabetes, leading to underdiagnosis of glucose intolerance. Aim of the present study was to compare the prevalence of glucose intolerance between CHB and CHC patients, using as criterion the OGTT and furthermore to explore possible associations of glucose intolerance with biochemical abnormalities characteristic of CHB or CHC and also with the degree of the histological lesions of the liver.

Materials and methods: We studied 83 consecutive CHB patients and 113 CHC patients examined at the outpatient liver clinic. Blood samples were obtained for laboratory investigations and OGTT was performed in all (except known diabetics). A liver biopsy was performed, according to clinical indications, in 57 CHB and 91 CHC patients. As glucose intolerance we considered impaired glucose tolerance (IGT), abnormal OGTT or known diabetes. All comparisons were done after adjustment for age and BMI.

Results: The prevalence of glucose intolerance was higher in CHC than CHB patients (42.5% vs 28.9%, $P = 0.050$). Among CHB patients, those with glucose intolerance compared with those with normal glucose tolerance had more frequent family history of diabetes (58.3% vs 23.7%, $P = 0.004$) and higher γ -GT (45.4 ± 5.7 vs 25.3 ± 4.0 IU/L, $P = 0.008$), while insulin resistance, by HOMA model and plasma insulin at every time point did not differ. Among CHC patients, those with glucose intolerance compared with those with normal glucose tolerance had higher insulin resistance (5.0 ± 0.5 vs 2.9 ± 0.4 , $P = 0.000$), higher plasma insulin at 120 min (70.2 ± 7.0 vs 39.2 ± 4.8 μ U/ml, $P = 0.001$) and higher prevalence of cryoglobulinemia (58.3% vs 32.8%, $P = 0.021$), while family history of diabetes and fasting insulin did not differ. In both groups of CHB and CHC patients, the grade of necroinflammatory activity, the stage of fibrosis, the presence of cirrhosis and the grade of steatosis, evaluated blindly, were not related with the presence of glucose intolerance. It is also noted that, the majority of patients had mild histological alterations of fibrosis.

Conclusion: Increased prevalence of glucose intolerance is documented in chronic hepatitis C compared with chronic hepatitis B, using OGTT. Factors associated with glucose intolerance are different in the two types of liver diseases, namely, family history of diabetes and higher γ -GT in CHB, while insulin resistance and cryoglobulinemia in CHC. Glucose intolerance could be another extrahepatic manifestation of CHC, as cryoglobulinemia. Mild histological lesions are not related with glucose intolerance.

Specific phenotype associated with diabetes mellitus secondary to chronic hepatitis C infection

A. Poussier¹, M. Lebouvier¹, A. Penfornis², V. Di Martino³, P. Buffier¹, B. Verges¹, P. Hillon⁴, J.-M. Petit¹

¹Endocrinology, CHU Bocage Dijon, Dijon, France, ²Endocrinology, CHU Besançon, Dijon, France, ³Hepatology, CHU Besançon, Dijon, France,

⁴Hepatology, CHU Bocage Dijon, Dijon, France

Background and aims: A link between chronic hepatitis C virus infection (HCV), type 2 diabetes mellitus and insulin resistance has been suggested by several studies. However, it seems that HCV infection is associated with insulin resistance but is not associated with metabolic syndrome. The following study, was undertaken to determine whether chronic HCV infection had an impact on the clinical characteristics of type 2 diabetes.

Materials and methods: To address this question, we studied retrospectively, a group of patients with diabetes mellitus associated with HCV infection (HCV-DM), and compared them with patients suffering from conventional type 2 diabetes (DM).

Results: The HCV-DM patients had a lower BMI ($p = 0.001$), and systolic blood pressure ($p = 0.04$) compared to patients with DM diabetes. Ten (27.0

%) patients in the HCV-DM group and 35 (47.3%) in the DM group had microalbuminuria ($p=0.04$). DM patients had significantly higher serum creatinine levels than HCV-DM patients (102.9 ± 62.9 vs 81.9 ± 32.4 mmol/l, $p=0.02$). One (2.7%) HCV-DM patients and 44 (59.4%) DM patients were treated with hypolipemic therapy ($p=0.0001$). Even though nearly two-thirds of the overall DM-group were receiving cholesterol-lowering drugs, DM patients had significantly higher total cholesterol, HDL cholesterol and triglyceride levels than HCV-DM patients.

Conclusion: Our study confirms that HCV-diabetic patients had specific clinical characteristics in comparison to classical type 2 diabetic patients. These data suggest a direct effect of HCV virus on the development of insulin resistance and diabetes mellitus without the association of the metabolic syndrome.

Ketosis prone type 2 diabetes and human herpes virus 8 in sub-Saharan Africans

E. Sobngwi¹, S.P. Choukem¹, F. Agbalika², B. Blondeau³, L.-S. Fetita¹, C. Lebbe⁴, D. Thiam², P. Cattani⁵, J. Larghero⁵, F. Fougelle³, P. Ferre³, P. Vexiau¹, F. Calvo⁶, J.-F. Gautier^{1,3}

¹Dept. of Endocrinology, Diabetology & Nutrition, Hôpital Saint Louis, Paris, ²Department of Virology, Hôpital Saint Louis, Paris, ³Inserm umrs 872, Centre de Recherche des Cordeliers, Paris, ⁴Department of Dermatology, Hôpital Saint Louis, Paris, ⁵Cell Therapy Unit, Hôpital Saint Louis, Paris, ⁶Centre d'Investigation Clinique CIC9504, INSERM, Hôpital Saint Louis, Paris, France

Background and aims: An atypical form of type 2 diabetes is revealed by ketosis (Ketosis-prone type 2 diabetes- KPD), frequently in black Africans, and characterized by an acute onset requiring transient insulin therapy. Its sudden onset suggests precipitating factors. Given the geographic prevalence of KPD, we investigated in a prospective and observational cohort study, the putative role of Human Herpes Virus-8 (HHV-8) in its pathogenesis.

Materials and methods: This prospective, observational cohort study took place at Saint-Louis University Hospital. We searched antibodies against latent and lytic HHV-8 antigens, using immunofluorescence, in 187 black African consecutive diabetic patients of whom 81 had KPD, and 106 type 2 diabetes (T2D) and in 90 black African non-diabetic subjects matched for age and sex (controls). The presence of HHV-8 in genomic DNA was investigated in 22 patients at clinical onset of diabetes. We also tested whether HHV-8 was able to infect human pancreatic beta cells in culture *in vitro*.

Results: HHV-8 antibodies were found in 87.7% of KPD patients versus 15.1% non-ketotic type 2 diabetes (T2D), OR=39.9 (17.1-93.4; $p<0.0001$) and 40.0% of the control subjects OR=10.7 (4.9-23.4; $p<0.0001$). HHV-8 DNA was present in 6/13 KPD tested at acute onset and in 0/9 T2D. Furthermore, we showed the presence of HHV-8 proteins in human islet cells cultured for 4 days in the presence of HHV-8.

Conclusion: In KPD patients of sub-Saharan African origin, HHV-8 DNA is found in almost 50% of patients at onset and the prevalence of HHV-8 seropositivity is unexpectedly high. These data together with the capacity of HHV-8 to infect human beta cells *in vitro* support that HHV-8 infection may convert T2D into KPD.

Interaction of early cow's milk-based formula exposure and enterovirus infection in infancy in the development of type 1 diabetes-associated autoimmunity

J. Aarnisalo¹, H. Honkanen², M. Mäkelä¹, S. Tauriainen², J. Marttila¹, R. Veijola³, M. Knip^{4,5}, O. Simell⁶, R. Hermann¹, H. Hyöty⁷, O. Vaarala⁷, J. Ilonen¹

¹Immunogenetics Laboratory, University of Turku, ²Department of Virology, University of Tampere, ³Department of Pediatrics, University of Oulu, ⁴Department of Pediatrics, University of Tampere, ⁵Hospital for Children and Adolescents, University of Helsinki, Finland, ⁶Department of Pediatrics, University of Turku, ⁷Laboratory of Immunobiology, National Public Health Institute, Helsinki, Finland

Aims: Both enterovirus infections in childhood and cow's milk based formula feeding during infancy have been implicated in the initiation of type 1

diabetes (T1D) -associated autoimmunity. Moreover, the timing of these triggering factors seems to be crucial. In this study we aimed to analyse further the influence of these factors on autoimmunity associated with T1D.

Subjects and methods: Study subjects were participants in the Diabetes Prediction and Prevention Study (DIPP) and carried HLA-genotypes conferring risk for T1D. According to the study protocol the subjects were observed for the appearance of T1D-associated autoantibodies (ICA, IAA, GADA, IA-2A) at 3-12 month intervals. 107 case subjects positive for multiple (≥ 2) autoantibodies and 447 autoantibody negative controls matched for age, gender and HLA DQB1 genotype (3-5 controls/case) were compared. Length of the follow-up was 4.5-11.9 years (median 8.0). Coxsackie B4 (CBV4) IgG and IgA, adenovirus IgG and IgA and RSV IgG antibodies were detected using EIA from serum samples collected at the age of 6, 12 and 18 months. 251 of the study subjects were exposed to cow's milk-based formula (CM) before the age of 3 months and 222 subjects later in infancy.

Results: By the age of 12 months 83 of the 518 (16.0%) subjects tested had antibodies against CBV4, 68 (13.1%) against adenovirus and 152 of the 508 subjects (30.0%) against RSV. In the Cox regression analysis, none of these virus infections detected by the age of 6, 12 or 18 months were associated with the appearance of any of the diabetes-associated autoantibodies or T1D. Similarly, no association could be observed between early exposure to CM and later signs of autoimmunity. Interestingly, when the combined effect of early exposure to CM and CBV4 infection during the first 12 months of life on the appearance of autoantibodies and T1D was analysed Cox regression analysis showed a strong association between early CM exposure and CBV4 infection in infancy. The association with the appearance of autoantibodies and clinical T1D was strongest among subjects exposed to CM before 3 months of age and emerging with CBV4 antibodies between 6 and 12 months of life (HR 11.4 (95% CI 2.9-44.9) $p=0.001$ for ICA, 15.9 (3.1-81.6) $p=0.001$ for IAA 16.1 (3.2-80.0) $p=0.005$ for GADA 7.7 (1.9-32.4) $p=0.005$ for IA-2A and 9.9 (0.98-99.9) $p=0.05$ for clinical T1D) when stratified according to the HLA DQB1-DQA genotype and PTPN22 +1858C/T, insulin gene -23 HphI A/T and CTLA4 +49 A/G polymorphisms. No interplay could be observed between CM exposure and adenovirus or RSV infection.

Conclusion: Our results suggest an interplay between early insulin immunisation through cow's milk-based formula and enterovirus infection during the second half of the infancy. The needed interaction between the two hypothesised environmental factors may explain the controversial results obtained in studies observing the effect of only one of these factors.

343

Dehydroascorbate protection against dioxin-induced toxicity in the beta cell line INS-1E

V. De Tata, L. Martino, M. Novelli, M. Masini, A. Casini, P. Masiello
Experimental Pathology & B.M.I.E., University of Pisa, Italy

Background and aims: Consistent epidemiological data have recently revealed a positive correlation between exposure to persistent organic pollutants and glucose metabolism disorders including type 2 diabetes and metabolic syndrome. These observations are particularly interesting, with reference to the continuous increase of the prevalence of type 2 diabetes in the last decades, suggesting a possible contribution of environmental factors to the pathogenesis of the disease, in addition to obvious nutritional habits. We have previously demonstrated that 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) is highly toxic for β cells and that it markedly impairs glucose-stimulated insulin secretion. As it is known that acute exposure to TCDD results in oxidative stress and that pancreatic β cells are highly vulnerable to reactive oxygen species (ROS)-mediated tissue damage, in this study we aimed at investigating the protective effect of dehydroascorbic acid (DHA), a well-known antioxidant agent, against TCDD-induced toxicity in the INS-1E β -cell line.

Materials and methods: INS-1E cells were preincubated for 30 min with 0.5 or 1.0 mM DHA and then exposed for 1 h to different concentrations (range 0-50 nM) of TCDD. We have then evaluated: 1) cell survival and ultrastructural alterations; 2) intracellular ROS production by fluorimetric methods; 3) mitochondrial membrane potential by cytofluorimetry; 4) glucose-stimulated insulin secretion.

Results: We have preliminarily verified that 30-min incubation of INS-1E cells with DHA led to a rapid, significant and dose-dependent increase of the intracellular levels of ascorbic acid. β -cell viability, markedly impaired upon TCDD exposure (12-50 nM), was significantly increased following 30-min preincubation with DHA. Electron microscopy showed that a peculiar ultrastructural alteration in TCDD-treated cells (12-25 nM) was the presence of several autophagic vacuoles containing mitochondria, which also occurred

after pre-treatment with 1 mM DHA. However, in most cells pre-exposed to DHA, these vacuoles appeared at early stages of formation (i.e., prior to lysosome fusion), a feature that was never observed in cells treated with TCDD alone. Surprisingly, we could not detect any increase in ROS production after 1 h exposure of INS-1E cells to TCDD; nevertheless, we observed TCDD-induced mitochondrial membrane depolarization which was significantly prevented when the cells were pre-exposed to 1 mM DHA. Finally, in INS-1E cells preincubated with 1 mM DHA for 30 min and subsequently exposed to TCDD at a very low, non cytotoxic dose (1 nM), the inhibitory effect of TCDD on glucose-stimulated insulin secretion was fully prevented.

Conclusion: Our data clearly show that DHA is able to protect INS-1E cells against TCDD-induced toxicity in terms of both cell function and survival. This protective effect could be related to the ability of DHA to preserve mitochondrial integrity or at least to limit TCDD-induced mitochondrial damage.

344

Insulin autoantibodies that cross-react with casein

K. Koczwara¹, D. Mueller¹, P. Achenbach¹, S. Krause¹, A.G. Ziegler^{1,2}, E. Bonifacio³

¹Institut für Diabetesforschung, Munich, ²Klinikum Schwabing, Städt. Klinikum München GmbH, ³Center for Regenerative Therapies – Dresden, University of Technology, Germany

Background and aims: Insulin autoantibodies (IAA) can appear early in life and precede clinical type 1 diabetes (T1DM) in children. Although the immunization events leading to IAA are unknown it has been shown that some low affinity IAA have an IgA component and a preferred binding to non-human insulin suggesting that IAA can result from immunization against molecules other than human insulin at mucosal sites. The aim of this study was to determine whether some IAA may be cross-reactive with and potentially primarily directed against exogenous antigens such as components of infant's diet.

Materials and methods: Antibody binding to ¹²⁵I labeled human insulin in the presence or absence of food proteins was analyzed in sera from IAA positive children with a first-degree T1DM family history from prospective follow-up studies (n=45; median age 2.3 years, IQR 1.8–5.2). Direct binding to food proteins was performed by radiobinding assay.

Results: Initial experiments identified IAA from 3 of 9 children that were significantly inhibited by whole bovine milk powder (98%, 85%, and 46% inhibition of IAA binding) but not by hydrolyzed hypo-allergic milk powder, wheat flour and fowl meal, respectively. IAA of the remaining 6 children and 2 patients with T1DM were not reactive with any of these food components. Subsequent screening of further 36 IAA positive children using 0.5 µg whole bovine milk powder for competition discovered 3 additional children whose IAA were partially inhibited by milk components. All of the milk-reactive IAA were of lower affinity (<10⁹ L/mol), and these children did not develop GAD and/or IA-2 autoantibodies or T1DM within a median follow-up of 6.1 years (IQR 2.6–7.1). The milk-reactive IAA occasionally had an IgA-IAA component. Further testing of defined milk protein components revealed that their IAA binding was completely inhibited by 0.25 µg of alpha- and beta-casein, respectively, but was not affected by lactoglobulin or BSA. Moreover, antibody binding to labeled human insulin was better inhibited by casein (alpha > beta) than by human insulin in these sera, indicating that the affinity of the antibodies was at least 1 log higher for casein than insulin. All sera tested bound ¹⁴C labeled bovine alpha-casein; binding to ¹⁴C-alpha-casein was not inhibited by insulin.

Conclusion: The data show that IAA can be cross-reactive to non-insulin proteins and suggest that in some cases, IAA could be secondary to immunization against food proteins. These cases do not appear to be associated with type 1 diabetes.

Islet cell antibodies associate with the presence of enteroviral RNA while glutamic acid decarboxylase antibodies do with insulin resistance in first degree relatives of type 1 diabetes

E. Cabrera-Rode¹, L. Sarmiento², I. Cuba¹, G. Molina¹, M. Fonseca², L. Heng-Hung², C. Arranz¹, E. Dominguez², P. González², O. Diaz-Horta¹

¹Department of Immunology and Genetics on Diabetes, National Institute

of Endocrinology, ²Department of Virology, "Pedro Kouri" Tropical Medicine Institute, ³Department of Endocrinology, Hospital "William Soler", Havana, Cuba

Background and aims: We have previously demonstrated that there is an association between the presence of enteroviral RNA and the onset of type 1 diabetes. Other groups have reported insulin resistance as a risk factor for progression of type 1 diabetes. We evaluated whether type 1 diabetes associated antibodies (ICA, GAD and IA-2 antibodies) are related to occurrence of enteroviral RNA and insulin resistance in first degree relatives of type 1 diabetic patients.

Materials and methods: Serum samples were collected from islet cell autoantibody-positive (n=32) and -negative (n=62) first degree relatives of type 1 diabetic patients. Plasma glucose concentrations were determined by glucose oxidase method. ICAs were determined by indirect immunofluorescence technique with prolonged incubation. Antibodies to GAD, IA-2, and insulin were determined by radioimmunoassay; and insulin resistance was estimated by the homeostasis model assessment (HOMA-IR). Enteroviral RNA was assessed using highly sensitive reverse transcriptase-polymerase chain reaction method.

Results: Occurrence of enteroviral RNA was higher in ICA-positive (5/32, 15.6%) first degree relatives of type 1 diabetic patients in comparison to ICA-negative subjects (1/62, 1.6%; p = 0.0164). In addition, the presence of enteroviral RNA was associated with high ICA titres (≥ 20 JDFunits, p = 0.0064). On the other hand, insulin resistance (HOMA-IR) was increased in GADA-positive (n=19, Mean 2.99 ± 2.1) versus GADA-negative first degree relatives (n=75, Mean 1.86 ± 1.48, p = 0.038). The insulin resistance was not related to GADA titres. The presence of IA2 antibodies was associated neither with the occurrence of enteroviral RNA nor with insulin resistance.

Conclusion: These data suggest that enterovirus infections and insulin resistance are two different and independent events related to the production of type 1 diabetes associated autoantibodies (ICA and GADA). This results support the hypothesis that different factors (virus and insulin resistance) are aetiologically important as trigger and/or accelerating factors for type 1 development.

Ethanol impairs GLUT4 expression in the isolated rat and human adipocytes: role of AMP-activated protein kinase alpha and myocyte enhancer factor 2

L. Feng, Q. Li, Q.B. Guan, J.J. Zhao

Endocrinology, Provincial Hospital affiliated to Shandong University, Jinan, China

Background and aims: Previous studies reported that heavy ethanol intake impaired GLUT4 expression in adipose tissues, but the precise mechanisms are not well elucidated. Recently, AMP-activated protein kinase (AMPK) is considered to be a new target of ethanol. Moreover, studies in skeletal muscle found that AMPK regulated GLUT4 via myocyte enhancer factor 2 (MEF2), a transcription regulator of GLUT4. Here, we explored whether the AMPK/MEF2 pathway was involved in the impairment effects of ethanol on GLUT4 expression in isolated rat and human primary adipocytes.

Materials and methods: The present study was consisted of two parts. (1) To test whether an AMPK/MEF2/GLUT4 pathway existed in adipose tissues and observe the regulation of AMPK on MEF2 and GLUT4 *in vivo*, eight male Wistar rats were randomly divided into two groups, subcutaneously injected with AICAR (an AMPK activator, 0.8 mg/g body weight) or with a corresponding volume of 0.9% NaCl (controls). Two hours later, epididymal adipose tissues were obtained. (2) To reconfirm the existence of this pathway in adipocytes *in vitro* and explore effects of ethanol on it, adipocytes isolated from normal Wistar rat and human adipose tissues were respectively incubated with and without edible ethanol, AICAR, or compound C (a selectively AMPK inhibitor) for 1h. Protein expression of phosphorylated-AMPK alpha (the activated AMPK), MEF2 and GLUT4 was tested by western blotting. GLUT4 mRNA levels were measured by RT-PCR.

Results: In experiments *in vivo*, AICAR injection led to a marked increase in AMPK α phosphorylation (1.9-fold over control, $P < 0.01$) in the rat adipose tissues. Following the activation of AMPK, MEF2 protein was elevated by 60.6% ($P < 0.05$). As the result, the GLUT4 mRNA levels were increased by 62.8% ($P < 0.05$) and subsequently its protein was enhanced by 58.94% ($P < 0.05$). Our data showed the activated-AMPK exerted positive regulations of MEF2 and GLUT4 expression *in vivo*. In experiments *in vitro*, in AICAR treated-rat and human adipocytes, the P-AMPK α expression was increased by 83.37- and 90.87% (both $P < 0.01$). Subsequently, MEF2 was enhanced by 73.31- and 53.92% ($P < 0.01$ and $P < 0.05$). Accordingly, for GLUT4, the mRNA levels were elevated by 51.89- and 54.89% (both $P < 0.05$), the protein expression was increased by 48.81- and 39.9% (both $P < 0.05$). However, if the cells were supplied with compound C prior to AICAR for 20min, the augmented effects of AICAR on activated-AMPK, MEF2, and GLUT4 were inhibited to nearly normal levels. These results reconfirmed the findings we observed *in vivo*.

To observe the action of ethanol on this pathway, the above cells were treated with edible ethanol. In relative to controls, in the rat and human adipocytes, ethanol decreased P-AMPK α protein by 38.6- and 56% (both $P < 0.05$), then MEF2 expression was attenuated by 32- and 44.84% (both $P < 0.05$). As a result, the mRNA and protein levels of GLUT4 were diminished by 51.75- and 40.03% (both $P < 0.05$) in rat adipocytes, by 39.86- and 59.51% (both $P < 0.05$) in human adipocytes. These results suggested that the impaired GLUT4 expression by ethanol was most probably due to the decline of AMPK activity, then the inhibition of MEF2 expression.

Conclusion: In this study, we demonstrated that an AMPK/ MEF2/ GLUT4 pathway existed in both rat and human adipose tissues, the activated-AMPK positively regulated MEF2 and GLUT4 expression. The ethanol-mediated inhibition of this pathway might contribute to the impairment of GLUT4 expression.

Glucose challenge test two-step screening for prediabetes and early diabetes

L.S. Phillips^{1,2}, K.M.V. Narayan³, D.C. Ziemer¹, P. Kolm⁴, M.K. Rhee¹, R. Chatterjee³, W.S. Weintraub⁴, V. Vaccarino⁵

¹Division of Endocrinology and Metabolism, Emory University School of Medicine, Atlanta, ²Research Service, VA Medical Center, Decatur, ³Department of Global Health, Rollins School of Public Health, Atlanta, ⁴Division of Cardiology, Christiana HealthCare, Newark, ⁵Division of Cardiology, Emory University School of Medicine, Atlanta, United States

Background and aims: Diabetes care is limited by lack of screening. Progression from prediabetes to diabetes can be prevented or delayed, but most individuals with prediabetes are not detected, and cannot receive interventions to reduce risk. Since we lack a good screening strategy, glucose intolerance progresses for 5-10 years, many patients have early complications by the time they are recognized, and diabetes control can be difficult. We hypothesized that screening could be accomplished with a two-step "glucose challenge test" (GCT) strategy, similar to screening for gestational diabetes: a 50g oral GCT at any time of day, regardless of meal status, with a single 1 hr sample. If the GCT exceeded a cutoff, patients would have a 75g oral glucose tolerance test (OGTT) after an overnight fast.

Materials and methods: We tested our hypothesis in 1,419 adult volunteer subjects who were generally well, not pregnant, and not known to have diabetes. At a first visit, they had measurement of random plasma and capillary glucose (RPG and RCG), followed by the 50g GCT with 1 hr samples for plasma and capillary glucose (GCTpl and GCTcap) - without prior restriction of food, and at different times during the day. All had an OGTT at a second visit - after an overnight fast, and beginning before 11 am. Glucose intolerance was defined by WHO criteria (FPG ≥ 6.1 , 2hPG ≥ 7.8 mM) and screening accuracy evaluated by ROC analysis.

Results: The subjects had average age 48 yr, BMI 30.2 kg/m², and were 60% female and 56% black; 5% had diabetes (DM), 21% had DM or IGT, and 24% had dysglycemia (DM or IGT or IFG). GCTpl provided area under the ROC curve (AROC) 0.89, 0.82, and 0.81 for detection of DM, DM or IGT, and dysglycemia, respectively, each higher than GCTcap (AROC 0.85, 0.77, and 0.76), $p < 0.05$. To detect DM or IGT, GCTpl was better than RPG (AROC 0.72) and GCTcap was better than RCG (0.65), both $p < 0.001$. GCTpl to detect DM or IGT was comparable in males and females (AROC 0.81 and 0.83), blacks and whites (0.85 and 0.80), unaffected by time after meals or time of day (both $p > 0.2$), and comparable in groups with differing prevalence of glucose intolerance (AROC 0.80, 0.82, and 0.80, for age < 40 , 40-55, and > 55 yr; AROC 0.81, 0.82, and 0.82, for BMI < 25 , 25-35, > 35 , both $p > 0.6$). Multivariate analysis showed that the *c*-statistic (equivalent to AROC) of GCTpl for detection of DM or IGT was highly significant and independent of age, sex, race, BMI, waist circumference, HDL, systolic BP, and family history ($p < 0.001$); inclusion of these variables produced an increase in AROC that was significant but small (0.85). The direct cost of GCTcap screening should be less than \$5 per person; economic modeling indicated that GCT screening and 3 years of management with metformin may be cost-saving vs. no screening in healthcare systems such as the VA in the U.S.A.

Conclusion: Two-step GCT-OGTT screening for prediabetes and unrecognized diabetes is accurate, convenient, and inexpensive. Widespread use of this strategy could help to revolutionize diabetes care, since early detection would allow preventive management which is efficacious and cost-effective. Supported by: NIDDK

Identification of high-risk individuals for implementation of a diabetes prevention program in an occupational setting. The DEPLAN Study

S. Grammatikou, S. Liatis, K. Makrilakis, M. Katsorida, P. Konstantopoulou, C. Pietris, C. Alexopoulos, K. Kyriakopoulos, K. Perrea, D. Perrea, N. Katsilambros
1st Internal Medicine Department, Athens University Medical School Laiko Hospital, Greece

Background and aims: DEPLAN is a European program for type 2 diabetes (T2D) prevention based on lifestyle intervention, implemented in a range of

populations across the European Union. In this study we explored the feasibility of implementing a diabetes identification risk score questionnaire at an occupational setting.

Materials and methods: In the first step of the project, persons working at four companies were distributed a simple, validated questionnaire (FIND-RISK), for identifying those at increased risk for T2D. As part of the screening procedure, the medical department of three public companies and one private company in the district of Athens, Greece, were contacted and informed about the aim of the study. A “day for diabetes prevention” was arranged, during which three doctors of the investigation team visited each company and, in collaboration with the local health professional staff, distributed the FINDRISK questionnaire to all the employees attending their job at that specific date. The questionnaires were completed on site and the employees were given their score. A score ≥ 15 (maximum possible 26) was considered as setting the person at high risk. The identified high-risk individuals were invited to receive an oral glucose tolerance test (oGTT) at a different day, in order to exclude persons with unknown diabetes. The remaining non-diabetic, high-risk employees were invited to attend the one-year diabetes prevention program.

Results: A total of 1001 employees (579 men and 422 women), aged 20 to 64 years completed the FINDRISK questionnaire. Fewer women than men (8.29% vs. 17.96%) were included in the eldest age group (55–64 years). Mean BMI was 27.19 ± 4.67 Kg/m² (men: 28.38 Kg/m², women: 25.55 Kg/m²) and mean waist circumference was 94.81 ± 13.62 cm. The median FINDRISK score was 9 (min: 0, max: 24). A total of 146 (14.59%) employees [93 men (16.43%) and 48 women (11.76%) had a score ≥ 15 and 83 of them (56.84%) accepted to receive an oGTT in order to enter the lifestyle intervention program. 16 persons (19.27%) were found to have diabetes (9 men and 7 women) while 36 (43.37%) had impaired fasting glucose (IFG, fasting blood glucose 100–125 mg/dl), 8 (9.64%) had impaired glucose tolerance (IGT) and 23 (27.71%) had normal glucose metabolism. Thus, the FINDRISK questionnaire yielded a positive predictive value of 72.29% for identifying any glucose abnormality. After exclusion of the individuals with diabetes, the remaining (n=67) employees were offered to enter the one-year lifestyle intervention program and 60 of them (89.55%) accepted.

Conclusion: The FINDRISK questionnaire has a high positive predictive value (72.29%) for identifying impaired glucose metabolism in a young and middle-aged working Greek population. A high percentage (14.59%) of Greek employees are at high-risk for developing T2D and more than half of them (56.84%) are willing to participate in T2D prevention programs using lifestyle modification.

Dietary energy density predicts the risk of type 2 diabetes: the EPIC-Norfolk Study, 1993–2005

J. Wang¹, R. Luben², K.-T. Khaw², S. Bingham², N.J. Wareham¹, N.G. Forouhi¹

¹Institute of Metabolic Science, Medical Research Council Epidemiology Unit, ²Department of Public Health and Primary Care, Institute of Public Health, Cambridge, United Kingdom

Background and aims: Accumulating evidence suggests that energy dense foods predispose to obesity, and there is speculation that such foods may also be associated with increased risk of type 2 diabetes (T2DM), but there is limited supportive evidence. Dietary energy density (DED) is defined as the available dietary energy per unit weight of foods. Our aim was to investigate whether there is an independent association between DED and incidence of T2DM.

Materials and methods: Population-based prospective study, the EPIC (European Prospective Investigation of Cancer)-Norfolk Cohort Study of persons aged 40–79 years at baseline. We calculated DED for overall diet (all solids and drinks) using self-reported dietary intake (from semi-quantitative food frequency questionnaire). During 12 years of follow-up, we documented 725 clinically incident cases of T2DM among 21,919 participants without diabetes, cancer or cardiovascular disease at baseline.

Results: Mean DED was 3.01 (95% CI 3.00–3.02) kJ/g in people without diabetes, and 3.08 (95% CI 3.03–3.13) kJ/g in those with incident T2DM after adjusting for age, sex, and baseline BMI (P , 0.012). DED at baseline was positively associated with incident T2DM (odds ratio, OR, 1.21, 95% CI 1.06–1.38) in analyses adjusted for age, sex, occupational status, smoking, alcohol, physical activity, family history of T2DM, total energy intake, and baseline BMI or waist circumference. There was a 60% higher risk of T2DM (OR 1.60, 95% CI 1.19–2.16, P for trend 0.002) in the highest quintile of DED (range

3.55–7.97 kJ/g) compared with the lowest quintile (range 1.04–2.43 kJ/g) in adjusted analyses. There was no significant interaction between DED and BMI or waist circumference, or DED and sex on the risk of T2DM.

Conclusion: This is the first large population-based prospective study to report that an energy dense diet may be associated with increased risk of developing type 2 diabetes, independently of obesity. The potential public health impact of a low energy dense diet on reducing the risk of diabetes deserves serious further study.

Low serum adiponectin predicts 10-year incidence of type 2 diabetes and HbA_{1c} levels independently of obesity, lipids and inflammation - Whitehall II study

A.G. Tabák¹, E.J. Brunner¹, M.A. Miller², S. Karanam², P.G. McTernan², F.P. Cappuccio², D.R. Witte¹

¹Department of Epidemiology & Public Health, University College London, ²Clinical Sciences Research Institute, Warwick Medical School, Coventry, United Kingdom

Background and aims: Several adipokines (most notably adiponectin) have emerged as possible risk factors for the development of type 2 diabetes mellitus (T2DM). While the cross-sectional association of adiponectin with obesity and insulin resistance is well-described, evidence on the prospective relationship between adiponectin and incident T2DM or glycemic control is limited. Our aim was to study the effect of adiponectin levels on the development of incident diabetes and HbA_{1c} values, taking the major T2DM risk factors and inflammation into account.

Materials and methods: We measured baseline serum adiponectin levels in a nested case-control selection of 142 participants of the Whitehall II Cohort. All participants were Caucasian, and had no prevalent T2DM, CHD, acute or longstanding inflammatory diseases at baseline. Cases (n=55) had incident T2DM according to a 75g OGTT during follow-up (mean: 11.5 ± 3.0 [SD] yrs), controls (n=87) were frequency matched on age, BMI and sex. The mean age of participants was 50.9 ± 6.3 yrs, BMI 26.8 ± 4.2 kg/m², and 68.3% was male.

Results: Adiponectin values were lower among cases at baseline ($8.8; 0.4$ [SE] vs. $10.2; 0.4$ μ g/mL, $p=0.01$). The risk of incident T2DM decreased by 11% (OR 0.89 95%CI 0.79–0.99, $p=0.03$) per 1 μ g/mL increase in adiponectin. This association remained stable and significant after adjustment for potential confounders including age, sex, BMI, blood lipids (BL), systolic blood pressure (SBP), CRP, and fasting plasma glucose (FPG) at baseline. The association was independent of the effect of physical activity and family history of DM ($p<0.05$ for all). Higher adiponectin levels at baseline were associated with lower HbA_{1c} values at follow-up 12 years later (β -0.24, 0.08% 95%CI 0.02–0.14 decrease in HbA_{1c} per μ g/mL increase in adiponectin, $p=0.008$). This association remained stable after adjusting for age, sex, BMI, BL, SBP, and CRP. The association was independent of the effect of physical activity and family history of DM ($p<0.05$ for all), however lost significance after further adjustment for FPG.

Conclusion: The prospective association between lower adiponectin levels and the risk of developing T2DM is independent of major T2DM risk factors and low grade inflammation, suggesting that the effect of adiponectin on T2DM may be causal. Further we showed that adiponectin predicts glycemic control 10 years later, independently of T2DM risk factors, indicating that mechanisms related to, or mediated by adiponectin may play a role in determining the severity of glycemic impairment.

Should an oral glucose tolerance test be performed in all patients with polycystic ovary syndrome?

S.V. Fica^{1,2}, A.I. Albu¹, C.G. Barbu^{1,2}, A.D. Reghina^{1,2}, R. Bunghez¹

¹Endocrinology and Diabetes, Elias University Hospital, ²Endocrinology, University of Medicine and Pharmacy Carol Davila, Bucharest, Romania

Background and aims: Polycystic ovary syndrome (PCOS) represents the most common endocrinopathy of reproductive age women (8–12%). Due to association between PCOS and insulin resistance, these patients are at increased risk of developing impaired glucose tolerance (IGT) and diabetes mellitus (DM), with combined prevalence previously reported of 20–35%. Nowadays there is no consensus concerning oral glucose tolerance test (OGTT) in patients with PCOS, although the majority of authors recommend it to all patients. The aim of our study was to evaluate the prevalence of glucose metabolism disturbances and OGTT utility in PCOS patients.

Materials and methods: Subjects were 258 PCOS patients with mean age 25.13 ± 5.82 years and mean body mass index (BMI) 29.03 ± 7.16 kg/m², selected from our PCOS research database. Clinical (anthropometric data, family history of type 2 DM, acanthosis nigricans (AN)) and paraclinical data (fasting and 2 hours glycemia during OGTT, insulinemia, lipid profile) were retrospectively obtained from patients medical records. PCOS diagnosis was based on Rotterdam Consensus criteria.

Results: Abnormal blood glucose levels were found in 18.9% of patients (5.4% IFG, 8.5% IGT and 5.03% DM). Among those patients with fasting glycemia <126 mg/dl (247 patients) OGTT revealed in 10.1% of them the presence of IGT or DM at 2 hours. Among clinical and paraclinical parameters we found that 2 hours glucose metabolism abnormalities were significantly associated with age ≥ 30 years ($p=0.017$), BMI ≥ 27 kg/m² ($p=0.018$), waist-hip ratio ≥ 0.8 ($p=0.036$), fasting blood glucose ≥ 100 mg/dl ($p<0.0001$), HOMA index ≥ 3 ($p=0.046$), total cholesterol >200 mg/dl ($p=0.019$), triglycerides levels ≥ 150 mg/dl ($p=0.002$). The positive predictive value of these parameters was: 18.86%, 13.9%, 13.39%, 42.85%, 14.13%, 15.13%, 23.68% respectively. We found no association with acanthosis nigricans (AN) or family history of type 2 DM in first degree relatives (FHD).

Conclusion: OGTT had a significant contribution to accurate characterisation of abnormal glucose metabolism in our PCOS patients. Clinical data known to be associated with increased risk for DM, as AN and FHD were not useful markers of 2h impaired glycemia. Due to low value of clinical and paraclinical data to predict 2h abnormal glucose levels we suggest that all patients with PCOS should be screened with OGTT in order to improve the therapeutic approach and prognosis.

352

Adipokines in the prevention of type 2 diabetes: the effect of a long-term lifestyle intervention

E.E. Blaak¹, C. Roumen¹, E. Corpeleijn¹, W.H.M. Saris¹, E.J.M. Feskens²

¹Human Biology, Maastricht University, ²Division of Human Nutrition, Wageningen University, Netherlands

Background and aims: We investigated the effect of a 4.2 year lifestyle intervention according to general recommendations on circulating adipokine concentrations and inflammation markers in subjects at risk for diabetes as well as the potential of leptin, adiponectin, resistin, plasminogen activator inhibitor 1 (PAI-1) and Complement factor 3 (C3) as biomarkers for lifestyle-induced improvements in glucose metabolism and insulin resistance.

Materials and methods: In the Study on Lifestyle intervention and Impaired glucose tolerance Maastricht, 147 men and women with impaired glucose

tolerance (IGT) were randomized to either a combined diet-and-exercise intervention (INT) or a control program (CON). At baseline and at the end of the study (after 4 or 6 years) adipokines and inflammation were measured in addition to performance of an oral glucose tolerance test, an exercise test, and anthropometric measurements. At the end of the study, complete data of 92 subjects (49 INT, 43 CON) were obtained.

Results: Lifestyle intervention increased carbohydrate intake, improved maximal aerobic capacity (VO₂ max) and reduced diabetes incidence by 31% ($p_{\text{all}} < 0.05$). Body weight first decreased in INT (-2.47 kg), but increased during the last part of the study (+1.31 kg), whereas body weight did not change in CON. 2-hr glucose levels increased less in INT compared to CON ($+0.24 \pm 0.39$ mM vs 0.95 ± 0.38 mM, respectively, $p=0.04$). HOMA-IR levels did not change between groups ($p=0.54$). Leptin levels increased more in the control group compared to the intervention group ($+0.34 \pm 0.09$ ng/ml vs 0.09 ± 0.44 ng/ml; $p=0.02$), whereas no differences were observed in adiponectin, resistin, PAI-1 and C3 concentrations. In the total population ($n=92$) changes in leptin level were correlated with changes in BMI, waist, body fat percentage, VO₂ max. Δ Leptin was related to Δ PAI-1 and Δ C3 ($p_{\text{all}} < 0.05$), but not with Δ adiponectin or Δ resistin. Δ Leptin, Δ PAI-1 and Δ C3 were related to improvements in estimated insulin sensitivity (HOMA-IR). The relationship between Δ leptin and HOMA-IR was independent of age, sex and changes in PAI-1, C3, BMI, body fat percentage and waist circumference (Multivariate regression $p=0.04$). Δ Leptin was the only marker related to 2-hr glucose, but not independent of Δ BMI.

Conclusion: A decrease in leptin was strongly associated with a decrease in insulin resistance, only partially explained by a reduction in BMI. During a long-term lifestyle intervention leptin can be regarded a biomarker for improvements in insulin sensitivity, independent of body weight loss and changes in body composition.

Lifestyle and socioeconomic status do not contribute to optimising screening strategies for type 2 diabetes. The ADDITION Netherlands Study

P.G.H. Janssen¹, K.J. Gorter¹, R.P. Stolk², G.E.H. Rutten¹

¹Julius Center for Health Sciences and Primary Care, University Medical Center, Utrecht, ²Department of Epidemiology, University Medical Center, Groningen, Netherlands

Background and aims: Level of fasting glycemic control at diagnosis is an indication of severity and duration of diabetes. We investigated whether cardiovascular risk factors, lifestyle behaviors and socioeconomic status (SES) are related to the level of fasting glycemic control in screen-detected type 2 diabetic patients. Such relationships may have consequences for screening strategies.

Materials and methods: A total of 498 screen-detected type 2 diabetic patients were divided into tertiles of fasting blood glucose. Blood pressure, BMI, waist circumference, lipids, adiponectin, hsCRP, uric acid, fasting insulin, and microalbuminuria were determined. Lifestyle factors included physical activity (≥ 4 days per week at least 30 minutes), smoking, consumption of alcohol (10–40 g/day), coffee (>2 cups of coffee daily), and vegetables (≥ 5 times per week). A composite index of socioeconomic status (high and low SES) was created by combining educational level, income and occupational status.

Results: Triglycerides, hsCRP (especially among people with low SES), and urinary albumin excretion were positively, adiponectin (only among those with high SES), and uric acid inversely related to fasting glucose levels. Better fasting glycemic control was associated with more favorable alcohol consumption, especially among men, and higher level of physical activity. Generally, cardiovascular risk markers and lifestyle behaviors did not differ substantially between tertiles.

Conclusion: Our data indicate that lifestyle factors and SES are not helpful to identify specific categories of patients to be screened for diabetes.

354**Trends of diabetes mellitus in Spain from 1987 to 2003**F.J. Basterra-Gortari^{1,2}, M. Bes-Rastrollo², L. Forga¹, J.A. Martínez³,C. Causso-Larriena¹, M.A. Martínez-González²¹Endocrinology, Hospital of Navarra, ²Preventive Medicine and Public Health, University of Navarra, ³Physiology and Nutrition, University of Navarra, Pamplona, Spain

Background and aims: Diabetes prevalence is increasing in Western countries. We evaluated the trend of the prevalence of diabetes mellitus in Spain from 1987 to 2003.

Materials and methods: The Spanish National Health Surveys (NHS) of 1987 (n=29,647), 1993 (n=21,061), 1995 (n=6,396), 1997 (n=6,396), 2001 (n=21,067) and 2003 (n=21,650) which are representative samples of the adult Spanish general population were used. Participants were classified as diabetics if they answered affirmatively to the following question “Has your doctor told you that you suffer currently from diabetes?” Linear trend chi squared test and multivariate logistic regression models (the year of the survey was used as an independent continuous variable) adjusted for age, sex and educational levels, were used. 95% confidence intervals were calculated.

Results: A significant increasing temporal trend for the prevalence of diabetes was observed in the univariate analysis ($p<0.001$) (Figure).

After adjusting for age, sex and educational level a significant increasing temporal trend was also observed ($p<0.001$). A statistically significant increasing trend was observed in males ($p<0.001$) and females ($p<0.001$) after adjusting for age and educational level. This significant increasing trend was present for men of most ages (except for those between 30–39 years) (table), however it was apparent only for women over 50 years, whereas, women between 30–39 years old had a significant decreasing trend in the prevalence of diabe-

tes ($p<0.001$) and women between 40–49 years had also a decreasing trend ($P=0.06$).

Conclusion: The prevalence of diabetes mellitus has increased in Spain between 1987 and 2003 in both males and females. Although self-reported data under-estimate the actual prevalence of diabetes, this does not necessarily invalidate this study about the prevalence trend of diabetes mellitus, because there is no reason to think that accuracy of self-reported data may have changed across surveys.

Prevalence (%) of self-reported diabetes in the different NHS. According to sex and ages categories.

Eight models of diabetes screening - impact on epidemiologic results

A.V. Dreval, I.V. Misnikova, I.A. Barsukov

Endocrinology, Moscow Regional Resaerch Clinical Institute, Russian Federation

Background and aims: Leading international organizations (WHO, American diabetes association, IDF) offer different models of screening of glucose metabolism abnormalities, which have certain impact on screening results. The aim of the study was to compare different screening models.

Materials and methods: Population-based screening for IFG, IGT and T2D in 2508 individuals of Moscow County. FPG was measured in all participants. Standard 2-h 75 g OGTT was performed using HemoCue analyzers in subjects previously undiagnosed with diabetes. Depending on diagnostic criteria (American diabetes association or WHO) and research method (only FBG, OGTT) 8 screening models were considered. Sensitivity(Se) and specificity(Sp) of models is compared based on definition of T2DM, IGT, IFG on formula: $Se = TP / (TP + FN)$, $Sp = TN / (TN + FP)$, TP-True Positive, TN-True Negative, FN-False Negative, FP-False Positive.

Results: Table 1

Prevalence (Pr) of T2DM, IFG, IGT, sensitivity (Se) and specificity(Sp) of different screening models

Conclusion: Prevalence of T2DM, IFG and IGT according to diagnostic criteria (American diabetes association or WHO) and research method (FBG only, OGTT) is changed due to different sensitivity of screening models. Specificity remains high in spite of screening model choice.

PS 012 Animal models for type 2 diabetes

Liver transcription factor ChREBP is modified by O'glycosylation (O-GlcNAc) in liver of control and insulin resistant mice

C. Guinez-Lelong, V. Fauveau, A.-F. Burnol, J. Girard, C. Postic

Endocrinologie, Métabolisme et cancer, Institut Cochin, Paris, France

Background and aims: Carbohydrate Responsive Element Binding protein (ChREBP) is a key transcription factor that mediates the transcriptional effects of glucose on glycolytic and lipogenic genes in liver. The elevated ChREBP protein levels observed in liver of obese ob/ob mice strongly correlate with their state of hepatic steatosis and insulin-resistance. Under low glucose concentrations, ChREBP is an inactive phosphorylated cytosolic protein while after a raise in glucose metabolism ChREBP undergoes dephosphorylation and is translocated into the nucleus to activate its target genes. However, controversy has recently emerged concerning ChREBP regulation by phosphorylation, suggesting that additional post-translational mechanisms may be required. O-linked beta-N-acetylglucosamine (O-GlcNAc) modification of proteins plays an important role in transcription, translation, nuclear transport and signal transduction. Recently, increased O-GlcNAc modification of proteins was linked to the development of insulin resistance in liver. Therefore, the aim of our study was to determine whether ChREBP is regulated by O-GlcNAc in liver of control and/or insulin-resistant mice.

Materials and methods: C57Bl/6J mice that were either fasted for 24 hours or refed on a high carbohydrate (HCHO) diet for 18 hours, were used as controls. To dissociate the effects of O-GlcNAc modification from those of glucose metabolism, glucosamine (2,5g/kg) was administrated orally to 18h-fasted C57Bl/6J mice. Glucosamine-treated mice were sacrificed 4, 8, 10 or 12 hours after the beginning of the gavage. In parallel, a group of mice receiving a glucose gavage (5g/Kg) was studied at similar time-points.

Results: Treatment with glucosamine resulted in O-GlcNAc modification of ChREBP and to an increase in ChREBP total protein content to similar levels than in liver of glucose and HCHO diet fed mice. Interestingly, in contrast to glucose gavage and to HCHO diet conditions, glucosamine-mediated induction of ChREBP occurred independently of a raise in hepatic glucose metabolism and was not linked to enhanced ChREBP transcription rates. In addition, while ChREBP was rapidly translocated into the nucleus after a glucose gavage (as soon as 4 hours post gavage), ChREBP remained cytosolic and as a consequence, did not activate its target genes under glucosamine treatment (all time tested). Additional experiments performed in mouse hepatocytes showed that glucosamine treatment (5 mM) stabilized the endogenous ChREBP protein and protected it against proteasomal degradation. Finally, the elevated expression of ChREBP in liver of ob/ob mice strongly correlated with high O-GlcNAc levels.

Conclusion: Taken together, our results suggest that O-GlcNAc modification may represent an important regulation of ChREBP protein content in liver under both physiological and physiopathological conditions.

Diet-induced abdominally obese rats with normal weight developed insulin resistance and muscular mitochondrial dysfunction

L. Cao, N.W. Tong, X.H. Liu

Dept. of Endocrinology, West China hospital of Sichuan University, Chengdu, China

Background and aims: Abdominal obesity is associated with reduced insulin sensitivity. Mitochondrial dysfunctions have been found involved in mechanisms of insulin resistance in muscle. The study are designed to investigate muscular ATP production in diet-induced abdominally obese SD rats with normal weight(AONW) and its possible mechanisms.

Materials and methods: The model of rats with normal body weight(BW) and increased visceral adipose tissue(VAT) were made by self-designed diet for 20 weeks. The control group(CG) were fed by common diet. Glucose tolerance was measured by intraperitoneal injection of glucose (2g/kg weight) after an overnight fast. Hyperinsulinemic-euglycemic clamp combined with intravenous infusion of 3-³H-glucose technique was administered to evaluate the insulin sensitivity of rats in both groups. Plasma glucose, free fatty acids, insulin were measured and compared with those in control to find metabolic disorders in model rats. Body and visceral adipose tissue were weighted just before and after sacrifice respectively. Light microscopy and electronic microscopy were used to detect changes in muscle. ATP ADP ratio(ATP/ADP) in muscle were measured by HPLC. Expression of genes in muscle involved in mitochondrial function were detected, including 1.mRNA of mitochondrial transcription factor A(TFAM), peroxisome proliferators activated receptor gamma co-activator-1α(PGC-1α), uncoupling protein 3(UCP3) and insulin receptor substrate-1(IRS-1) by RT-PCR;2.protein level of TFAM, PGC-1α and IRS-1 by western blot.

Results: Comparing to CG, BW of AONW was normal but VAT increased significantly($p=0.01$), while the percentage of VAT/BW(%) 5.80(AONW) vs 3.45(CG). Glucose disposal rates (mg/min·kg) were 16.57±5.41(AONW) vs 10.74±5.16(CG), $p=0.03$. Hepatic glucose output (mg/min·kg) was not suppressed by insulin infusion in AONW(7.28±6.01 vs 8.48±3.50, before vs after infusion, $p=0.61$). Glucose intolerance during IPGTT and high plasma FFA(836.1±142.1 vs 673.9±177.2μmol/L in AONW vs CG, $p=0.048$) were found in AONW. Adipose increment, capillary necrosis and mitochondria swelling were found in AONW muscles by microscopy. ATP/ADP in muscle of AONW was 62.1% of control, although the difference was not significantly($p=0.06$). PGC-1α mRNA level increased by 2.24 fold in AONW than in CG($p=0.07$), and UCP3 mRNA level increased by 6.38 fold in AONW than in CG($p=0.007$). No significant differences in TFAM and IRS-1 mRNA expression were found between groups. TFAM protein level in AONW was 13.5% of that in CG($p<0.005$).PGC-1α level in AONW was 148.2% of that in CG($p<0.005$). IRS-1 protein expression didn't change significantly.

Conclusion: The self-designed diet-induced AONW SD rats were abdominal obese and muscular insulin resistant. High plasma FFA was the most likely one among the reasons of compensatory increased expression of PGC-1α and UCP3 in muscle of AONW. The results support a hypothesis that ATP production were probably impaired by increased plasma FFA. The disparity between PGC-1α, UCP3 and TFAM expression in AONW muscle suggests low TFAM protein might be related to the mitochondrial dysfunction, and accompanying with IRS-1 non-upregulation, the mitochondrial dysfunction might be play some role in the development of insulin resistance.

Intrauterine programming of beta cell development and function by maternal diabetes. What does embryo-transfer experiments in GK/Par rats tell us?A. Chavey¹, M.-N. Gangnerau¹, L. Maulny², D. Bailbé¹, J. Movassat¹, J.-P. Renard², B. Portha¹¹Laboratoire de physiopathologie de la nutrition, CNRS UMR 7059, Paris, France, ²Biologie du développement et reproduction, INRA UMR 1198, Jouy-en-Josas Cedex, France

Background and aims: Epidemiological findings strongly suggest that *in utero* exposure to diabetes is associated with abnormal insulin secretion and glucose homeostasis in offspring of diabetic mothers and may participate in the excess of maternal transmission in T2D. From human studies however, isolation of the respective contribution of genetic vs. intrauterine environmental factors is hardly attainable. We have therefore used the GK/Par rat, a spontaneous model of type 2 diabetes, to determine whether the altered

metabolic intrauterine/postnatal milieu of the GK mother may cause malprogramming of the beta-cell mass and adversely alter beta-cell function later in adult life. To that aim we have used an embryo transfer technology.

Materials and methods: Fertilised GK or Wistar (W) oocytes (oW and oGK) were transferred into pseudo-pregnant W or GK females. Pregnancies were allowed to go to term. In some experiments, W newborn pups reared by gestating GK mothers (gGK) were cross-fostered to W mothers for suckling (sW). Male offspring were tested at 8 weeks of age for phenotyping (intravenous glucose tolerance test, insulin release in response to glucose *in vivo* (GSIS), pancreatic insulin stores, pancreatic beta-cell mass).

Results: We found that: 1/ Offspring from GK embryo transfers into GK mothers [oGK/gGK/sGK] were similarly hyperglycaemic compared to the non-manipulated GK/Par stock colony. 2/ Offspring from W embryo reared in hyperglycaemic GK mothers [oW/gGK/sGK] were normoglycaemic, normotolerant to glucose and normal insulin releaser in response to glucose. However, their pancreatic insulin stores (ng/mg pancreas) and beta-cell mass (μg/mg pancreas) were significantly reduced (by 40% and 31% respectively) as compared to the non-manipulated W offspring from our stock colony. 3/ Offspring from W embryo reared in hyperglycaemic GK mothers and then milked by W mothers [oW/gGK/sW] were normoglycaemic, normotolerant to glucose and normal insulin releaser in response to glucose. Again, their pancreatic insulin stores and total beta-cell mass were reduced (by 40% and 30% respectively) as compared to the non-manipulated W offspring from our stock colony. 4/ Offspring from GK embryo reared in normoglycaemic W mothers [oGK/gW/sW] exhibit basal hyperglycaemia, glucose intolerance and low GSIS, to the same extent as the oGK/gGK/sGK offspring. This was associated with reduced pancreatic insulin stores (by 65% vs W) and beta-cell mass (by 69% vs W), to a more severe extend than that in non-manipulated GK/Par rats from the stock colony.

Conclusion: We conclude that: 1/ in W rats with no risk of diabetes, exposure to hyperglycaemia *in utero* only or *in utero* and during suckling, significantly decreases the total beta cell mass and insulin stores in their pancreas. However this does not cause long-term damages to glucose homeostasis, despite discrete alteration of GSIS. Whether or not this reflects an early (foetal) alteration of beta-cell mass development is under examination. 2/ Offspring from GK embryos transferred in the uterus of euglycaemic W mother, still develop low GSIS *in vivo*, low pancreatic insulin stores and low beta-cell mass when adults, therefore highlighting a major role for morbid genes.

Non-invasive imaging of pancreatic islets targeting glucagon-like peptide-1 receptorsE. Mukai^{1,2}, K. Toyoda¹, H. Kimura³, H. Kawashima⁴, M. Ueda⁵, T. Temma³, K. Hirao⁶, K. Nagakawa⁶, Y. Seino⁷, H. Saji³, N. Inagaki¹¹Department of Diabetes and Clinical Nutrition, Graduate School of Medicine, Kyoto University, Kyoto, ²Japan Association for the Advancement of Medical Equipment, Tokyo, ³Department of Patho-Functional Bioanalysis, Graduate School of Pharmaceutical Sciences, Kyoto University, ⁴Department of Diagnostic Imaging and Nuclear Medicine, Graduate School of Medicine, Kyoto University, ⁵Radioisotopes Research Laboratory, Kyoto University Hospital, Faculty of Medicine, Kyoto University, ⁶Arkray, Inc., Kyoto, ⁷Division of Diabetes and Clinical Nutrition, Kansai Denryoku Hospital, Kyoto, Japan

Background and aims: The volume of pancreatic β-cells is known to decrease during diabetes development and progression. A technique for measurement of β-cell volume *in vivo* is required, but a non-invasive method to detect pancreatic β-cells has not been developed. In the present study, specific imaging of pancreatic β-cells targeting glucagon-like peptide-1 receptors (GLP-1R) was evaluated using its antagonist, exendin(9-39).

Materials and methods: For evaluating receptor specificity, binding assay *in vitro* was performed using dispersed cells of islets isolated from 6-week-old male ddY mice. For assessment of *in vivo* selectivity, biodistribution studies were performed by intravenous administration of [¹²⁵I]-Exendin(9-39) (1 μCi) to 6-week-old male ddY mice. At appropriate time points after administration, selected organs and blood were harvested and their radioactivities were measured. In a blocking study, excess nonradioactive Exendin(9-39) (50 μg) was administered before the [¹²⁵I]-Exendin(9-39) injection. After [¹²⁵I]-Exendin(9-39) injection into transgenic mice with pancreatic β-cells expressing GFP (kindly provided by Dr. Hara, University of Chicago), fluorescent and radioactive signals of sections of pancreas were evaluated with an image analyzer.

Results: Binding assay analysis using mouse pancreatic islet cells showed competitive inhibition of specific [125 I]-Exendin(9-39) binding by nonradioactive Exendin(9-39). Biodistribution study by intravenous administration of [125 I]-Exendin(9-39) showed that radioactivity of pancreas was high at 60 and 120 min compared to other organs, while radioactivity of lung was highest. Pre-administration of excess nonradioactive Exendin(9-39) considerably and specifically blocked the radioactivity of pancreas and lung two hours after [125 I]-Exendin(9-39) injection. Image analysis using sections of pancreas of [125 I]-Exendin(9-39)-administered mice expressing GFP in pancreatic β -cells showed that the fluorescent GFP signal and the radioactive signal were similarly located, indicating accumulation of Exendin(9-39) specifically in pancreatic β -cells. The intensity of the fluorescent signal was also correlative with that of the radioactive signal.

Conclusion: For imaging of pancreatic β -cells, Exendin(9-39) and GLP-1R can serve as a useful probe and target molecule, respectively.

Novel potential biomarkers for detection of type 2 diabetes based on transcriptome analyses of Cohen rat models

P. Ikonomi¹, S. Zangen², S. King¹, I. Raz², C. Gelber¹

¹Translational Research, American Type Culture Collection, Manassas, United States, ²Diabetes Unit, Hadassah University Hospital, Jerusalem, Israel

Background and aims: The Cohen diabetic (CD) rat is a versatile animal model comprised of 2 strains that manifest many of the common features of type 2 diabetes (T2D) in humans. The sensitive strain (CDs) develops diabetes within 30 days when maintained on a high sucrose/copper poor diet (HSD), whereas the resistant strain (CDr) retains normal blood glucose levels. Neither strain shows any signs of diabetes when provided regular rodent diet (RD). Thus, incidence of T2D in the CD rat model results from synergistic effects of genetic susceptibility and dietary composition. Pair-wise comparisons of gene expression profiles are indicative of; predisposition, resistance, progression or protection against T2D.

To identify specific markers that can potentially characterize resistance, progression or predisposition to T2D, transcriptome changes of epididymal fat and pancreatic tissue of these two strains were studied by microarray analyses using the rat expression arrays.

Materials and methods: Total RNA was extracted from epididymal fat and pancreatic tissue for each of the strains and analyzed using the Rat Expression Arrays (Affymetrix, CA). The data was analyzed using GeneSpring GX (Agilent, CA) and expression of selected transcripts was confirmed by Real Time PCR

Results: Microarray transcriptome profiling of epididymal fat tissue from CD rats revealed numerous biomarkers that may correlate with resistance, progression and predisposition to disease. Our analyses reveal 48 transcripts that show inverse expression trends in relevance to resistance or progression of the disease. Thus, in the model indicative of genetic resistance, we found that T2D-related genes such as *Gyk*, *Scd2* and *Nr1h3* were upregulated; interestingly, progression of T2D is characterized by downregulation of the same transcripts. In contrast, expression levels of other markers such as *Lypla3*, *Acaa2* and *Anxa1* increase with progression of disease but are expressed at lower levels in the resistance model. The expression pattern of the above transcripts was confirmed by quantitative PCR, and was followed throughout the development of the disease. Results show that specific quantitative changes of transcript levels are observed as early as 10 days after exposure in high sucrose diet and become more pronounced as the duration of high sucrose diet is extended to 30 days.

Similarly, our microarray and quantitative PCR analyses in pancreatic tissue resulted on selection of 14 transcripts with the quantitative changes indicative of development and resistance of Type 2 diabetes. Eight of these transcripts show quantitative expression changes associated to the disease in both epididymal fat and pancreatic tissue.

Conclusion: In conclusion, our analyses using epididymal fat and pancreatic tissue from Cohen rat models could indicate novel modification mechanism involved in T2D. We are currently profiling the expression of selected markers in whole blood cells. Such analyses will result in identification of a combination of transcripts whose monitored expression could be used not only as biomarkers for predisposition or development of the disease, but also as the basis for therapeutics for Type 2 Diabetes.

Differences between global miRNA expression profiles in diabetic and normoglycaemic rats

B.M. Herrera^{1,2}, H.E. Lockstone¹, S. Collins², P.J. Kaisaki¹, A. Barrett², J.C. Randall¹, K. Argoud¹, D. Gauguier¹, C. Fernandez¹, J.M. Taylor¹, M.I. McCarthy¹, C.M. Lindgren¹

¹Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, United Kingdom, ²OCDEM, Oxford Centre for Diabetes, Endocrinology and Metabolism, Oxford, United Kingdom

Background and aims: MicroRNAs (miRNAs) are recently discovered non-coding RNA molecules (~22 nucleotides in length) that play an important role in post-translational regulation of gene expression. MiRNA-mediated expression regulation relies on sequence-specific alignment to target mRNA molecules, and thus a single miRNA can potentially bind to a large number of target mRNAs. MiRNAs have been shown to be involved in a broad range of biological mechanisms including cell differentiation and development and more recently have been implicated in energy homeostasis. To investigate the potential involvement of miRNAs in T2D, we assessed expression of miRNAs in fat, skeletal muscle and liver samples from T2D rats and compared it to expression in genetic and physiological controls.

Materials and methods: Total RNA was extracted from skeletal muscle, fat and liver from three-month-old male rats representing: spontaneous T2D (Goto-Kakizaki [GK], n=5), normoglycaemic (Wistar-Kyoto [WKY], n=5) that share genetic background with GK rats and normoglycaemic genetically distant controls (Brown-Norway [BN], n=5). Expression levels of 239 rat miRNAs were quantified using the EXIQON microarray platform. After background correction and normalization, we looked for differences between tissues and then within tissues across strains. Validation of expression results for a selected number of miRNAs was carried out using q-RT-PCR on the TaqMan platform. In-silico prediction of miRNAs targets was carried using miRBase and Target-scan 4.1. The involvement of target genes in biological pathways was assessed using g:Profiler software.

Results: We observe considerable differences in miRNA expression profiles in our tissue specific comparisons between strains. Differential expression was detected for 20 miRNAs; 2 in muscle, 7 in fat and 11 in liver (p<0.05, corrected for multiple testing) suggesting that these differences provide signatures of the T2D phenotype modeled by the GK strain. Notably, in fat, the GK rat showed over-expression of miR-222 and miR-27a (Fold change [FC] =2.4 and 1.74, p<0.005) which target genes involved in apoptosis (g:Profiler p-value =7.6x10⁻⁷). In liver, under-expression of miR-100 and miR-125b (FC=-1.2 and -1.44, p<0.003) and in muscle under-expression of miR-let-7e and miR-10b (FC=-1.31 and -1.58, p<0.02) which target a number of genes involved in the insulin signaling pathway (g:Profiler p-value= 8.4x10⁻⁴). Nine differentially expressed miRNAs were selected for validation using q-RT-PCR and of these, results were replicated for miR-140*, miR-222, miR-487b, miR-103, miR-195 and miR-10b.

Conclusion: We have assessed and compared global miRNA expression profiles in three insulin target tissues from three different rat strains (GK, WKY and BN) and identified tissue and strain specific profiles, further supporting evidence for miRNA involvement in the T2D phenotype. Our results suggest that altered miRNA expression levels are associated with disturbances in glucose homeostasis, likely to arise through their role in the regulation of genes involved in insulin signaling mechanisms in liver and muscle.

A novel genetic mouse model of diabetes, *Buttermouse*, has been identified

N.L. Absalom¹, M. Goldsworthy¹, H.C. Matthews², D. Bogani¹, C. Church¹, R.D. Cox¹

¹Mammalian Genetics Unit, Medical Research Council, Oxfordshire,

²Department of Hepatology, Imperial College, London, United Kingdom

Background and aims: Type 2 diabetes is a complex disease that is caused by genetic and environmental factors, of which the genetic factors are not all understood. Population studies and murine models are complementary approaches to identifying such genetic factors. Our approach was to identify novel genetic mutations causative for diabetes in a murine model. Initially, BALB/c male mice were treated with the chemical mutagen ENU to create random mutations throughout the genome. These mice were mated to female C3H/HeH mice and the progeny screened for high free fed plasma glucose.

Here we describe the genetic and physiological characterization of one mutant where male mice were identified with high plasma glucose, *buttermouse*.

Materials and methods: After identification of the mutant mouse, the F1 male was successively backcrossed onto a C3H/HeH background. Genotyping analysis was performed using microsatellite markers and pyrosequencing of single nucleotide polymorphisms between C3H and Balb/c mouse strains. Candidate genes were sequenced to identify the mutation. Phenotyping was done with an intraperitoneal glucose tolerance test measuring plasma glucose at 12 weeks and plasma insulin at 16 weeks. At 19 weeks blood plasma and tissues were collected and analyzed.

Results: Genotyping analysis identified a region of 350kbp of DNA that contained the mutation. Candidate gene sequencing revealed a putative missense mutation in a chromatin remodeling enzyme. During an IPGTT plasma glucose concentrations prior to, 60 and 120 minutes after injection were significantly higher for male *buttermouse* than wild-type controls (10.2 ± 2.7 , 25.6 ± 5.9 , 20.5 ± 6.1 compared to 7.7 ± 1.9 , 15.0 ± 4.1 , 10.2 ± 2.8 , $p < 0.01$, $n > 60$). Liver sections at 19 weeks of age indicated that male *buttermouse* developed hepatic steatosis and hepatocyte ballooning consistent with non-alcoholic fatty liver disease. The plasma cholesterol (5.1 ± 0.5 vs 4.3 ± 0.4 , $p < 0.05$, $n = 10$) and triglyceride concentrations (6.1 ± 1.5 vs 4.4 ± 1.5 , $p < 0.05$, $n = 10$) were significantly higher for male *buttermouse* compared to wild-type.

Conclusion: We have identified a novel genetic mouse of diabetes and plan to continue to study *buttermouse* to understand how alterations in gene expression can lead to type 2 diabetes and its complications. We aim to confirm the mutation is causative for the mouse model by using complementary techniques of knockout murine models and functional assays.

PS 013 Classification of type 1 diabetes

363

Two subtypes of type 1 diabetes of Japanese adult patients with low and high titers of GAD autoantibody

T. Aoyama¹, H. Ikeda¹, S. Honjo¹, K. Nabe¹, T. Kimura¹, K. Nomura¹, Y. Wada¹, Y. Hamamoto², J. Fujikawa³, H. Koshiyama¹

¹Center for Diabetes & Endocrinology, The Tazuke Kofukai Foundation Medical Research Institute Kitano Hospital, Osaka, ²Division of Diabetes & Clinical Nutrition, Kyoto University, ³Department of Laboratory Medicine, The Tazuke Kofukai Foundation Medical Research Institute Kitano Hospital, Osaka, Japan

Background and aims: About 5–10% of patients with clinically diagnosed type 2 diabetes were reported to have markers of islet autoantibodies, such as GAD autoantibodies (GADAb). They are variably referred to as latent autoimmune diabetes in adults, slowly progressing insulin-dependent diabetes, non-insulin-requiring autoimmune diabetes or type 1.5 diabetes, and it has been reported that their β -cell function then slowly declines to insulin-dependent state in several years. A recent study from Italy has reported that GADAb could define heterogeneity of adult “type 1 diabetes” and their titration might predict future risk of progression to insulin dependence. Nevertheless, there has been no such a study in Japanese patients. The aim of this study is to investigate whether GADAb can define adult “type 1 diabetes” of Japanese patients.

Materials and methods: Between December 2000 and July 2007, the serum GADAb levels were measured in a total of 1857 consecutive diabetic patients with age over 20 years in our center. GADAb were tentatively defined to be positive with a level ≥ 1.5 U/ml. Diabetic patients with GADAb were then divided into two subgroups; those with low (< 10 U/ml:L group) and high (≥ 10 U/ml:H group) titers of GADAb. Their clinical characteristics, including autoantibodies to thyroid peroxidase (TPO), were investigated. Diabetic patients without GADAb who were matched for age and gender with those with GADAb were selected as control group.

Results: A total of 103 (5.5%) diabetic patients (male/female:48/55, mean age: 57 ± 16 years) had GADAb. Clinical profiles of diabetic patients with GADAb were significantly different from those without GADAb, showing higher HbA_{1c} level ($7.9 \pm 2.5\%$ vs. $9.2 \pm 2.7\%$, $P < 0.005$), lower BMI (25.3 ± 3.9 kg/m² vs. 23.1 ± 4.6 kg/m², $P < 0.005$), serum triglycerides (179 ± 124 mg/dL vs. 141 ± 111 mg/dL, $P < 0.005$) and serum uric acid level (5.5 ± 1.6 mg/dL vs. 4.8 ± 2.3 mg/dL, $P < 0.001$). Of all 103 diabetic patients with GADAb, 65 (63%) were classified as L group (male/female:36/29), and 38 (37%) were classified as H group (male/female:12/26). Compared with L group, H group were younger at age (61 ± 14 years vs. 52 ± 17 years, $P < 0.05$) and showed higher HbA_{1c} level ($8.4 \pm 2.3\%$ vs. $10.2 \pm 2.7\%$, $P < 0.005$), lower serum triglycerides (152 ± 110 mg/dL vs. 119 ± 109 mg/dL, $P < 0.05$) and serum uric acid level (5.4 ± 2.6 mg/dL vs. 3.9 ± 1.1 mg/dL, $P < 0.001$), and higher prevalence of TPO autoantibody (15% vs. 48%, $P < 0.05$). Clinical profiles of L group showed no significant differences except for lower BMI (25.3 ± 3.9 kg/m² vs. 23.1 ± 4.8 kg/m², $P < 0.05$) from control group.

Conclusion: This study suggests that GADAb level of 10 U/ml discriminates two subtypes of type 1 diabetes of Japanese adult patients.

Are GAD antibodies helpful in classification of patients with diabetes? Evidence from studies of a random population of middle-aged Danes. The Inter99 study

S. Engberg¹, C. Glümer¹, T. Jørgensen², O. Pedersen¹, K. Borch-Johnsen¹

¹Steno Diabetes Center, Gentofte, ²Research Centre for Prevention and Health, Research Centre for Prevention and Health, Glostrup, Denmark

Background and aims: The aim of this cross-sectional study was to assess the prevalence of circulating GAD antibodies in a general Danish population according to glucose tolerance class and consequently to evaluate whether GAD antibodies are helpful in classification of patients with diabetes.

Materials and methods: In the population based Inter99 study, serum from individuals with IFG ($n = 520$), IGT ($n = 751$), screen-detected diabetes ($n = 265$), known diabetes ($n = 139$) and from a random sample of individuals with NGT ($n = 1490$) were analysed for GAD antibodies. Individuals with known diabetes were divided into clinical type 1 and type 2 diabetes mellitus according to clinical characteristics.

Results: No significant difference in the prevalence of positive and weak positive GAD antibodies was found between individuals with NGT (4.4%), IFG (2.8%), IGT (3.5%) or screen-detected diabetes (4.3%), whereas it was higher in individuals with known diabetes (14.3%) compared with NGT ($p<0.0001$). Among individuals with known diabetes, 8.5% in the clinical type 2 diabetes subgroup were GAD antibody positive and weak positive compared to 60% in the clinical type 1 diabetes subgroup ($p<0.0001$). The prevalence of positive and weak positive GAD antibodies was not significantly different when comparing the clinical type 2 diabetes subgroup with NGT.

Conclusion: In a general Danish population, the prevalence of circulating GAD antibodies is surprisingly high in individuals with NGT. Therefore, there is a considerable risk of misclassification if GAD antibody positivity is used to reclassify individuals with clinical type 2 diabetes to aetiological type 1 diabetes according to WHO's recommendations.

Classification of childhood-onset diabetes in Norway - The Norwegian Childhood Diabetes Registry

T. Skrivarhaug¹, M. Bjørnsvold², D.E. Undlien², P.R. Njølstad³, G. Joner¹

¹Dept. of Pediatric, Ullevål University Hospital, Oslo, Norway, ²Institute of Medical Genetics Faculty Division, Ullevål University Hospital, Oslo, Norway, ³Dep. of Clinical Medicine, University of Bergen, Norway

Background and aims: The Norwegian Childhood Diabetes Registry has registered newly diagnosed cases of childhood-onset diabetes nationwide with biological samples in the five-year period 2002–2007. The aim was to study the epidemiology of different forms of diabetes and classify incident cases on the basis of family history, clinical data, C-peptide, autoantibodies and HLA- genotypes.

Materials and methods: In the period 2002–2007, 1551 new cases have been diagnosed below 15 years. In addition to family history and clinical data, blood samples were collected and analyzed for autoantibodies (anti-GAD, insulin-antibodies, anti-IA-2), HLA-genotypes and C-peptide. HLA genotypes were grouped into four risk categories (high, moderate, neutral and low) based on DQB1, DQA1 and DRB1 genotypes including DRB1*04 sub typing. Due to the following criteria patients were classified as: 1) Type 1 diabetes (T1D): Antibodies pos. + neutral/moderate/ high risk HLA-genotype. 2) Probably T1D: Antibodies neg. + high risk HLA- genotype. 3) Unclassified: Antibodies neg. + low/moderate risk HLA-genotype. The patients were classified as autoantibodies positive (ab+) if one or more of the three tested was positive.

Results: Autoantibodies and HLA- genotypes were analyzed in 995 patients; 932 (94%) were ab+ positive. HLA-genotype risk categories: 9 (1%) patients were low risk, 259 (26%) neutral risk, 473 (48 %) moderate risk and 254 (25 %) high risk. On this basis of this 925 (93%) of the patients were classified as T1D, 21 (2%) were classified as probably T1D and 49 (5%) patients were unclassified. A first degree relative with T1D were registered in 126 (12%) of the patients and a first degree relative with Type 2 Diabetes (T2D) were registered in 21 (2%) of the patients. A multiplex family (1 parent and 1 sibling with T1D) were registered in 9 (1%) of the patients. In patients classified as T1D; 118 out of 925 patients (13%) had a first degree relative with T1D, 9 out of 925 (1%) had a multiplex family and 15 out of 925 (2%) had a first degree relative with T2D.

In patients classified as probably T1D; 2 out of 21 (10%) had a first degree relative with T1D. In patients registered as unclassified; 3 out of 49 (7%) had a first degree relative with T1D. 21 out of 1089 patients (19 %) had diabetic ketoacidosis at diabetes onset ($ph < 7.3$). Eight patients were discharged without insulin, none had high risk HLA-genotype and one of them was autoantibodies positive. This patient may represent T2D.

Conclusion: National diabetes registries are valuable tools in studying the epidemiology of different types of diabetes. The majority of childhood-onset diabetes was classified as T1D due to clinical data, HLA- genotypes and autoantibodies. 93% of the patients had T1D diabetes. In at least 5 % of the cases further data is needed before a final diagnosis. Few children and adolescents below the age of 18 years get T2D in Norway, max 1–2 % of new onset diabetes cases.

366

Diabetes in Down's syndrome: is it heterogeneous?

K.M. Gillespie, R.J. Aitken, J.P.H. Shield

University of Bristol, United Kingdom

Background and aims: There is an increased frequency of autoimmune thyroid disease, coeliac disease and diabetes in Down's syndrome. Understanding how an extra chromosome 21 increases the risk of autoimmune disease could provide vital insights into the mechanisms underlying autoimmunity in the general population. Diabetes in Down's syndrome in particular, is understudied. In a previous study of 40 children with Down's syndrome and diabetes in our laboratory, it was shown that children with Down's syndrome diagnosed with diabetes under the age of 21 share the same HLA characteristics as type 1 diabetes but have fewer "high risk" HLA class II genotypes than age matched children from the general population with type 1 diabetes. We therefore postulated that increased expression of genes on chromosome 21 increase the penetrance of autoimmune diabetes in children with Down's syndrome.

Materials and methods: A further 16 individuals in the UK with Down's syndrome and diabetes were identified. Clinical data and, where possible, genetic samples were collected. The frequency of diabetes according to age at diagnosis was calculated. HLA class II genotyping was carried out using DYNAL Autoreli PCR-SSOP.

Results: An unusual pattern emerged in the age at diagnosis of children with Down's syndrome and diabetes: 18% were diagnosed at, or under the age of 2 years (Fig 1) compared to an expected frequency of 7% for type 1 diabetes in the same age group in the general population. Of 9 children diagnosed under 2 years, 5 (55%) were negative for high risk HLA class II genotypes, approximately the same frequency as the general population. Peaks in age at onset possibly consistent with type 1 and type 2 diabetes were also observed.

Conclusion: These data indicate that diabetes in very young children with Down's syndrome may not be of autoimmune origin and diabetes diagnosed in older individuals with Down's syndrome may be either type 1 or type 2 diabetes. This is consistent with the observed reduction of high risk HLA class II genotypes in individuals with Down's syndrome and diabetes, diagnosed under the age of 21. There is therefore an urgent requirement for improved phenotyping, classification and diagnosis of diabetes in individuals with Down's syndrome.

Figure 1. Age at onset of diabetes in Down's syndrome

Post transplant diabetes mellitus: role of insulin-resistance and pro-inflammatory cytokines in first year post-transplant

V. Bonato^{1,2}, D. Cataldo¹, M. Calabrese¹, C. Tondi¹, M. Carmellini³, F. Dotta^{1,2}

¹Department of Internal Medicine and Endocrine and Metabolic Sciences, University of Siena, ²Fondazione Umberto Di Mario, Toscana Life Sciences,

³Transplant Unit, AOU Senese, Siena, Italy

Background and aims: Post Transplant Diabetes Mellitus (PTDM), a common complication of solid organ transplant, has a negative impact on graft and patient prognosis. Age, ethnicity, type 2 diabetes family history, and Hepatitis C were identified as non modifiable risk factors of PTDM. In addition type of immune-suppressive therapy, and overweight are modifiable risk factors for PTDM. Several studies demonstrated that pro-inflammatory molecules, such as MCP-1 and IL-6, are involved in the pathogenesis of type 2 diabetes. In a retrospective analysis, we found that 17% of 250 kidney transplant recipients developed an altered fasting glucose (PTDM 12.2% and impaired fasting glucose, IFG, 4.8%), with the highest incidence in first year post transplant. In the present study we aimed to evaluate the role of insulin-resistance and proinflammatory molecules in PTDM and IFG.

Materials and methods: At the day of kidney transplantation 53 non diabetic consecutive patients were recruited, and followed up to 1 year. At baseline the following data were collected: age, sex, body mass index (BMI), prevalence of overweight (BMI>25 Kg/m²), hepatitis C status, prevalence of diabetes mellitus family history, prevalence of hypertension, dyslipidemia and smoke. At follow up a blood sample was collected to determine glycaemia, lipid profile, basal insulin, creatinine, serum MCP-1 and IL-6. HOMA-IR and QUICKI were calculated to determine insulin-resistance and insulin-sensitivity. Type of immune-suppression (cyclosporine vs tacrolimus) and occurrence of acute rejection was evaluated at follow up. According with ADA guidelines patients were classified as PTDM, IFG or normoglycemic (NG).

Results: During the first year 9% of patients developed PTDM, while 28.3% developed IFG. PTDM and IFG patients were older than NG ($p<0.05$ and $p<0.03$). In IFG patients HOMA-IR resulted higher than in NG group (3.10 ± 2.72 and 1.96 ± 2.37 $p=0.0082$), while QUICKI was lower (0.34 ± 0.03 and 0.36 ± 0.03 $p=0.0113$). PTDM and IFG prevalence was higher in tacrolimus-treated recipients than in cyclosporine-treated ($p=0.002$ and $p=0.07$). No differences were observed in pro-inflammatory molecules, MCP-1 and IL-6. Multivariate analysis confirmed tacrolimus as independent risk factors for PTDM ($p<0.02$).

Conclusion: Our data confirm the role, in PTDM development, of known risk factors, in particular age and tacrolimus treatment, during the first year post transplant. In our work PTDM is only in part associated with insulin resistance, which is observed mainly in IFG patients. In the general population IFG is considered a “pre-diabetic” state and here we speculate that it precedes the onset of PTDM and may progress to PTDM in the presence of failure of beta cell function.

368

Heterogeneity of patients with LADA: linkage to autoimmunity is apparent only in those with perceived need for insulin treatment. Results from the Nord-Trøndelag Health Study (HUNT 2)

M. Radtke¹, T.I. Lund Nilsen², K. Midthjell², V. Grill¹

¹Department of Cancer Research and Molecular Medicine, ²Department of Public Health, Trondheim, Norway

Background and aims: Heterogeneity of Latent Autoimmune Diabetes in the Adult (LADA) has not been examined in detail. We compared phenotypes of LADA with and without perceived need for insulin treatment and contrasted these data with type 2 diabetes (T2D).

Materials and methods: We used data from the all-population-based Nord-Trøndelag Health Survey ($n=64931$), performed 1995-97. Data were assembled for LADA ($n=106$) and T2D ($n=943$) during times when diagnosis of LADA was not investigated.

Results: Comparing LADA with and without insulin: Markers of metabolic syndrome, such as BMI and blood pressure were similar. Insulin-treated subjects had higher titers of anti-GAD ($p<0.001$) and lower fasting C-peptide ($p<0.001$). Titre of anti-GAD and level of C-peptide in the insulin treated LADA group correlated negatively ($r=-0.40$; $p=0.009$). Comparing LADA and T2D both without insulin: Groups were similar in all tested respects. Comparing insulin-treated LADA and insulin-treated type 2 diabetes: LADA patients were leaner, but still overweight, (BMI $28.7(27.4-30.1)$ vs. $30.9(CI: 30.2-31.5)$ in T2D, $p<0.001$). More LADA patients received insulin (40% vs. 22%, $p<0.001$) Diabetes duration before start of insulin tended to be shorter ($p=0.157$), and insulin dose lower ($p=0.190$) despite lower C-peptide ($p<0.001$). Comparison between T2D with and without insulin: Insulin treated subjects were more obese, had higher HbA1c and lower C-peptide ($p<0.001$ for differences between groups).

Conclusion: Perceived need for insulin in LADA is dictated to a major extent by autoimmunity, despite presence of a metabolic syndrome. In contrast, in T2D a combination of insulin resistance and beta cell insufficiency prompts the decision to start insulin treatment.

The prevalence of metabolic syndrome is much less in LADA and type 1 diabetes than type 2 diabetes: ACTION LADA 3

M.I. Hawa¹, E. Cipponeri¹, D. Collier¹, Y. Loh¹, P. Pozzilli¹, S. Brophy², S. Hunter³, C. Thivolet⁴, M. Didac⁵, R.D.G. Leslie¹

¹Department of Diabetes & Metabolic Medicine, Barts and The London School of Medicine and Dentistry, London, United Kingdom, ²The Clinical School, University of Wales Swansea, United Kingdom, ³Department of Diabetes, Royal Victoria Hospital, Belfast, Ireland, ⁴Dept. of Endocrinology, Hospital Edouard Herriot, Lyon, France, ⁵Unit of Endocrinology, Hospital de Sabadell, Spain

Background and aims: The aim of this study was to estimate the frequency of the Metabolic Syndrome in adult European patients with diabetes and to assess whether it is associated with the type or age at onset of autoimmune diabetes.

Materials and methods: A consecutive series of patients attending hospital-based diabetes clinics in the Europe were assessed for the frequency of Metabolic Syndrome and compared with population-based controls as part of the Action LADA study. In total, 2079 subjects (age range 30 - 70 years) were studied, including 1289 recent-onset type 2 diabetes patients without glutamic acid decarboxylase autoantibodies (GADA), 140 non-insulin requiring patients with GADA who remained off insulin therapy at least 6 months post-diagnosis and were designated latent autoimmune diabetes of adults (LADA), 291 type 1 diabetes patients and 359 control subjects. Metabolic Syndrome was defined according to both the National Cholesterol Education Program diagnostic criteria and the International Diabetes Federation.

Results: In both type 1 diabetes and LADA, levels of waist circumference and HDL cholesterol were similar, but in each group lower than in patients with type 2 diabetes ($p<0.0001$ for both comparisons). The frequency of Metabolic Syndrome was similar in type 1 diabetes (55.0%) and LADA (54%), but less than in type 2 diabetes patients (81.5%) and more than controls (36.5%) ($p<0.0001$ for all comparisons). However when glucose was removed as a variable Metabolic Syndrome frequency was similar in type 1 diabetes (27.5%), LADA (27.0%) and controls (35.0%), but still less frequent in all groups than in type 2 diabetes (47.5%) ($p<0.0001$). Factors associated with Metabolic Syndrome included diabetes, older age and male gender. The hierarchy of frequency of features of Metabolic Syndrome in all groups, including controls, was similar.

Conclusion: Metabolic Syndrome is as prevalent in adults with LADA as in type 1 diabetes, but the frequency is nearly half that seen in type 2 diabetes. When glucose is excluded as a variable, Metabolic Syndrome is as prevalent in patients with autoimmune diabetes as controls. In terms of Metabolic Syndrome, autoimmune diabetes is distinct from type 2 diabetes.

Similarities and differences between Caucasian and Asian LADA

A. Petrone¹, Y. Park², S. Genovese³, J.T. Woo⁴, C. Giordano⁵, K.W. Lee⁶, A.E. Pontiroli⁷, S.H. Paik⁸, M.S. Nam⁶, P. Pozzilli⁹, Y.S. Kim¹⁰, R. Buzzetti¹, NIRAD Study Group, Korean National Diabetes Program

¹Clinical Sciences, “Sapienza” University, Rome, Italy, ²Endocrinology, Hanyang University, Seoul, Republic of Korea, ³Endocrinology, Istituto Clinico Humanitas IRCCS, Milan, Italy, ⁴Endocrinology and Metabolism, Kyung Hee University School of Medicine, Seoul, Republic of Korea, ⁵Endocrinology, University of Palermo, Italy, ⁶Endocrinology and Metabolism, Ajou University, Suwon, Republic of Korea, ⁷San Paolo Hospital, Milan, Italy, ⁸Endocrinology, Korea University, Seoul, Republic of Korea, ⁹Endocrinology, University Campus Bio-Medico, Rome, Italy, ¹⁰Endocrinology, Inha University, Seoul, Republic of Korea

Background and aims: Latent autoimmune diabetes in adults (LADA) is an autoimmune form of diabetes in adults. Patients with LADA show more preserved beta-cell function than classic T1D, but have also clinical features of type 2 diabetes (T2D). T1D and T2D vary in epidemiology, clinical and metabolic features between Caucasian and Asian patients. Prevalence of T1D is at least ten fold lower in Asians compared to Caucasians, whereas few epidemiological studies on LADA have shown that this form of diabetes is only slightly less prevalent in Asians vs. Caucasians. No studies however, have compared the features of LADA in these ethnic groups. In a joint collaborative project between Italy and South Korea, we compared anthropometric, clinical and metabolic data of Caucasian vs. Asian LADA patients.

Materials and methods: Two large studies on prevalence of LADA are carried out in Italy and South Korea whose results are reported elsewhere. A cross sectional analysis was performed in the 193 LADA patients diagnosed in Italy and in the 39 LADA patients diagnosed in South Korea. The same ascertainment criteria were applied for diagnosis of LADA in both groups as published in Diabetes Care in 2007. Biochemical parameters were measured centrally in both countries, respectively, GAD antibodies were evaluated in two centralized laboratories, one in Italy and one in Korea, and both participated in the DASP autoantibody Workshop. Data were analyzed with one way ANOVA test.

Results: Prevalence of LADA (reported elsewhere) was very similar (4.4% in Italy and 4.4% in South Korea). Mean age at diagnosis was nearly identical between Caucasian and Asian LADA (50.3 yrs.±12 vs. 49.6 yrs.±8.3), as well as HbA1c values (7.5%±1.7 vs. 7.4%±1.5). Despite similar HbA1c levels, fasting blood glucose (BG) levels were significantly higher in Caucasian vs. Asians (168.1 mg/dl ± 58 mg/dl vs. 134 mg/dl ± 34 mg/dl, $p < 0.001$) implying that post-prandial glucose values were higher in Asian LADA. There was a significant higher BMI in Caucasian vs. Asian LADA (27.± 5.1 vs. 25.3 ± 3.3, $p < 0.01$) and higher HDL (but not total) cholesterol levels (50 mg/dl.±3 mg/dl vs. 44.7 mg/dl ± 11 mg/dl, $p < 0.03$). By contrast, triglyceride levels were significantly higher in Asians vs. Caucasian (201 mg/dl ± 169 mg/dl vs. 144 mg/dl±104 mg/dl, $p < 0.01$) probably reflecting differences in diet habits.

Conclusion: Asian LADA patients are leaner than Caucasians, have similar both age at diagnosis and overall metabolic control, although fasting BG appears higher in Caucasians. LADA in these two ethnic groups has similar prevalence, clinical and some metabolic features in common, but also some relevant differences in lipid profile which may help in designing strategies for intervention according to the ethnic group.

PS 014 Incidence of type 1 diabetes

371

The trend curve of type 1 diabetes incidence in Czech children has flattened

O. Cinek¹, M. Kulich², Z. Sumnik¹

¹Department of Pediatrics, ²Department of Probability and Mathematical Statistics, Charles University in Prague, Czech Republic

Background and aims: The incidence of childhood type 1 diabetes (T1D) is increasing in most populations, and this increase often forms a basis for long-term forecasts. Using data from one of the largest population-based paediatric diabetes registers, we show how unpredictably the incidence can change: a sudden stagnation can follow immediately after a very rapid relative increase.

Materials and methods: The population-based Czech Childhood Diabetes Register records new cases of childhood-onset T1D (using EURODIAB criteria), manifested at the age of 0-14 completed years, as reported by a network of paediatric diabetologists. The completeness of the ascertainment was calculated to 99% using data from parent organization as the secondary source. The observed numbers of cases diagnosed over 1989 - 2006 were modelled by Poisson log-linear regression with logarithm of the total follow-up time as an offset. The predictors were age, gender, calendar time, and their interactions. Effect modification of calendar time by age was modelled by interacting calendar time with age group; this means the effect of calendar time was allowed to vary with age group. The analyses were adjusted for varying completeness of ascertainment. The time trends in T1D incidence were modelled by piecewise linear function of calendar time with breaks at years 1996 and 2002. The breaks were suggested by descriptive analyses.

Results: A total of 4296 cases was ascertained over 1989 - 2006 from an average paediatric population of 1.8 million. The observation period can be divided into three parts: a moderate increase in incidence over 1989-1995, followed by a steep increase between 1996-2001, and a stagnation 2002-2006. While the upward inflection of the incidence curve between the first and the second period is statistically significant only for the youngest age group (0-4 years at onset, $p = 0.02$), the flattening of the incidence after 2002 is highly significant in the whole group 0-14 years of age ($p < 0.001$), as well as the two younger subgroups 0-4 ($p < 0.001$) and 5-9 years ($p = 0.005$).

Conclusion: Stagnations in populations with previously rising T1D incidence exist and have been documented in sufficiently large datasets (e.g. from Norway with a stable incidence over 1989-1998 that was followed again by an increase). Further reports on lack of significance for the increase in incidence come from smaller registers, being related mostly to low number of cases; this is however not the case for our dataset from one of the largest operative paediatric diabetes registers. The environmental exposure (or its change) responsible for this recent inflection is unknown, but is most likely population-specific: Austria, our close neighbour both geographically and genetically, undergoes an uninterrupted increase in incidence lasting now about two

decades. Our data seem to contribute to the notion that no simple long- and intermediate-term trends in incidence can be reliably predicted.

Seasonal variation of the onset of type 1 diabetes among children worldwide

E.V. Moltchanova, N. Schreier, N. Lammi, M. Karvonen

Dept of Health Promotion and Chronic Disease Prevention, National Public Health Institute, Helsinki, Finland

Background and aims: Type 1 diabetes mellitus (T1DM) is thought to result from a combination of genetic and environmental factors. Among the latter, e.g., viral infections and the intake of vitamin D may be subject to seasonal variations. Several studies worldwide have found evidence of seasonality of birth and diagnosis of T1DM. However, the generalisation of the results is usually difficult due to different methods of data collection and statistical analysis. The WHO Diabetes Mondiale (DIAMOND) project provides unified data collection framework. Our aim was to study the seasonal patterns exhibited by these data.

Materials and methods: During the period 1990–1999, population-based registries were used to collect standardized data on incidence of T1DM among 0–14 year-olds worldwide within the framework of the WHO DIAMOND project. A total of 104 centers from 52 countries have provided incidence and population data sufficient to analyse seasonal patterns. Geographical coordinates for each center were also obtained. A regression model with linear trend term and seasonal Fourier terms was fitted, adjusted by age and sex.

Results: Of the 104 studied centers 42 exhibited significant seasonality ($p \leq .05$) in the incidence of T1DM. Of these 28 had peaks in winter months (October – January) and 33 had troughs in summer months (June – August). However, some of the centers in Southern hemisphere demonstrated different pattern with peak in July–September and trough in January–March. The existence of significant seasonal pattern correlated with the higher level of incidence ($p \leq .001$). This effect disappeared when adjusted for the geographical location, namely the latitude. Centers further away from the equator were on average more likely to exhibit seasonality ($p \leq .001$). The longitude, on the other hand, had no effect. Incidence for boys exhibited significant seasonality more often than that for girls (33 vs 26 centers). When divided into three age groups, 0–4 years of age, 5–9 years of age, and 10–14 years of age, the incidence in older age groups showed significant seasonality more often than that in younger age groups.

Conclusion: The analysis of worldwide data on T1DM, provided by the WHO DIAMOND Project, largely confirms the findings of smaller studies reported so far: existence of seasonal pattern of T1DM incidence with peak in winter and trough in summer in the Northern hemisphere, more often observed among boys than among girls, and among older age-groups than among the younger. In addition, the Southern hemisphere centers have shown seasonality patterns different from those in the Northern hemisphere.

373

Infant feeding patterns during the first year of life in offspring of mothers with and without type 1 diabetes: results from the TEDDY (The Environmental Determinants of Diabetes in the Young) Study

J.M. Norris¹, S. Hummel², S. Schoen³, S.M. Virtanen⁴, W. McLeod⁵, C. Andren Aronsson⁶, P. Gesualdo⁷ for the TEDDY Study Group

¹Preventive Medicine and Biometrics, University of Colorado Denver, United States, ²Immunology, Diabetes Research Institute, Munich, Germany, ³Research Institute of Child Nutrition, Dortmund, Germany, ⁴Epidemiology, University of Tampere, Finland, ⁵Pediatrics Epidemiology Center, University of South Florida, Tampa, United States, ⁶Diabetes and Celiac Disease Unit, Lund University, Malmö, Sweden, ⁷Barbara Davis Center, University of Colorado Denver, Aurora, United States

Background and aims: Previous studies have suggested that infant feeding patterns may influence the risk of islet autoimmunity and type 1 diabetes (T1D). Pediatric authorities have recommended exclusively breast-feeding newborns during the first 6 months of life. Recently the German BABYDIAB study showed that mothers with T1D breast-feed their babies less and for a shorter duration compared to mothers without T1D. The international TEDDY study has assessed the effect of maternal T1D on breast-feeding behaviour and the introduction of various foods during the first year of life.

Materials and methods: The TEDDY study is conducted in three U.S. centers (Denver, Seattle, Georgia/Florida) and three European centers (Finland, Sweden, Germany) with the aim of identifying environmental factors that may trigger islet autoimmunity and T1D. A total of 4,207 children at genetically high risk for T1D have been enrolled into the study. The 2,343 children followed for more than one year were included in the present analyses. Of these, 96 have a mother with T1D, 151 have a non-diabetic mother but a father or sibling with T1D and 2,096 have no first-degree relative with T1D. Data on early infant diet were collected at 3-month intervals.

Results: Mothers with T1D breast-fed their children less than non-diabetic mothers. During the first 4 weeks of life only 28.1% (SE 2.4) of the children with a T1D mother were exclusively breast-fed compared to 47.7% (SE 2.8) of the children with a father/sibling with T1D and 43.3% (SE 0.7) of the children from the general population ($p < 0.001$). Also the total breast-feeding duration was shorter in the offspring of mothers with T1D ($p < 0.01$). During the first 4 weeks of life, 64.9% (SE 2.9) of the children with a mother with T1D were introduced to cow's milk vs. 49.0% (SE 2.9) of the children with a father/sibling with T1D and vs. 54.5% (SE 0.7) of the children from the general population ($p < 0.001$). In contrast, 65.5% (SE 0.8) of the children of the general population were introduced to gluten by 5 months of age, whereas only 37.6% (SE 4.3) of the children with a mother with T1D and 42.3% (SE 3.6) of the children with a father/sibling with T1D were exposed to gluten by that age ($p < 0.001$).

Conclusion: This study confirms earlier findings that mothers with T1D breast-feed less and for a shorter duration compared to mothers without T1D. Furthermore offspring of mothers with T1D were exposed to cow's milk earlier, and children with a mother or other first-degree relative with T1D were exposed to gluten later compared to children from the general population.

Increasing temporal trend in incidence of type 1 diabetes in children in Piedmont Region, Italy, period 1990–2004

G. Novelli¹, F. Cerutti², F. Cadario³, A. Perino³, G. Bona³, C. Zucco¹, M. Perotto¹, F. Panero¹, G. Bruno¹

¹Internal Medicine, University of Turin, ²Dept of Pediatrics, University of Turin, ³Dept of Pediatrics, University of Novara, Italy

Background and aims: Incidence of type 1 diabetes is increasing in many countries. In Northern Italy, the incidence rates among persons up to 29 years of age have been estimated by the Registry of the Province of Turin, which has achieved high estimated completeness of ascertainment for both children and young adults. In this report, we aimed to extend the study base of the registry to all children aged 0–14 years in the whole Piedmont Region in the period 1990–2004.

Materials and methods: The study-base is the population 0–14 years of age of the Piedmont Region (500,000 children), period 1990–2004, identified through two independent sources of ascertainment. Diagnosis of type 1 diabetes was based on permanent insulin treatment. The two sample capture-recapture method was employed to estimate completeness of ascertainment.

Results: 948 incident cases of diabetes have been identified (completeness of ascertainment 99%). Incidence was 12.1/100,000 person-years (95% CI 11.4–12.9) in the age group 0–14 yrs, similar in both sexes. The highest risk in both sexes was found in the age-group 10–14 yrs (0–4: 9.2/100,000 person-years, 5–9: 12.7/100,000, 10–14: 14.3/100,000). Large fluctuations in incidence rates/year were evident; moreover, comparing 5-years time periods incidence rate, a significant increase in risk was evident: 1990–94: 10.9/100,000 person-years; 2000–2004: 14.4/100,000 person-years (RR 1.32, 95% CI 1.13–1.53, $p < 0.0001$). The highest risk was found in males in 2001 (18.0/100,000, 95% CI 13.5–23.9). Large geographical variations within the Region area were also found, not related to urban/rural characteristic, and therefore mostly unexplained at present.

Conclusion: This population-based study shows: 1) large geographical variations in risk of childhood type 1 diabetes within a single Italian Region; 2) an increasing temporal trend in risk, similar to that found in other European countries. Monitoring of the disease over time and geographical area through registries is essential to suggest hypothesis on the etiopathogenesis of the disease.

375

Incidence of childhood type 1 diabetes (0–14 yrs) in La Palma Island: 1993–2007

B.M. Belinchón Sz.-Somoza¹, J.A. Hernández Bayo²,
R. Cabrera Rodríguez³

¹Family Care, Primary Care Center, San Andrés y Sauces, ²Endocrinology, General Hospital of La Palma, Breña Alta, ³Pediatrics, General Hospital of La Palma, Breña Alta, Spain

Background and aims: The incidence of type 1 diabetes shows wide geographical variability and heterogeneity. The aim of this study was to determine the incidence of type 1 diabetes in children and adolescents younger than 15 yr in La Palma Island (the most northwest of Canary Islands, Spain: 730 Km², 85000 habitants and subtropical climate).

Materials and methods: All subjects with type 1 diabetes (according WHO and/or ADA criteria) diagnosed between January 1993 and December 2007 (prospectively 1995–2007) were included. The population at risk (0–14 yr) fluctuated between 15711 habitants -1991 General Census- and 11899 habitants -2001 General Census-. All the reported cases were on insulin treatment. All subjects were living in La Palma Island at least six months before diagnosis of type 1 diabetes. Autoimmunity was checked measuring tyrosine phosphatase (IA₂) and glutamic acid decarboxylase (GAD) auto-antibodies. Using the capture-recapture method (primary source was hospital records, while secondary sources were membership files of La Palma Diabetic Association and Primary Care Physicians), the ascertainment was 100 %. The incidence rates were expressed as number of cases per 10⁵ habitants per year. The 95% Confidence Intervals were estimated assuming the Poisson distribution of the cases. The age adjustment for the rates was done using the direct method with a World and European Standard Population.

Results: Sixty eight subjects younger than 15 yr had presented type 1 diabetes at the last 15 yr [37 boys, 31 girls; sex ratio 1.2; medium age: 8.5±3.8 yr (95% CI: 7.6–9.4)]. In 8 subjects (11.8%) type 1 diabetes was present in other first degree families (brothers, not twins). Autoimmunity (positive IA₂ and/or GAD auto-antibodies) was present in 79.7% (51/64): 89.2% at diagnosis (33/37), 66.7% after diagnosis (18/27). The annual incidence fluctuates between 12.7 and 67.2/10⁵, being the average annual incidence 33.2/10⁵ (95% CI: 30.3–36.1). No seasonal differences were observed (spring 23.5%, summer 26.5%, autumn 26.5%, and winter 23.5%). The incidence in males was higher than in females [35/10⁵ per yr (95% CI: 32–38) versus 31.2/10⁵ per yr (95% CI: 28.4–34)]. The incidence was higher in the 10–14 yr age-group (38.3/10⁵ per yr, 95% CI: 35.2–41.4), followed by the 5–9 yr age-group (37.6/10⁵ per yr, 95% CI: 34.5–40.7) and the 0–4 yr age-group (21.6/10⁵ per yr, 95% CI: 19.2–24). The age-adjusted incidence to World Standard Population was 31.6/10⁵ per yr (95% CI: 28.8–34.4). The age-adjusted incidence to European Standard Population was 32/10⁵ per yr (95% CI: 29.1–34.9).

Conclusion: The incidence of type 1 diabetes in La Palma Island is the highest reported up to date in a Spanish community, and is close to the highest of the world. It is inconsistent with the hypothesis of a north-south gradient in diabetes risk. The knowledge of the incidence rates in La Palma Island can contribute to study the role that genetics and environmental factors may play in these differences.

376

Incidence of insulin-dependent diabetes mellitus among Italian-heritage children living in Germany

S. Muntoni^{1,2}, S. Ehehalt³, P. Popovic³, A. Willasch³, R. Hub³, M.B. Ranke³, S. Muntoni², A. Neu for the DIARY Group Baden-Wuerttemberg³

¹Department of Toxicology, Oncology and Molecular Pathology Unit, University School of Cagliari, Cagliari, Italy, ²Centre For Metabolic Diseases and Atherosclerosis, The ME.DI.CO. Association, Cagliari, Italy, ³University Hospital for Children and Adolescents, University School of Tuebingen, Germany

Background and aims: In order to investigate the role of genetic and environmental factors in the pathogenesis of Type 1 diabetes, we set up in Germany a migrant study with a comparative study of disease prevalence and incidence in (A) children of migrant Italians from high-risk (Sardinia) and low-risk (continental Italy) regions *versus* (B) German children.

Materials and methods: Children from Italy were identified by the “Baden-Wuerttemberg (BW) Diabetes Incidence Registry” (DIARY), in which 4,017 newly-diagnosed type 1 diabetic patients, aged 0–14 years, were registered from 1987 to 2003. In addition, data relating to type 1 diabetic children from Sardinia were elicited from more than 2,000 questionnaires.

Results: (1) Type 1 diabetes is more frequent in German children than in children of Italian migrants (IR 14.8/100,000/year, 95% CI 14.4–15.4 vs IR 10.8/100,000/year, 95% CI 8.2–13.6). (2) The incidence of type 1 diabetes among Italian children residing in Germany is similar to that of Italian children in the home country (IR 10.8/100,000/year, 95% CI 8.2–13.6 vs 8.4/100,000/year, 95% CI 7.9–8.9). (3) The prevalence of type 1 diabetes among Sardinian children is higher than that of German children (0.11%, 95% CI 0.11–0.12) independently of the place where Sardinian children are living (Sardinian children in Germany 2.3%, 95% CI 0.5–6.5 vs Sardinian children in Sardinia 0.30%, 95% CI 0.27–0.32).

Conclusion: Children from high- and low-risk areas of Italy have incidence rates closer to the rates of their native regions than to those of German children. This indicates that genetic factors play a predominant role in the pathogenesis of type 1 diabetes.

377

Menopause in women with type 1 diabetes

L. Sjöberg¹, L. Haapala², V. Harjutsalo³, J. Pitkaniemi², J. Tuomilehto², R. Kaaja⁴

¹Department of General Practice and Primary Health Care, University of Helsinki, ²Department of Public Health, University of Helsinki,

³Department of Health Promotion and Chronic Disease Prevention, National Public Health Institute, Helsinki, ⁴Department of Obstetrics and Gynaecology, Helsinki University Central Hospital, Finland

Background and aims: Earlier studies have suggested a significantly earlier menopause in type 1 diabetic women. This could be related to ovarian dysfunction due to microangiopathy and/or to autoimmune processes related to diabetes. The aim of this study was to study the timing of menopause and the factors influencing it in a large cohort of Finnish women with type 1 diabetes.

Materials and methods: The subjects of the DERI (Diabetes Research International Group) study were diagnosed with type 1 diabetes at 17 years of age or under during the years 1965–1979, placed on insulin treatment at diagnosis and residing in Finland. The cases were identified from the National Diabetes Registry and the drug reimbursement registry with an ascertainment rate approaching 100 %. From this cohort, we selected all women who were born in 1962 or before that and thus were in the perimenopausal age (40–55) in 2002, when the study started. Of the 1 004 subjects who were alive at the start of the study, 980 could be contacted. A questionnaire on their gynaecological and reproductive history, diabetes-related facts, other diseases and life-style factors was sent. The response rate was 65% (635/980). To study the transition from premenopause to postmenopause a similar questionnaire was sent three years later. The response rate was 81% (513/635).

The probability of reaching menopause was evaluated by using Kaplan-Meier method and associated factors (number of deliveries, retinopathy, nephropathy, autoimmune diseases, smoking) were evaluated using Cox's proportional hazards regression modelling.

Results: Of the 635 respondents, a total of 78 had undergone hysterectomy, 4 had experienced premature menopause because of chemotherapy and 41 used hormonal contraception causing amenorrhea. These women were excluded from the analyses. Those who could report their age at the cessation of menstruation had a menopausal age of 47.8 years (median; 95% CI 46.8–48.8). In the study population there were, however, over one hundred women over 50 years of age who had not yet reached menopause.

We found a significant association between the age at menopause and the number of deliveries ($p=0.02$). The presence of diabetic retinopathy or nephropathy did not have a significant influence on the age at menopause, neither did the presence of other autoimmune diseases.

Conclusion: The results of our study do not indicate a significantly earlier menopause in type 1 diabetic patients in Finland. This is in contradiction to earlier study results on this subject.

PS 015 Cardiovascular risk

378

Predictive value and risk of the metabolic syndrome defined by NCEP III and IDF for the development of type 2 diabetes

C. Temml¹, R. Obermayer², G. Gutjahr³, B. Ludvik³

¹Health care, MA15 Dez.IV, Vienna, ²Internal Medicine III, Donauespital SMZ-OST, Vienna, ³Internal Medicine III, University of Vienna, Austria

Background and aims: The metabolic syndrome (MS) is associated with an increases risk of type 2 diabetes (DM2). Among others, the criteria of the National Cholesterol Education Programs (NCEP- ATP III panel) or International Diabetes Federation (IDF) are used for diagnosis. The aim of the present study is to evaluate the predictive value of these criteria as regards to the development of DM2.

Materials and methods: In this longitudinal study, parameters relevant to the diagnosis of MS were assessed in 13,852 non-diabetic subjects (7,270 males (56,6%), age 44 ± 3 y and 5,582 females (43,3%), age 46 ± 14 y, means \pm SEM). The subjects were followed up to an average of 6 years.

Results: According to IDF, 13.3% and to NCEP III 10.4% (NCEP vs. IDF, $p > 0.05$) of all subjects presented with MS at study entry. In all age groups, the prevalence of MS was higher by IDF than by NCEP definition, between 50 to 59 years of age it was 24.4 vs. 16.5% in males, and 19.1 vs. 13.8% in females. The prevalence was higher in men compared to women in both definitions for all age categories, except for female subjects over 60 years. Concordance between both definitions was modest as expressed by a kappa value of 0.63 (95% CI 0.61-0.65). The diagnosis of MS increased the relative risk to develop DM2 over a period of 6 years according to IDF vs. NCEP in males by 7.6 vs. 7.0 in females by 13.7 vs. 16.6 ($p > 0.05$).

Conclusion: The results of this study reveal a higher prevalence for MS in a non-diabetic population when the IDF vs. NCEP criteria are used. The presence of MS imposes a considerably increased risk for the subsequent development of DM2. In female subjects, NCEP criteria allow a better assessment of the risk for DM2.

379

Comparison of the population specific clinical model and the IDF definition of metabolic syndrome for the prediction of type 2 diabetes in a Japanese population

T. Nakagami¹, M. Tominaga², R. Nishimura³, M. Daimon⁴, T. Oizumi⁴, N. Yoshiike⁵, N. Tajima³

¹Diabetes Center, Tokyo Women's Medical University, ²Department of Laboratory Medicine, Yamagata University School of Medicine, ³Division of Diabetes, Metabolism and Endocrinology, Department of Internal Medicine, Jikei University School of Medicine, Tokyo, ⁴Department of Neurology, Hematology, Metabolism, Yamagata University School of Medicine, ⁵International Business-Academia Collaboration Center, National Institute of Health and Nutrition, Tokyo, Japan

Background and aims: The metabolic syndrome (MetS) has been highlighted as high-risk for type 2 diabetes (T2DM) and cardiovascular disease (CVD). Thus, we sought to compare the MetS to the clinical prediction model for DM, which is developed in the Funagata Diabetes Study, as predictors of T2DM.

Subjects and methods: A total of 1,189 non DM in the Funagata-town inhabitants were followed for 5 years, with 4,720 person years accumulated. The incident DM was identified by the 1999-World Health Organization criteria. MetS was identified by the definition according to the International Diabetes Federation (IDF). Baseline measurements included age, sex, smoking status, alcohol habits, physical activity, family history of DM, body mass index (BMI), waist circumference (Wc), systolic and diastolic blood pressures (BPs), fasting plasma glucose (FPG) and 2-hour plasma glucose, HbA1c, fasting insulin, total and high density lipoprotein cholesterol (HDL-C) and triglyceride (TG). The multivariate logistic regression model was used to develop DM prediction model in the Funagata-town inhabitants.

Results: During 5 year of follow-up, 57 subjects developed DM. The prevalence of the MetS at baseline was 11.1%. The multivariate logistic regression model showed that age (odds ratio [OR] per 10 years, 1.60 [95% CI: 1.19-2.16]), Wc (OR per 1SD, 1.69 [1.26-2.28]), family history of DM (2.97 [1.22-7.22]), and log transformed FPG (OR per 1SD, 3.44 [2.44-4.84]) were associated with incident DM. The presence of high BP, high TG and low HDL-C by

the IDF definition of MetS increased the risk of development of DM by 55%, 62%, and 68%, respectively, in comparison to the absence of these conditions. However they were not statistically significant. Then, the population specific prediction model for DM was calculated as following regression parameters: $P = 1 / (1 + e^{-x})$, where $x = -30.463 + (0.472 \times \text{Age}/10 + 0.526 \times \text{Wc}/\text{SD} + 1.234 \times \text{Log FPG}/\text{SD}) + 1.088$ (if 1st degree relative has DM). The area under the receiver operating characteristic curve for the prediction model was 0.84 (95% CI: 0.79-0.89) and the optimal cut-off point for the prediction of incident DM was defined as a probability value ≥ 0.04 . The model's sensitivity was 87.7%, specificity 68.3%, and false-positive test 26.6%. While the sensitivity, specificity and false-positive test for predicting DM with MetS were 31.6%, 89.9%, and 86.4%. At corresponding sensitivity, the prediction model had a significantly lower false positive rate ($p < 0.001$) and, at corresponding false positive rate, significantly higher sensitivity ($p < 0.001$) than the MetS for predicting DM. Combining the MetS with DM prediction model did not improve the prediction of DM.

Conclusion: The MetS is inferior to the population specific prediction model for T2DM.

380

Association of endothelial function with components of the metabolic syndrome and lifestyle factors in subjects without previously diagnosed diabetes. Results from the KORA F4 Study

B. Thorand¹, A. Schneider¹, A. Peters¹, W. Rathmann², H.-E. Wichmann¹, C. Meisinger¹

¹Department of Epidemiology, Helmholtz Zentrum München, Neuherberg,

²Institute of Biometrics and Epidemiology, German Diabetes Center, Düsseldorf, Germany

Background and aims: Endothelial dysfunction plays an important role in the pathogenesis of atherosclerosis and may also be of particular importance for the development of type 2 diabetes. Therefore, the aim of the present study was to investigate associations between endothelial function and different components of the metabolic syndrome, including glucose concentrations, as well as lifestyle factors related to the development of atherosclerosis and type 2 diabetes.

Materials and methods: This abstract includes preliminary data from 364 men and 374 women aged 52-71 years without previously diagnosed diabetes who participated in the ongoing prospective KORA (Cooperative Research in the Region of Augsburg) F4 study. This study is a follow-up examination of the KORA S4 study conducted between 1999 and 2001. Endothelial function was measured using reactive hyperemia-peripheral artery tonometry (Endo-PAT, Itamar, Israel). Changes in pulse wave amplitude were observed at the fingertips using fingertip plethysmography probes before and after 5-minute forearm cuff inflation. The hyperemic response was determined as the log of the ratio of the post-deflation (measured 90-120 seconds following cuff deflation) to baseline pulse amplitude in the hyperemic finger normalized to the contralateral finger (log PAT ratio). A standardized oral glucose tolerance test (OGTT) was performed in all participants after an overnight fast. Endothelial function was measured approximately 50 minutes after the OGTT had been terminated and after the subjects had received a standardized breakfast. The association between sex, age, metabolic (body mass index (BMI), actual hypertension, ratio of total cholesterol/HDL-cholesterol, baseline and 2 hour glucose concentrations) as well as lifestyle factors (smoking status, physical activity, alcohol consumption) and endothelial function was assessed using linear regression analysis with log PAT ratio as the dependent variable.

Results: The mean (\pm SD) log PAT ratio was 0.49 ± 0.42 in the total study population and 0.39 ± 0.36 in men and 0.58 ± 0.45 in women. In a multivariable linear regression model which included all covariables mentioned above except the 2 hour glucose concentration, male sex, age, BMI and fasting glucose were significantly inversely associated with log PAT ratio (all p -values < 0.002). The p -value for glucose was slightly higher when the 2 hour glucose concentration was used instead of fasting glucose ($p = 0.009$) and the association was only significant for fasting glucose ($p = 0.03$) when both glucose concentrations were included in the model simultaneously. None of the examined lifestyle factors was significantly associated with the log PAT ratio.

Conclusion: Male sex, age, BMI and fasting glucose concentrations as well as glucose levels measured 2 hours after an OGTT were strongly inversely associated with endothelial function. Future prospective studies are needed to

determine the temporal relationship between derangements in glucose metabolism and endothelial dysfunction.

381

The association of serum cystatin C with metabolic syndrome and its related components

Y. Kang, S. Kim, S. Kim, S. Lee, S. Son, I. Kim, Y. Kim

Internal Medicine, Pusan National University School of Medicine, Busan, Republic of Korea

Background and aims: Serum cystatin C has been proposed as a better marker than serum creatinine for estimation of kidney function and associated with cardiovascular disease (CVD), especially in the elderly. The aim of this cross-sectional study was to investigate the association of serum cystatin C with metabolic syndrome (MS), a gathering of cardiovascular risk factors, and its related components.

Materials and methods: Total 1,468 adults (20–70 years of age, 813 men and 655 women) who visited Center for Health Promotion in Pusan National University Hospital for routine checkup were studied. We checked metabolic parameters and biochemical markers including serum cystatin C, hs-CRP, gamma glutamyltransferase, and uric acid. We defined metabolic syndrome using modified, revised ATP III criteria.

Results: Serum cystatin C was more increased in old ages (≥ 50 years, 0.91 ± 0.18 mg/L vs. < 50 years, 0.83 ± 0.14 mg/L). After adjustment for age and sex, cystatin C was positively correlated with waist circumference ($r = 0.222$, $p < 0.001$), BMI ($r = 0.115$, $p < 0.001$), SBP ($r = 0.110$, $p < 0.001$), DBP ($r = 0.273$, $p < 0.001$), and TG ($r = 0.166$, $p < 0.001$), GGT ($R = 0.198$, $P < 0.001$), hs-CRP ($r = 0.101$, $p < 0.001$), and uric acid ($r = 0.377$, $p < 0.001$) and inversely related with HDL cholesterol ($r = -0.181$, $p < 0.001$). Age, waist circumference, DBP, and HDL cholesterol were major independent determinant of cystatin C in multivariate regression analyses. Serum cystatin C was increased according to the increase of the number of metabolic syndrome component disorders and significantly increased in subjects with metabolic syndrome (MS, 0.90 ± 0.19 mg/L vs. non-MS, 0.86 ± 0.16 mg/L).

Conclusion: These findings raise the possibility that increased serum cystatin C level might be associated CVD risk factors and inflammatory markers and would be a useful tool for cardiovascular assessment.

382

Adverse cardiometabolic profiles amongst construction workers in Ireland

S. Shah, H. Thabit, N. Burns, J. Nolan, RISC Investigators

Metabolic Research Unit, St James Hospital, Dublin, Ireland

Background: Previous epidemiological studies have shown that construction workers are at increased risk for a range of chronic diseases.

Methods: The cardiometabolic risk factors of 433 male Irish construction workers (CW) were compared to 672 age- and sex-matched healthy non-diabetic European (HS) subjects from the EGIR-RISC study. Anthropometric data were collected as well as fasting blood samples for glucose, and lipid profiles. Questionnaires pertaining to physical activity were also collected from the CW. The baseline characteristics of the two cohorts are outlined in Table 1.

Results: The prevalence of the Metabolic Syndrome (MS) by the International Diabetes Federation (IDF) criteria in the CW was twice that of the HS (28.2% vs 14.2%, $p = < 0.0005$). The CW had more adverse components of the MS compared to HS. The CW were significantly more overweight with central obesity. They had significantly higher LDL cholesterol, systolic and diastolic blood pressure. Those with abnormal plasma glucose (fasting plasma glucose ≥ 5.6 mmol/l) in both groups, (CW = 61, HS = 133) were of similar age (46.6 vs 45.8 years, $p = 0.58$). However when compared to HS, CW still had a higher BMI (29.1 vs 27.8 kg/m², $p = 0.021$), waist circumference (102.7 vs 97.7 cm, $p = 0.002$) systolic BP (140 vs 127 mm/Hg, $p < 0.0005$) and diastolic BP (86.5 vs 78.5 mm/Hg, $p < 0.0005$).

Conclusion: In the CW cohort, there were no differences in the BMI or metabolic profile in those who reported being physically active at work and those who reported a sedentary work pattern. However, those who reported exercising 3 or more times a week had significantly lower BMI (26.6 vs 27.8 kg/m², $p = 0.006$), waist circumference (95.4 vs 98 cm, $p = 0.037$) and triglycerides (1.1 vs 1.4 mmol/l, $p = 0.02$) than those who exercised at most once a week.

Thus, despite a physically demanding occupation, CW demonstrate higher cardiometabolic risk, probably as a result of lifestyle and other factors outside the workplace.

Table1. Data are expressed as mean (SEM). P value <0.05 are significant

	CW	HS	p value
Age (years)	42.5 (0.46)	43.4 (0.33)	0.13
Weight(kg)	86.4 (0.55)	84.4 (0.49)	0.006
BMI (kg/m ²)	27.8 (0.16)	26.5 (0.13)	<0.0005
Waist (cm)	99.4 (0.50)	93.8 (0.4)	<0.0005
Waist:hip ratio	1.0 (0.01)	0.9 (0.003)	<0.0005
Systolic BP (mm/Hg)	135.1 (0.71)	123.2 (0.44)	<0.0005
Diastolic BP (mm/Hg)	82.5 (0.48)	77.1 (0.31)	<0.0005
Cholesterol (mmol/l)	5.12 (0.04)	5.24 (0.03)	0.04
LDL-C (mmol/l)	3.27 (0.04)	3.08 (0.03)	<0.0005
HDL-C (mmol/l)	1.23 (0.01)	1.24 (0.01)	0.8
Triglycerides (mmol/l)	1.36 (0.05)	1.34 (0.03)	0.67

Validity of Indian anthropometric reference limits versus standard definitions in determining the metabolic syndrome in young South Indians

S. Vasan¹, S. Christopher², N. Thomas¹, S.B. Carani³

¹Endocrinology, Diabetes & Metabolism, Christian Medical College, Vellore, India, ²Biostatistics, Christian Medical College, Vellore, India, ³Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden

Background and aims: The prevalence of the metabolic syndrome has never been studied using Asian Indian reference intervals in young Indians. The purpose of this study is to validate standard definitions for metabolic syndrome in young Indians using Indian reference limits and to determine the prevalence rates.

Materials and methods: This was a prospective cross sectional study which involved screening for Metabolic syndrome indices in young postpubertal adults (n=1378) between the age of 12 - 28 (Mean age 17.1 ± 2.4) years in a suburban Indian region with a population of 400,000. Informed consent was obtained from all participants. Anthropometric measurements included height, weight, waist circumference, Waist-Hip ratio (WHR), Skin fold thickness in the subscapular, triceps and abdominal regions. Blood was collected for fasting lipid profile and blood sugar was measured at fasting and 2 hours postprandial intervals. The prevalence was estimated by incorporating standard Asian reference limits for anthropometry (Waist circumference - 85 Men / 80 Women, Waist-Hip ratio -0.88 Men / 0.81 Women and BMI cut off > 23 kg/m²) in standard definitions for metabolic syndrome using World Health Organisation (WHO), Adult Treatment Panel III (ATPIII) and International Diabetes Federation (IDF) criteria.

Results: The overall prevalence of the Metabolic syndrome in this group of young Asian Indians was -112 (8.1%) [Men -74(7.3%), women -38 (10.4%)] as defined by any criteria using Asian reference limits for anthropometry, while, the prevalence rate is 5.3% using standard definitions. The prevalence rates were significantly higher with inclusion of modified reference limits of waist circumference and BMI in place of the existing reference limits of waist circumference in the NCEP ATPIII (5.7%), WHO (6.5%) or IDF(4.6%) criteria. Age-specific group analysis has shown higher prevalence among age groups 14 -17 years (50.8%) as compared to other groups 18-21 (43.5%) and 22-25 years (5.7%). There were significant gender differences in the mean values of several components of the metabolic syndrome like blood pressure ($p < 0.001$), HDL cholesterol ($p < 0.001$), Fasting glucose ($p < 0.001$) and triglycerides ($p = 0.002$). The 95th centile for Skin fold thickness at three regions correlated significantly with body mass index (Subscapular $\rho = 0.51$, Triceps $\rho = 0.39$ and Biceps $\rho = 0.45$). Impaired fasting glucose (IFG) was present in 27% of males and 40% of females and impaired glucose tolerance was seen in 3.2% of males and 2.7% of females. Dyslipidaemia was evidenced by elevated triglycerides (9.3% in males & 5.7% in females) and low HDL cholesterol (62.2% in males & 65.4% in females) in this post pubertal age group and was diagnosed based on the 95th percentile adjusted for age and sex.

Conclusion: Our data has shown a high prevalence of the metabolic syndrome among young South Indians which is a potential early onset risk factor for macrovascular disease. Skin fold thickness, low HDL cholesterol levels and impaired fasting glycaemia are the most important risk factors that seemed to occur in this age group.

Indian anthropometric reference limits in standard definitions improve the sensitivity of defining metabolic syndrome in such a setting, when describing an Indian population.

384

Resting energy expenditure in overweight-obese non diabetic patients with metabolic syndrome

G. Seghieri¹, R. Anichini¹, A. De Bellis¹, G. Fabbri¹, R. Malagoli¹, L. Alviggi¹, F. Franconi²

¹Internal Medicine, Spedali Riuniti, Pistoia, Italy, ²Pharmacology, University of Sassari, Italy

Background and aims: Increase in resting energy expenditure (REE) has been shown significantly associated with obesity, while insulin resistance has been found related with the decrease in REE. In addition diabetes and hypertension have been associated with higher REE levels, whereas conflicting results exist about REE in subjects with altered glucose metabolism or dyslipidemia. As a consequence of this, there are no clear-cut data about the relation, if any, between metabolic syndrome (MS) and REE.

Materials and methods: To study this aspect we evaluated 334 (118M/216F) non diabetic overweight-obese subjects ($\text{BMI} \geq 25 \text{ Kg/m}^2$), who consecutively attended the Obesity Outpatient Clinic of our hospital to obtain dietetic advice. In all patients, divided into two groups [those with MS (MS+, n=173) and those without it (MS-, n=161) according to ATP-III criteria], we measured body weight composition and REE by electrical bioimpedance, validated in a consistent sample by indirect calorimetry.

Results: Mean REE, expressed as kJ/d/Kg fat-free mass (FFM) \pm SD was similar in MS+ and in MS- patients (116.1 ± 21.4 vs 115.7 ± 21.8 kJ/d/Kg; $p = \text{NS}$). The relative MS risk adjusted for age, sex, fat mass, and waist girth, expressed as odds ratio (OR; 95%CI), was not significantly related with increase in each 1 REE SD [OR:1.167 (0.913-1.525)], while single MS components behaved differently. For impaired fasting glucose, as well as for dyslipidaemia the adjusted ORs were not significantly associated with REE, while, on the contrary, each increase in 1 REE SD (21.628 kJ/d/Kg FFM) augmented the risk of arterial hypertension of ~ the 50%: [OR:1.458; (1.100-1.995)]. Likewise, after adjusting for age, sex, waist circumference and fat mass, fasting plasma glucose was unrelated with REE, whereas mean blood pressure was significantly and independently related to REE ($p = 0.011$).

Conclusion: In conclusion in overweight-obese non diabetic patients MS is unrelated to changes in REE, while, examining any single MS component, rise in REE seems to be significantly related to blood pressure, and, at the same time, to be an independent predictor of arterial hypertension in these patients.

Prevalence, treatment and control of cardiometabolic risk factors in subjects with high waist circumference - 5A study

J.C.N. Chan¹, C.A. Aguilar-Salinas², A. Avezum³, E. Bruckert⁴, A. Misra⁵, I. Raz⁶, A.M. Sharma⁷, M.-T. Van der Merwe⁸

¹Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Shatin, Hong Kong, ²Department of Endocrinology and Metabolism, INCMNSZ, Mexico City, Mexico, ³Research Division, Dante Pazzanese Institute of Cardiology, Sao Paulo, Brazil, ⁴Departement d'Endocrinologie, Hopital Pitie Salpetriere, Paris, France, ⁵Department of Diabetes and Metabolism, Fortis Group of Hospital, New Delhi, India, ⁶Hadassah Diabetes Center, Hadassah University Hospital, Jerusalem, Israel, ⁷Obesity Research & Management, University of Alberta, Edmonton, Canada, ⁸Unitas Hospital, Pretoria, South Africa

Background and aims: In this pandemic of overweight and obesity, there is an urgent need to document the pattern of medical care in these high risk subjects although data in this regard is generally scarce especially in developing countries. The aim of the 5A Study is to assess the prevalence and control of cardiometabolic risk factors (CMRF) in a cohort of subjects with high waist circumference (WC) of 90 cm (35.5 inches) or more for males and 80 cm (31.5 inches) or more for females.

Materials and methods: Data on diagnosis and treatment of CMRF (dyslipidemia [DL], type 2 diabetes [T2D], hypertension [HT] and cardiovascular diseases [CVD]) were collected from 6291 adults in 8 countries by 3 physician specialties (17.3% GP, 52.7% cardiologist and 30.1% Diabetologist). For each CMRF, we assessed its prevalence (as diagnosed by physician and/or abnormal clinical/laboratory value), the percentage diagnosed by physician, the percentage of subjects treated, and the percentage of subjects reaching internationally recommended targets ($\text{HbA}_{1c} < 7\%$, $\text{BP} < 130/80$ mmHg, triglyceride (TG) < 1.7 mmol/L, $\text{LDL-C} < 2.6$ mmol/L, $\text{HDL-C} > 1$ mmol/L).

Results: We analyzed subjects with DL (high LDL-C and/or TG and/or low HDL-C; n=4162, 66.2%), T2D (n=1895, 30.1%), HT (n=4128, 65.6%) and CVD (n=1566, 24.9%). The management of each CMRF is shown in the table below.

Overall, in subjects with 1 CMRF (excluding CVD), 8.3% were at target; in those with 2 CMRF, 0.9% were at target for both parameters; and for subjects with 3 CMRF, 1.3% were at target for 3 parameters. In subjects with CVD: percentages of patients controlled with DL or T2D or HT were 42.8% (N=328), 32.8% (N=115) and 10.7% (N=58) respectively.

Conclusion: In subjects with high WC, there were high prevalences of CMRF clustering which were often not diagnosed, treated or controlled, even in the presence of clinical CVD.

5A study = Awareness of Abdominal Adiposity As A marker of cardiometabolic risk study

	Type 2 Diabetes	Dyslipidemia	Hypertension	CVD
Prevalence	30.1 % (N=1895/6291)	66.2 % (N=4162/6291)	65.6 % (N=4128/6291)	24.9% (N=1566/6291)
Diagnosed	31.0% (N=1895/6109*)	51.4% (N=3233/6291)	54.6% (N=3434/6291)	24.9% (N=1566/6288*)
Treated	92.8% (N=1755)	57.7% (N=2366)	80.5% (N=3322)	74.6% (N=1168)

Low-grade inflammation mediates the association between the metabolic syndrome and the ankle-arm index (The CODAM Study)

M. Jacobs^{1,2}, M.M.J. van Greevenbroek^{1,2}, C.J.H. van der Kallen^{1,2}, I. Ferreira^{2,3}, E.E. Blaak^{4,5}, E.J.M. Feskens⁶, C.G. Schalkwijk^{1,2}, C.D.A. Stehouwer^{1,2}

¹Cardiovascular Research Institute Maastricht (CARIM), Maastricht University, Netherlands, ²Department of Internal Medicine, University Hospital Maastricht, Netherlands, ³Department of Clinical Epidemiology and Medical Technology Assessment (KEMTA), University Hospital Maastricht, Netherlands, ⁴Department of Human Biology, Maastricht University, Netherlands, ⁵Nutrition and Toxicology Research Institute Maastricht (NUTRIM), Netherlands, ⁶Division of Human Nutrition, Wageningen University, Wageningen, Netherlands

Background: The Metabolic Syndrome (MetS) is associated with CHD and this association may be related to low-grade inflammation. The metabolic syndrome may also be related to peripheral arterial dysfunction although this relation has not been described extensively. Low-grade inflammation has been implicated in peripheral arterial dysfunction as well.

Aims: To determine associations between the metabolic syndrome and ankle-arm index (AAIx; an available and reproducible method for the detection of peripheral arterial dysfunction) and to address the role of low-grade inflammation therein.

Materials and methods: The study population consisted of 574 subjects (age: 59.6 ± 7.0 years, 61.3% men, 54.7% MetS; NCEP-ATP 2005 criteria) from the Cohort Study Diabetes and Atherosclerosis (CODAM) cohort, who were invited from a large population based cohort on basis of an elevated risk for type 2 diabetes and cardiovascular diseases. The AAIx was calculated by dividing the highest of the ankle pressures (a. dorsalis pedis or a. tibialis) in either leg by the highest pressure at the brachial artery. The following inflammatory markers were measured in fasting plasma: C-reactive protein (CRP), IL6, soluble vascular cell adhesion molecule, soluble intercellular adhesion molecule (sICAM) and serum amyloid A. For each inflammation marker the Z-score was calculated and an inflammation score was then calculated as the average of the Z-scores of the five inflammation markers listed above. Multiple linear regression analyses were used to determine associations between the metabolic syndrome and low-grade inflammation on the one hand, and the AAIx on the other.

Results: The metabolic syndrome was associated with the AAIx (Beta [β] = -0.02, 95%CI: -0.04; -0.002, $P = 0.03$). Adjustment for age, sex and smoking did not change this association. Inflammation markers that were associated with the AAIx were CRP ($\beta = -0.04$, 95%CI: -0.06; -0.01, $P = 0.002$), IL6 ($\beta = -0.05$, 95%CI: -0.08; -0.02, $P = 0.002$), and sICAM ($\beta = -0.10$, 95%CI: -0.17; -0.02, $P = 0.017$), all adjusted for age, sex and smoking. When both the metabolic syndrome and the inflammation score were included in the linear regression model, the metabolic syndrome was no longer associated with AAIx, but the association between inflammation and the AAIx remained ($\beta_{\text{MetS}} = -0.01$, 95%CI: -0.03; 0.01 $P = 0.19$; $\beta_{\text{inflammation}} = -0.02$, 95%CI: -0.04; -0.01 $P = 0.002$, adjusted for age, sex, smoking).

Conclusion: Subjects with the metabolic syndrome show greater levels of peripheral arterial dysfunction (as expressed by AAIx). Importantly, chronic low-grade inflammation mediated, in a great deal, that association, and was independently associated with AAIx.

The heritability of HbA_{1c} and fasting glucose is caused by different genetic factors

A.M.C. Simonis-Bik¹, E.M.W. Eekhoff¹, R.J. Heine¹, E.J.C. de Geus², M. Diamant¹, J.M. Dekker³, M. van Leeuwen², D.I. Boomsma²

¹Diabetes Centre, VU University Medical Centre, ²Biological Psychology, VU University, ³EMGO institute, VU University Medical Centre, Amsterdam, Netherlands

Background and aims: The proportion of glycated haemoglobin, HbA_{1c}, reflects the mean blood glucose level of the preceding 8-10 weeks. Although the relation between HbA_{1c} and complications, including nephropathy and retinopathy, is established, the genetic contribution to variation in HbA_{1c} has not been examined in detail. Specifically, it is unclear whether the genetic factors that influence the variability of HbA_{1c} are the same as those that influence fasting blood glucose.

Materials and methods: We included 77 families of the Netherlands Twin Register in an extended twin study of different aspects of beta-cell function. All participants were healthy, age 20-45 years, with siblings of the same sex. Fasting blood glucose was measured in three different settings: at home before an OGTT, and at 2 clinic visits (2-3 samples/visit). HbA_{1c} was measured in one of the clinic samples.

Results: The present analysis is based on 180 persons, consisting of 51 monozygotic pairs (21 male), 21 dizygotic pairs (8 male), 5 incomplete twin pairs (3 male) and 31 siblings (15 male). The mean age was 30.6 ± 4.6 years, mean fasting blood glucose at home 4.63 ± 0.46 mmol/l, and at the 2 clinic visits 4.37 ± 0.40 and 4.44 ± 0.35 mmol/l respectively. Men had a significant higher mean fasting blood glucose level than women: 4.63 vs 4.40 respectively, and a higher HbA_{1c} (men 5.30 ± 0.26 %, women 5.21 ± 0.22 %, $p < 0.001$). Raw data were used in a 4-variate structural equation model in the mx software package. This model incorporated sex and age differences and estimated heritability of each parameter as well as their genetic correlations. Additive genetic effects (heritability) explained 75 % of the population variance in HbA_{1c}, the remainder was attributable to unique environment. The heritability of fasting blood glucose was prominent in all settings (66% in the OGTT, and 57% and 40 % in the clinic visits samples respectively). There was a significant correlation between the fasting blood glucose levels in all three settings (r 0.34 - 0.55) which was mostly due to a common genetic factor influencing individual differences in glucose level in all three settings. The correlation between HbA_{1c} and fasting blood glucose was low (r 0.11 - 0.23) and the genetic factors influencing HbA_{1c} and fasting glucose were non-overlapping.

Conclusion: The present results suggest a high heritability of HbA_{1c} (75%) and a consistent substantial heritability for fasting glucose levels in various settings (40 - 63%) in healthy, normoglycaemic adults. Genetic factors influencing HbA_{1c} and fasting blood glucose levels were independent, suggesting that heritability of HbA_{1c} largely reflects genes responsible for variability in the glycation rate of haemoglobin, independent of glycaemia.

Can HbA_{1c} replace glucose as a diagnostic test for diabetes?

D. Vistisen, R. Borg, K. Borch-Johnsen
Steno Diabetes Center, Gentofte, Denmark

Background and aims: Diabetes is a condition defined by hyperglycaemia giving specific microvascular complications and increased risk of macrovascular complications. Since 1980 the WHO has defined diabetes on the basis of the oral glucose tolerance test (OGTT), but this test is time consuming, has low reproducibility, and is based on glucose-measurements sensitive to handling and transportation. Glycosylated haemoglobin (HbA_{1c}) can be measured non-fasting, is easily and reliably measured and relatively cheap. With the recent world-wide standardisation of HbA_{1c} measurements to the IFCC reference method a global standardisation is possible. This reopens the question whether HbA_{1c} can replace glucose as a diagnostic test for diabetes. The aim of this project was to evaluate the implications of using HbA_{1c} as a diagnostic test for Type 2 diabetes in a Danish population.

Materials and methods: This analysis is based on the population based Inter99 study (age range 30–60 years, N=6,258), excluding individuals with known diabetes or incomplete data on fasting (FPG), 2-hour plasma glucose (2hPG) or HbA1c (HCLC BioRad variant 1). Micro- and macroalbuminuria were defined as a urine albumin concentration ≥ 30 mg/l and > 300 mg/l respectively. According to the WHO 1999 classification, 259 (4.1%) had undiagnosed diabetes and 1,271 (20.3%) had impaired glucose metabolism (IGM). Consequently, we defined diabetes by HbA1c as the 259 individuals with the highest HbA1c levels and IGM by HbA1c as the next 1,271 individuals to retain unchanged prevalence of DM and IGM. The two definitions were compared based on the micro- and macrovascular risk profile. Furthermore, the 10 year risk of developing ischaemic heart disease (IHD) was compared using the PRECARD program. ROC analysis was used to assess the ability of FPG, 2hPG and HbA1c to distinguish between individuals in high- and low risk of developing IHD.

Results: Individuals defined by HbA1c were older, had male predominance, higher levels of smokers, total- and HDL cholesterol levels. Furthermore they were leaner and had lower BP levels. The prevalence of micro- or macroalbuminuria and retinopathy is higher.

Table1 Characteristics of individuals with diabetes defined by an OGTT and HbA1c

	DM		IGM	
	OGTT	HbA1c	OGTT	HbA1c
Macrovascular risk profile				
Age (years)	50.7 (6.9)	51.5 (6.2)	48.5 (7.4)	48.9 (7.3)
Males (%)	63.3 (57.1–69.2)	64.9 (58.7–70.7)	58.9 (56.2–61.7)	60.6 (57.8–63.3)
BMI (kg/m ²)	30.2 (5.8)	29.2 (5.5)	28.1 (4.9)	27.0 (5.0)
Waist (cm)	98.6 (14.2)	96.3 (14.9)	92.3 (13.2)	89.7 (13.3)
BP Diastolic (mmHg)	90.7 (11.7)	87.4 (12.5)	87.0 (11.6)	83.7 (11.1)
BP Systolic (mmHg)	146.5 (20.2)	139.7 (20.7)	137.7 (17.9)	132.3 (17.7)
Total Cholesterol (mmol/l)	5.5 (1.0)	5.6 (1.1)	5.4 (1.0)	5.4 (1.0)
HDL-cholesterol (mmol/l)	1.3 (0.4)	1.2 (0.4)	1.4 (0.4)	1.4 (0.4)
Triglycerides (mmol/l)	2.2 (1.6)	1.9 (1.3)	1.7 (2.1)	1.4 (1.0)
Antihypertensive treatment (%)	20.5 (15.7–25.9)	15.4 (11.3–20.4)	11.5 (9.8–13.4)	7.1 (5.7–8.5)
Smoking (%)	35.9 (30.1–42.1)	57.9 (51.6–64)	35.3 (32.7–38.0)	49.3 (46.5–52.0)
Family disposition to DM (%)	27.4 (22.1–33.3)	25.1 (19.9–30.8)	21.4 (19.2–23.8)	20.1 (18.0–22.5)
Microvascular risk profile				
Microalbuminuria (%)	8.5 (5.4–12.6)	9.7 (6.3–13.9)	3.9 (2.9–5.2)	3.2 (2.3–4.4)
Macroalbuminuria (%)	0.4 (0.0–2.1)	1.2 (0.2–3.3)	0.6 (0.3–1.2)	0.3 (0.1–0.8)
Retinopathy (%) ^a	2.4 (0.6–5.9)	3.1 (0.6–8.7)	2.5 (1.0–5.2)	2.7 (0.9–6.1)

Means (SD) and proportions (95%-CI). ^aRetinopathy assessed in a sub-sample of 970 individuals.

HbA1c distinguishes between individuals in high- and low risk of developing IHD over a 10 year period better than FPG and 2hPG.

Figure 1 ROC curves for identifying individuals at high risk for developing IHD

Conclusion: Individuals with diabetes defined by HbA1c have a worse microvascular risk profile compared with those identified by the glucose based on the WHO definition. The macrovascular risk profile is not as conclusive. HbA1c is better at distinguishing between individuals in high- and low risk of developing IHD over a 10 year period compared with FPG and 2hPG.

Reference values for deoxyfructosyl haemoglobin (beta) in healthy paediatric and adult population

A. Gerasimidi-Vaseou¹, C. Maragou¹, T. Bachou¹, D. Papadatos¹, L. Spanou², I. Drakopoulos², L. Stamoyannou¹, K. Makris²

¹A Department of Pediatrics, P&A Kyriakou Childrens Hospital, ²Clinical Biochemistry, KAT General Hospital, Athens, Greece

Background and aims: There are at least 30 different laboratory assays commercially available to measure the proportion of HbA1c in blood all producing different results. Harmonization of the HbA1c reported results from different laboratory assays until now was achieved through national initiatives like the National Glycohemoglobin Standardisation Program (NGSP). Based on the work of NGSP the current HbA1c assay has been harmonised on reference methods that measure a mixture of glycated haemoglobins. The International Federation of Clinical Chemistry (IFCC) has recently approved a reference measurement procedure for HbA1c that specifically measures the concentration of only one molecular species of HbA1c. A new name, deoxyfructosyl haemoglobin (beta) (DOFH), and measurement units, mmol/mol, were proposed to replace HbA1c and %. DOFH represents the fraction of the b-chains of hemoglobin that has a stable hexose adduct on the N-terminal amino acid valine. This study examines the impact of these changes on laboratory result reporting and clinical practise by trying to establish reference ranges for deoxyfructosyl haemoglobin (beta) for pediatric and adult population and compare it to the traditional HbA1c measurement.

Materials and methods: Blood samples were collected from 106 healthy non-diabetic children (59 boys, 47 girls) and 264 adults (112 men, 151 women). DOFH was measured in addition to HbA1c using an HPLC (HA8160 Menarini-Arkray) which is calibrated and traceable to the IFCC reference method. Our population was divided in 11 age groups: infants (<2years), pre-school age children (2–6years), school age children (6–11years), adolescents (11–16) and 7 adult groups. All adults had normal glucose tolerance in a standard 0–2hrs OGTT.

Results: In the paediatric population (table) DOFH values were not significantly different among the five age groups and between boys and girls (30.4 vs 32.79 mmol/mol). In the adult population (table) the differences observed in the mean DOFH were statistically significant. Mean DOFH seems to increase with age. There was a positive correlation between age and DOFH in the adult population ($r=0.351$, $p<0.0001$). No differences were observed between men and women (35.1 vs 34.4 mmol/mol).

Conclusion: A single reference range can be used for the entire pediatric population (25.7 – 39.7 mmol/mol). Age related reference values should be used in the adult population

age group (years)	n	mean age	DOFH (mmol/mol) –mean(SD)	2.5percentile	97.5percentile	HbA1c(%) – mean(SD)	2.5percentile	97.5percentile
<2	25	1.0	33.9(2.9)	30.1	39.7	5.3(0.3)	4.9	5.8
2–5	23	3.4	32.2(2.4)	28.0	36.6	5.1(0.2)	4.7	5.5

Diagnostic value of HbA_{1c} in different clinical settings with different prevalence of diabetes mellitus

Y. Ku, Y. Cho, S. Yoo, H. Jung, S. Choi, S. Lim, M. Moon, H. Jang, C. Shin, K. Park, S. Kim, H. Lee
Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea

Background and aims: In general, HbA_{1c} is currently not recommended as a diagnostic test for diabetes. However, its utility as a screening tool of diabetes has recently been revisited. In the 1999–2004 National Health and Nutrition Examination Survey (the prevalence of previously undiagnosed diabetes was 3.4%), an HbA_{1c} level of 5.8% showed the highest combination of sensitivity (86%) and specificity (92%). Since the diagnostic value of a particular test varies depending on the prevalence of the disease of interest, we addressed this issue in two different clinical settings with different prevalence of previously undiagnosed diabetes in Korea.

Materials and methods: We analyzed data from 17,739 subjects for routine health check-ups (9,836 men and 7,903 women, 49.4 ± 11.2 yrs), who had not been diagnosed with diabetes, at Kangnam Healthcare Center (KHC); and 456 subjects (184 men and 267 women, 52.7 ± 9.5 yrs), who had not been diagnosed with diabetes but were concerned with diabetes due to various reasons, from Diabetes Clinic of Seoul National University Hospital (SNUH). HbA_{1c} was measured by HPLC (Bio-Rad VARIANT™ II TURBO, CA, USA). Diabetes was diagnosed by fasting plasma glucose in KHC cohort and by oral glucose tolerance test in SNUH cohort.

Results: The receiver operating characteristics curve analysis showed that an HbA_{1c} level of 5.9% was the best for the diagnosis of diabetes in KHC cohort while an HbA_{1c} level of 6.1% for SNUH cohort. The HbA_{1c} level of 5.9% had a sensitivity of 84.6% and a specificity of 86.3% in KHC cohort, whereas the HbA_{1c} level of 6.1% had a sensitivity of 87.2% and a specificity of 82.2% in SNUH cohort. Of interest, there was a marked difference in positive and negative predictive values (PV). In KHC cohort (the prevalence of previously undiagnosed diabetes was 2.8%), the HbA_{1c} level of 5.9% had a very low positive PV (14.9%) but had a very high negative PV (99.5%). Therefore, in routine health check-up condition, an HbA_{1c} level below 5.9% could rule out diabetes. However, an HbA_{1c} level ≥ 5.9% should be re-evaluated with other methods. In SNUH cohort (the prevalence of previously undiagnosed diabetes was 25.9%), the HbA_{1c} level of 6.1% had a moderate positive PV (63.1%) but had a high negative PV (94.8%). Therefore, in the Diabetes Clinic setting, an HbA_{1c} < 6.1% could also rule out diabetes. However, an HbA_{1c} level ≥ 6.1% needs to be re-evaluated with other methods, although it might be useful for the diagnosis of diabetes in part.

Diagnostic value of HbA_{1c} (Data are shown as percent (95% CI))

	Healthcare center	Diabetes clinic	Diabetes clinic
A1c cutoff	5.9	5.9	6.1
Sensitivity	84.6 (81.2–87.7)	92.3 (86.0–96.4)	96.5 (93.5–98.4)
Specificity	86.3 (85.8–86.8)	74.2 (69.2–78.8)	82.2 (77.8–86.1)
Positive predictive value	86.3 (85.8–86.8)	55.6 (48.3–62.7)	63.1 (55.3–70.6)
Negative predictive value	99.5 (99.3–99.6)	96.5 (93.5–98.4)	94.8 (91.6–97.1)

Conclusion: HbA_{1c} could be used as a screening tool for the diagnosis of diabetes. However, caution should be exercised in its interpretation according to the prevalence of diabetes in the population of interest.

Limited agreement between HbA_{1c} and glucose levels in the general Dutch population: The New Hoorn Study

E. van 't Riet, J.M. Rijkkelijkhuizen, G. Nijpels, J.M. Dekker
EMGO Institute, VU University Medical Center Amsterdam, Netherlands

Background and aims: Recent research suggests HbA_{1c} can be used to estimate average blood glucose levels in subjects with type 2 diabetes. It may be questioned whether HbA_{1c} could be a good indicator of mean blood glu-

cose in people without diabetes. To our knowledge, information on the correlations between HbA_{1c} and glucose in the general population, including subjects without diabetes, is lacking. Therefore, we investigated the correlations of HbA_{1c}, fasting plasma glucose (FPG) and 2 hour postload plasma glucose (2hrPG) in subjects with normal glucose tolerance (NGT), impaired hyperglycaemia (IH), known diabetes (KDM2) and screen-detected diabetes (NDM2) to investigate whether harmonisation of these markers of hyperglycaemia can be applied in different categories of glucose status.

Materials and methods: For the analysis we used data of 2748 subjects 40–65 years old, randomly selected from the population register of Hoorn, The Netherlands, who underwent an OGTT in 2006/2007 (The New Hoorn Study). To define glucose status we used the WHO '06 criteria. Spearman correlations were used to investigate the correlations between markers of hyperglycaemia. To investigate whether HbA_{1c} could be used to identify people with diabetes, we excluded subjects with known diabetes (n=90) and calculated ROC curves for HbA_{1c} as a predictor of fasting glucose ≥ 7.0 and/or postload glucose ≥ 11.1.

Results: In subjects with NGT, IH and newly detected DM2, the correlations between HbA_{1c} and FPG were higher than between HbA_{1c} and 2hrPG, but all correlations were rather low (table 1). In subjects with KDM2, the correlations were higher and reached levels between 0.74 and 0.92. The optimal cut-off point for identifying diabetes with HbA_{1c}, was a HbA_{1c} level of 5.65, with a sensitivity and specificity of 78.5% and 83.5% respectively. Table 1 shows that using this HbA_{1c} cut-off point for the diagnosis of diabetes compared to using the WHO '06 criteria would lead to inclusion of 20% of the non-diabetic and non-IH subjects and to not identifying 22% of the cases with diabetic glucose levels.

Conclusion: In subjects with known diabetes correlations are high, which supports the ongoing research into the use of HbA_{1c} to estimate mean glucose in subjects with known diabetes. Using HbA_{1c} as an indicator of mean glucose in subjects with NGT, IH or screen-detected diabetes should be considered with caution based on the low correlations. In addition, using HbA_{1c} levels to identify diabetes in the general population without known diabetes at present is not recommendable. First question to address would be whether a HbA_{1c} of ≥ 5.65 predicts future diabetes complications in subjects with normal glucose levels.

Table 1. Spearman correlations between markers of hyperglycaemia and numbers of subjects with NGT, IH and DM2 with HbA_{1c} levels below or above 5.65

Correlations	Total	NGT	IH	KDM2	NDM2
N(%)	2748(100)	2114(77)	435(16)	90(3)	109(4)

Treatment approach and HbA_{1c} control among U.S. adults with type 2 diabetes

A. Hedley-Dodd¹, K. Boye², M. Colby³, C. Fahlman³, S. Kim⁴, R. Briefel⁵

¹Health Research, Mathematica Policy Research, Washington, ²Global Health Outcomes, Eli Lilly and Company, Indianapolis, ³Health Research, Mathematica Policy Research, Inc., Washington, ⁴Stempel School of Public Health, Florida International University, Miami, United States

Background and aims: Long-term blood glucose control can substantially reduce the risk of complications from diabetes. Concurrent with the development of new diabetic therapies, glucose control in the U.S. has gradually improved in recent years, but it remains suboptimal. By supplementing the self-reported treatment approach with prescription medication data, we will show the changing pattern of diabetic therapies and the association between population level glucose control and treatment approach.

Materials and methods: Interview and prescription medication data from the National Health and Nutrition Examination Survey (NHANES) 1999–2000,

2001–2002, and 2003–2004 were used to determine the treatment approach for adults with type 2 diabetes in the U.S. Individuals diagnosed before age 30 who reported insulin-only therapy were classified as having type 1 diabetes and excluded; all other adults with the diagnosis of diabetes were assumed to have type 2 diabetes. Oral agents were classified by primary generic ingredient (sulfonylurea, metformin, thiazolidinedione (TZD)). We calculated the proportion of adults with type 2 diabetes utilizing each major therapeutic and oral agent approach in 1999–2004. Within each treatment category, we computed the mean level of blood glucose (HbA_{1c}) and proportion of adults whose HbA_{1c} levels met recommended guidelines for control. Differences between groups were tested at the 0.05 significance level, with an adjustment for multiple comparisons.

Results: In 1999–2004, approximately 60% of adults with type 2 diabetes used only oral agents to manage their diabetes. As the distribution of oral treatment therapies changed over time, with the most prevalent treatment shifting from sulfonylurea monotherapy in 1999–2000 (23.0%) to any oral agent regimen containing TZD in 2003–2004 (21.4%), the mean HbA_{1c} level decreased from 7.8 to 7.2. Only 38% of adults with type 2 diabetes met the International Diabetes Federation (IDF) goal for HbA_{1c} control (HbA_{1c} less than or equal to 6.5%) in 1999–2004. The proportion meeting the IDF goal differed across treatment therapies, ranging from 10.6% of those who used both insulin and oral agents to 70.0% of those who used no diabetic agents. Nearly 37% of the group using oral agents only met the IDF goal. Across the oral agent treatment categories, the proportion with HbA_{1c} controlled at the 7.0% level was significantly lower for those on a therapy consisting of TZD, sulfonylurea, and metformin (31.9%) than those on metformin alone (62.2%), likely reflecting a progressive treatment approach of prescribing additional medications for those whose HbA_{1c} level is not controlled. Analyses of HbA_{1c} control by sex, race/ethnicity, obesity status, and length of diagnoses revealed no clear patterns of differences by treatment therapy.

Conclusion: Oral treatment regimens for adults with type 2 diabetes continue to change over time, with more adults using multiple oral agent therapies in an effort to improve HbA_{1c} control. However, more than 60% of adults with type 2 diabetes have an HbA_{1c} level that remains above the IDF guideline, an indication that currently available treatments could be used more optimally and new agents to improve HbA_{1c} control may be needed.

Association of FTO gene with morbid obesity and relation with insulin resistance in a women population from Southern France

R. Attaoua¹, S. Ait El Mkaem¹, S. Kaouache¹, J.-F. Brun², J.-C. Gris³, E. Renard⁴, F. Grigorescu¹;

¹Molecular Endocrinology Laboratory (EA 4188), University of Montpellier 1 (IURC), France, ²Centre d'Exploration et de Réadaptation des Anomalies du Métabolisme Musculaire (CERAMM), Lapeyronie Hospital, Montpellier, France, ³Haematology Laboratory, Doumergue University Hospital, Nîmes, France, ⁴Department of Endocrinology, Lapeyronie Hospital, Montpellier, France

Background and aims: FTO (*fat mass and obesity associated*) gene (Chr 16q12.2) was recently discovered by genome wide scanning as being associated with type 2 diabetes through the effect of body mass index (BMI). Association was replicated in many populations. This study was aimed to explore FTO gene association to obesity in women from Southern France in relation to *in vivo* insulin sensitivity.

Materials and methods: Case-control study was performed in women with class II (simple) obesity ($n = 128$), class III (morbid) obesity ($n = 65$) and lean control women ($n = 42$). Insulin sensitivity was measured by HOMA-IR and Minimal Model (IVGTT). FTO gene was genotyped through SNP rs1421085 (T/C) by sequence specific oligonucleotide (SSO)-PCR and confirmed by sequencing.

Results: Allelic frequencies (q) of rs1421085 were 0.41, 0.50 and 0.61 for controls, simple and morbid obesity, respectively ($P < 0.02$). Prevalence of homozygous C/C were 23.1 and 40.5% in simple and morbid obesity compared to only 18.7% in controls ($P < 0.01$). A gene dosage effect was revealed on BMI (29.0 ± 1.0 , 31.0 ± 0.8 and 33.7 ± 1.5 kg/m²) between T/T, T/C and C/C carriers ($P < 0.01$). The best association of C/C was found between controls and morbid obesity with $P < 0.02$, OR 4.2, 95%CI [1.6–11.0], but it remained non-significant for simple obesity. No correlation was found between C/C genotypes and impaired glucose tolerance (IGT) or impaired fasting glucose (IFG). By contrast, FTO genotypes were well correlated with insulin resistance (mean HOMA-IR was 1.7 ± 0.1 , 2.0 ± 0.1 , 2.6 ± 0.3 in T/T, T/C and C/C genotypes, respectively, $P < 0.0035$). In logistic regression, C/C was associated with insulin resistant patients (HOMA-IR > 2.49) with $P < 0.0023$, OR 4.16, 95%CI [1.66–10.43]. In ANOVA, HOMA-IR index was well explained by C/C genotype with $P < 0.0035$, interaction factor $\alpha = 0.9$, values which were abolished after adjustment for BMI. Although C/C carriers with morbid obesity had lower sensitivity index (Si) than lean women (3.0 ± 0.5 versus 7.8 ± 2.6 , respectively) with a parallel increased of AIRg (28.2 ± 19.8 versus 12.2 ± 3.5), no gene dosage effect was detected on IVGTT parameters. Analysis of other features composing the metabolic syndrome indicated good correlation between C/C genotype and the triglycerides levels ($P < 0.04$).

Conclusion: These data confirmed in morbidly obese women from Southern France population the previous relationship between FTO gene and BMI and indicate that relation between FTO genotypes and insulin resistance is more subtle and indistinguishable from the effect of BMI. In the context of our recent results on this gene in obese and infertile women, these data suggest that FTO may provide useful genetic markers for assessing the effect of obesity in metabolic complications.

Polymorphisms in the adiponectin encoding gene and susceptibility to type 2 diabetes in the Polish population

M. Szopa¹, M. Malecki¹, P. Wolkow², J. Skupien¹, A. Dembinska-Kiec³, J. Sieradzki¹

¹Department of Metabolic Diseases, ²Department of Pharmacology, ³Department of Clinical Biochemistry, Jagiellonian University Medical College, Krakow, Poland

Background and aims: Recently, several association studies of type 2 diabetes mellitus (T2DM) and adiponectin gene polymorphisms have been reported with conflicting results. Our aim was to search for associations between three polymorphisms (-11.391G>A, +45T>G, +276G>T) of adiponectin gene with T2DM and related quantitative traits in Polish Caucasians.

Materials and methods: The study groups comprised of unrelated 495 T2DM cases and 435 controls. We compared the distribution of alleles, genotypes and haplotypes between study groups. Genotype-quantitative trait analysis in the controls included BMI as well as glucose and insulin data from the oral glucose tolerance test (OGTT). All the study subjects were genotyped for three adiponectin gene polymorphisms using the restriction fragment length polymorphism (RFLP) technique.

Results: Frequencies of minor alleles were as follows: 15.5% in T2DM vs. 19.8% in controls ($p=0.0145$) for +276G>T; 10.6% vs. 8.2% for -11.391G>A ($p=0.0722$) and 7.0% vs. 8.0% for +45T>G ($p=0.48$), respectively. The difference of genotype distribution between the T2DM group and the control group was statistically significant ($p=0.0247$) for the 276G>T variant: 71.31% vs. 62.99%, 26.46% vs. 34.48% and 2.22% vs. 2.53%, respectively for the GG, GT and TT. Alleles of +45T>G and +276G>T were in linkage disequilibrium ($D' = 0.81$, $r^2 = 0.011$) and they formed two frequent haplotypes: T-G and T-T. Their frequencies were as follow: 77.7% in T2DM vs. 72.5% in controls for T-G ($p=0.055$); and 15.1% vs. 20.1% for T-T ($p=0.0024$), respectively. However, logistic regression analysis revealed that the effect of the T-T diplotype could be explained entirely by the SNP +276G>T. In quantitative traits analysis, the T allele of +276G>T was significantly associated ($p<0.05$) with lower insulin resistance (HOMA-IR, fasting insulin) among non-diabetic subjects. In addition, the A allele at position -11.391 was significantly associated ($p<0.05$) with higher insulin resistance (HOMA-IR, fasting insulin). In multiple regression analysis all identified associations remained significant after gender, BMI and age were included in the multiple regression model. In addition, in this model -11.391G>A and +276G>T were independently associated with T2DM.

Conclusion: We conclude that adiponectin gene polymorphisms are associated with T2DM and diabetes related phenotypes in Caucasians of Polish origin.

Common genetic variation in the retinoic acid receptor alpha gene is associated with body fat content in subjects at increased risk for type 2 diabetes

K. Müssig¹, H. Staiger¹, F. Machicao¹, C. Thamer¹, J. Machann², F. Schick², C.D. Claussen², N. Stefan¹, A. Fritsche¹, H.-U. Häring¹

¹Division of Endocrinology, Diabetology, Angiology, Nephrology, and Clinical Chemistry, Germany, ²Section on Experimental Radiology, University Hospital of Tübingen, Germany

Background and aims: Modulating effects of retinoic acid on adipocyte differentiation are mediated by the nuclear transcription factor retinoic acid receptor-alpha (RAR-alpha). We studied whether genetic variation within the RARA gene encoding RAR-alpha contributes to the development of obesity and obesity-related traits, such as insulin resistance and beta-cell dysfunction.

Materials and methods: We genotyped 943 subjects with an increased risk for type 2 diabetes for the four single nucleotide polymorphisms (SNPs) rs2715554, rs2715553, rs9303286, and rs482284 and performed correlational analyses with anthropometric data and parameters of insulin sensitivity and beta-cell function. For metabolic characterization, all subjects underwent an oral glucose tolerance test (OGTT), a subset additionally a hyperinsulinemic-euglycemic clamp. In a subgroup of 314 subjects, whole body fat distribution was assessed by nuclear magnetic resonance imaging. In 312 subjects, metabolic traits and anthropometric data were reevaluated after a 9-months lifestyle intervention.

Results: The four chosen SNPs cover 100% of common genetic variation (minor allele frequency > 0.10) within the RARA gene ($r^2 > 0.8$). We found significant associations of the SNP rs9303286 with whole body adiposity, with carriers of the minor allele displaying lower values for body mass index (BMI), waist circumference, and body fat content ($p=0.0151$, $p=0.0041$, and $p=0.0002$, respectively). Moreover, the minor allele of SNP rs2715554 was significantly associated with a better improvement of BMI, waist circumference, and body fat content after a 9-months lifestyle intervention ($p=0.0476$, $p=0.0009$, and $p=0.0073$, respectively).

Conclusion: We conclude that common genetic variation within the RARA gene might affect regulation of adipose tissue mass.

³Harvard Medical School, Joslin Diabetes Center, Boston, United States,

⁴Medical Department, St. Elisabeth Hospital of Leipzig, Germany

Background and aims: Family of bone morphogenetic proteins (BMP) is involved in regulation of adipogenesis. We measured the mRNA expression of BMP members in paired samples of visceral and subcutaneous adipose tissue from 198 subjects and examined its relation to obesity. Amongst others, mRNA expression of the human bone morphogenetic protein receptor 1A (BMPRIA) was significantly increased in both visceral and subcutaneous adipose tissue of 51 overweight (BMI > 25 and < 30 kg/m²) and 91 obese (BMI > 30 kg/m²) subjects compared with 56 lean subjects (BMI < 25 kg/m²) ($P < 0.05$ and $P < 0.001$, respectively). We therefore investigated whether genetic variants within the BMPRIA are associated with mRNA expression in fat and whether these variants affect the pathophysiology of human obesity and type 2 diabetes (T2D).

Materials and methods: We sequenced the BMPRIA (13 exons, exon-intron boundaries, 5' and 3' UTRs) in DNA samples from 48 non-related Caucasian subjects to identify genetic variants. Twenty representative variants including HapMap tagging SNPs (single nucleotide polymorphisms) (www.hapmap.org) were initially genotyped for subsequent association studies in German Caucasian (N=1808) with detailed metabolic testing. For replication analyses we used an isolated population of Sorbs from Germany (N=933).

Results: In a case control study including 461 lean (BMI < 25 kg/m²) and 678 obese (BMI > 30 kg/m²) subjects, four SNPs (rs7095025, rs7922846, rs11202222 and rs10788528) were significantly associated with obesity (all $P < 0.05$, adjusted for age and sex). Consistent with this, we found significant associations between BMPRIA SNPs and obesity/diabetes related quantitative traits (body mass index (BMI), circulating serum leptin, fasting plasma glucose, 2-h plasma glucose in oral glucose tolerance test; all $P < 0.05$, adjusted for age, sex and BMI) in 896 subjects without T2D. Finally, the rs17426348 was moderately associated with T2D in a case-control study including 912 cases with T2D and 718 healthy controls with normal glucose tolerance (adjusted $P=0.05$). For 3 SNPs (rs7095025, rs11202222 and rs10788528), the association with measures of obesity and related traits could be replicated in the independent cohort of Sorbs (all adjusted $P < 0.005$). In addition, in a subgroup of German Caucasian subjects with measured BMPRIA mRNA expression in fat, several variants were associated with the visceral gene expression levels (all adjusted $P < 0.05$).

Conclusion: Our data suggest that genetic variation in the BMPRIA may play a role in the pathophysiology of human obesity and T2D, possibly mediated through effects on mRNA expression.

Fasting and 2-hour plasma glucose levels are affected by food patterns. Longitudinal data from the Inter99 Study

C. Lau¹, U. Toft², I. Tetens³, B. Carstensen¹, T. Jørgensen², O. Pedersen^{1,4}, K. Borch-Johnsen^{1,4}

¹Steno Diabetes Center, Gentofte, Denmark, ²Research Centre for

Prevention and Health, Glostrup, Denmark, ³Technical University of

Denmark, National Food Institute, Søborg, Denmark, ⁴Faculty of Health Sciences, University of Aarhus, Denmark

Background and aims: The effect of food patterns on long term changes in continuous plasma glucose levels needs to be determined. An advantage using food patterns is the potential to detect the combined effect of foods, especially if the individual components of a pattern contribute to only a small amount of risk. We therefore examined whether food patterns previously identified at baseline in the Inter99 study were predictive of changes in plasma glucose and whether the association differed between individuals with different glucose tolerance status.

Materials and methods: At baseline 5,824 men and women (30–60y) without diabetes were included and followed up after 1, 3 and 5 years. A traditional food pattern (primarily characterised by high-fat meat, mayonnaise salads, potatoes, butter and lard) and a modern food pattern (primarily characterised by vegetables, fruit, vegetable oil/vinegar dressing, poultry, pasta, rice and cereals) have previously been identified at baseline. A score for each of the two patterns was estimated for each person. Fasting plasma glucose (FPG) and post-challenge 2-hour plasma glucose (2h-PG) were used as continuous outcomes. Individuals were classified into normal-glucose-tolerance (NGT), isolated impaired-fasting-glycemia (i-IFG), isolated impaired-glucose-tolerance (i-IGT) and a combined group of IFG and IGT (IFG/IGT) at baseline. The effect of the baseline food patterns on changes in plasma glucose during follow-up was examined with and without taking account of glucose tolerance status using random effect models adjusting for relevant confounders.

Results: Considering the modern pattern a higher score predicted a significant annual fall in 2h-PG between 0.010–0.017 mmol/l ($p < 0.05$), but no significant change was observed for FPG. The traditional pattern did not predict general changes for FPG or 2h-PG values. However, clear interactions between groups of glucose tolerance status for the modern pattern and FPG and for the traditional pattern and both FPG and 2h-PG were observed (p -interaction < 0.05).

Conclusion: All significant effects observed for a higher modern score indicated that the modern pattern had a protective effect on changes in plasma glucose, whereas all significant effects observed for a higher traditional score indicated a detrimental effect for changes in plasma glucose. The food patterns may be more likely to affect plasma glucose levels in individuals with i-IFG, i-IGT or IFG/IGT than individuals with NGT. We suggest that the risk of worsening the plasma glucose levels may be reduced by shifting from a traditional food pattern, consisting of especially fatty meats, potatoes and butter, to a modern food pattern primarily characterised by vegetables, fruit, oil and poultry.

Body weight change between pregnancies is associated with the risk of gestational diabetes (GDM)

A. Ferrara, S.F. Ehrlich, M.M. Hedderston, T.Y. Peng

Division of Research, Kaiser Permanente Northern California, Oakland, United States

Background and aims: The prevalence of both GDM and obesity have increased in women of reproductive age during the last decade. Obesity and being overweight are among the major risk factors for GDM. However, it is unclear whether the risk of GDM varies by weight gain or loss before pregnancy. We examined the associations between change in body weight from the first to the second pregnancies and the risk of GDM during the second pregnancy in a multiethnic population of 25,880 women who had their first two consecutive births between 1996 and 2005 at Kaiser Permanente of Northern California (USA).

Materials and methods: Electronic medical records were used to obtain data on age, race/ethnicity, body weight measured during the first trimester, gestational age at body weight measurements and GDM. GDM was defined according to the American Diabetes Association plasma glucose thresholds obtained from a 100-g OGTT.

Results: Mean age at the first pregnancy was 26.4 \pm 4.8 years, and the race/ethnicity distribution was as follows: 46% Caucasians, 5% AA, 18% Asian, 22% Hispanic and 9% other. On average, the interval between the first and second pregnancy was 34 months and women gained 3.7 kg between the first and second pregnancy. 5.1% women had GDM at the first pregnancy, 5.6% had GDM at the second pregnancy and 1.9% had GDM at both pregnancies. The risk of GDM increased linearly with weight change between pregnancies,

after adjustment for age, body weight and GDM at the first pregnancy, race/ethnicity, gestational age at weight measurements and time between pregnancies. Compared with women whose weight remained stable (± 3.0 kg), the adjusted odds ratios for GDM at the second pregnancy for those who gained 3.1 to 5.9 kg and for those who gained 6.0 kg or more were: 1.67 (1.44–1.95) and 2.45 (2.11–2.84), respectively. The adjusted odds ratios for GDM for those who lost 3.1 to 5.9 kg and those who lost 6.0 kg or more were: 0.63 (0.46–0.87) and 0.42 (0.25–0.68), respectively. In the same model, the odds ratio for GDM at the second pregnancy for those who had GDM at the first pregnancy was 13.84 (12.04–15.90). When women were grouped according to their GDM status at the first and second pregnancy, on average those who had GDM at the first but not at the second pregnancy gained the least amount of weight, while women who did not have GDM at the first pregnancy and developed GDM at the second pregnancy gained the greatest amount of weight between pregnancies (Figure). Similar results were obtained when women were stratified by race/ethnicity.

Conclusion: Our results provide epidemiological evidence for implementing postpartum weight loss programs in women with GDM and to prevent postpartum weight gain in women without a history GDM.

399

Only regional adiposity, but not general adiposity, is associated with type 2 diabetes in Korea

S.-W. Park¹, D.-J. Kim², Y.-K. Lee¹, S.-K. Kim¹, Y.-L. Kim¹, W.-K. Park¹, Y.-K. Choi¹, S.-J. Lee¹, Y.-W. Cho¹

¹Department of Medicine, Pochon CHA University, Sungnam, ²Department of Medicine, Ajou University School of Medicine, Suwon, Republic of Korea

Background and aims: Although general adiposity, usually assessed by BMI, is a strong risk factor for type 2 diabetes (T2DM), some studies have suggested that the pattern of body fat distribution might be more important predictor of T2DM. The purpose of the study was to investigate the associations between different measures of adiposity (BMI, waist circumference) and T2DM in ethnically non-obese population. We hypothesized that regional adiposity measured by waist circumference (WC) is a key factor associated with T2DM in Korea, where majority of subjects with T2DM is non-obese even though obesity is defined by BMI ≥ 25 kg/m².

Materials and methods: We conducted a cross-sectional analysis of a nationally representative sample of 5,294 adults aged ≥ 20 years, from the Third Korean National Health and Nutrition Examination Survey (KNHANES) performed in 2005. All subjects were examined and fasting plasma glucose

The odds ratio of type 2 diabetes in Koreans, stratified by BMI and waist circumference (WC).

	All	(n, 5294)	Men	(n, 2244)	Women	(n, 3050)
	OR	(95% CI)	OR	(95% CI)	OR	(95% CI)
Normal BMI, Normal WC	1	Reference	1	Reference	1	Reference
Normal BMI, High WC	2.64	1.81–3.85	2.29	1.31–3.99	2.89	1.71–4.88
High BMI, Normal WC	1.33	0.93–1.92	1.50	0.94–2.39	1.11	0.62–1.99
High BMI, High WC	2.16	1.71–2.73	2.14	1.54–3.00	2.18	1.55–3.06

(FPG) was measured. General obesity was defined by BMI ≥ 25 kg/m² and central obesity was defined by the ethnicity specific cutoff for Koreans (WC ≥ 90 cm in men and ≥ 85 cm in women). Diabetes mellitus was defined by previous diagnosis of diabetes or use of anti-diabetic medications or FPG ≥ 7.0 mmol/l. Multiple logistic regression analyses were used to identify independent factors associated with T2DM.

Results: Among various clinical parameters, age, male sex, BMI, waist circumference, family history of diabetes, and smoking status were associated with T2DM in bivariate analyses. In multiple logistic regression models, WC but not BMI was associated with diabetes controlling for age, sex, family history and smoking status. When the subjects were divided into four groups by the presence of general obesity and/or central obesity, the odds ratio of T2DM was the highest in subjects with normal BMI and high WC in both men and women. But the risk of T2DM was not increased in subjects with high BMI and normal WC (Table). The results were similar even if the outcome was restricted to newly diagnosed diabetes excluding those with known and/or treated cases.

Conclusion: In conclusion, only regional adiposity assessed by waist circumference, but not general adiposity measured by BMI, is independently associated with type 2 diabetes in Korea.

400

Associations between abdominal fat distribution and glucose intolerance and fasting insulin. The Inuit Health in Transition Study

M.E. Jørgensen¹, K. Borch-Johnsen¹, P. Bjerregaard²

¹Steno Diabetes Centre, Gentofte, Denmark, ²Centre for Health Research in Greenland, National Institute of Public Health, University of Southern Denmark, Copenhagen, Denmark

Background and aims: Inuit populations have lower mean values of various metabolic risk factors for a given level of obesity compared to western populations. The Inuit are suggested to be protected from a high amount of subcutaneous adipose tissue (SAT) which is less metabolically active than visceral adipose tissue (VAT). We aimed to study associations between ultrasound measurements of intraabdominal fat and glucose tolerance status and fasting insulin.

Materials and methods: Data were collected from 2005 to 2007 among adult Inuit on the west coast of Greenland. Diabetes, IGT and IFG were diagnosed using the OGTT. Glucose and insulin were measured. VAT and SAT were measured by ultrasound.

Results: A total of 1633 Inuit participated. The median age of the sample was 44 years (range 18–89), and 57% were women. The prevalence of IFG, IGT, and diabetes was 10%, 7%, and 7.6%. Mean values of abdominal fat according to glucose tolerance group are shown in the table. While SAT and VAT increased with glucose intolerance, the ratio between SAT and VAT decreased. Both SAT and VAT were positively associated with fasting insulin. SAT and VAT were highly correlated; therefore each of the two variables were modelled as a linear spline with three knots in a mixed model with fasting insulin as dependent variable. For a given level of VAT, an increase in SAT was associated with a decrease in fasting insulin.

Conclusion: The data indicate for a given level of VAT an inverse association between SAT and glucose intolerance and fasting insulin, respectively.

Association between glucose tolerance status and ultrasound measurements of fat distribution

Increased prevalence of retinopathy in patients of South Asian ethnicity persists, even after adjustment for potentially confounding risk factors

K. Bush^{1,2}, L. Varadhan¹, N.T. Raymond¹, D. Reynold¹, S. Sankaran¹, S. Bellary³, A.H. Barnett³, S. Kumar⁴, J.P. O'Hare¹

¹Health Sciences Research Institute, The University of Warwick, Coventry,

²Ophthalmology, Southampton General Hospital, Southampton, ³Diabetes and Endocrinology, Birmingham Heartlands Hospital, Birmingham,

⁴Clinical Sciences Research Institute, The University of Warwick, Coventry, United Kingdom

Background and aims: Diabetes is four times more common in Asians but the prevalence of microvascular complications is disputed. The aim of this study was to estimate and compare retinopathy prevalence and evaluate relative risk for patients of South Asian (SA) and White European (WH) ethnic background with type 2 diabetes.

Materials and methods: We used data from the Coventry Diabetes Retinal Screening service, with baseline data from the United Kingdom Asian Diabetes Study (UKADS) and Primary care practices to establish the prevalence of diabetic retinopathy in a community setting. 4316 retinal photographs (2 eyes x 2 fields per patient) were graded by the retinal screening team according to National screening committee guidelines and staged based on the worst eye. Any retinopathy, sight threatening retinopathy (STR), maculopathy and previous photocoagulation prevalences were estimated and compared between ethnicity defined groups. Demographic and clinical risk factors data were collected and to allow for confounding effects, multivariable analyses were performed using conditional logistic regression matched for duration of diabetes.

Results: A total of 1079 patients were included in the study, comprising 430 SA and 649 WH. The SA group comprised more females, were younger and had shorter duration of diabetes, all factors likely to confound comparison of crude prevalence estimates. Prevalence of diabetic retinopathy comparing the SA and WH groups were: any retinopathy 45% vs. 39%, P=0.06, STR 16% vs. 12%, P=0.054, maculopathy 13% vs. 9%, P=0.08 and previous photocoagulation 4% vs. 5%, P=0.28. Conditional logistic regression showed a significant effect for ethnicity, with any retinopathy unadjusted OR SA:WH = 1.66 (1.22 to 2.25), P=0.001 and adjusted for gender, age at diagnosis, systolic blood pressure, HbA1c and total cholesterol = 1.41 (1.01 to 1.97), P=0.045. Similar analysis for STR gave unadjusted OR = 1.61 (1.04 to 1.68) and adjusted OR = 1.44 (0.90 to 2.28), P=0.13.

Conclusion: Crude prevalences of any retinopathy and STR were similar comparing the two ethnicity defined groups, but the risk profiles were quite different, with potential for confounding effects. Adjustment for confounding factors showed higher OR for any retinopathy for the SA group. Risk of STR was raised in the SA, but not statistically significant. The SA group may need more aggressive management of established risk factors to reduce development of retinopathy.

Objective: Recent studies have focused on the measurement of high sensitivity CRP as a predictor of subsequent cardiovascular outcomes. Patients with type 2 diabetes mellitus tend to have higher CRP concentrations than do those without it, suggesting an increased role of inflammation in the accelerated atherosclerosis seen in these patients. The aim of this study was to determine to what extent a CRP value in type 2 diabetic people influences

5-year all causes and cardiovascular mortality, independently on AER and other cardiovascular risk factors.

Research design and methods: In the Casale Monferrato Study centralized measurements of CRP-hs values were available in 2381 (73.3%) persons with type 2 diabetes out of a population-based cohort of 3249 persons with diabetes in 2000. They were identified using independent sources of identification, obtaining an estimated completeness of ascertainment 80%. All measurements were centralized. The independent role of CRP-hs as predictor of all-cause and cardiovascular mortality in the follow-up period 2000–2006 was assessed with multivariate Cox proportional hazards modeling.

Results: Results are based on 496 deaths in 11,717 person-years of observations. With respect to subjects with CRP ≤ 3 mg/l, those with CRP values > 3 mg/l had a hazard ratio (HR) = 1.52 (95% CI 1.20–1.94) for all-cause mortality and HR = 1.42 (95% CI 0.98–2.06) for cardiovascular mortality, after adjustment for age, sex, smoking, hypertension, apoB/apoA1, HbA1c, CVD, AER, eGFR, antidiabetic treatment. When analyses were limited to diabetic persons without CVD, respective HRs were 1.66 (95% CI 1.23–2.23) for all-cause mortality and 1.32 (0.82–2.14) for cardiovascular mortality.

Conclusion: our population based study indicates that CRP-hs measurement is an independent predictor of short-term mortality risk in type 2 diabetic people, even in those in primary prevention of the disease. These findings would suggest the usefulness in clinical practice of CRP measurement for better stratification of risk.

Reduced plasma levels of glucagon-like peptide-1 predict impaired glucose tolerance, but not cardiovascular disease, in elderly men

D. Nathanson¹, B. Zethelius², Å. Sjöholm¹, C. Berne³, J.J. Holst⁴, T. Nyström¹

¹Department of Internal Medicine, Stockholm South Hospital, Karolinska Institutet, Stockholm, Sweden, ²Outpatient Clinic for Obesity Care and Metabolic Diseases, Uppsala University Hospital, Uppsala, Sweden,

³Department of Medical Sciences, Uppsala University Hospital, Sweden,

⁴Department of Biomedical Sciences, The Panum Institute, University of Copenhagen, Denmark

Background and aims: Glucagon-like peptide-1 (GLP-1) is a promising new drug for treatment of type 2 diabetes. Its extensively documented extra-pancreatic effects, for example beneficial influence in connection with endothelial dysfunction and myocardial ischemia, are extremely interesting in this context. Also, insulin resistance is of major importance in terms of type 2 diabetes and coronary heart disease (CHD). Earlier studies demonstrated reduced plasma levels of GLP-1 in type 2 diabetes patients. However, no previous longitudinal study has investigated the association between plasma levels of GLP-1 and CHD. Therefore, we wanted to study cross-sectional and longitudinal relationships between oral glucose-stimulated GLP-1 plasma levels and: development of CHD, insulin sensitivity index (M/I) assessed by euglycemic clamp, early insulin response to an oral glucose tolerance test (OGTT), and type 2 diabetes mellitus.

Materials and methods: A population-based cohort study was conducted from August 1991 to May 1995 among 510 men in Uppsala, Sweden, aged 70 years at baseline with a follow-up of up to 12 years using registry data obtained from the National Board of Health and Welfare in Sweden. At baseline, insulin sensitivity, assessed by euglycemic insulin clamp, and early insulin response to a 75 g oral glucose tolerance test (OGTT) were determined. Fasting GLP-1 and the dynamic response of Δ GLP-1 (i.e., the difference between 60 min OGTT-stimulated GLP-1 and fasting GLP-1 levels), measured in frozen plasma samples with a radioimmunoassay using antiserum 89390, were the predicting variables in the subsequent analyses. CHD was defined as death, as recorded in the Cause of Death Registry, or the first time hospitalisation for CHD as recorded in the In-Patient Registry (International Classification of Disease [9th revision] codes 410 to 414). Potential associations were analyzed using logistic regression (Wald test), presented as odds ratios (OR) with their 95% confidence intervals (CIs). To adjust for possible confounders, we used a multivariable model.

Results: In multivariate analyses, Δ GLP-1 (OR 0.70, CI 0.96–0.99) predicted impaired glucose tolerance (IGT). In contrast, Δ GLP-1 did not predict type 2 diabetes (OR 1.0, CI 0.98–1.0). There were no associations between Δ GLP-1 and CHD (OR 0.99, CI 0.98–1.0) or risk factors i.e. hypertension, lipids, glucose, BMI, M/I or urine albumin. Finally, using both fasting GLP-1 and the OGTT-stimulated GLP-1 level at 60 minutes as predictors in the above models, did not reveal any further associations.

Conclusion: Impaired secretion of GLP-1 after an OGTT seems to predict for IGT in elderly men. In contrast, no association was seen between GLP-1 and type 2 diabetes, which may be confounded by oral treatment in that group (e.g. metformin has been shown to increase GLP-1 plasma levels). More importantly, no association between Δ GLP-1 and CHD, and potential risk factors for CHD, were discerned in this cohort study, suggesting that plasma levels of GLP-1 may not reflect cardiovascular disease in this group of elderly men.

High triglycerides, low HDL cholesterol, and small LDL particles predict incident type 2 diabetes in non-diabetic coronary patients

C.H. Saeely^{1,2}, A. Vonbank¹, S. Beer¹, P. Rein¹, S. Aczel¹, T. Marte¹, H. Drexler^{1,2}

¹VITIT Institute, Feldkirch, Austria, ²University for Human Sciences, Triesen, Liechtenstein

Background and aims: Patients with type 2 diabetes mellitus (T2DM) exhibit a typical pattern of dyslipidemia with high triglycerides, low HDL cholesterol, and small LDL particles, which is also frequently observed in pre-diabetic patients. We therefore aimed at testing the hypothesis that these lipid abnormalities predict incident T2DM in the high-risk population of angiographed coronary patients.

Material and methods: The incidence of T2DM was recorded over 6 years in a population of 503 consecutive non-diabetic patients undergoing coronary angiography for the evaluation of stable coronary artery disease.

Results: During follow-up, T2DM was newly diagnosed in 86 (17.1%) of our patients. Impaired fasting glucose (IFG) ≥ 100 mg/dl at baseline was present in 53.4% of the study population, and IFG patients were at a significantly higher risk of incident T2DM than patients with normal fasting glucose (24.3% vs. 8.9%; $p < 0.001$); in logistic regression analysis adjusting for age, gender, BMI, hypertension, and smoking the standardized OR for fasting glucose as a predictor of T2DM was 1.72 [95% CI 1.36–2.18]; $p < 0.001$. In line with our hypothesis, also the serum levels of triglycerides (OR = 1.57 [1.25–1.98]; $p < 0.001$) and HDL cholesterol (OR = 0.62 [0.45–0.86]; $p = 0.004$) as well as the LDL particle diameter (OR = 0.57 [0.44–0.75]; $p < 0.001$) proved significantly predictive of incident T2DM. Importantly, triglycerides (OR = 1.49 [1.18–1.88], $p = 0.001$), HDL cholesterol (OR = 0.66 [0.47–0.91], $p = 0.012$) and the LDL particle diameter (OR = 0.61 [0.45–0.80], $p < 0.001$) still significantly predicted T2DM after additional adjustment for the baseline fasting glucose values.

Conclusion: High triglycerides, low HDL cholesterol, and a small LDL particle diameter significantly and independently predict the 6-year incidence of T2DM among non-diabetic coronary patients.

ICAM-1 is independently associated with incident diabetes but not incident coronary events or stroke in the elderly at risk

N. Sattar¹, P. Group²

¹Vascular Biochemistry, Glasgow Royal Infirmary, ²Prosper, Glasgow, Leiden, Cork, United Kingdom

Background and aims: To determine whether circulating ICAM-1 as a surrogate of 'endothelial activation' was associated with risk for vascular events and/or incident diabetes in the elderly.

Materials and methods: We related baseline ICAM-1 levels to vascular events (866 combined incident fatal and non-fatal CHD and stroke from 5685 participants) and to incident diabetes (292 from 4945 without baseline diabetes) in the elderly at risk over 3.2 years follow up.

Results: At baseline, ICAM-1 levels correlated positively to triglyceride but negatively to LDL- and HDL-cholesterol. ICAM-1 levels were higher in smokers, and those with prior diabetes or peripheral arterial disease. ICAM-1 level was higher in those who developed diabetes [388.6 (1.42) ng/ml versus 369.4 (1.39) ng/ml, $p = 0.011$]. Furthermore, higher ICAM-1 was associated with new onset diabetes, HR 1.84 (1.26, 2.69), $p = 0.0015$ per unit logICAM-1 with adjustment for risk factors including age, gender, smoking, BMI, lipids, blood pressure, fasting glucose and CRP. By contrast, ICAM-1 levels were not elevated (374.7 (1.4) ng/ml versus 370.8 (1.4) ng/ml, $p = 0.40$) in those who had an incident vascular event compared to those who remained event

free. The hazard ratio (HR) (95% Confidence Interval) and p-value for 1 unit logICAM increment was 1.13 (0.93, 1.38); $p=0.23$ falling to 0.98 (0.80, 1.22); $p=0.89$ in analyses adjusted for other risk factors in the whole cohort.

Conclusion: We show for the first time the elevated ICAM-1 levels are associated with incident diabetes risk in the elderly, despite lack of association with risk for vascular (fatal or non-fatal coronary or stroke) events. ICAM-1 appears to be more closely aligned to diabetes rather than CVD risk in the elderly, a finding which significantly extends relevant data in younger populations.

Non-invasive skin fluorescence indicates cumulative glycaemic exposure

J.D. Maynard¹, T. Orchard², B. Conway², N. Matter¹

¹VeraLight, Inc., Albuquerque, United States, ²Epidemiology, University of Pittsburgh, Pittsburgh, United States

Background and aims: Skin advanced glycation endproducts (AGEs) are biomarkers for tissue damage related to hyperglycemia. Skin AGEs levels may also be influenced by renal function. This study evaluated the association between glycemic exposure, renal function and skin AGEs measured by noninvasive fluorescence spectroscopy.

Materials and methods: Noninvasive measurements were made on the volar forearm of 29 individuals with type 1 diabetes enrolled in the Pittsburgh Epidemiology of Diabetes Complications (EDC) Study. Fluorescence was excited with a 375nm LED and detected over the 400 to 496nm emission window. Reflectance was measured with 375nm and white LEDs. The reflectance measurements enable compensation for skin pigmentation, hemoglobin content and light scattering. The resulting intrinsic fluorescence (IF) was age-corrected to account for the accumulation of skin AGEs in normal health and then integrated to yield a single value.

Results: The mean subject age was 52 and the mean duration of diabetes was 40 years. 4 subjects had overt nephropathy (ON, albumin excretion > 200 µg/min or history of dialysis/transplant). Skin IF was correlated ($r = 0.66$, $p = 0.0004$) with mean A1c (9 measurements over ~20 years) in the 25 ON free subjects, but was not correlated ($r=0.16$, $p=0.41$) when assessed in all 29. Correcting the IF by the natural log of the subject's renal function (MDRD formula) improved correlation ($r=0.37$, $p=0.051$) with mean A1c for the 29. In the ON free group, skin IF was also correlated with A1c months ($r=0.55$, $p=0.005$, calculated by multiplying the number of HbA1c units above normal at each cycle by the number of months between the midpoints of the preceding and succeeding cycle intervals), mean of A1c's taken between 10 and 20 years ago ($r=0.66$, $p=0.0003$), mean of A1c's taken between 1 and 10 years ago ($r=0.57$, $p=0.003$), and most recent A1c ($r=0.40$, $p=0.047$).

Conclusion: Both skin AGEs and mean A1c have been shown to be better predictors of diabetic complications than most recent A1c. Since physicians typically do not have access to a patient's multi-year mean A1c, the skin IF measurement may provide a simple means of assessing the historic glycemia of a person with diabetes that does not have overt nephropathy.

Changes in triglyceride levels over time and risk of type 2 diabetes.

The Metabolic Life-style and Nutrition Assessment in Young Adults (MELANY) Study

A. Tirosh¹, I. Shai², R. Bitzur³, T. Shochat⁴, A. Rudich⁵

¹Department of Internal Medicine A, Sheba Medical Center, Tel-Hashomer, ²The S. Daniel Abraham Center for Health and Nutrition, Ben-Gurion University of the Negev, Beer-Sheva, ³The Institute of Lipid and Atherosclerosis Research, Sheba Medical Center, Tel-Hashomer, ⁴Medical Corps Headquarters, Israel Defense Forces (IDF), ⁵Department of Clinical Biochemistry, Ben-Gurion University of the Negev, Beer-Sheva, Israel

Background: The association between changes in triglycerides (TG) levels over time and diabetes is unknown.

Methods: For 13,953 26-45 years old apparently healthy men, with TG <300 mg/dL (3.39mmol/L), we obtained TG measurements at baseline (Time1) and 3-5 years later (Time2), and followed for a mean of 5.5 years for incident type 2 diabetes.

Results: 322 type 2 diabetes cases occurred during 76,742 person-years. A multivariate model adjusted for age, body mass index (BMI), total cholesterol:HDL-cholesterol ratio, family history of diabetes, fasting glucose, blood pressure, physical activity, and smoking status, revealed a continuous independent rise in incident diabetes with increasing baseline TG levels, (P trend<0.001). Men in the lowest tertile of Time1 TG who progressed to the highest tertile over follow-up (Low-High), exhibited hazard ratio (HR) of 12.62 (95%CI;3.52-31.34) compared to those remaining in the lowest tertile at both time points (reference group: Low-Low). While men who were at the top TG tertile throughout follow-up (High-High) had a HR for diabetes of 7.08 (95%CI;2.52-14.45), those whose TG decreased to the lowest tertile (High-Low) exhibited HR of 1.97(95%CI;0.67-6.13). Alterations in TG during follow-up were associated with changes in BMI, physical activity, and breakfast-eating habits ($p<0.05$), but remained an independent modifier of diabetes risk even after adjustment for such changes.

Conclusion: Two measurements of fasting TG obtained 3-5 years apart can assist in identifying apparently healthy young men at increased risk for diabetes, independent of traditional risk factors and of associated changes in BMI and life-style parameters.

IGF-I/IGF-binding protein 3 ratio: a mechanistic insight into cardiometabolic risk

J. Sierra-Johnson¹, R.M. Fisher¹, A. Romero-Corral², V.K. Somers²,

F. Lopez-Jimenez², A. Malarstig¹, A. Hamsten¹, K. Brismar¹,

M.-L. Hellenius¹

¹Medicine, Karolinska Institutet, Stockholm, Sweden, ²Internal Medicine, Mayo Clinic, Rochester, United States

Background and aims: Recent reports suggest that IGF-I and IGFBP-3 have independent and opposing mechanistic effects on insulin, which lead us to hypothesize that by calculating the ratio of these two proteins we could detect subjects at particular high cardiometabolic risk. To assess the relationship between the insulin-like growth factor 1/ insulin-like growth factor binding protein 3 (IGF-I/IGFBP-3) ratio and the metabolic syndrome/insulin resistance.

Materials and methods: We examined 3,281 subjects (1,463 men; 1,818 women aged 20 to 49 years), otherwise healthy adults, who participated in the Third National Health and Nutrition Examination Survey (NHANES III) and had the recently released measurements of IGF-I and IGFBP-3. Insulin resistance was estimated using the computer homeostatic model assessment (HOMA-2). The updated ATP-III definition of the metabolic syndrome was used. We applied adjusted logistic and linear regression models.

Results: After adjusting for age and race, men and women in the lowest quartile of the IGF-I/IGFBP-3 ratio were 3 times more likely to meet the ATP-III definition of the metabolic syndrome and twice as likely to be insulin resistant. Mean values of the IGF-I/IGFBP-3 ratio decreased significantly as the number of metabolic syndrome components increased (ANOVA $p<0.0001$). Area under the curve for detecting metabolic syndrome/insulin resistance using the IGF-I/IGFBP-3 ratio was 0.760, significantly improving upon either protein alone ($p=0.01$).

Conclusion: The IGF-I/IGFBP-3 ratio is significantly associated with the metabolic syndrome and insulin resistance. A low IGF-I/IGFBP-3 ratio may provide a mechanistic insight into development of the different cardiometabolic entities and its clustering phenomenon.

Quality of care of the risk factors in patients with and without diabetic foot syndrome in a German diabetic population The Diabetes in Germany (DIG) Study: 4 years follow-up data

P. Ott, J. Stelzer, I. Benke, C. Koehler, M. Hanefeld

Zentrum für Klinische Studien, GWT-TUD GmbH, Dresden, Germany

Background and aims: The prevention of diabetic foot syndrome requires an optimal control of blood glucose/HbA1c and of the other risk factors. The DIG study presents population based data on the quality of type 2 diabetes treatment and of major coronary risk factors in Germany for a four years period. This report analyses the data of the patients with and without diabetic foot syndrome (DFS) with the question: Is an optimal treatment of the cardiovascular risk factors connected with a lower rate of diabetic foot syndrome in the clinical practice?

Materials and methods: 4020 patients with type 2 diabetes between 35 and 80 years old were recruited by 238 physicians from general and specialised practices across Germany. Medical history, risk factor profile and clinical data were registered. We analysed HbA1c, fasting blood glucose (FBG), postprandial blood glucose (ppBG), blood pressure (BP), triglycerides (TG), HDL and LDL-Cholesterol at baseline and the influence of concomitant disease on the development of diabetic foot syndrome. DFS was diagnosed if typical ulcer and/or amputation). 2959 patients were seen at 4 years follow-up. 91 patients have a DFS. Polyneuropathy was diagnosed if typical symptoms and/or vibration <4/8 and/or drugs for polyneuropathy was given. Diagnosis of peripheral arterial disease (PAD) was diagnosed if claudication, peripheral revascularisation procedure or missing of pulses of foot were reported.

Results: The patients with DFS were significantly older (63.2 vs. 61.4 years, $p<0.05$), had a longer diabetes duration (12.8 vs. 8.3 years $p<0.001$) and had a larger abdominal circumference (111.7 vs. 104.7 cm $p<0.001$). The glycaemic control was worse in patient with DFS (HbA1c -7.4 vs. 7 % $p<0.01$ / pp blood glucose - 9.9 vs. 9.0 mmol/l $p<0.05$). Puls pressure (62.6 vs. 57.4 mm Hg $p<0.01$) and Systolic blood pressure (144.8 vs. 138.9 mmHg $p<0.01$) were higher too. No significant differences were found for lipids, FBG and diastolic blood pressure.

Multivariate analysis reveals polyneuropathy, PAD in combination with polyneuropathy and abdominal circumference as significant predictor for development DFS.

Conclusion: Patients with diabetic foot syndrome show a significantly worse control of HbA1c, BP and central obesity. Therefore a better control of these three major risk factors seems to be essential. This is especially necessary for patients with polyneuropathy and/or PAD.

The impact of age on lung function in U.S. patients with diabetes: data from the National Health and Nutrition Examination Survey III (NHANES III, 1988-1994)

P.-Y. Berclaz¹, H. Gao¹, D. Swanson², D. Webb¹, J. Tobian¹, J. Li¹, R. Crapo³, R. Jensen³

¹Eli Lilly & Co., Indianapolis, United States, ²Medical Writing, i3 Statprobe, Ann Arbor, United States, ³Pulmonary Division, LDS Hospital, Salt Lake City, UT, United States

Background and aims: Patients with diabetes have lower average forced vital capacity (FVC) and forced expiratory volume (FEV₁) than individuals without diabetes. Since lung function eventually declines with age in adults, it is important to know how the rate of decline in patients with diabetes compares to that of subjects with normal glycaemic control. We conducted a retrospective analysis of the NHANES III data set to determine whether patients with diabetes have accelerated age-related decline in lung function.

Material and methods: In the NHANES III study, spirometry was performed on 20,624 subjects who were randomly selected from across the United States. For our analysis, the Diabetes group was defined as a subset of participants who answered "yes" to the question, "Has a doctor ever told you that you had diabetes (sugar in the blood)?" The No Diabetes group consisted of subjects who answered "no" to having diabetes and had glycosylated haemoglobin A_{1c} (HbA_{1c}) <6.0%. Additional exclusion criteria for both groups included age >90, smoking, presence of asthma or chronic lung disease, or presence of pulmonary symptoms (ie, cough, wheezing or whistle in the chest, shortness of breath, or mucus). Subjects were divided into younger (18-29 y) and older (≥30 y) age groups to control for normal age-related lung development and decline. The effect of age on spirometry was assessed using an ANCOVA while controlling for sex, height, ethnicity and body mass index.

Results: Compared to the No Diabetes group (n=6,678), the Diabetes group (n=496) had fewer males (46% vs. 38%), was older (41.2 vs. 60.1 y) and had higher mean HbA_{1c} values (5.15% vs. 7.91%). The ethnic distribution of the No Diabetes and Diabetes groups was: Caucasian (39.2% vs. 30.0%), Non-Hispanic black (25.6% vs. 27.4%), Hispanic (30.7% vs. 40.1%), and other (4.5% vs. 2.4%). For the 18-29 y old participants, the mean values for the Diabetes group were lower but not significantly different for FEV₁ (-.096 L, $p=.29$) and FVC (-.130 L, $p=.21$) and there were no significant differences in the rates of change between the groups. There was increased variation within the 18-29 y old Diabetes group due to the small sample size (n=25). For the ≥30 y old participants, the mean values for the Diabetes group were significantly lower for FEV₁ (-.094 L, $p<.001$) and FVC (-.166 L, $p<.001$) and the rate of change for the Diabetes group differed from the No Diabetes group by .0004 L/y ($p=.78$) for FEV₁ and -.0005 L/y ($p=.77$) for FVC.

Conclusion: In the NHANES III population, patients with diabetes had small reductions in pulmonary function that were statistically significant in the older (≥30 y) group. There were no significant differences in the rate of change between the Diabetes and No Diabetes groups.

Antidiabetic treatments and the risk of hospitalisation with myocardial infarction: a nationwide case-control study

H.T. Horsdal^{1,2}, J. Rungby^{2,3}, F. Søndergaard¹, S.P. Johnsen^{1,4}¹Department of Clinical Epidemiology, ²Department of Pharmacology,³Department of Endocrinology C, ⁴Center of Cardiovascular Research, Aarhus University Hospital, Denmark

Background and aims: Data on cardiovascular risk of different types of antidiabetic treatment are sparse and conflicting. Here, we examined the risk of myocardial infarction (MI) among patients treated with sulphonylureas, metformin, insulin, any combination and no antidiabetic pharmacotherapy.

Materials and methods: We conducted a population-based case-control study among all patients with type 2 diabetes mellitus in Denmark with a first-time MI and age- and gender-matched non-MI controls in the 1996–2004 using data from computerized registries. Using conditional logistic regression with adjustment for multiple covariates, we estimated odds ratios (ORs) of MI associated with antidiabetic treatment, using patients treated with sulphonylureas as the reference group.

Results: We identified a total of 10,616 cases hospitalized with MI and 90,697 controls, of which 7,134 (67.2%) and 53,821 (59.3%) had filled a prescription for an antidiabetic drug, respectively. We found lower risk of MI among users of metformin (adjusted OR=0.86, 95% CI: 0.78–0.95), insulin (adjusted OR=0.92, 95% CI: 0.86–0.99), and among patients not receiving any antidiabetic pharmacotherapy (adjusted OR=0.75, 95% CI: 0.71–0.79) compared with users of sulphonylureas. Users of any combination had similar risk of MI as users of sulphonylureas (adjusted OR=0.99, 95% CI: 0.92–1.06). We found no differences between individual sulphonylureas, and glycaemic control had only minor impact on the risk estimates in a subanalysis including HbA_{1c}.

Conclusion: Our findings provide some support for the hypothesis that sulphonylureas may be associated with increased risk of hospitalization with MI.

Cardiovascular disease risk in type 2 diabetes patients, non-obese that meet and obese who do not meet goals for glucose and blood pressure control. A Swedish National Diabetes Registry report

B. Zethelius¹, J. Cederholm², B. Eliasson³, K. Eeg-Olofsson³, P.M. Nilsson⁴, S. Gudbjörnsdottir³¹Dept. of Public Health and Caring Sciences/Geriatrics, Uppsala University,²Dept. of Public Health and Caring Sciences/Family Medicine and Clinical Epidemiology, Uppsala University, ³Dept. of Medicine, Göteborg University,⁴Dept. of Clinical Sciences Medicine, Lund University, Sweden

Background and aims: Glycaemic and blood pressure control are considered two important parts of multi factorial risk factor control in type 2 diabetes patients for reducing cardiovascular disease (CVD) morbidity and mortality. The aim of the present study was to estimate the relative risk for fatal and non-fatal CVD and all cause mortality in patients who meet and do not meet goals for glycaemic (HbA_{1c} <7%, DCCT-standard, adopted by the ADA) and blood pressure control (SBP/DBP ≤130/80 mmHg) considering if patients were obese or not.

Materials and methods: Data from type 2 diabetes patients in the Swedish National Diabetes Register (NDR), age ≤85 years, followed-up 6 years from 1998 to 2003 was used. Non-obese patients (n=744) with excellent baseline control (HbA_{1c} <7%, BP ≤130/80 mmHg and BMI <30 kg/m²) and obese patients (n=1857) with adverse baseline control (HbA_{1c} ≥7%, BP >130/80 mmHg and BMI ≥30 kg/m²) were studied.

Results: Comparison of type 2 diabetes patients, non-obese with excellent and obese with adverse control showed that risk for first incident fatal/non-fatal CVD, was 40% lower with excellent control (RR, 0.60; 95%CI, 0.47–0.76; p<0.001), after adjustment for age, sex, diabetes duration, smoking and microalbuminuria >20 µg/min. Corresponding risks for myocardial infarction was 39% lower (RR, 0.61; 95%CI, 0.43–0.85; p=0.004), for coronary heart disease 26% lower (RR, 0.74; 95%CI, 0.56–0.97; p=0.03), for stroke 61% lower (RR, 0.39; 95%CI, 0.26–0.60; p<0.001), and for all cause mortality 21% lower (RR, 0.79; 95%CI, 0.56–1.12; n.s.).

Conclusion: In this population of type 2 diabetes patients from the Swedish NDR, a reduced risk for fatal and non-fatal CVDs was observed among non-obese patients who met the goals for glycaemic and blood pressure control as compared to obese patients who did not. These results support the importance of glucose and blood pressure control obtained in randomized clinical trials on multifactorial risk factor control, in order to reduce CVD. Results observed emphasize on applying target oriented treatment in type 2 diabetes as well as a need for further clinical studies on effective weight reducing treatments to be applied in type 2 diabetes patients.

Cardiovascular risk increases sharply in hypercholesterolaemic patients with fasting plasma glucose of 95–110mg/dL, but not in the patients treated by low-dose pravastatin

H. Kurata, N. Tajima

Internal Medicine, Jikei University School of Medicine, Tokyo, Japan

Background and aims: Accumulated research evidence demonstrated that impaired glucose tolerance is the risk factor for developing cardiovascular (CVD) risk, but it is still controversial in impaired fasting glucose (IFG). The aim of the current study is to investigate the relationship between the hypercholesterolemia and future development of CVD in patients with hypercholesterolemia, and additionally evaluated effect of the pravastatin in post-hoc analysis of the large scale primary prevention study with pravastatin (MEGA Study).

Materials and methods: The MEGA Study aimed to evaluate the effect of low dose pravastatin (10–20mg/day) on primary prevention of cardiovascular disease in a total of 7,832 Japanese patients (male, 40 to 70 years; female, post-menopause to 70 years) with mild to moderate hyperlipidemia without cardiovascular disease. Patients were randomized to diet alone or diet + pravastatin and followed up more than 5-years. A total of 6,673 patients with baseline and follow-up fasting glucose level were analyzed, and which included 68% of female and 42% of hypertension, and its fasting plasma glucose (FPG) level was 109mg/dL. The relationship between FPG and risk of CVD events was evaluated using multivariate Cox proportional hazards model with restricted quadratic spline based on three knots for FPG quartiles, adjusted by sex, age, low-density lipoprotein cholesterol, high-density lipoprotein cholesterol, hypertension, and smoking.

Results: A total of 231 CVD events were observed in 6,673 patients with FPG value. The spline curve in diet group drew the sharp ascending curve in around 95 to 110 mg/dL in FPG, and it got to gentle in 110mg/dL or more. In contrast, the curves in the diet plus pravastatin group drew the liner ascending curves from around 95mg/dL. The hazard ratio was constantly lower in diet plus pravastatin group than in diet group irrespective of FPG level.

Conclusion: The IFG is associated with the risk for CVD in hypercholesterolemia, but it is not under the pravastatin treatment.

The change in serum Gamma-glutamyltransferase is associated with those in triglyceride and blood pressure and with worsening of glucose tolerance in Japanese male subjectsY. Wada¹, Y. Hamamoto^{2,1}, S. Honjo¹, J. Fujikawa³, R. Hosokawa⁴, H. Ikeda¹, K. Nabe¹, T. Kimura¹, T. Aoyama¹, K. Nomura¹, H. Koshiyama^{1,2}¹Center for Diabetes and Endocrinology, The Tazuke Kofukai Foundation Medical Research Institute Kitano Hospital, Osaka, ²Department of Diabetes and Clinical Nutrition, Kyoto University Graduate School of Medicine, Kyoto, ³Department of Clinical Laboratory, The Tazuke Kofukai Foundation Medical Research Institute Kitano Hospital, Osaka, ⁴Department of Preventive Medicine, The Tazuke Kofukai Foundation Medical Research Institute Kitano Hospital, Osaka, Japan**Background and aims:** While the prevalence of metabolic syndrome is explosively increasing in Japan, it is of great interest which factors can be markers to predict the progress into the metabolic syndrome. In the present study, we investigated the possibility of gamma-glutamyltransferase (GGT) as a marker for aggravation of blood pressure, dyslipidemia and glucose tolerance in subjects who received the oral glucose tolerance tests (OGTT) annually in clinical check-up in our Institute.**Subjects and methods:** The study included a total of 198 male subjects (age 30 to 80 years). They received OGTT, routine blood chemistry tests as well as physical examinations in the annual regular check-up of Department of Preventive Medicine of our Institute during 2004 to 2006. The same examinations were performed one year after the first examinations. Their age was 60.3 ± 0.8 SE years. The subjects were divided into two groups depending on the presence ($n = 124$) or absence ($n = 74$) of fatty liver, which was based on the diagnosis by ultrasonography. The correlation between the changes in GGT and those in other parameters during one year follow up were studied by linear regression analyses.**Results:** First, we investigated the relationship between the changes in all parameters in the subjects as a whole. There was a significantly positive correlation between the changes in GGT and those in 2-hour OGTT post-challenge plasma glucose levels in all subjects ($r = 0.24$, $P = 0.001$). Furthermore, there was a significantly positive correlation between the changes in GGT and those in triglyceride levels ($r = 0.19$, $P = 0.02$).Second, we investigated the relationship between various parameters in a subgroup of subjects who showed NGT on the first examination. There was no correlation between the changes in any parameters. Third, we investigated the relationship between the changes of parameters in a subgroup of subjects who showed IGT or DM pattern on the first examination. There was a weak but significantly positive correlation between the changes in GGT and those in both systolic and diastolic blood pressure (systolic pressure: $r = 0.19$, $P = 0.03$; diastolic pressure: $r = 0.23$, $P = 0.01$). Finally, the relationships between the changes in parameters were examined in a subgroup of subjects with fatty liver. The changes in GGT showed a significant positive correlation with those in post-challenge plasma glucose levels ($r = 0.24$, $P = 0.008$), triglyceride ($r = 0.18$, $P = 0.04$), systolic blood pressure ($r = 0.23$, $P = 0.008$), and diastolic blood pressure ($r = 0.26$, $P = 0.004$). In contrast, among the subjects without fatty liver, the change in GGT showed no correlation with those in other parameters.**Conclusion:** The change in serum GGT levels for one year can be a predictor of aggravation of hypertriglyceridemia, hypertension and glucose intolerance in Japanese male subjects, especially in those with fatty liver.

415

The association of dyslipidaemia with cardiovascular mortality in individuals without a prior history of diabetes in the DECODE StudyL. Zhang^{1,2}, Q. Qiao^{1,2}, J. Tuomilehto^{1,2}, N. Hammar^{3,4}, G. Ruotolo^{3,4}, C.D.A. Stehouwer⁶, R.J. Heine⁷, M. Eliasson⁸, B. Zethelius⁹¹Department of Public Health, University of Helsinki, Finland, ²Department of Health Promotion and Chronic Disease Prevention, National Public Health Institute, Helsinki, Finland, ³Department of Epidemiology, Institute of Environmental Medicine, Karolinska Institute, Stockholm, Sweden, ⁴AstraZeneca, Mölndal, Sweden, ⁵Cardiovascular Biology Research Centre, San Raffaele Scientific Institute, Milan, Italy, ⁶Department of Medicine, University Hospital Maastricht, AZ Maastricht, Netherlands, ⁷VU University Medical Center, Amsterdam, Netherlands, ⁸Department of Public Health and Clinical Medicine, Umeå University, Sweden, ⁹Department of Public Health/Geriiatrics, Uppsala University Hospital, Sweden**Background and aims:** Dyslipidaemia is associated with an increased risk of cardiovascular disease (CVD), particularly in diabetic individuals. However,

whether lipid levels predict CVD death to the same extent in different prediabetic states is not clear yet. Therefore, we evaluated the role of dyslipidaemia on the risk of CVD mortality in individuals without a prior history of diabetes by categories of glucose tolerance.

Materials and methods: Data from population-based prospective studies of 9,043 men and 8,594 women aged 25–89 years representing 14 studies in 6 European countries were jointly analysed. A total of 732 CVD deaths occurred during the average 9 years of follow-up. Multivariate-adjusted hazard ratios (HRs) and 95% confidence intervals (CIs) for CVD mortality were estimated using Cox proportional hazard analysis.**Results:** For HDL cholesterol (HDL-C), multivariate adjusted HR for CVD mortality was 0.69 (0.49–0.96) in individuals with isolated fasting hyperglycaemia (fasting plasma glucose [FPG] ≥ 6.10 mmol/l and 2-hour plasma glucose [2hPG] < 7.80 mmol/l), 0.64 (0.48–0.86) in those with combined glucose intolerance (CGI, FPG ≥ 6.10 mmol/l and 2hPG ≥ 7.80 mmol/l), and 0.66 (0.48–0.90) in patients with newly diagnosed diabetes, but not in those with isolated post-load hyperglycaemia (FPG < 6.10 mmol/l and 2hPG ≥ 7.80 mmol/l). As a consequence, total cholesterol to HDL-C ratio (TC/HDL-C) was also positively associated with CVD death in the same groups. Furthermore, non-HDL-C was positively associated with CVD death in individuals with IFG, even though was significant only for isolated fasting hyperglycaemia (1.39 [1.06–1.82]). Finally, triglycerides (TG) were positively associated with CVD death only in individuals with CGI (HR=1.20 [1.04–1.39]) or newly diagnosed diabetes (1.20 [1.02–1.40]).**Conclusion:** Distinct patterns of dyslipidaemia are associated with increased CVD mortality in individuals with isolated fasting hyperglycaemia or IFG, but not in those with isolated post-load hyperglycaemia or IGT, suggesting that a different pathophysiology underlies these two prediabetic states.*Supported by: Academy of Finland, Future Forum Research Grant and Novo Nordisk Foundation. Mortality in a representative sample of diabetic patients in France - the ENTRED StudyD. Simon^{1,2}, I. Romon³, A. Weill⁴, M. Varroud-Vial⁵, E. Eschwege², E. Jouglu⁶, A. Fagot-Campagna³¹Service de Diabétologie, Hôpital de la Pitié-APHP, Paris, ²U-780, INSERM, Villejuif, ³Département des Maladies Chroniques, Institut National de Veille Sanitaire, Saint-Maurice, ⁴Direction de la stratégie, des études et des statistiques, CNAMTS, Paris, ⁵Service de Diabétologie, ANCREC, Corbeil, ⁶Cepi-DC, INSERM, Le Vésinet, France**Background and aims:** Very few data are available concerning mortality rates and causes of death in national representative samples of diabetic patients, and use of routine data mortality statistics to measure the Public Health impact of diabetes in a country is debated. Based on a random sample of pharmacologically-treated diabetic patients living in France, death rates, causes of death and the proportion of death certificates mentioning diabetes were assessed from 2001 to 2006.**Materials and methods:** In 2001, 9,446 adults living in France who claimed refund of oral antidiabetic agents or insulin were randomly selected from the database of the major National Health Insurance System which covers more than 70% of the French population. In 2006, the vital status was successfully extracted from the national registry for 9,101 subjects (96%). Among the 345 cases with unknown vital status, around the 3/4 were born out of France. Death certificates were available for 99% of the deceased patients.**Results:** At baseline, these 9,101 diabetic patients were men for 54%, had a mean age of 65 years and a mean diabetes duration of 12 years. Between October 1st 2001 and September 14th 2006, 1,388 subjects died (15.3%), i.e. 32.4/1,000 person-years. Death rates by age and sex are shown in the Figure. Mean age at death was 74 years in men and 80 years in women. Causes of deaths were: circulatory diseases in 60% in multiple-cause (MC) analysis [32% as underlying cause(UC)], including ischaemic heart disease in 18% MC (11% UC) and stroke in 14% MC (8% UC); all neoplasms in 32% MC (29% UC); all respiratory diseases in 18% MC (5% UC); diseases of the digestive system in 11% MC (4% UC) and diseases of the genito-urinary system in 10% MC (2% UC), including renal failure in 9% MC (2% UC). Diabetes was mentioned in 35% of death certificates including 12% as UC of death. In the 253 subjects who died with ischaemic heart disease, diabetes was mentioned in only 136 death certificates (54%).**Conclusion:** This study relies upon a national sample of diabetic patients quite representative of the French diabetic population, who could be traced

over 5 years for vital status and causes of death with a high degree of exhaustiveness. It shows a high mortality rate, higher in men in all age classes. Circulatory diseases are the most frequent cause of deaths. Diabetes is mentioned in about one third of death certificates only, and is obviously underreported in death certificates even when taking into account multiple causes of death.

UKPDS outcomes model predicted total mortality in U.S. adults with type 2 diabetes

Q. Zhang¹, N.D. Wong², M. Song², S. Malik², V.A. Lopez², H.M. Phatak³, M. Panagiotis³, C.M. Alexander³

¹Global Outcomes Research, Merck & Co, Inc, Whitehouse Station, NJ, United States, ²University of California, Irvine, United States, ³Merck & Co, Inc., Whitehouse Station, United States

Background and aims: The validity of the United Kingdom Prospective Diabetes Study (UKPDS) Outcomes Model is not established in populations with type 2 diabetes outside the United Kingdom. We compared the total mortality predicted from the UKPDS model with the observed mortality seen among U.S. adults with type 2 diabetes who were comparable to the UKPDS study cohort at entry.

Materials and methods: We studied participants with diabetes from the National Health and Nutrition Examination Survey 1988-1994 (NHANES III) with characteristics comparable to the UKPDS cohort, including age 25-64 years, age at diagnosis of diabetes ≥ 30 years, diabetes duration 0-5 years, and no evidence of cardiovascular disease (CVD). The 10-year observed total mortality was compared to the UKPDS model-predicted mortality based on age, gender, height, weight, diabetes duration, glycated hemoglobin (HbA1c), total and HDL-cholesterol, systolic blood pressure, and smoking status.

Results: Participants ($n=156$) were on average aged 49.6 ± 1.0 years at baseline, aged 47.1 ± 1.0 years at diagnosis of diabetes, with a mean duration of diabetes of 2.6 ± 0.2 years and were followed for an average of 10.4 ± 2.0 years. The UKPDS model-predicted 10-year total mortality was 15.0%, similar to the observed total mortality of 13.7% (42.6% due to CVD) (Figure). The average annual difference between predicted and observed mortality was 0.6 years. Age and duration of diabetes were the most important variables that affected the ability of the UKPDS model to predict total mortality among diabetic patients with no CVD at baseline and age of diagnosis ≥ 30 years.

Conclusion: The UKPDS Outcomes Model accurately predicted observed mortality in the subgroup of NHANES III participants with characteristics similar to the UKPDS.

Figure 1. Expected vs. Observed Risk Rates per Year for Any Cause Mortality Aged 25–64 years with Diabetes Duration <6 years (N=156)

Does fasting plasma glucose predict mortality or coronary heart disease in senior citizens without diabetes or in those with undiagnosed diabetes? The Dubbo Study of Australian elderly

L.A. Simons¹, J. Simons¹, Y. Friedlander², J. McCallum³

¹Lipid Research Dept, University of NSW, St Vincent's Hospital, Darlinghurst NSW, Australia, ²Epidemiology Unit, Hebrew University-Hadassah School of Public Health, Jerusalem, Israel, ³Vice-Chancellor's Dept, Victoria University, Melbourne, Australia

Background and aims: The burden of cardiovascular disease (CVD) in diabetes is well known, falling heavily on females. But fasting plasma glucose (FPG) levels below diabetes "thresholds" may also be important, although current data are meagre and controversial. This study aims to confirm whether FPG predicts death or coronary heart disease (CHD) (a) in non-diabetic subjects in the presence or absence of prior CVD (i.e. CVD at study entry), and (b) in the presence of undiagnosed diabetes.

Materials and methods: We have analysed 16 year follow-up data in a cohort of Australian senior citizens, born before 1930 and first examined in 1988-89 (www.dubbostudy.org). Key outcomes were all-causes mortality and CHD (ICD-9 & 10). Diabetes was defined on historical grounds (previous diagnosis or use of medication), undiagnosed diabetics were those without history but with FPG >6.9 mmol/L. Cox models were used to calculate point estimates and 95% CI's for the Hazard Ratio of the specified outcomes, FPG being entered as a continuous variable (unless otherwise specified).

Results: Death rates in males and females with prior CVD but no diabetes were 49 and 32/1000 person-years respectively (corresponding rates in the presence of diabetes were 86 and 67). CHD event rates were 39 and 27/1000 person-years respectively (76 and 85 in diabetes).

Table 1 presents Cox models for each 1mmol/L increment in FPG (other standard variables in the models not shown). Historical diabetes was excluded from all 4 models, but models 3-4 include those with undiagnosed diabetes or lesser degrees of glucose intolerance.

FPG did not significantly predict any outcome in any model in males!

In females, FPG was a significant predictor of death or CHD in the cohort which included prior CVD but excluded all diabetes (model 1). In this model FPG levels 5.3-6.0 predicted a 41 % greater risk of death and a 33% greater risk of CHD than with FPG <4.6 mmol/L.

In females with undiagnosed diabetes, FPG predicted death independently of prior CVD presence, but did not significantly predict CHD (models 3-4).

Conclusion: FPG in female senior citizens without diabetes significantly predicts all-causes mortality and CHD in those with prior CVD. FPG predicts

TABLE 1. COX MODELS, HAZARD RATIOS (95% CI'S) OVER 16 YEARS FOLLOW-UP (n=number of males, females)

	Model 1 (incl CVD & excl FPG >6.0) (n=1048,1371)	Model 2 (excl CVD & excl FPG >6.0) (n=768,1079)	Model 3 (incl CVD & incl FPG >6.0) (n=1145,1470)	Model 4 (excl CVD & incl FPG >6.0) (n=831,1160)
Deaths, male	1.07(0.91–1.27)	1.02(0.82–1.25)	1.00(0.92–1.09)	1.00(0.89–1.12)
Deaths, female	1.30(1.09–1.56)	1.17(0.95–1.44)	1.18(1.10–1.26)	1.18(1.04–1.35)
CHD, male	1.13(0.93–1.38)	1.24(0.95–1.63)	0.95(0.86–1.05)	0.98(0.86–1.12)
CHD, female	1.24(1.02–1.51)	1.07(0.84–1.37)	1.05(0.98–1.12)	1.11(0.94–1.30)

all-causes mortality (but not CHD) in females with undiagnosed diabetes. FPG does not predict any outcome in males in the present study design.

419

Mortality in a cohort of individuals with and without diabetes mellitus in a Swedish community during 30 years of follow up

S.P.O. Jansson, D.K.G. Andersson, K. Svärdsudd

Department of Public Health and Caring Sciences, Family Medicine and Clinical Epidemiology Section, Uppsala University Sweden, Sweden

Background and aims: An excess mortality in people with diabetes compared to those without diabetes is well documented. This higher mortality is in the vast majority of cases due to cardiovascular disease (CVD). Studies of mortality rates concerning sex differences are inconsistent. In Sweden, the population have experienced a substantial decline in CVD the past 25 years but if this holds true for the diabetic population is unclear. Our aim in this prospective cohort study was to compare mortality (all causes) in individuals with and without diabetes during the time period 1972–2004.

Materials and methods: Since 1972 all patients with diabetes are registered in a diabetes register at Laxå primary healthcare centre. The register has been complemented with a reference population consisting of 5 age- and gender matched nondiabetic referents per diabetic subject. During 1972–2001, a total of 776 new cases of diabetes were found. The “Laxå register” (cases and controls) has further been updated from 1972–2004 with data from the national Cause of Death Register.

Results: During the follow-up period, 473 diabetic subjects died, 233 women (3 type 1- and 230 type 2 diabetes individuals) and 240 men (1 type 1- and 239 type 2 diabetes individuals) and 2077 nondiabetic referents (995 women and 1082 men). The 10-year mortality rate for diabetic men was 40% among those diagnosed 1972–1981, 35.4% among those diagnosed 1982–1991 and 29.7% among those diagnosed 1992–2001. Corresponding rates for male referents were 45.6%, 35.1% and 19.8%. Among diabetic women the mortality rates were 30.1%, 26.6% and 20.9% and among female referents 34.8%, 26.3% and 13.7%.

The referents on average reduced their mortality by 5 % per five-year period throughout the whole study period as compared with the diabetic subjects who reduced their mortality by 0.1 % per 5-year period.

Conclusion: Individuals with diabetes showed only a marginally reduction in mortality during the three time periods compared with the referents, a significant trend difference. Women with diabetes had a lower mortality than diabetic men.

Type 2 diabetes in the non-obese children and adolescents in Bangladesh

M.A. Sayeed¹, H. Mahtab², A. Banu², P.A. Khanam², Z.A. Latif³, A.U. Ahmed⁴, J.S. Nahar², K. Khatun², A. Azad Khan²

¹Community Medicine, Ibrahim Medical College, Dhaka, ²Epidemiology, BIRDEM, Dhaka, Bangladesh, ³Epidemiology, BIRDEM, Dhaka, ⁴Biochemistry, BIRDEM, Dhaka, Bangladesh

Background and aims: Burdened with the highest population density (1007 per sq.km) and frequent natural disasters Bangladesh has been striving against poverty, hunger and diseases. Inequitable distribution of food, education and healthcare has led to undernutrition in one and obesity in the other. Additionally, rapidly urbanized environment influenced the traditional life. Childhood obesity is a well-known risk, while under-nutrition in pregnancy and low birth weight (LBW) was also attributed to T2DM and cardiovascular diseases. It is not known, however, how many of our children are underweight and how many of them are obese; and how many of them started developing diabetes. This is the first study to address the prevalence of diabetes among the obese and non-obese children and adolescents in Bangladesh.

Materials and methods: We investigated school children of age group 10 - 18 years in rural and urban communities in 2007. Investigations included socio-demographic information, height, weight, mid-upper-arm circumference (MUAC), blood pressure (SBP, DBP), fasting blood glucose (FBG), triglycerides (TG), and HDL-c. We used ADA criteria (1997) for impaired fasting glucose (IFG) and diabetes. For obesity and overweight, we used sex- and age-specific body mass index (BMI) criteria for the Asians recommended by the International Obesity Task Force.

Results: Overall, 2152 students (m / f: 1064 / 1088) volunteered the study. Their mean (SD) age was 13.3 (2.0) y, BMI was 18.5 (3.1) and MUAC was 21.2 (3.4) cm. The mean (SD) FBG, TG and HDL were 4.6 (0.87) mmol/l, 107 (44) mg/dl and 45.0 (10.6) mg/dl, respectively. The prevalence of normal weight was only 35.8% (m / f: 31.8 / 39.8%, $p > 0.05$), whereas, underweight was in excess (m / f: 60 / 56.1%, $p > 0.05$). In contrast, overweight and obesity were only 5.1 and 3.0%, respectively. The prevalence of IFG (95% CI) was 3.4% (2.63 - 4.17) and T2DM was 1.5% (0.99 - 2.01). FBG showed significant positive correlation with HDL in all age groups (10–12, -14, -16, -18y) and significant inverse correlation with MUAC but limited to age <14y. In either sex for all ages, BMI showed no association with FBG. In assessing risk for hyperglycemia (FBG ≥ 5.6 mmol/l), logistic regression showed [odds ratio (OR) with 95%CI] that higher age ($>14y$, OR 2.04, 1.27 - 3.26), urban area (OR 11.60, 5.57 - 24.17) and higher family income (taka $>10,000$: OR 2.03, 1.30 - 3.18) were found to be significant; whereas, obesity related variables (BMI, MUAC) were proved not significant.

Conclusion: Despite lower obesity prevalence among these children the development of IFG and T2DM were found not negligible. The cut-offs for obesity measures we used might be inappropriate. The lower cut-offs or waist-girth could have been proved more useful. Significant positive correlation of FBG with HDL and significant negative correlation with MUAC (not BMI) indicate a complex interrelationship among obesity indices, glycemia and dyslipidaemia. A prospective cohort including other variables like waist-girth, insulin or macro- / micro-nutrients may explain how diabetes starts developing in the non-obese young children.

Can ethnic group differences in insulin resistance and dyslipidaemia be explained by differences in muscle mass and visceral fat?

T. Tillin¹, A. Hughes¹, I. Goddard², N. Forouhi³, P. McKegue⁴, N. Chaturvedi¹

¹International Centre for Circulatory Health, Imperial College, London, ²Metabolic Medicine, Imperial College, London, ³Epidemiology Unit, MRC, Cambridge, ⁴MRC Human Genetics Unit, University of Edinburgh, United Kingdom

Background and aims: People of Indian Asian and African Caribbean descent have high rates of diabetes and insulin resistance (IR). However the consequences of diabetes and IR differ, with Indian Asians displaying the classical pattern of dyslipidaemia and elevated rates of coronary heart disease (CHD), whilst people of African Caribbean descent have favourable lipid profiles and, in the UK, low rates of CHD.

We studied whether differences in fat and lean tissue could explain elevated levels of IR and differing lipid profiles in British African Caribbeans and Indian Asians.

Method: Population based study of 1732 European White, 1234 Indian Asian and 405 African Caribbean non-diabetic men aged 40–69 years in West London. Measurements included fasting bloods, skinfold thicknesses and waist, hip, mid-arm and thigh circumferences. Visceral adipose tissue (VAT) and whole body skeletal muscle mass (SMM) were estimated using ethnicity-specific formulae validated against whole-body MRI and CT.

Results: Compared with European men, African Caribbeans were significantly more insulin resistant but less dyslipidaemic. They had more SMM and less VAT (table). Conversely, Indian Asians were significantly more insulin resistant and more dyslipidaemic, with more VAT and less SMM than Europeans. Adjustment for SMM abolished the ethnic difference in HOMA IR for African Caribbeans. Adjustment for VAT abolished the ethnic difference in HOMA IR for Indian Asians and obliterated ethnic differences in triglycerides in both African Caribbeans and Indian Asians compared with Europeans (table and figure).

Conclusion: Reduced visceral fat explained the favourable lipid profiles of British African Caribbean men, whilst their increased IR relative to European men appeared to be explained by increased muscle mass, suggesting abnormalities of skeletal muscle metabolism in African Caribbeans.

In contrast, increased IR and dyslipidaemia in Indian Asian men was explained by increased visceral fat. Marked ethnic differences in body fat distribution contribute to ethnic differences in IR consequences.

Questioning the appropriateness of recommended waist cut-points for Caucasians and Asian Indians based on relationships with incident diabetes
A.J. Cameron¹, P.Z. Zimmet¹, G. Alberti², R.A. Sicree¹, J. Tuomilehto³, J.E. Shaw¹

¹Epidemiology Department, International Diabetes Institute, Caulfield, Australia, ²Department of Medicine, University of Newcastle, United Kingdom, ³Department of Public Health, University of Helsinki, Helsinki, Finland

Background and aims: Cut-points for waist circumference, as currently used in the IDF definition of the Metabolic Syndrome, are based on concordance with BMI cut-points for overweight and obesity (Europids) and cross-sectional associations with components of the metabolic syndrome (Asians). Minimal evidence exists as to whether these bear any relation to important outcomes such as diabetes, particularly for non-Europid populations. The aim of this work is to use data from prospective cohort studies conducted in Asian Indian and Europid populations to determine whether the currently recommended waist cut-points are appropriate for these populations.

Materials and methods: Data are from 5759 non-pregnant Europid participants (45.0% male) in the Australian Diabetes, Obesity, and Lifestyle (AusDiab) study (1999–2004) and 2233 non-pregnant ethnically Asian Indians (45.5% male) from the Mauritius Non-Communicable Disease Study (1987–1992). An oral glucose tolerance test was used to obtain fasting and 2-hr plasma glucose at both baseline and follow-up, and diabetes diagnosed according to 1999 WHO recommendations. Waist circumference (WC) was measured at the testing site. Ethical approval to conduct the studies was obtained, and informed consent was obtained from participants in both studies.

Results: Mean WC was 97.1cm and 84.9cm for Europid men and women, and 77.6cm and 72.9cm for Asian Indian men and women. A total of 240 Europid and 187 Asian Indian participants developed diabetes over five years. For a 50 year old Europid with WC of 94cm (male) or 80cm (female) (note - recommended cut-points for Europids), annual diabetes incidence is estimated as 0.6% for both sexes. For 50 year old Asian Indians with WC of 90cm (male) or 80cm (female) (note - recommended cut-points for Asians), annual diabetes incidence is estimated as 5.3% and 2.2% for men and women respectively. The WC at which a 50 year old is estimated to have a 1% annual diabetes incidence is 105cm (male) and 93cm (female) in Europids and 67cm (male) and 63cm (female) in Asian Indians. Compared to a WC at the 10th percentile (84cm and 70cm in Europid men and women; 66cm and 60cm in Asian Indian men and women), age-adjusted annual diabetes incidence doubles at WC of 97cm and 85cm in Europid men and women, and 76cm and 75cm for Asian Indian men and women.

Conclusion: We have demonstrated here that the difference between currently recommended WC cut-points for Europids and Asians (4cm for men, identical for women) appear to underestimate the difference in WC at which risk for diabetes increases in these populations. This is true for men and particularly so for women (where current WC cut-points are identical for all ethnic groups). Similar studies in other Asian populations are needed to determine whether this is a finding common to all Asian populations. The results of prospective, outcome based studies such as these should be considered when revising ethnicity-specific waist circumference cut-points, which are vitally important as a global public health tool.

Diabetes susceptibility in five ethnic minority groups compared to Norwegians - the impact of adiposity measures and other risk factors

A.K. Jennum¹, L.M. Diep², G. Holmboe-Ottesen³, B.N. Kumar³, K.I. Birkeland¹

¹Aker/Ullevaal Diabetes Research Center, Aker University Hospital, ²Aker Research Center, Aker University Hospital, ³Institute of General Practice and Community Medicine, University of Oslo, Norway

Background and aims: Ethnicity exerts a strong influence on diabetes susceptibility. Europeans seem to be the least affected by the increasing rates of obesity and sedentary behaviours. Immigrants from non-Western countries to Europe may have even higher diabetes prevalence rates than found in their countries of origin. The aim of this study was to assess diabetes prevalence in

Oslo in five ethnic minority groups compared to Norwegians, and the differential impact of adiposity measures and environmental factors.

Materials and methods: Data from questionnaires, physical examinations and serum samples from two population-based health surveys in Oslo, conducted by the Norwegian Institute of Public Health according to established standards in 2000–2002, were analysed. In the Romsås in Motion Study all 31–67 year old subjects in two districts were invited, whereas in the Oslo Immigrant Health Study all 31–60 years olds born in Sri Lanka, Pakistan, Vietnam, Turkey and Iran. Subjects with non-fasting serum glucose (NFSG) levels >6.0 mmol/l were asked to return for a fasting serum glucose (FSG) and HbA_{1c} (normal reference range of 4.1–6.4%). Subjects not reporting diabetes, but with FSG ≥ 7.0 mmol/l, or HbA_{1c} $>6.4\%$, or when not attending for fasting samples, NFSG ≥ 11.1 mmol/l, were categorised as having undiagnosed diabetes. Of the 4929 subjects who met, 2212 were from Norway, 459 from Iran, 563 from Vietnam, 390 from Turkey, 880 from Sri Lanka and 425 from Pakistan.

Results: 196 women and 272 men had diabetes ($N=468$), of which 277 cases were known and 191 (41%) screening-diagnosed. Diabetes prevalence differed significantly between ethnic groups (Figure 1). Based on preliminary sex specific logistic regression analyses with Norwegians as a reference, the OR for diabetes for Sri Lankaan women and men were 9.2 and 3.0, for Pakistanis 8.4 and 2.3, for Vietnamese 4.8 and 2 and for women from Turkey 3.1 ($p<0.001$ for all) adjusted for age, waist/hip-ratio, physical activity, smoking, education, full time work, body height, and parity in women. The age-adjusted impact of BMI, waist/hip ratio and waist on diabetes prevalence varied significantly by ethnicity, with higher estimated age-adjusted prevalence rates for all BMI values in the range 18–35 for all ethnic groups compared to Norwegians except for Iranians.

Conclusion: Vietnamese, Turkish, Sri Lankaan and Pakistani women had 3–10 times higher age-standardized prevalence rates than Norwegian and Iranian women. Higher diabetes susceptibility for three measures of adiposity was found for Sri Lankans, Pakistanis, Vietnamese and Turkish immigrant groups compared to Norwegians and Iranians.

Figure 1: Diabetes prevalence (95% CI) in 31–60 year olds according to sex and ethnicity, age standardized with the Norwegian population in 2000 as reference.

Higher leptin levels in Asian Indians than in Creole and Caucasians – a potential explanation to increased metabolic risk; data from Mauritius and Northern Sweden

M. Lilja¹, M. Eliasson², B. Stegmayr², T. Olsson², P. Zimmet³, J.E. Shaw³, A. Cameron³, K. Pavuadaya⁴, J. Tuomilehto⁵, G. Alberti⁶, S. Soderberg²

¹The Research and Development Unit, Jamtland County council, Östersund, Sweden, ²Department of Public Health and Clinical Medicine, Umeå University, Sweden, ³International Diabetes Institute, Melbourne, Australia, ⁴Ministry of Health and Quality of Life, Port Louis, Mauritius, ⁵Department of Public Health, University of Helsinki, Finland, ⁶Department of Endocrinology and Metabolic Medicine, Imperial College, London, United Kingdom

Background and aims: Leptin is an independent predictor of type 2 diabetes, cardiovascular disease and it predicts worsening of the metabolic syndrome

independently of obesity. Experimental data also show that leptin may have detrimental effects on the cardiovascular system and on the insulin producing beta cell. Asian Indians have been shown to be highly susceptible to type 2 diabetes and other features of the metabolic syndrome. We hypothesised that leptin may explain this difference and the aim of this study was to explore if levels of leptin, leptin per BMI unit (leptin/BMI) and leptin per cm in waist circumference (leptin/waist) differed between different ethnicities (Caucasians, Asian Indians and Creoles [mainly African ancestry]).

Materials and methods: In the Northern Sweden MONICA study cross-sectional population surveys were performed in 1986, 1990 and 1994. In 1999 all survey participants were offered a follow-up with 1720 men and 1793 women participating (all Caucasians). In Mauritius, population based surveys were undertaken 1987 with a follow up in 1992. 1075 men and 1341 women of Indian ($n=1815$) and Creole ($n=602$) ethnicity participated both studies. All subjects were 25–74 years and leptin samples from the initial surveys were used. Leptin levels were determined with the same method (Linco, RIA) on samples that had been stored for approximately 10 years. Data were explored with an ANCOVA with post hoc Bonferroni analysis. Adjustment was made for BMI, smoking habits and actual age. Pregnant women were excluded.

Results: Asian Indian men and women had higher leptin, leptin/BMI and leptin/waist than Creole and Caucasian men and women (all $p<0.0005$). For men the difference between Creole (in the middle) and Caucasians (lowest values) for leptin, leptin/BMI and leptin/waist were also significant (all $p<0.0005$).

The association between age and each of leptin, leptin/waist and leptin/BMI did not differ between ethnicities.

Conclusion: Asian Indian men and women have higher levels of leptin, leptin/BMI and leptin/waist than Creole and Caucasian men and women. This could partly explain the increased vulnerability for features of the metabolic syndrome in Indians.

Diabetes, IGT and IFG: risk factors for all-cause mortality over 15 years in the multi-ethnic nation of Mauritius

D.J. Magliano¹, S. Söderberg^{1,2}, K. Pavuadaya³, S. Kowlessur³, J. Tuomilehto⁴, G. Alberti⁵, J.E. Shaw¹, P.Z. Zimmet¹

¹Epidemiology, The Baker IDI Heart and Diabetes Institute, Melbourne, Australia, ²Department of Public Health and Clinical Medicine, Cardiology, Umeå University, Sweden, ³Non Communicable Diseases Unit, Ministry for Health and Quality of Life, Port Louis, Mauritius, ⁴Department of Public Health, University of Helsinki, Helsinki, Finland, ⁵Department of Endocrinology and Metabolism, St Mary's Hospital and Imperial College, London, United Kingdom

Background and aims: To explore the relationship between diabetes, impaired glucose tolerance (IGT) and impaired fasting glycaemia (IFG) and all-cause mortality adjusted for conventional risk factors in a large multi-ethnic cohort living in the developing nation of Mauritius.

Methods: Population-based surveys were undertaken in Mauritius in 1987, 1992 and 1998 ($n=9559$). Participants were aged 18 years or greater and 66%, 27%, and 7% were of Indian, Creole, and Chinese descent, respectively. Response rates for all surveys were greater than 85%. Questionnaires, anthropometric measurements, and a 2 hour 75-g oral glucose tolerance test were undertaken at each survey. Glucose tolerance was classified according to World Health Organisation 1999 criteria. In 2007, a mortality follow-up was undertaken. Cox's proportional hazards model was used to obtain hazard ratios (HRs) for risk of mortality, adjusted for age, sex, prior cardiovascular disease, hypertension, smoking, total cholesterol, education, body mass index, waist and hip circumference.

Results: Over a median follow-up of 15.1 years, there were 1559 deaths, 7168 survivors and 832 participants were lost to follow-up. Compared with those with normal glucose tolerance (NGT), the all-cause mortality HRs and 95% confidence intervals (CIs) for known diabetes mellitus (KDM), newly diagnosed diabetes mellitus (NDM) and IGT were 3.7 (2.9 to 4.6), 2.2 (1.8 to 2.7), 1.3 (1.1 to 1.6) in males and 3.1 (2.4 to 3.8), 2.0 (1.6 to 2.5), 1.1 (0.9 to 1.4) in females, respectively. Those with IFG were not at increased risk of mortality in either males (1.2 [0.9 to 1.6]) or females (0.7 [0.4 to 1.3]). The HRs of mortality from all diabetes fell from 6.4 (3.7 to 11.3) in those aged 18–34 years to 1.7 (1.4 to 2.2) in those aged 65 years or greater. Among the Indians, compared to those with NGT, those with KDM (3.6 [3.0 to 4.4]), NDM

(2.4, [2.0 to 2.8]) and IGT (1.3 [1.1 to 1.5]) were at increased risk of all-cause mortality, but in the Creole population, only those with KDM (2.6 [1.9 to 3.5]) and NDM (1.8 [1.4 to 2.4]) were at increased risk of death; IGT (1.1 [0.9 to 1.4]) and IFG (0.9 [0.6 to 1.4]) were not associated with an increased risk of all-cause mortality. Among those of Chinese descent, only KDM were at increased risk of mortality (3.7 [1.9 to 7.2]).

Conclusion: This is one of the largest ever studies of diabetes and mortality in a developing country. The ethnic mix of Mauritians is said to be a microcosm of the world's population as it represents over 60% of the world's peoples. This study shows that mortality risk from diabetes decreases with age and that KDM and NDM were independent risk factors for all-cause mortality in the three ethnic groups. IGT was only associated with mortality in the Indians, while IFG was not associated with an increased risk of death in any ethnic subgroup.

426

Insulin resistance and secretion in different ethnic populations of Kenya

D.L. Christensen¹, D.L. Mwaniki², M.K. Boit³, B. Kilonzo⁴, H. Friis⁵,

I. Tetens⁶, L. Kaduka², B.O. Omondi², K. Borch-Johnsen¹

Kenya, ³Department of Exercise, Recreation and Sport Science, Kenyatta

University, Nairobi, Kenya, ⁴CPHR, Kenyatta University, Nairobi, Kenya,

⁵Department of Human Nutrition, University of Copenhagen, Denmark,

⁶Department of Nutrition, Technical University of Denmark, Copenhagen, Denmark

In Africa, the aetiology of glucose intolerance has not been systematically investigated in representative populations. Differences in lifestyle are still apparent in the rural areas, and urbanisation occurs at a high rate, but their association with insulin secretion and insulin resistance is unknown. Therefore, the aim of this study was to estimate insulin secretion and action in different ethnic groups of Kenya.

In a cross-sectional study, the Luo, Kamba and Maasai were chosen as study populations to represent a fishing-agricultural, an agricultural, and an agropastoralist rural society, respectively. In total, 1,306 men and women (age range 17–68 yrs) had an OGTT. Of these, 58 individuals had diabetes and were subsequently excluded from further analysis. Insulin and glucose concentrations from venous blood samples at 0 min and 30 min from the remaining 1,248 individuals were analysed. Estimates of insulin sensitivity (HOMA-IR), absolute insulin secretion (insulinogenic index) and beta cell function (Disposition Index, $DI = \text{HOMA} \times \text{insulinogenic index}$) were calculated.

In the rural and urban populations, geometric mean HOMA-IR was 0.59 (95% CI: 0.56; 0.61) and 0.85 (0.76; 0.95), respectively, geometric mean insulinogenic index was 88.9 (84.0; 94.1) and 127.3 (107.7; 150.5), respectively, and geometric mean DI was 153.3 (144.9; 162.3) and 153.4 (127.9; 183.8). Results on insulin resistance and secretion as well as biological background of study population stratified by ethnic groups are shown in Table 1.

HOMA-IR and insulinogenic index were higher in the Maasai and Kamba compared to the Luo. This indicates a higher absolute insulin secretion in order to compensate for insulin resistance among the Maasai and Kamba. Consequently, this was reflected in the estimated beta cell function where no difference could be found between the ethnic groups. A higher HOMA-IR in the urban population was also compensated for by a higher insulinogenic index and thus there was no difference in DI between urban and rural populations. This study indicates that lifestyle differences with or without urbanisation have an effect on insulin resistance and secretion in African populations.

Table 1. Biological background characteristics and derived variables of OGTT. Results are presented as mean or geometric mean values (95% CI).

	Luo	(95% CI)	Kamba	(95% CI)	Maasai	(95% CI)	P-value
n	429		459		360		
Females (%)	51.5		68.2		51.7

Diabetes prevalence among migrant populations in Australia: prevalence and risk factor associations

R.A. Sicree, P.Z. Zimmet, A.J. Cameron, D.J. Magliano, J.E. Shaw

International Diabetes Institute, Melbourne, Australia

Background and aims: Ethnicity is a key factor affecting diabetes prevalence, with obesity linked to diabetes amongst all ethnic groups. However, there are little data on the choice of cut-points for obesity for different ethnic groups. Our objectives were to examine the relationship between ethnicity and diabetes prevalence in the Australian population, and to assess whether the relationship between obesity and diabetes is consistent across ethnicities.

Materials and methods: The AusDiab Study was a population-based cluster survey of 11,247 adults conducted in Australia during 1999–2000, in which fasting glucose and glucose tolerance were assessed for 11,078 participants. Ethnic background was coded according to country of birth, with modification for main language used at home. Waist circumference and BMI were used as indices of obesity. Diabetes was classified according to 1999 WHO criteria.

Results: Diabetes prevalence (age- and sex-standardised to 50 years) was significantly higher for those from South European (9.9%), and Asian background (11.3%), compared to 5.8% for the Australian/New Zealand born (both at $p < 0.001$). Compared to the Australian/New Zealand born, mean age- and sex-adjusted waist circumference was ~2 cm greater for South European participants ($p = 0.001$) and ~5 cm less for the Asian born ($p < 0.001$); similarly mean BMI was 1.5 kg/m² more for the South Europeans and 2.0 kg/m² less for Asian participants (both at $p < 0.001$), with the Australian/New Zealand born adjusted means being 98.8 and 86.4 cm, and 27.7 and 27.4 kg/m² for males and females respectively. The Asian born group had lower rates of central obesity based on current World Health Organization and International Diabetes Federation criteria. The association of obesity measures with diabetes prevalence were the same across ethnicity groups, with interaction terms for ethnicity and waist, and ethnicity and BMI having p values of 0.4 and 0.8 respectively. Overall differences of about 5 kg/m² in BMI, or 11 cm in waist circumference were associated with twice the diabetes prevalence irrespective of ethnicities. Adjustment for obesity did not explain differences in diabetes prevalence between ethnicities; the parameter estimates suggest that to have similar prevalence to the Australian born the Asian migrant populations would need waist circumferences at least 10 cm lower or BMI 5 kg/m² than those of the Australian/New Zealand born participants. Migrants from other regions (other English speaking countries, and elsewhere in Europe) had similar rates of obesity and diabetes to the Australian/New Zealand born. Among the Australian born, those of Indigenous background had a 4-fold risk of diabetes ($p < 0.001$), and mean waist 7 cm and BMI 2.8 kg/m² (both at $p < 0.001$) greater than other Australian born.

Conclusion: There are marked differences in measures of obesity and diabetes prevalence among the Australian population related to ethnic background. The greater level of obesity among South Europeans partly explained their higher diabetes prevalence, but the higher diabetes rate among Asians, despite less central obesity suggests current waist cut-offs for Asian populations may be too high.

428

Incidence and prevalence of diabetes among Inuit in Alberta, Canada, 1995 to 2006L.W. Svenson¹, R.L. Campbell², J.A. Johnson³¹Community Health Sciences, University of Calgary, ²Continuing Education, Concordia University College of Alberta, ³Public Health Sciences, University of Alberta, Edmonton, AB, Canada

Background and aims: It is generally known that the prevalence of diabetes is significantly higher among indigenous populations. In Alberta, there is solid evidence of this disparity for Aboriginals holding treaty status under the Canadian Indian Act. However, little is known about the epidemiology of diabetes among the Inuit in Canada. The purpose of this analysis was to examine the incidence and prevalence of diabetes among Inuit compared with status Aboriginals and the non-Aboriginal population.

Methods: The Alberta Diabetes Surveillance System (ADSS) tracks population trends in diabetes based on International Classification of Disease (ICD) diagnostic codes in physician (ICD-9-CM) and hospital claims (ICD-9 and ICD-10-CA) from administrative records collected by Alberta Health and Wellness. We applied the diabetes case definition based on the Canadian National Diabetes Surveillance System for adults aged 20 years and older. Incidence and Prevalence were tracked from 1995 to 2006. All rates were age-standardized to the 2001 Alberta population using the direct method. The federal government pays health insurance premiums on behalf of status Aboriginals in Canada. As a result the Alberta Health Care Insurance Plan identifies these individuals. Among the groups included are the Inuit.

Results: In 2006, the prevalence of diabetes was 4.3% (95% C.I. 4.28, 4.32), 6.2% (95% C.I., 4.8, 7.7) and 11% (95% C.I., 10.6, 11.3) for non Aboriginal, Inuit, and Status Aboriginals respectively. From 1995 to 2006, prevalence increased 51.8% for non Aboriginals, 24.5% for status Aboriginals, and 115.5% for Inuit. The incidence of diabetes was highest among status Aboriginals (6.5 per 1,000) followed by the Inuit (6.2 per 1,000) and the non Aboriginal population (3.7 per 1,000). From 1995 to 2006, incidence increased 44.1%, 1.7% for non Aboriginal and status Aboriginals respectively. The incidence fluctuated from year to year among the Inuit, due to their relatively small population, ranging from a low of 1.1 per 1,000 in 1999 to a high of 9.5 in 2005. In 2006, the incidence was 3.6 per 1,000.

Conclusion: The prevalence of diabetes among Inuit in Alberta is higher than the general population, but lower than status Aboriginals. However, the rate of increase in prevalence among the Inuit is greater.

Risk of non-trauma lower extremity amputation in patients with type 1 diabetes - a population-based cohort study in SwedenJ. Miao Jonasson¹, W. Ye², P. Sparén², J. Apelqvist³, O. Nyrén², K. Brismar¹¹Molecular Medicine and Surgery, Karolinska Institutet, Stockholm,²Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm,³Medicine, Lund University Hospital, Lund, Sweden

Background and aims: To estimate the risk of non-trauma lower extremity amputations (LEAs) in patients with type 1 diabetes mellitus (T1DM).

Materials and methods: We identified, in the Swedish Inpatient Register between 1975 and 2004, 31354 patients (15001 women and 16353 men) who had been hospitalized for diabetes before age 31 years. They were followed for non-trauma LEA through cross-linkage in the Inpatient Register until December 31, 2004. Information on censoring was obtained through linkages to the Death and Migration registers. Poisson regression modeling was used to compare the risk of LEAs in different calendar periods of follow-up, simultaneously adjusting for gender and attained age at follow-up. Standardized incidence ratio (SIR) was used to estimate the relative risk with the age-, sex-, and calendar-period-matched Swedish general population as reference. The cumulative probability of LEA was calculated using the Kaplan-Meier method.

Results: In total, 465 T1DM patients underwent LEAs. The risk had decreased in the most recent calendar period (2000-2004) compared to the period before 2000 (relative risk = 0.6, 95% confidence interval [CI] 0.5-0.8). However, even in the most recent period, these fairly young patients had 86-fold risk of LEAs (SIR = 85.8, 95% CI 72.9-100.3) compared with the matching general population. By the age of 65 years, the cumulative probability of a LEA was 11.0% for women, and 20.7% for men.

Conclusion: Despite of a tendency of decreased risk in recent calendar period, patients with type 1 diabetes are still at very high risk for LEAs.

Glycaemic goal and comorbidities of elderly patients with type 2 diabetes mellitus in the USM. Bron¹, F.T. Shaya², X. Yan², B.J. Pandya¹, R.W. Baran¹¹Global Health Economics and Outcomes Research, Takeda Global Research & Development Center, Inc., Deerfield, United States, ²Pharmaceutical Health Services Research, University of Maryland, Baltimore, United States

Background and aims: Diabetes affects a substantial proportion of the US population. Among US adults 65 years or older, the prevalence of diagnosed diabetes was 15.3% in the National Health and Wellness Survey (NHANES) data sample (1999-2002); when applied to the 2000 US census population, this represented 5.4 million individuals. Effective treatment of type 2 diabetes mellitus (T2DM) in elderly patients is especially challenging for several reasons, including an increased prevalence of comorbidities such as hypertension, heart failure, renal insufficiency, and diabetic nephropathy. This study aimed to determine the estimated prevalence of T2DM, level of glycemic control, and comorbidities in elderly patients in the US.

Materials and methods: A cross-sectional study methodology was used to examine 6 years of patient data. Elderly patients (≥ 65 years of age) with T2DM were identified from the US NHANES from 1999 to 2004. T2DM, hypertension, renal insufficiency, and heart failure were identified by physician diagnosis. Nephropathy was defined as the presence of microalbuminuria (albumin/creatinine ratios 30-299 $\mu\text{g}/\text{mg}$) or macroalbuminuria (albumin/creatinine ratios ≥ 300 $\mu\text{g}/\text{mg}$). Renal insufficiency was defined further by the question "Had the doctor ever told you had weak/failing kidneys?" Current use of insulin and oral antidiabetic drugs (OADs) were based on self-reporting. Targets for glycemic control were defined as HbA1c $< 7.0\%$ and $< 6.5\%$, as proposed by the ADA and the EASD, respectively. Data were analyzed using SAS version 9.1.

Results: Results of our analysis found the prevalence of T2DM in the elderly over the years 1999 to 2004 was 16.6%. Of these patients, most were women

(56.6%) 65 to 74 years of age (58.9%); 34.1% were 75 to 84 years of age, and 7.1% were 85 years or older. Mean (SD) HbA1c in these elderly patients was $7.0\% \pm 1.2\%$ (median [range], 6.8% [4.3% to 14.3%]); $43.8 \pm 2.6\%$ and $60.0 \pm 2.4\%$ of patients did not achieve the HbA1c target of $<7.0\%$ and $<6.5\%$, respectively. Approximately 14.5% of elderly patients relied on diet and exercise alone as a treatment option. Most elderly patients were treated with OAD alone (56.4%); the remainder was treated with insulin alone (18.7%) or a combination of OADs and insulin (10.5%). Hypertension, present in 73.1% of patients, was the most prevalent comorbid disease. Nephropathy, represented by the presence of micro- or macroalbuminuria, was present in 38.1% of patients and was the second most prevalent comorbid disease. Heart failure, renal insufficiency, microalbuminuria, and macroalbuminuria were present in 19.0%, 10.6%, 27.1%, and 11.0% of patients, respectively.

Conclusion: Results of this study suggest that the prevalence of T2DM has increased in the elderly and that the majority of these patients are treated by OADs alone. Additionally, a large percentage of elderly patients with T2DM have substantial comorbidity burden. Thus, more effective therapeutic management is needed for elderly patients with T2DM. Therapy selection demands careful consideration of prevalent comorbidities such as hypertension, nephropathy, renal insufficiency, and heart failure.

Natural course of health-related quality of life in screen-detected type 2 diabetes patients and effects of a multifactorial, intensified treatment.

The ADDITION Netherlands Study

M. Van den Donk, K.J. Gorter, G.E.H. Rutten

Julius Center for Health Sciences and General Practice, University Medical Center Utrecht, Netherlands

Background and aims: Type 2 diabetes mellitus is related to worsened health-related quality of life (HRQOL). However, not much is known about the course of HRQOL after development of type 2 diabetes and the influence of intensified treatment. In this study, we examine the effects of a multifactorial, intensified treatment on HRQOL, and the course of HRQOL in screen-detected type 2 diabetes patients until 3.5 years after diagnosis.

Materials and methods: This study is the Dutch part of the ongoing ADDITION Study (Anglo-Danish-Dutch Study of Intensive Treatment in People

with Screen-detected Diabetes in Primary Care). In this cluster randomised controlled trial, 498 screen-detected type 2 diabetes patients from 77 general practices are assigned to intensified ($n=255$) or routine treatment according to Dutch guidelines ($n=243$). At baseline and yearly thereafter, patients filled out the Euroqol-5D and Short-Form(SF)-36 questionnaires. We analysed the effects of intensified treatment on HRQOL, and the course of HRQOL using random effects models to account for clustering and time effects.

Results: There were no differences between intensified and routine treatment on HRQOL. Therefore, we analysed the course of HRQOL in the total study population. At follow-up, patients scored lower on the SF-36 scale Social Functioning, and higher on the scales Mental Health, Physical Functioning, Vitality, and General Health, compared with baseline. During 0.5 and 3.5 years of follow-up, the scores did not significantly change.

Conclusion: Multifactorial, intensified treatment does not influence HRQOL in screen-detected DM2 patients. Therefore, healthcare professionals do not have to fear negative effects of an intensified treatment on HRQOL. After screen-detection of DM2, HRQOL improves on the SF-36 scales Mental Health, Physical Functioning, Vitality, and General Health, and worsens on the scale Social Functioning. During the next three years, HRQOL remains stable. This may be the effect of treating the disease.

Time to anti-hyperglycaemic treatment increases with age in patients with type 2 diabetes mellitus (T2DM) in the UK

P. MAVROS, C. Zhao, C.M. Alexander

Global Outcomes Research, Merck & Co. Inc., Whitehouse Station, United States

Background and aims: T2DM is a chronic metabolic disease with increasing incidence and prevalence with age. Adequate glycaemic control is essential in reducing the risk of various micro and macro vascular complications associated with T2DM. This study was undertaken to examine whether there have been differences in treatment rates or changes in treatment trends across different age groups in the UK from 1995 to 2005.

Materials and methods: This retrospective cohort study used a sample from the MediPlus (UK) database that covers 1.8 million patients from general practitioners throughout the UK. Included in this study were newly diagnosed T2DM patients from 1995–2005 (index period). At the date (index date) of the first observed diagnosis (ICD10-CM code: E10–E14) patients were at least 30 years old with at least one year of recorded prior medical history and 2 subsequent years of recorded medical history. There were neither prior diagnoses of T2DM nor anti-hyperglycaemic treatments for at least 12 months prior to initial diagnosis. We examined the effect of age on the time to treatment and differences in treatment trends over time.

Results: 20,983 newly diagnosed T2DM patients were identified, 46.3% of which were female. The mean (standard deviation) age at time of diagnosis was 61.0 (12.6) years. The percent of patients in the age groups of 30–45, 45–65, 65–75, 75+ were 11.0%, 47.3%, 27.0%, and 14.7% respectively. The percentages of patients in these age groups without diabetic treatment 1 year after initial diagnosis are 49.0, 57.6, 62.6 and 64.7 respectively; at 2 years after initial diagnosis are 40.1, 47.1, 53.3 and 58.0 respectively. The hazard (to treatment) ratio (HR) associated with one additional year of age was .988 ($p<0.0001$). There is a time trend towards faster treatment times from 1995 to 2005 (HR 1.021; $p<0.0001$). These trends were mostly evident among the 30–45 and 45–65 age groups (HR: 1.069 and 1.036 respectively; $p<0.0001$) than in the 65–75 or 75+ age groups (HR 1.01; $p=0.1703$ and 0.982 ; $p=0.0856$ respectively).

Conclusion: In this cohort of newly diagnosed T2DM patients, we observed consistently lower treatment rates with antihyperglycemic medications for older individuals. Differences in the treatment rates by age are attributed to increasing treatment rates for younger patients over time. Treatment rates for elderly patients have remained constant and lower than younger patients.

* $P<0.05$ compared with baseline

Diabetes in the UK: trends in the prevalence, incidence and treatment 1996–2005E.L. Massó González¹, S. Johansson^{2,3}, M.-A. Wallander^{2,4}, L.A. García-Rodríguez¹¹CEIFE, Centro Español de Investigación Farmacoepidemiológica, Madrid, Spain, ²AstraZeneca, Mölndal, Sweden, ³Institute of Medicine, Sahlgrenska Academy, Göteborg University, Sweden, ⁴Department of Public Health and Caring Science, Uppsala University, Sweden**Background and aims:** There are limited data from longitudinal studies on time trends and treatment patterns of diabetes in the UK. The aim of this study was to estimate the incidence, prevalence, and changes in treatment of type 1 and type 2 diabetes in the UK general population from 1996 to 2005.**Materials and methods:** Using The Health Improvement Network database, we identified patients with type 1 or type 2 diabetes who were aged 10–79 between 1996 and 2005. Prevalent cases ($n = 49\,999$) were separated from incident cases ($n = 42\,642$; type 1 = 1256, type 2 = 41386). Data were collected on treatment patterns in incident cases, and on BMI in prevalent and incident cases.**Results:** Incidence of diabetes in the UK increased from 2.7 per 1000 person-years in 1996 to 4.4 per 1000 person-years in 2005. Incidence of type 1 diabetes remained relatively constant throughout the study period; however, incidence of type 2 diabetes increased from 2.6 per 1000 person-years in 1996 to 4.3 per 1000 person-years in 2005. Between 1996 and 2005, the proportion of individuals newly diagnosed with type 2 diabetes who were obese increased from 46% to 56%. Diabetes prevalence increased by 54% over the course of the study, from 2.8% in 1996 to 4.3% in 2005. Treatment of both type 1 and type 2 diabetes with metformin increased across the study period, while treatment with sulfonylureas decreased. In 1996, no patients with type 1 diabetes were treated with glitazone; however, by 2005 it was being prescribed to a small number of patients. We stratified the different treatments by BMI and noted that in 2005 metformin was the most prescribed diabetes treatment among obese diabetic type 2 patients, while sulfonylureas was in 1996.**Conclusion:** The prevalence and incidence of diabetes have increased in the UK over the past decade. This increase might be primarily explained by the changes in obesity prevalence. Changing diagnostic criteria over time could have influenced our findings. Finally, in the last ten years there was also a change in the treatment pattern from sulfonylureas to metformin.

Relation between glycaemic control and mortality in patients with type 2 diabetes in daily practice (Zodiac-11)G.W.D. Landman^{1,2}, N. Kleefstra^{2,3}, S.J.J. Logtenberg², K.H. Groenier⁴, S.T. Houweling^{3,2}, H.J.G. Bilo^{2,5}¹Internal Medicine, Isala clinics, Zwolle, Netherlands, ²Diabetes Centre, Isala clinics, Zwolle, ³Medical Research Group, Langerhans, Zwolle, ⁴General Practice, UMCG, Groningen, ⁵Internal Medicine, UMCG, Groningen, Netherlands**Background:** Recently, the relationship between the degree of glycaemic control and all-cause mortality in type 2 diabetes (T2DM) has been questioned. Therefore we analyzed mortality risk in a large group T2DM patients, stratified in different HbA1c ranges.**Material and Methods:** The ZODIAC study started in 1998 as part of a shared care diabetes project in the Netherlands. A group of 1143 patients with T2DM was enrolled that year and seen annually. Data on mortality were assessed after an average period of 5.8 years. Mortality rates were evaluated using standardized mortality ratios (SMR).Cox Proportional Hazard Modeling was used to assess the association between HbA1c and (cardiovascular and all-cause) mortality. Separate analyses were made for HbA1c as a continuous variable and as a grouped variable (<6, 6–7, 7–8, 8–9, ≥ 9). For visualization of the results, a Kaplan-Meier curve was made. The following variables were included in the model as possible confounders: Age, gender, smoking (never, previous and current), duration of diabetes, Cockcroft, body mass index, systolic blood pressure, Chol/HDL, macrovascular complications (yes or no), use of statins (yes or no), insulin use (yes or no), and albuminuria (yes or no).**Results:** The study population consisted of 653 women and 490 men. Median HbA1c at baseline was 7.3% (interquartile range: 6.6–8.3), and 335 (31%) patients died. SMR for all cause mortality was 1.86 (CI 1.66–2.06), and for cardiovascular mortality 2.24 (CI 1.91–2.61).

The hazard ratios (HRs) of HbA1c as a continuous variable was 1.19 (95%CI: 1.08–1.31) for all-cause mortality.

HRs for the HbA1c groups 6–7, 7–8, 8–9 and ≥ 9 were 0.92 (CI 0.55–1.55), 1.06 (CI 0.63–1.79), 1.43 (CI 0.84–2.46), 1.80 (CI 1.02–3.17) (figure 1; survival curve) compared to HbA1c <6 ($n=100$) for all-cause mortality.**Conclusion:** Poorer glycaemic control is associated with increased all-cause mortality; this is in confirmation with the results of the UKPDS-study. A recent trial concluded that intensive therapy, resulting in HbA1c values below 6%, is associated with increased mortality. The very small differences in mortality in the lower HbA1c cohorts in our study, which was not an intervention study, but an example of daily diabetes practice, indeed suggested that there is no basis for an ever decreasing target level of HbA1c in type 2 diabetes mellitus, at least not with the current therapeutical arsenal.

Functional characterisation *in vivo* and *in vitro* of encapsulated insulin-producing cells derived from mouse embryo progenitor

S. Shao, F. Xie, G. Li

National University Medical Institutes, Yong Loo Lin School of Medicine, National University of Singapore, Singapore

Background and aims: Type 1 diabetes is an autoimmune disease caused by the destruction of pancreatic β -cells. It is traditionally treated with insulin replacement therapy by injection or insulin pump. However, such treatment involves complicated administration and is unable to cure the disease. Consequently, alternative approaches are being explored for developing better therapy.

Materials and methods: We generated lines of insulin-producing cells, named MEPI (Mouse Embryo Progenitor-derived Insulin-producing) cells, from differentiating mouse early embryo-derived progenitor cells. Detached MEPI-1 cells were cultured overnight in suspensions before mixed up with barium alginate (5 million cells in 1 ml alginate) to generate microcapsules (500 μ m) using an electrostatic encapsulator. Insulin secretion capability of encapsulated cells was assessed before and after transplantation. An aliquot of capsules containing 2.5 million MEPI-1 cells were peritoneally transplanted into each immune-competent, streptozotocin-induced diabetic mouse (C57J and Balb/c) with blood glucose levels >350 mg/dL. The transplanted capsules were washed out at different intervals for assessments of insulin fluorescence staining and cell growth rates.

Results: Dose-response study revealed that glucose-stimulated insulin secretion from attached MEPI-1 cell monolayer reached a maximum at 11.2 mM glucose. However, insulin secretion was further increased by 1.8 folds when glucose elevated from 8.4 to 16.7 mM in freshly made capsules. After transplantation of encapsulated cells, the diabetic mice become normoglycemia in 1–3 days and then developed hypoglycemia at various degrees (40 ± 6 mg/dL, $n=10$). Despite that, these mice exhibited similar physical activity and body weight to the non-diabetic controls. When capsules were washed out during this period, a relapse of hyperglycemia occurred immediately, and positive insulin staining was found within the capsules. Separate experiments showed that about 2 months after implantation, all the mice regained hyperglycemia; the days between capsule transplantation and relapse of hyperglycemia were 52.2 ± 4.5 ($n=10$). The number of transplanted MEPI-1 cells per capsule increased initially (5–9 folds) and then decreased after 90 days transplantation on average. Additionally, the doubling time of cell population *in vivo* varied from 7–14 days within 42 days after transplantation, longer than that (~ 3.2 days) of attached MEPI-1 cells cultured *in vitro*. Moreover, the blood glucose level started to increase when the cell number in capsules decreased below that in the originally transplanted ones. Similar results were obtained in both strains of C57J and Balb/c mice.

Conclusion: These results indicated that encapsulated MEPI-1 cells displayed an improved dose-response of glucose-stimulated insulin secretion over the attached cells. Transplantation of encapsulated MEPI-1 cells could correct hyperglycemia in immune-competent diabetic mice. Cells in capsules were still able to grow *in vivo* but in a slower rate, while maintaining the function of insulin secretion for a considerable period. However, the capsule-transplanted mice eventually returned back to hyperglycemic apparently due to the failure of implanted cells during the protracted term.

Proliferation of dedifferentiated adult human pancreatic beta cells *in vitro* revealed by cell-lineage tracing

H.A. Russ¹, Y. Bar¹, P. Ravassard², S. Efrat¹

¹Human Genetics and Biochemistry, Tel Aviv University, Israel, ²National Center for Scientific Research, Pierre and Marie Curie University, Paris, France

Background and aims: Expansion of insulin-producing beta cells from adult human cadaver islets could alleviate donor shortage for cell-replacement therapy of diabetes. A major obstacle to development of effective expansion protocols is the rapid loss of beta-cell markers in the cultured cells. We developed a genetic cell-lineage tracing approach for following the fate of cultured beta cells.

Materials and methods: Cells dissociated from isolated human islets were infected with 2 lentiviruses, the first expressing Cre recombinase under control of the insulin promoter, and the second a reporter cassette with the structure CMV promoter-loxP-DsRed2-loxP-eGFP.

Results: Beta cells were efficiently labeled by the dual virus system. Dedifferentiated cells derived from beta cells were shown to proliferate for a maximum of 16 population doublings. Labeled cells could be isolated and expanded in the absence of other pancreas cell types, if provided with medium conditioned by non-beta pancreatic cells.

Conclusion: Our findings provide for the first time direct evidence for dedifferentiation, survival, and replication of cultured adult human beta cells, unlike mouse beta cells. The tracing system will allow optimization of beta-cell expansion for transplantation. These findings demonstrate the feasibility of cell-specific labeling of cultured primary human cells, using a genetic recombination approach that was previously restricted to transgenic animals.

Expression of pluripotent stem cell markers within intact adult human pancreas and proliferative adherent cell cultures derived from digested pancreas

H.R.H. Al-Turaifi¹, A.I.M. Aldibbia¹, G.N. Holliman¹, S.C. Campbell¹, J.A.M. Shaw¹, G.G.C. Huang², S.G.C. Amiel²

¹Clinical Medical Sciences, North East England Stem Cell, Newcastle Upon Tyne, United Kingdom, ²School of Medicine, Department of Diabetes, King's College London, United Kingdom

Background and aims: Pancreatic β -cell replacement offers the potential of a 'cure' for Type 1 diabetes. Shortage of suitable donors limits widespread implementation of this approach. Recent research has been focussed on potential new sources of β -cells. The existence of true stem cells within pancreas remains contentious. The aim of this study was to investigate expression of the classical stem cell markers Oct4, Sox2, Nanog and ABCG2 in adult human pancreas and evaluate potential for isolation and maintenance of stem cell marker +ve cells in proliferative culture.

Materials and methods: Human pancreatic tissue was obtained from deceased donors following ethical approval and relative consent. Unmanipulated pancreas was snap frozen for sectioning and immunofluorescence staining for differentiated / stem cell markers. Islet and ductal / exocrine-enriched fractions from fresh pancreas were separated by collagenase digestion and density gradient centrifugation. Purified cell fractions were seeded in adherent culture with proliferative 'islet survivor cell (ISC)' and 'ductal / exocrine survivor cell (DESC)' cultures established and characterised by RT-PCR / immunocytochemical staining.

Results: Pancreatic expression of Oct4 was confirmed by positive staining localised in close proximity to ducts and within islets. There was no co-localisation with CK19-expressing differentiated duct cells or insulin-expressing mature β -cells. Expression of Oct4, Sox2, Nanog and ABCG2 in addition to differentiated markers for endocrine, exocrine, ductal and mesenchymal phenotype was confirmed by RT-PCR in isolated islets and ductal / exocrine-enriched cell fractions. ISCs were maintained in proliferative culture for up to 12 passages with maintained expression of Oct-4 +ve cells in addition to proliferative Ki67 +ve ductal cells. DESCs were maintained in proliferative culture for up to 10 passages with persistence of a single ductal (CK19 +ve) / mesenchymal (vimentin +ve) / β -cell precursor PDX1 +ve) phenotype. Oct4 expression was lost by passage 3, while Sox-2 and ABCG2 mRNA expression were maintained at late passage.

Conclusion: Expression of classical stem cell markers has been confirmed in unmanipulated adult human pancreas with maintained expression in proliferative cell cultures. Further studies are required to elucidate the potential for β -cell neogenesis from these survivor cells.

Retinoid acid attenuates amylase expression in human embryonic stem cells-derived endoderm and improves hepatic fate

J.K. Mfoupou¹, B. Chen², L. Sui¹, K. Sermon², J. Van der Elst², L. Bouwens¹

¹Cell Differentiation Unit, Vrije Universiteit Brussel, ²Stem Cell Lab - Centre for Reproductive Gynecology, Vrije Universiteit Brussel, Belgium

Background and aims: Human embryonic stem cell (hESC) derivatives are now regarded as potential surrogates for cell therapy. Many patients suffering

from various diseases would benefit from it provided the in vitro differentiation of functional cells is well mastered. As far as diabetes is concerned, hESC have been coaxed towards insulin-producing cells, but the differentiation efficiency and functional status of these cells remain to be improved. In an attempt to design a better protocol, we sequentially cultured hESC in the presence of several growth factors and chemicals previously described as improving pancreas differentiation.

Materials and methods: The hESC line VUB07 generated and characterized in our institute was maintained undifferentiated on inactivated mouse embryonic fibroblasts and differentiated into definitive endoderm by treatment with ActA (50 ng/ml) and Wnt3a (25 ng/ml), with or without BMP4 (8 ng/ml) and ITS supplement (1x) for 4 days. Retinoic acid (2.5–10 μ M) and ITS (1x) were added for 2 days and the cells further maintained in low FCS (2%), FGF2 (5 ng/ml), ActB (10 ng/ml) and KAAD-Cyclopamine (250 nmol/l) for 4 days. During the last 5 days, Cyclopamine and ActB were replaced by Nicotinamide (10 mmol/l). Pancreatic and hepatic markers were analyzed at each stage by immunocytochemistry and PCR.

Results: Definitive endoderm was induced in this system as evaluated by Sox17 and Foxa2 co-expression (up to 60%) on day 4. Analysis of pancreatic markers indicated that in the absence of retinoic acid treatment, a large majority of differentiated cells (50–60%) strongly express amylase and low levels of Pdx1. On the contrary, addition of retinoic acid (days 4 to 6) attenuated amylase expression in the progenies, but did not result in a significant increase in Pdx1 expression. Furthermore, retinoic acid considerably improved the generation of albumin-expressing hepatocyte-like cells organized in colonies that co-expressed Foxa2, in contrast to the rare albumin-positive cells observed in its absence. The role of retinoic acid in this process and in hepato-pancreas development is further discussed.

Conclusion: Sequential exposure of hESC to growth factors and chemicals would allow controlling their differentiation towards desired progenies such as pancreatic cells needed in diabetes cell therapy. hESC-derived definitive endoderm was easily converted to amylase-expressing cells within 2 weeks, whereas its early treatment with retinoic acid shifted the progenies to a hepatic fate. This negative effect of retinoic acid on exocrine pancreas differentiation is concordant with data from mouse studies, but does not support the established requirement of retinoic acid for pancreas induction from the endoderm.

Generation of insulin-synthesising pseudo-islets from adult stem cell cultures derived from the human pancreas

A. Aldibbiat¹, G.N. Holliman¹, H. Al-Turaifi¹, S.C. Campbell¹, G. Huang², J. Shaw¹

¹Diabetes Research Group, Newcastle University, ²Diabetes Research Group, King's College London, United Kingdom

Background and aims: Despite nearly 90 years of insulin therapy, diabetes remains a leading cause of blindness, kidney failure and amputation. Intensive conventional treatment can reduce risk of complications but is associated with increased risk of hypoglycaemic collapse. True sustainable normalisation of blood glucose in Type 1 diabetes can only be achieved through replacement or regeneration of functional beta cells with insulin release in response to glucose and other stimuli. While this is possible through transplantation of whole pancreas or isolated islets retrieved from deceased donors, organ availability is sufficient for <1% of potential recipients. The aim of the current study was to derive and characterise proliferative progenitor cells from adult human pancreas and to explore potential for generation of new insulin-synthesising cells.

Materials and methods: A proliferative population of adherent cells, termed islet survivor cells (ISCs), was derived from isolated human islets following 3 day culture in serum-supplemented CMRL medium. Cellular aggregates,

termed pseudo-islets, were generated following culture of ISCs in serum-free CMRL medium. Expression of stem cell and pancreatic markers was determined by RT-PCR and ICC in ISCs and differentiated pseudo-islets. Insulin and C-peptide content was quantified by ELISA.

Results: Maintained proliferative capacity was demonstrated up to passage 10 with preserved expression of Oct4, Vimentin and cytokeratin-19 in addition to insulin, PDX1, Pax4, Glut2, Glut1, Sur1 and glucokinase. Stem cell phenotype was confirmed by positive Oct4 in addition to cytokeratin-19 and vimentin immunostaining. Endocrine phenotype was confirmed by insulin, C-peptide, glucagon, pancreatic polypeptide and somatostatin immunostaining. Differentiated pseudo-islets demonstrated down-regulation of stem cell markers in addition to positive fluorescence with the Newport Green zinc indicator, characteristic of insulin-rich beta cells. C-peptide storage and release was significantly higher in differentiated pseudo-islets in comparison to ISCs (C-peptide storage: 3.7 ± 0.03 vs 1.8 ± 0.009 pmol/million cells (mean \pm SD), $p=0.02$. Secretion: 5.1 ± 0.02 vs 3.4 ± 0.009 pmol/million cells/24 hours, $p=0.04$).

Conclusion: Presence of stem cells within proliferative adult human pancreas cultures has been confirmed with continued expression of end-differentiated islet phenotypic markers. Generation of new islet-like clusters with enhanced ability to store and secrete human C-peptide has been attained in vitro.

Pancreatic duodenal homeobox 1 expression is not essential for differentiation of mouse bone marrow mesenchymal stem cells into insulin-producing cells

Y. Hamamoto, N. Inagaki

Department of Diabetes and Clinical Nutrition, Kyoto University Graduate School of Medicine, Japan

Background and aims: Several published papers have reported that bone marrow mesenchymal stem cells (BM-MSCs) have the capacity to differentiate into insulin-producing cells (IPCs). Pancreatic duodenal homeobox-1 (Pdx1) plays a key role in the development of pancreas, and is reported that its ectopic expression induces transdifferentiation into pancreatic endocrine cells from pancreatic duct cells, hepatocytes, or BM-MSCs. Glucagon-like peptide-1 (GLP-1) is reported to promote islet neogenesis and reduce β -cell apoptosis. Here we examined the effect of constitutive Pdx1 expression and exendin-4 (Ex4) stimulation in cultured mouse BM-MSCs on differentiation into IPCs, and evaluated the expression of genes of β -cell specific transcription factors and hormones.

Materials and methods: BM-MSCs were isolated from femurs and tibias of C57BL/6 mice, and cultured under defined conditions. Pdx1 expression vector was made by insertion of cloned Pdx1 gene into the downstream of CMV promoter, and the vector for control was made by inserting green fluorescence protein (GFP) gene instead of Pdx1 gene. Transfection of the vectors was carried out by lipofection on day 10–14. Ex4 (10nM) was added into culture medium at multiple time points to evaluate the effect. Four experimental groups were made by the combination of Pdx1 or GFP vector transfection and the addition of Ex4 or PBS in culture medium. On day 7, 21 and 42, cells were collected and expression of β cell specific genes such as insulin 1 (INS1), insulin 2 (INS2), Pdx1, glucose transporter 2 (GLUT2), glucokinase (GK), Neurogenin 3 (Ngn3), and GLP-1 receptor was assessed using RT-PCR. Insulin content and pdx1 expression was examined using ELISA assay and immuno-staining, respectively.

Results: After plastic adherence selection, BM-MSCs were cultured until 42 days. At first, MSCs showed spindle and fibrocyte-like appearance, but gradually some of the cells started to show morphological change into spherical appearance. Around day 14 to 21, a part of the cells aggregated and formed islet-like clusters. In order to determine whether the cells had differentiated into IPCs, mRNA expression profiles were assessed. Not only Pdx1 transfected group but also GFP transfected group, insulin expressions were observed. The probability of insulin mRNA expressions detected by RT-PCR in the two groups was about a half of total cultured dishes, and was not significantly different. Analysis of β -cell specific gene expression profiles in IPCs revealed that IPCs are expressing GK, GLUT2, and GLP-1 receptor, suggesting that the cells are equipped with machineries essential for insulin secretion. However, in the analysis of IPCs in GFP transfected group, although the expressions of β -cell specific genes were detected, Pdx1 expression was found to be absent or quite low level, and it was not different even at the early phase of differ-

entiation evaluated on day 7. Ex4 stimulation increased probabilities of IPC differentiation by 1.5 fold without increasing endogenous Pdx1 expression.

Conclusion: Although Pdx1 is an essential factor in the development of pancreas, our data suggest that pdx1 expression is not required for differentiation of mouse BM-MSCs into IPCs, and enhanced expression of Pdx1 is not enough to generate IPCs. Ex4 could increase differentiation into IPCs, suggesting that GLP-1 signal is more favorable to generate IPCs from BM-MSCs.

Human placental lactogen-A and human fibroblast growth factor-2b induce ductal PANC-1 cells to form beta cell like aggregates

M.F. Lombardo¹, K. Basello¹, D. Pastore¹, F. Ferrelli², B. Capuani¹, A. Coppola¹, M. Tesaro¹, P. Sbraccia¹, M. Federici¹, G. Donadel¹, D. Lauro¹

¹Department of Internal Medicine, University of Rome Tor Vergata, Rome,

²IRCCS, San Raffaele, Pisana, Rome, Italy

Background and aims: The increasing number of Diabetic patients (Type 1 and 2 DM) and the encouraging results obtained from islet transplantation has driven many scientists to deeply analyze the process of beta-cell development from precursor/staminal cells. Several evidences suggest that ductal cells or precursor/staminal cells present in the ductal layer could originate beta cells during adult life. It has been shown that mouse Placental Lactogen (PL) expression in pancreatic beta cells result in hyperplasia and hypertrophy that could be mediated by prolonged beta cell survival or by increased beta cell proliferation. There are also evidences from mice studies that attenuation of Fibroblast Growth Factor (FGF)-2b Receptor 1c signaling in the pancreas leads to beta-cell defects that are characteristic of Type 2 DM. This is characterized by reduced beta cells mass, impaired glucose sensing and perturbed pro-insulin processing. It has also been reported that FGF-2b can act in an autocrine/paracrine manner to stimulate the initial process of cell aggregation and cluster formation, an important step in the development and differentiation of endocrine pancreas. The aim of the present study is to investigate the ability of hPL-A and hFGF-2b to induce differentiation from ductal cells (PANC-1) into beta-like cells.

Materials and methods: PANC-1 cells have been treated with hPL-A, hFGF2b and hPL-A plus hFGF-2b for 96h, in order to induce islet-like cell aggregates. Then cell clusters have been analyzed by immunofluorescence and FACS to detect the expression of beta cell antigens (Insulin, PDX-1, Glut-2, Nkx6.1, Nkx2.2, and PAX-4) and ductal markers (Cytokeratin 19 and CA 19.9). Insulin concentration has been measured by RIA analysis in islet-like cell aggregates in basal condition (intracellular) and in response to glucose and potassium challenge. FACS analysis was performed to determine before and after cell differentiation the replication time of PANC-1 using Bromodeoxyuridine (BrdU) incorporation and apoptosis/necrosis using PI/Annexin V.

Results: Treatment with hPL-A, hFGF2b and hPL-A/hFGF-2b for 96h induced PANC-1 differentiation to islet-like cell aggregates. The newly cell aggregates showed an increased expression of Insulin, PDX-1, Glut-2 and C-peptide. In particular the co-treatment with hPL-A/hFGF-2b improved expression of Insulin (+20%; $p<0.05$), PDX-1 (+40%; $p<0.05$), Nkx2.2 (+45%; $p<0.01$), Nkx6.1 (+35%; $p<0.05$) and, interestingly, hPL-A/hFGF-2b co-treatment reduced the expression of the typical ductal cell marker Cytokeratin19 (-35%; $p<0.01$). We also found that islet-like cell aggregates induced by hPL-A/hFGF-2b treatment were able to secrete insulin after glucose and potassium stimulation. BrdU incorporation after 48h and 96h of treatment showed a reduction of cells in S-phase (-20% and -18%, respectively; $p<0.01$), as well as a reduction in the number of apoptotic and necrotic cells, confirming the idea that hPL-A/hFGF-2b can induce cell differentiation.

Conclusion: hPL-A/hFGF-2b treatment induce PANC-1 differentiation to islet-like aggregates that are able to secrete insulin in response to glucose, suggesting a role for these two growth factors/hormones in inducing beta cell neogenesis and differentiation towards an endocrine phenotype.

Selective removal of residual undifferentiated embryonic stem cells from differentiation cultures

O. Naujok, S. Lenzen

Institute of Clinical Biochemistry, Hannover Medical School, Germany

Background and aims: Embryonic stem (ES) cells have the potential to produce unlimited numbers of surrogate insulin-producing cells for cell replacement therapy of type 1 diabetes mellitus. However, the transplantation of differentiated ES cells harbors the risk of uncontrolled proliferation and onset of tumors such as teratoma formation. In order to control teratoma formation and to minimize cellular overproliferation, ES cells must be generated with a negative selection marker such as a suicide gene. Here we report the generation of a mouse ES cell line, which expresses a splice-corrected variant of the HSV1 thymidine kinase and eGFP under the control of the Oct4 promoter for negative selection and ablation of undifferentiated ES cells.

Materials and methods: A 3 kb promoter fragment of the human *Pou5f1* gene (Oct4) was cloned to drive the expression of a splice-corrected variant of the HSV1 thymidine kinase and eGFP in a bicistronic gene cassette. Mouse ES-D3 cells were stably transfected and eGFP positive cells were selected and characterized. Clonal HSVtk⁺ cells were subjected to a short differentiation protocol and the cultures were treated with ganciclovir for negative selection of residual undifferentiated cells. Treated HSVtk⁺ and untreated HSVtk⁺ cells were analyzed using quantitative RT-PCR, FACS and immunohistochemistry.

Results: The pOct4-scHSVtk-eGFP construct was successfully integrated into ES cells, called HSVtk⁺ cells. These cells remained pluripotent and stained positive for the embryonic markers SSEA-1, alkaline phosphatase, Oct4 and Nanog. Treatment with varying concentrations of ganciclovir revealed sensitivity to ganciclovir with an EC₅₀ value of 0.17 μ M. When HSVtk⁺ cells were differentiated for 19 days comprising a seven day treatment with 1 μ M ganciclovir the cells lost very quickly eGFP fluorescence while in the untreated group up to 40 % of the cells remained eGFP-positive. Staining for SSEA-1 showed negligible populations of SSEA1-positive cells in the treated group while in the untreated group the residual population of eGFP-positive cells remained also positive for SSEA-1. Staining for alkaline phosphatase showed undifferentiated clusters in the group of untreated HSVtk⁺ cells while in treated HSVtk⁺ cells alkaline phosphatase staining was very faint. Analysis of the gene expression of Oct4 revealed an 80 fold higher Oct4 expression in untreated HSVtk⁺ cells when compared to treated HSVtk⁺ cells. Nanog, as a second marker for ES cells, showed a 27 fold decrease in treated cells. Quantitative analysis of gene expression revealed a significant 25 fold lower expression of embryonic RAS (eRAS) in treated cells. Another embryonic marker, namely Sox2, showed also a decrease in treated cells. Immunohistochemical staining of Oct4 and Nanog revealed that cells with embryonic properties could be easily detected if the cells were not treated with ganciclovir. In treated cells Oct4 and Nanog was barely detectable.

Conclusion: ES cells offer great potential for cell replacement therapy. Besides the need for efficient differentiation protocols for generation of insulin-producing cells or other cell types, efforts must be undertaken to minimize the risk of tumor formation after transplantation of differentiated ES cells. Oct4 together with Nanog is a master regulator for pluripotency in embryonic stem cells. Our results show that the *Pou5f1* gene (Oct4) can be utilised to specifically target undifferentiated cells and to effectively remove these unwanted cells.

Intermediate filament expression in the adult and developing rat pancreas

E. Bertelli¹, A. Di Bella¹, M. Regoli¹, C. Nicoletti²¹Dept. of Pharmacology, Sect. of anatomy, University of Siena, Italy, ²GI Biology and Health Programme, Institute for Food Research, Norwich, United Kingdom

Background and aims: Intermediate filaments are frequently used as markers of cell differentiation. In order to assess if they can be useful to identify differentiating pancreatic cells, we have examined the pattern of expression of nestin, cytokeratin 20 (CK20) and vimentin in rat adult and developing pancreas

Materials and methods: Embryos from E12.5 up to E21.5 as well as pancreas from newborn, 3-days old, and adult rats were sampled and immediately frozen. Cryosections were fixed in cold acetone and laser scanning confocal microscope analysis was carried out on sections double-labelled with antibodies against nestin, vimentin or CK20 and markers of endocrine or exocrine cells. Double-labelling experiments were also carried out with antibodies anti-vimentin and anti-CK20

Results: In the developing gland CK20 was strongly expressed by duct cells, whereas endocrine cells showed a less intense staining and acinar cells were provided with a weak labelling that outlined a fine network of filaments. Since the beginning of the development of the dorsal and ventral pancreatic buds, some cells located within the dorsal pancreatic rudiment also displayed vimentin immunofluorescence. The number of these cells progressively increased with time, reaching its highest peak in newborn rats when most of the duct cells contained vimentin, and rapidly decreasing soon after. Acinar cells were always CK20-immunoreactive since the beginning of their cytodifferentiation but they never showed vimentin fluorescence. Since endocrine cells differentiate from precursor cells located in the epithelial lining of the primitive ducts we decided to verify whether vimentin-immunoreactive duct-like cells could be transitional cells in the process of differentiation into endocrine cells. Delta, beta and PP cells, though always containing a well-developed network of CK20 intermediate filaments, never showed vimentin-immunoreactivity at any time-point even in newborn animals when vimentin-containing duct cells were at their highest number. On the contrary, in addition to a network of CK20 filaments that was present throughout the entire development of the pancreas, alpha cells also displayed vimentin-immunoreactivity starting from the earliest gestational age studied (E12.5). At this stage of development almost all vimentin-containing cells within the dorsal pancreatic bud were alpha cells and even the reverse (i.e. alpha cells displaying a vimentin network) applied almost constantly (fig 5d-f). At E13.5 even the ventral pancreatic bud displayed the same pattern of staining. With time, however, alpha cells seemed to progressively lose vimentin filaments. Still, in newborn animals several vimentin-expressing glucagon cells could be easily found, but the number of these cells declined very quickly and after a few days from birth they were virtually absent. Nestin was observed exclusively in mesenchymal cells and in particular in endothelial cells of blood vessels

Conclusion: Under our experimental conditions CK20 is not an exclusive marker of duct cells. However, the pattern of its labelling still allows the identification of the three major cell types (duct, acinar, endocrine cells). Vimentin is expressed in cells located within pancreatic ducts from the beginning of pancreatic development. Its presence in glucagon-secreting cells likely identifies immature or recently differentiated alpha cells

444

Expression and function of lutheran, a laminin alpha5 binding glycoprotein receptor on human pancreatic islet cells

M. Banerjee¹, I. Virtanen², O. Korsgren³, T. Otonkoski¹¹Biomedicum Stem Cell Center, University of Helsinki, Finland, ²Institute of Biomedicine/Anatomy, University of Helsinki, Finland, ³Department of Clinical Immunology, University of Uppsala, Sweden

Background and aims: Lutheran blood group glycoprotein (Lu), and its truncated form known as BCAM, is a transmembrane protein of the immunoglobulin superfamily, which serves as a receptor for alpha5 chain of laminins (Lm), constituent of Lms-511 and -521. Lm-511 is found in many epithelial basement membranes (BMs) and recently we have identified it as

the sole laminin isoform of the BM surrounding human pancreatic islets. The high affinity of Lu/BCAM for laminin is thought to contribute to various developmental processes including organogenesis and vascular development. In red blood cells, Lu/BCAM is activated through cAMP signaling. The aims of the present study were (1) to examine the expression of Lu/BCAM in adult and fetal human pancreas and (2) to investigate its possible role in islet cell adhesion dependent or independent of cAMP.

Materials and methods: Frozen human pancreatic sections, freshly isolated islet cells (dispersed into single cells) and cultured endocrine cells (48 hours cultured) were used to examine the expression of Lu. Purified Lm511 and soluble recombinant Lu (sol-Lu) proteins were used for short-term adhesion experiments. Forskolin (activator of adenylate cyclase) and PKA-i (specific inhibitor of c-AMP dependent protein kinase A) were employed to examine cAMP dependency.

Results: Immunofluorescent staining of human pancreatic frozen sections showed bright immunoreactivity for Lu in a polarized fashion co-aligned with the BM Lm alpha5 chain surrounding islets. Faint immunoreactivity was recorded in the more centrally located islet cells. Human fetal pancreas at 17-22 gestational weeks showed an essentially similar pattern of Lu immunoreactivity. Competitive inhibition by sol-Lu in short-term adhesion experiments (90 min) resulted in severe impairment of islet cell adhesion (insulin and chromogranin-A positive cells) on Lm511 matrix, suggesting a central role of Lu in islet cell adhesion to Lm511. The inhibitory effect of sol-Lu was equal to that achieved with monoclonal antibodies against $\alpha 3$ and $\beta 1$ integrin subunits. To examine the role of cAMP signaling on Lu expression and islet cell adhesion, dispersed islets were pretreated with forskolin and/or PKA-i prior to adhesion to Lm511 matrix (overnight incubation). Forskolin treatment clearly enhanced islet-cell membrane expression of Lu. Quantitative analysis of cell adhesion showed significant enhancement of beta-cell adhesion by forskolin while PKA-i treated cells adhered poorly to Lm511.

Conclusion: The present study discloses Lu as a previously unrecognized laminin binding receptor on human pancreatic endocrine cells. Islet cell adhesion to Lm511 is at least partially mediated via Lu and is cAMP dependent. Further studies are required to undertake in order to establish a relationship between Lu and functional status of human islets.

Long lifespan and very low neogenesis and proliferation of human islet beta cells estimated by mathematical modelling of beta cell lipofuscin accumulation

M. Cnop^{1,2}, S.J. Hughes³, F. Sayeed⁴, L. van de Laar⁴, J.H. Gunter⁴,D.W.R. Gray³, P.R.V. Johnson³, B.C. Hansen⁵, J.F. Morris⁶,M. Pipeleers-Marichal⁷, I. Cnop⁸, A. Clark⁴¹Laboratory of Experimental Medicine, Universite Libre de Bruxelles, Belgium, ²Division of Endocrinology, Erasmus Hospital, Brussels, Belgium, ³DRWF Islet Isolation Facility, Churchill Hospital, Oxford, United Kingdom, ⁴Oxford Centre for Diabetes, Endocrinology and Metabolism, Churchill Hospital, Oxford, United Kingdom, ⁵Obesity, Diabetes, and Aging Research Center, University of South Florida, Tampa, United States, ⁶Department of Human Anatomy, Genetics and Physiology, University of Oxford, United Kingdom, ⁷Diabetes Research Centre, Vrije Universiteit Brussel, Brussels, Belgium, ⁸Department of Mathematics, Vrije Universiteit Brussel, Brussels, Belgium

Background and aims: The longevity of pancreatic islet β -cells in man is largely unknown. A decreased β -cell mass resulting from an imbalance in turnover of insulin-secreting pancreatic islet β -cells has been proposed as a contributory factor for type 2 diabetes. Lipofuscin body (LB) accumulation is a hallmark of ageing in post-mitotic cells. Using this marker, we estimated the proportion of newly formed human β -cells.

Materials and methods: Using electron microscopical morphometry, we examined the relationship of LB accumulation in β -cell sections (two dimensions) to age in islets of human donors (aged 1-81 years, n=50), human insulinoma cells and non-human primate islets (n=10). To estimate the proportion of lipofuscin-positive β -cells and the number and size of LBs in three dimensions, a three dimensional mathematical model was constructed using Mathematica software.

Results: The β -cell content of LBs increased with age. β -cell area of lipofuscin (% of cytoplasmic area) was highly correlated with donor age ($r=0.87$, $p<0.0001$), increasing from 0.03% of cytoplasm for the youngest donor to 14% in the oldest, and not different in type 2 diabetes (n=6). By multiple regression analysis, LB content was unrelated to body mass index. Modelling

of the total cellular lipofuscin content in 3D from the 2D data showed that, in the oldest individuals, total LB volume reached 35% of the cytoplasmic volume. LBs also accumulated in non-human primate β -cells ($r=0.88$, $p<0.001$). A low LB content, unrelated to patient age, was observed in human proliferative insulinoma cells. The percentage of human β -cell sections imaged which contained a cross-section of at least one LB positively correlated with age ($r=0.82$, $p<0.0001$). The percentage of LB-positive cell sections increased logarithmically from 7% at age 1 year to 100% at age 52, whereas it remained low in insulinoma cells (10–40%). The model indicated that the 3D LB-positive β -cell population (ageing cells) was >90% in the first decade of life and rising to close to 100% by age 20.

Conclusion: Our data suggest that *in vivo* in humans the proportions of LB-negative, newly formed β -cells are very low and that β -cells progressively accumulate LBs with time. Unlike the proposed scenario in rodents, neogenesis and/or replication are not major contributors to the islet β -cell population in humans. Ageing of long-living human β -cells could contribute to the decline of insulin secretion with age and to the onset of type 2 diabetes.

Beta cell regeneration in type 1 diabetes: the role of Reg genes in NOD mice

E. Astorri^{1,2}, M. Bombardieri², C. Guglielmi¹, C. Pitzalis², P. Pozzilli^{1,3}

¹Area Endocrinologia e Diabetologia, University Campus Bio Medico, Rome, Italy, ²Experimental Medicine & Rheumatology, Queen Mary University, Barts & the London, United Kingdom, ³Centre of Diabetes & Metabolic Diseases, Queen Mary University, Barts & the London, United Kingdom

Background and aims: Type 1 Diabetes (T1D) is an autoimmune disease characterised by pancreatic islet destruction. There is evidence that the beta-cell mass is not static but in a constant process of death and renewal. Reg genes, a multigene family discovered by screening the cDNA library derived from rat regenerating islets, may represent an important therapeutic target for islet regeneration.

The specific aim of this study was to evaluate the expression of Reg genes in the pancreas of NOD mice, the animal model of T1D, and to correlate gene expression with different stages of life/disease and different degrees of islets inflammatory infiltrate.

Materials and methods: 68 female pre-diabetic and diabetic NOD mice and 20 BALB/c mice as controls were culled at different time points (4, 8, 12, 16, 20, 24, 30 and >30 weeks). RNA was extracted from pancreas and reverse-transcribed to cDNA. Quantitative real-time PCR was performed in order to investigate the mRNA expression of all Reg genes (Reg1, Reg2, Reg3a, Reg3b, Reg3c, Reg3d). Results were expressed as relative quantification using two endogenous controls, β -actin and 18S. Paired snap-frozen, OCT-embedded samples were analysed by Haematoxylin and Eosin staining and immunohistochemistry for T and B lymphocytes in order to evaluate immune cell infiltration as peri-islet or intra-islet infiltrates and the degree of lymphoid organization using a semiquantitative score.

Results: NOD mice showed high pancreatic expression of all Reg genes, except for Reg 4. The expression profile of all Reg genes was similar with high expression in very young mice (4 weeks) and progressive decrease almost to zero at 10 weeks. This was followed by a dramatic peak in all Reg genes in NOD mice at disease onset (12 weeks) which lasted until around 18–20 weeks and was followed by a progressive and rapid decline. The peak in Reg genes expression was associated with the maximum rate and organization of islet inflammatory infiltrate. In control BALB/c mice, we observed a strong constitutive expression of Reg genes at 4 weeks which decreased dramatically from high expression to undetectable at 10 weeks (similar to NOD mice). However, differently from NOD mice, this was not followed by a later peak with no residual expression up to 20 weeks of age.

Conclusion: Here we report the first quantitative analysis of Reg genes expression profile in NOD and control mice at different stages of life/disease. These results suggest that Reg genes might have an active role in the physiological expanding process during the growth of the pancreas in early life. However, once the organ has reached its adult volume, Reg genes gradually decrease their expression levels until undetectable from 10 weeks onwards. Conversely, in NOD mice Reg genes are induced at disease onset (12–15 weeks) most likely as an attempt to regenerate the β -cells mass following the autoimmune destructive process. Evidence that Reg gene expression peaks in parallel with the maximum inflammatory infiltrate also suggests a role of

local inflammation in inducing Reg genes expression. Overall, our data contribute to clarify the role of Reg genes in the pancreas during normal and pathologic conditions. The degree of expression of Reg genes may constitute a new tool in the evaluation of beta-cell regeneration in T1D.

Pancreatic regenerating protein (reg) inhibits human pancreatic stellate cell proliferation

L. Li¹, M.G. Bachem², S. Zhou², D. Bimmler³, R. Graf³, Z. Sun¹

¹Department of Endocrinology, Southeast University, Nanjing, China,

²Department of Clinical Chemistry, Ulm University, Germany, ³Department of visceral and transplantation surgery, Zurich University, Switzerland

Background and aims: Pancreatic regenerating protein (*reg*) has been discovered in the fields of diabetes and pancreatitis. In diabetes, *reg* is up-regulated and plays a key role in islet neogenesis/regeneration by induction of cellular proliferation. During acute and chronic pancreatitis, *reg* is also dramatically increased. However, the functional role of *reg* in pancreatitis remains unclear. Pancreatic stellate cells (PSC) play a central role in fibrogenesis associated with pancreatitis. To develop an integrated concept regarding *reg* protein in endocrine and exocrine pancreas we investigated its effect on PSC.

Materials and methods: *reg* was expressed in the yeast *Pichia pastoris* and purified from medium supernatants. Human PSC were obtained by outgrowth from fibrotic human pancreas tissue. *reg* was added at concentrations of 10ng/ml and 100ng/ml to cultured PSC (passage 3–8). Cell proliferation was determined by BrdU incorporation. PSC migration was assessed by the wound-assay. Extracellular matrix (collagen type I and fibronectin), matrix metalloproteinases (MMPs), tissue inhibitors of matrix metalloproteinases (TIMPs) and reversion-inducing cysteine-rich protein with Kazal motifs (RECK) were demonstrated on protein and mRNA level.

Results: *reg* inhibited PSC proliferation and migration in a dose-dependent manner. Soluble collagen I and fibronectin were reduced. *reg* slightly decreased the synthesis of MMP-1 and -2 and strongly decreased TIMP-1 and -2 concentrations in PSC supernatants. RECK expression was slightly induced after *reg* application.

Conclusion: While *reg* promotes pancreatic islet β -cell growth and regeneration, our results provide novel insights that *reg* inhibits PSC proliferation and TIMP1/2 secretion. These data endorse our view that *reg* plays an important role in the reorganization of the injured pancreas. The findings suggest that *reg* may have a protective function during the repair phase of pancreatic injury by promoting fibrosis resolution and boosting pancreatic islet β -cell regeneration.

Epithelial cells within the adult pancreas do not co-express mesenchymal antigens *in vivo*; evidence that epithelial-mesenchymal transition is an artifact of cell culture

K.L. Seeberger, A. Eshpeter, R.V. Rajotte, G.S. Korbutt
Surgery, University of Alberta, Edmonton, Canada

Background and aims: Currently there is an inherent shortage of cadaveric donors necessary to meet the transplantation requirements of type-1 diabetics. Identification of an islet progenitor that could generate an unlimited supply of transplantable islets could potentially alleviate the shortage of donor islets. Previously we have demonstrated that mesenchymal stem cells (MSCs) can be expanded from the non-endocrine pancreas (ductal epithelium) that is normally discarded following islet isolation. Although pancreatic MSCs can be partially differentiated into islet-like cells that express endocrine hormone mRNA and transcription factors critical to islet development they do not express insulin protein. It has been proposed that these MSC progenitors are actually derived from human β -cells undergoing reversible epithelial-mesenchymal transition (EMT), suggesting that these cells could be a potential source of new β -cells. In this study we sought to identify a population of epithelial cells in the non-endocrine pancreas that give rise to multipotent MSCs.

Materials and methods: Double immunofluorescent (IF) staining and flow cytometry were used to assess the cell phenotype of non-endocrine pancreas tissue following islet procurement and to follow changes to cell phenotype during *in vitro* expansion (24 hours to 21 days) and differentiation of MSCs.

IF staining of paraffin embedded pancreatic biopsy sections was used to assess cell phenotype *in vivo*. Several antibodies against MSC and epithelial cell antigens along with antibodies to pancreatic endocrine and exocrine hormones were used in both methods. Flow cytometry analysis data are expressed as mean percent \pm SEM.

Results: In this study we demonstrate that: 1) pancreatic epithelial cells do not express MSC antigens *in vivo*; 2) following islet isolation epithelial cells (EpCAM and CK19 positive) express the MSC antigens CD44 (32 ± 8 and 38 ± 10) and CD29 (85 ± 4 and 64 ± 4); 3) during *in vitro* expansion the number of single positive epithelial and double positive epithelial/MSCs declines while the number of single positive MSCs increases and; 4) differentiated MSCs do not revert to a true epithelial cell phenotype in our culture conditions, as epithelial cell surface markers (EpCAM, CK19 and E-Cadherin) are not re-expressed, although the MSC phenotype is altered.

Conclusion: This study demonstrates that MSCs may be derived *in vitro* via a pancreatic epithelial cell undergoing EMT; however it is likely that a small percentage of MSCs that reside in the adult pancreas are proliferating while the epithelial cells are negatively selected for by the experimental culture conditions.

The induction of pancreatic islet regeneration *in vitro* with islet neogenesis associated protein-related pentadecapeptide

T. Yang

Dept. Endocrinology, First Affiliated Hospital of Nanjing Medical University, Nanjing, Jiangsu, China

Background and aims: To establish protocol for the isolation of mesenchymal stem cells (MSCs) from adult rat pancreatic duct and differentiation *in vitro* with islet neogenesis associated protein-related pentadecapeptide (INGAP-PP). The insulin secreting cells produced with the novel multi-step differentiation method are the source for islet transplantation for diabetic rat model.

Materials and methods: The pancreas from adult SD rat was digested with type V collagenase solution (0.5mg/ml) and ductal epithelial cells were isolated from the digests by centrifugation of Ficoll density gradient to delete the islet tissue. The islet-depleted ductal-epithelial cells were cultured in PRMI 1640 (pH 7.4) medium with 10% fetal calf serum at 37°C in 5% CO₂ and the epidermal growth factor (EGF) and basic fibroblast growth factor (bFGF) were supplemented 4 days later. The medium were switched to serum-free medium supplemented with EGF and bFGF after continuous single cell layer appeared in about 7th day. At the last step of the differentiation the cells were divided into two groups, one cultured in the medium supplemented with islet INGAP-PP (1.0µg/ml) and the others with the control peptide (1.0µg/ml), with which the same amino acids but arranged in the completely difference sequence. After the differentiation, the insulin producing test were performed for the new generated islet-like clusters (ILCs), and the expression of insulin, glucagons, Pdx-1, CK-19 and nestin in the ILCs were tested with immunohistochemistry and reverse transcription-polymerase chain reaction (RT-PCR). The insulin content of the ILCs cells in the supernatant after glucose stimulation was assayed with ELISA. The regenerated ILCs were harvested and implanted into the subcapsular region of one kidney for the streptozotocin-induced diabetic rat, and the blood glucose levels were observed after transplantation.

Results: The expression of CK-19, Pdx-1 and nestin in the ductal-epithelial cells before differentiation were detected with immunofluorescence stain and RT-PCR, and the expression of insulin and glucagons are negative. After induction with EGF and bFGF, spherical-like aggregates appeared and islet-like cells in different sizes were formed after 12 days. The expression of insulin and glucagon of the ILCs from INGAP-PP group were significantly higher than that of control group ($p<0.01$). Insulin release experiment indicated that insulin secretion ratio of ILCs from INGAP-PP group under glucose stimulation were significantly higher than that of control group ($p<0.01$). The blood glucose level of the streptozotocin-induced diabetic rat were notably decreased than that of control group, after the kidney subcapsular implantation with ILCs harvested from the multi-step differentiation procedure with INGAP-PP.

Conclusion: The novel INGAP-PP involved differentiation protocol for the islet-like clusters from the rat pancreatic mesenchymal stem cells was established. The insulin producing capability of the ILCs were sufficient to reverse the blood glucose level for the streptozotocin-induced diabetic rat after kidney subcapsular transplantation.

PGC-1alpha, potential mediator of the effects exerted by the glucocorticoids on pancreatic beta cell function and development

B. Valtat, A. Singh-Estivalet, B. Bréant, B. Blondeau

Team 8, INSERM UMRS 872, Paris, France

Background and aims: The pancreatic development is a complex process controlled by transcription factors and extrinsic signals. In this context, we have shown that glucocorticoids (GC) are negative regulators of pancreatic beta-cell development. To investigate by which mechanisms GC exert their effects, we aim at defining the GC-regulated genes and the potential implication of the transcriptional coactivator PGC-1alpha whose expression is controlled by GC and which binds to the glucocorticoid receptor.

Materials and methods: *In vitro* studies were performed on a beta cell line, the MIN6 cells that were treated with Dexamethasone (Dex, a synthetic glucocorticoid), infected with an adenovirus expressing PGC-1alpha or transfected with a small interfering RNA (siRNA) specific to PGC-1alpha. *In vivo* studies were performed on CD1 pregnant mice submitted or not to 50% food restriction and foetal pancreas were analysed at stages E13.5 to E18.5. Protein and RNA were extracted from cells or pancreata. Gene expression was measured by Western Blot and real-time quantitative PCR.

Results: First, we showed on the MIN6 cells that Dex treatment increased the expression of PGC-1alpha and decreased the expression of key beta-cell transcription factors, Pdx-1, MafA, Pax4, Pax6, Nkx2.2 and Isl1. Next, we determined the implication of PGC-1alpha in these gene regulations by over-expressing PGC-1alpha in MIN6 cells using an adenovirus and showed that it reduced the expression of the same transcription factors, suggesting that PGC-1alpha is involved in the glucocorticoid effects. We partially blocked the Dex-induced increase of the PGC-1alpha expression using a siRNA and found that Pdx-1 was also partially reduced by the Dex treatment, suggesting that PGC-1alpha is involved in the negative regulation of Pdx-1. Finally, we showed that PGC-1alpha is expressed in the foetal mouse pancreas at E13.5 with a peak of expression at E14.5-E15.5 when the pancreas is mainly composed of undifferentiated cells. When fetuses are exposed to undernutrition and thereby excess GC, the expression of PGC-1alpha is increased at the late stage E18.5 while the expression of Pdx-1 is decreased.

Conclusion: Our work showed that 1) GC regulate PGC-1alpha expression in beta cells both *in vitro* and *in vivo*, 2) GC modulate the expression of key transcription factors for the development and the function of the beta-cells and 3) the transcriptional coactivator PGC-1alpha is involved the majority of the effects of the GC on the beta-cell transcription factors, especially the regulation of the expression of Pdx-1.

Raf-1 activation by insulin requires calcium signalling in pancreatic beta cells

E.U. Alejandro, K.J. Jacob, J.D. Johnson

Department of Cellular and Physiological Sciences, University of British Columbia, Vancouver, Canada

Background and hypothesis: The metabolic hormone insulin enhances growth and survival in many cell types including pancreatic β -cells. We previously reported that physiological doses of insulin protect β -cells from death and promote proliferation mediated by Raf-1 signalling. We hypothesized that insulin directly stimulates the activation of Raf-1, a pro-survival serine/threonine kinase upstream of Mek and Erk.

Materials and methods: Human and mouse islets were isolated via filtration and treated with insulin with or without BAPTA-AM, KN-62, KN93, or thapsigargin. Phosphorylated and total protein expression of Raf-1, Erk, and Bad were examined by western blotting. Primary islet cells and MIN6 cells were stained for propidium iodide and BrdU to estimate apoptosis and proliferation.

Results: First, we showed that critical protein components of the insulin/Raf-1/Erk cascades are present in both human and mouse islets and MIN6-cells. Next, we demonstrated that insulin promoted dephosphorylation of the inhibitory site of Raf-1 at serine 259, and phosphorylation of the activation site of Raf-1 at serine 338, key events that are likely to fully activate the kinase. Over-expression of Raf-1 increased Erk phosphorylation. Indeed, insulin-induced Raf-1 activation also led to an increase in Erk phosphorylation. In addition to activation of the Raf-1/Mek/Erk pathway, we observed that insulin

induced the phosphorylation of Bad, a novel target of Raf-1 in the mitochondria. We have previously shown that insulin generated rapid cytosolic calcium signals in dispersed human and mouse β -cells. Thus, we tested the role of calcium signalling in Raf-1/Erk activation by insulin. The effect of insulin on Erk phosphorylation was abrogated by inhibitors of calcium signalling, such as BAPTA-AM, an intracellular calcium chelator, KN-62 and KN-93, specific inhibitors of the calcium/calmodulin-dependent protein kinase. These data suggest that calcium may be required for the activation of Raf-1 and its downstream targets such as Erk and Bad. Blocking Raf-1 and calcium signalling individually resulted in Erk and Bad dephosphorylation and cell death. Moreover, dual inhibition of Raf-1 and calcium signalling did not have an additive effect, suggesting that they might be acting through the same pathways. The proliferative effects of insulin were blocked by thapsigargin, an inhibitor of the sarco/endoplasmic reticulum calcium-ATPase.

Conclusion: Our data suggest that insulin activates Raf-1/Erk and Raf-1/Bad pathways and calcium signalling may be required in the growth and survival effect of insulin in pancreatic β -cells.

Protein-caloric maternal malnutrition affects pancreatic levels of Insulin-Like Growth Factor-1 and -2 during neonatal period: repercussions on beta cell mass

E. Fernández¹, L. de Miguel¹, M.A. Martín², F. Escrivá¹, C. Álvarez¹

¹Bioq. y Biol. Mol. II, Fac. Farmacia, UCM, Madrid, ²Instituto del Frío, CSIC, Madrid, Spain

Background and aims: Developing endocrine pancreas undergoes substantial remodelling along the neonatal period and replication, neogenesis and apoptosis play a main role in the process. Insulin-like growth factors (IGFs) are major contributors to beta-cell growth, maturation and function, and are highly sensitive to nutritional status. We have previously shown that protein-caloric food restriction applied during the last third of gestation caused, in fetuses at term, an increase of beta-cell mass related to the stimulation of beta-cell proliferation due to locally increased pancreatic IGF-1. Nevertheless, at 4 days of life the beta-cell mass was decreased in undernourished (U) neonates and this effect persisted until adult age. In order to clarify whether remodelling of endocrine pancreas occurs by the same mechanisms in control (C) and U neonates we quantified beta-cell mass, neogenesis and replication at 4, 14 and 23 days of age. To determine the impact of food-restriction on the protein expression profile of IGFs and the consequences for the growth of beta-cells we measured serum GH, IGF-1/-2 levels and IGF-1/-2 protein content in pancreas and liver at the same age.

Materials and methods: Food-restricted pregnant rats received 35% of control diet since the last week of gestation until the time of sacrifice of neonates. Beta-cell mass, neogenesis and replication were evaluated by immunocytochemistry and morphometry. Serum concentrations of GH and IGF-1 were measured by radioimmunoassay and of IGF-2 by radioreceptor assay. The protein content of IGF-1 and -2 was analyzed in pancreas and liver by Western blot.

Results: Beta-cell mass increased in C neonates from day 4-14 but it remained stable from 14-23 days of age. In U group we did not observe any difference along the neonatal period but the beta-cell mass was significantly lower at each time point as compared to C. Beta-cell neogenesis progressively decreased with time in C whereas in U it remained stable between 4-14 days of age and then declined on day 23 staying higher than the C value at the same time. Beta-cell replication peaked on day 14 in C and decreased on day 23. In U rats beta-cell replication remained stable from 4-14 days of age and then decreased on day 23. Differences between C and U groups were only found at 14 days of age.

Pancreatic and hepatic IGF-2 protein levels decreased progressively with time in both groups but pancreatic IGF-2 concentration was significantly higher at each time point in U animals. Both groups showed the same IGF-1 protein expression profile in pancreas and liver with a peak of concentration in pancreas at 14 days of age. The protein levels of hepatic IGF-1 increased linearly with time in both groups. Serum GH levels decreased progressively throughout the time of study in both populations. Serum IGF-1 levels increased progressively in both groups but these values were higher in U rats as compared to C neonates on day 14 and 23.

Conclusion: 1) Despite beta-cell mass is decreased in U animals along neonatal period, the endocrine pancreas still has the capacity to regenerate; 2) The enhancement of pancreatic IGF-1 levels at 14 days of age could favour both stimulation of beta-cell replication in C neonates and beta-cell neogenesis in U animals; 3) In the same manner, the pancreatic IGF-2 overexpression in U rats may contribute to maintain an elevated rate of beta-cell neogenesis during a longer period of time.

Reversal in beta cell mass and glucose tolerance of diabetic mice by reactivation of Cyclin-dependent kinases with *in vivo* gene transferY. Hiki^{1,2}, T. Sasaki^{1,3}, M. Nemoto^{1,3}, Y. Hirai⁴, T. Ohashi³, N. Tajima¹¹Division of Diabetes, Metabolism and Endocrinology, Department of Internal Medicine, Jikei University School of Medicine, Tokyo, ²Division of Metabolism, Department of Internal Medicine, Nishisaitama-chuo National Hospital, Saitama, ³Department of Gene therapy, Institute of DNA Medicine, Jikei University School of Medicine, Tokyo, ⁴Department of Biochemistry and Molecular Biology, Division of Gene Therapy Research, Center for Advanced Medical Technology, Nippon Medical School, Tokyo, Japan

Background and aims: Impairment of compensatory proliferation of β cells is assumed to be critical for development of diabetes. In this process, inactivation of Cyclin-dependent kinases (CDK4/6) caused by increased expression of negative regulator, p16^{INK4a} is essential. Therefore molecular intervention to cell cycle regulation of residual islet cells has therapeutic potential. In the present study, we aimed to restore β cell mass by reactivating CDK4 with *in vivo* gene transfer technique in adult diabetic mice.

Materials and methods: Adeno-associated virus (AAV)8 vector was concentrated by ultracentrifugation with iodixanol gradient. For the transient *in vivo* gene expression, 10w-old STZ mice were randomized for the treatment with CDK4^{R24C} gene, a variant that promotes G1/S transition with least suppression by p16^{INK4a} (R24C treated), or with GFP gene (mock treated). The 8x10¹²vg/body virus was directly injected to pancreas by an open surgery. At 16w after the treatment, paraffin-embedded tissues were analyzed by immunohistochemistry (IHC). In order to know changes in β cell mass, total islet area of whole pancreas (total islet area) of 210 slices and β cell area within each islet (β cell mass) of 360 islets for each treatment were measured. For evaluation of cellular proliferation, staining with PCNA and CDK were also performed. For evaluation of β cell differentiation, staining with insulin, glucagons, MafA, and MafB were performed.

Results: Observation of GFP indicated about 30% of islet cells expressed the transgene as long as 16w. IHC of CDK staining revealed that CDK4 was localized exclusively at cytoplasm of β cells in the mock treated mice, while it localized at nucleus in addition to cytoplasm in most of β cells in the R24C treated islets, suggesting reactivation and nuclear translocation of Cyclin D/CDK4 complex. Both total islet area and β cell mass of the R24C treated mice turned out to be 2.5 fold greater than those of mock treated mice. Histogram analysis revealed that distribution of β cell mass of the R24C treated mice almost recovered to that of normal mice. PCNA and TUNEL staining of the R24C treated mice showed that proliferating β cells were significantly increased while apoptotic cells did not changed. All of the insulin-expressing cells including PCNA(+) cells in islets of the R24C treated mice were shown to be MafA(+) MafB(-), indicating the proliferated islet cells should be terminally differentiated β cell. Plasma glucose level of the R24C treated mice after glucose load until 120 min were significantly lower than that of mock treated mice; 12.5 \pm 0.6 vs. 17.9 \pm 0.9mM, $p=0.0002$ at 120'.

Conclusion: Our data demonstrate that the aberrant islet structure and glucose intolerance in diabetic mice was restored with improved growth regulation of β cells when CDK4^{R24C} gene was expressed in adult islets *in vivo*.

PTB1 regulates the cell cycle suppressor p27Kip1 in insulinoma cellsF. Ehehalt¹, K.-P. Knoch², E. Wuendrich², R. Meisterfeld¹, C. Wegbrod², A. Altkrueger², H.-D. Saeger¹, M. Solimena²¹Dept. of Surgery, Dresden University of Technology, Germany,²Experimental Diabetology, Dresden University of Technology, Germany

Background and aims: After glucose entry in the pancreatic beta-cell the rapid biosynthesis of insulin secretory granules (SG) starts parallel to the activation of the secretory machinery. We have shown that glucose promotes the nucleocytoplasmic translocation of polypyrimidine tract-binding protein 1 (PTB1) in beta-cells. Cytosolic PTB1 binds mRNAs encoding SG proteins, thus enhancing their stability and translation, while knockdown of PTB1 by RNA interference depletes SG stores. In this study we have focussed on the role of PTB1 for proliferation of beta cells.

Materials and methods: We investigated whether the knockdown of PTB1 is affecting the proliferation rate (BrdU incorporation) of INS-1 cells and searched for possible PTB1 targets involved in cells cycle regulation by quantitative PCR and western blot.

Results: Parallel to the depletion of SGs, PTB1 knockdown correlated with decreased expression of the proliferation repressor p27Kip1 and increased replication of INS-1 cells. Knockdown of p27Kip1 was associated with increased proliferation of INS-1 cells, due to its reduced binding to the Cdk2/cyclinE complex, and with reduced expression of several beta-cell specific marker proteins. The similar phenotypes observed following the knockdown of PTB1 and p27Kip1 could be rescued by the independent overexpression of either protein fused to an epitope tag.

Conclusion: These data suggest that PTB1 promotes the expression of the proliferation repressor p27Kip1 in INS-1 cells, thereby inhibiting their proliferation while promoting granule biogenesis. Accordingly, the PTB1/p27Kip1 pathway may act as a switch between differentiation and proliferation of pancreatic beta-cells.

Expression of the master repressor RE-1 silencing transcription factor (REST) in beta cells leads to diabetesD. Martin¹, D. Caille², P. Meda², J.-A. Haefliger¹¹Department of medicine, University Hospital, Lausanne, ²Department of Cell Physiology and Metabolism, University Medical Center, Geneva, Switzerland

Background and aims: The repressor RE-1 silencing transcription factor (REST) is a master regulator of neuroendocrine genes. The generation of transgenic mice expressing REST specifically in beta cells (RIP-REST mice) represents a reliable system to identify the importance of REST target genes in insulin producing cells. The observation that RIP-REST mice feature intolerance to glucose, together with the identification of several REST target genes that are key to exocytosis, such as *Snap25* or synaptotagmin isoforms, attested for the essential role of these genes in beta cell function. Evidences suggest that a number of additional REST target genes are crucial for insulin secretion, beta cell survival and overall beta cell identity.

Materials and methods: Transgenic mice were characterized by Southern blot analyses of genomic DNA, and by immunohistochemical staining of pancreatic sections. The secretory response of these mice was assessed by pancreas perfusion and by measuring glycemia. Transcriptional regulation of target genes was assessed by quantitative PCR.

Results: Glucose intolerant RIP-REST animals show a decrease in beta cell mass, arguing that REST target genes are also involved in cell proliferation/survival. This was further confirmed with a particular RIP-REST mice line that display a profound hyperglycemia leading to death after few months. This frank diabetes, observed from weaning onward, was accounted for by a major loss of beta cell mass, as assessed by immunohistochemistry and pancreatic insulin content measurements. The morphological analyses of pancreas from mice at postnatal day 2 (P2), revealed a significant insulin immunolabelling in RIP-REST diabetic mice, as compared with control animals, suggesting that the loss of beta cells occurred after birth, and did not arise from defects in embryonic development. In contrast, the islet morphology in these P2 transgenic mice was strongly affected, with glucagon and insulin positive cells scattered randomly among the islets. This phenotype, more severe than that observed with the glucose intolerant RIP-REST mice, is thought to be accounted for by a higher level of transgene expression. RE-1 sequence databases searches revealed a number of substantial putative target genes, either involved in growth signal transduction pathways, or in mechanisms of mitogenesis, that could be responsible for the observed beta cell loss. Preliminary results point out two known regulator of cell proliferation/survival, *Ica512* and islet-brain 1, as well as an uncharacterized neuroendocrine-specific regulatory subunit of cdk5, *Cdk5r2* (p39), as *bona fide* REST target genes.

Conclusion: We point out our RIP-REST mice as a pertinent model underlining the functional importance of REST target genes in pancreatic beta cells. Specifically, we show that the expression in beta cells of a "forbidden" key master repressor, REST, can lead to diabetes, by a mechanism that may rely on beta cell dysfunction, survival or differentiation. Further comprehensive analyses of these mice will help to build up a list of essential genes of pancreatic beta cell fate, that may play a critical role in the pathophysiology of diabetes.

ARNT is required for normal glucose tolerance and beta cell proliferation in pregnancy

S.M. Lau, R. Stokes, K. Cheng, J.E. Gunton

Immunology and Inflammation, Garvan Institute of Medical Research, Sydney, Australia

Background and aims: We demonstrated that the ubiquitous and highly conserved transcription factor ARNT is reduced in expression by >90% in the islets of people with Type 2 diabetes and is thus an important candidate gene for beta cell dysfunction. 3 of the 5 women with Type 2 diabetes also had a known history of gestational diabetes, suggesting that ARNT may also play a role in the pathogenesis of this condition. We hypothesise that ARNT may be important in regulation of beta cell proliferation during pregnancy. ARNT forms an obligate heterodimer with partners such as hypoxia inducible factor (HIF) -1 alpha, HIF-2 alpha and the aryl-hydrocarbon receptor. In beta cells, the ARNT-HIF-1 alpha complex is important in the regulation of glucose sensing, glycolysis and insulin signalling. Knockdown of ARNT in cultured Min6 islets results in decreased expression of antiapoptotic genes BCL-2 and BCL-xL. Thus ARNT may play a particularly important role in the adaptation of beta cells to stressors such as the increased insulin secretory demands of pregnancy. Beta cell dysfunction is an important component of gestational diabetes, but the cause of this defect has not been fully elucidated. We hypothesise that ARNT is required for adequate beta-cell proliferation in pregnancy, and that loss of ARNT will result in impaired glucose tolerance and decreased beta-cell proliferation. We studied mice with a beta-cell specific deletion of ARNT (beta-ARNT mice). Females have mild glucose intolerance by 9 weeks of age due to beta cell dysfunction. They have a normal body weight, insulin sensitivity and fertility.

Materials and methods: 12-14 week old nulliparous beta-ARNT and floxed control female mice underwent timed mating. An intraperitoneal glucose tolerance test was performed on gestational day 16.5. In a separate group of mated females, 5-bromo-2-deoxyuridine (BrdU) (30mg/kg body weight) was injected intraperitoneally on day 14.5, 16 hours prior to removal of the pancreas for formalin fixation and paraffin embedding. Pancreatic sections were stained (immunofluorescence) for insulin, BrdU and DAPI. 3 sections per mouse were analysed for islet number, beta cell area and number of BrdU-positive nuclei per islet. The BrdU labelling index (total number BrdU positive nuclei * 100000 / total beta cell area) was calculated for each mouse.

Results: Beta-ARNT mice have impaired glucose tolerance in pregnancy (Fig 1). Beta cells from beta-ARNT dams have a significantly decreased BrdU labelling index and fewer BrdU-positive cells per islet.

Conclusion: Loss of beta cell ARNT results in a greater deterioration of glucose tolerance during late pregnancy. This is associated with decreased BrdU staining in beta cells. These data suggest that impaired glucose tolerance in pregnancy in beta-ARNT mice is secondary to a combination of decreased glucose sensing and reduced beta cell proliferation.

B-ARNT mice have greater deterioration of glucose tolerance during pregnancy

Glucose metabolism and insulin secretion in islets from pregnant protein-restricted ratsD.F.I. Souza¹, L.M.I. Souza², S.R.L. Reis³, R.V. Veloso², M.A.B. Reis³, A.C. Boschero⁴, E.M. Carneiro⁵, V.C. Arantes², M.Q. Latorraca²

¹Pós-Graduação em Ciências da Saúde, Universidade Federal de Mato Grosso, Cuiabá-MT, ²Departamento de Alimentos e Nutrição, Universidade Federal de Mato Grosso, Cuiabá-MT, ³Departamento de Ciências Básicas em Saúde, Universidade Federal de Mato Grosso, Cuiabá-MT, ⁴Departamento de Fisiologia e Biofísica, Universidade Estadual de Campinas, Campinas-SP, ⁵Departamento de Fisiologia e Biofísica, Universidade Estadual de Campinas, Cuiabá-MT, Brazil

Background and aims: Protein restriction reduces glucose-induced insulin secretion, due, in part, to decrease glucose transporter 2 expression and glucose metabolism. In contrast, pregnancy increases glucose-induced insulin release and reduces glucose-stimulation threshold through enhancing glucose transporter 2, glucokinase and hexokinase expressions and activities. We investigated the effect of low protein diet during pregnancy on expression levels of these proteins, the rate of glucose oxidation and the insulin secretion.

Materials and methods: Adult control non-pregnant (CNP) and control pregnant (CP) rats were fed a normal-protein diet (17%), whereas low-protein non-pregnant (LPNP) and low-protein pregnant (LPP) rats were fed a low-protein diet (6%) for 15 d. Islets were isolated to determination of insulin secretion, rate of glucose oxidation and expression of glucokinase, hexokinase, and glucose transporter 2 by Western blot.

Results: Islets from pregnant rats exhibited the dose-response curves to glucose shifted to the left compared to islets from non-pregnant rats. The half-maximal response (EC_{50}) from LPP group was lower in relation to other groups (CNP: $8.6 \pm 0.3 \times 10^{-3}$ mM; CP: $7.4 \pm 0.2 \times 10^{-3}$ mM; LPNP: $9.9 \pm 0.6 \times 10^{-3}$ mM; LPP: $6.5 \pm 0.1 \times 10^{-3}$ mM de glucose). In the presence of 2.8 mmol glucose/L, insulin secretion (ng/islet/90min) by islets of CNP and LPNP was similar and lower than that by islets of CP and of LPP rats. However, the insulin secretion by islets of LPP rats was higher than all groups (CNP: 0.19 ± 0.02 ; CP: 0.50 ± 0.03 ; LPNP: 0.21 ± 0.01 ; LPP: 0.80 ± 0.02). In 2.8 mmol glucose/L, pregnancy produced increase in the islet glucose oxidation rates (pmol/islet/h), but in greater degree in CP than in LPP group (CNP: 1.37 ± 0.33 ; CP: 7.23 ± 1.59 ; LPNP: 4.33 ± 0.75 ; LPP: 5.86 ± 0.68). Glucokinase (CNP: 12270 ± 1037 ; CP: 12282 ± 1040 ; LPNP: 10894 ± 611 ; DP: 7054 ± 1330) and glucose transporter 2 expression levels (CNP: 16978 ± 1676 ; CP: 15963 ± 528 ; LPNP: 16143 ± 2586 ; LPP: 9714 ± 1973) were lower in islets from LPP group compared the other groups. Hexokinase levels were lower in malnourished than in the control islets and pregnancy increased its expression only in CP islets (CNP: 14257 ± 1679 ; CP: 17245 ± 1157 ; LPNP: 12013 ± 2198 ; LPP: 10057 ± 677).

Conclusion: Protein restriction during pregnancy improved islets glucose sensitivity despite decreased expression of proteins involved in the glucose metabolism.

The role of R-spondin-1/canonical Wnt signalling in glucagon-like peptide-1 regulation of beta cell growthV.S.C. Wong, W.J. Schultz, P.L. Brubaker
Physiology, University of Toronto, Canada

Background and aims: Glucagon-like peptide-1 (GLP-1) functions as an incretin hormone, as well as a β -cell growth factor stimulating β -cell proliferation. Canonical Wnt (cWnt) signaling is an important component of pancreatic development and plays a role in β -cell proliferation. We have recently demonstrated the presence of R-spondin-1 (Rspo1), a gut growth factor and secreted activator of cWnt signaling, in murine MIN6 β -cells. These cells have also been shown to express multiple Wnt ligands, their receptors, and downstream molecules of the intracellular cWnt signaling pathway. Furthermore, we found that the GLP-1 receptor agonist, exendin-4 (Ex4) enhances Rspo1 mRNA levels in a time- (up to 8 hr), dose- (up to 10 nM) and high glucose-dependent manner. We have therefore now investigated the role of Rspo1 in GLP-1 regulation of β -cell growth.

Materials and methods: MIN6 or β TC cells or mouse islets were treated with EX4 (10 nM) in the absence or presence of inhibitors of PI3K (LY294002; 10 nM), PKA (H89; 10 μ M), MEK1 (PD98059; 20 μ M), or p38 MAPK (SB203580; 10 μ M), or with immuno-purified FLAG-Rspo1 protein. Changes

in mRNA transcript levels for Rspo1 and the cWnt target gene, c-myc, were assessed via qRT-PCR, β -catenin nuclear localization was determined by immunoblot of cell nuclear fractions, and proliferation was examined by thymidine incorporation assay.

Results: Consistent with our findings in MIN6 cells, Ex4 increased Rspo1 and c-myc mRNA levels in β TC cells, peaking at 8 and 24 hr, respectively ($p<0.05$). A preliminary study showed that Rspo1 expression was also stimulated by approximately 80-fold in isolated mouse islets after 4 hr incubation with Ex4. In MIN6 cells, treatment with FLAG-Rspo1 alone (8 hr, 0.001 and 10 μ g/ml) also stimulated c-myc expression by approximately 3-fold. Co-treatment of the cells with Ex4 and LY294002 abolished the effect of Ex4 on Rspo1 mRNA. In contrast, the stimulatory effect of Ex4 to increase β -catenin nuclear localization (by 2-fold, $p<0.05$), was found to be MEK1- ($p<0.01$) but not PI3K-, PKA-, or p38-dependent. Furthermore, analysis of MIN6 cell proliferation revealed that, while Ex4 stimulated cell growth by 1.2-fold ($p<0.01$), FLAG-Rspo1 was inhibitory, decreasing thymidine incorporation by 60% (1 μ g/ml; $p<0.01$). An MTT cell survival assay did not reveal any detrimental effect of FLAG-Rspo1 on overall MIN6 cell viability.

Conclusion: Ex4 stimulation of Rspo1 expression is not limited to the MIN6 β -cell line, but is also found in β TC and primary islet cells. While the effects of Ex4 to increase Rspo1 mRNA are PI3K-dependent, Ex4 stimulation of nuclear β -catenin is ERK-1-dependent, suggesting that Ex4 regulates Rspo1 and cWnt signaling through alternative pathways. Moreover, the inhibitory effects of Rspo1 on β -cell proliferation suggests that the role of Rspo1 in the β -cell may be to modulate the balance between proliferative behaviour and differentiated function.

Calcium-dependent transcription pathways are required for stimulation of beta cell proliferation by extracellular matrix

G. Parnaud^{1,2}, E. Hammar¹, M.Y. Donath³, P.A. Halban¹

¹Department of Genetic Medicine and Development, University Medical Center, ²Cell Isolation and Transplantation Center, Division of Surgical Research, Department of Surgery, University Hospital, ³Division of Endocrinology and Diabetes, University Hospital, Geneva, Switzerland

Background and aims: Rat beta-cell proliferation is increased on extracellular matrix (ECM) and this requires an elevation of $[Ca^{2+}]_i$. The aim of this study was to determine Ca^{2+} -dependent growth signalling pathways activated by ECM with a particular focus on nuclear-factor B (NF- κ B) and Nuclear Factor of activated T cells (NFAT).

Materials and methods: Autofluorescence FACS-sorted rat pancreatic beta-cells were plated on poly-L-lysine (PLL) or on 804G-ECM (derived from rat bladder carcinoma cells) with(out) inhibitors for 48h with addition of BrdU for the last 24h. Cell replication was determined by BrdU incorporation and the identity of beta-cells confirmed by insulin immunofluorescence. NF- κ B nuclear translocation was assessed by immunofluorescence. NF- κ B transcriptional activity was analyzed by quantification of mRNA levels of I κ B α (established NF- κ B target gene) vs. L3 (housekeeping gene) by real-time quantitative RT-PCR. Data are mean \pm SEM for 3 or more independent experiments.

Results: Treatment of beta-cells with diazoxide (opens K_{ATP} channels, thereby preventing depolarization and Ca^{2+} entry) reduced 804G-ECM induced NF- κ B nuclear translocation (by $51.84 \pm 11.93\%$; $p<0.02$) as well as I κ B α gene expression (3.3 ± 0.49 vs. 1.5 ± 0.16 ; 804G-ECM - vs. + diazoxide; $p<0.01$). NF- κ B inhibitor Bay 11-7082 (5 μ M) blocked almost completely beta-cell proliferation (2.07 ± 0.43 vs. $0.17 \pm 0.07\%$ BrdU⁺ cells; 804G-ECM - vs. + Bay 11-7082; $p<0.02$). Since IL-1 β is a known target of NF- κ B that is secreted from rat beta-cells on ECM, we blocked the IL-1 receptor with IL-1Ra (2 μ g/ml) and this resulted in $57 \pm 9\%$ decrease in beta-cell proliferation on 804G-ECM ($p<0.001$). Having shown previously an inhibitory effect of cyclosporin A (inhibitor of calcineurin/NFAT), we now show that direct inhibition of NFAT by VIVIT peptide inhibits partially 804G-ECM-induced beta-cell proliferation (4.5 ± 0.3 vs. $3.1 \pm 0.2\%$ BrdU⁺ cells 804G-ECM - vs. + VIVIT; $p=0.02$). NFAT is also modulated by non-calcineurin-dependent pathways, including MAPK, PKA and GSK3 β . Compatible with these known mechanisms, the p38 and c-Jun N terminal Kinase (JNK) MAPK inhibitors SB20358 and SP600125 (10 μ M) increased beta-cell proliferation on 804G-ECM by 4.3 and 1.8 fold respectively ($p=0.02$ vs. control) as did the GSK3 inhibitor BIO (1

μ M) (3.3 ± 0.3 vs. $5.7 \pm 0.8\%$ BrdU⁺ cells, 804G-ECM - vs. + BIO; $p=0.04$) while the PKA inhibitor H89 (10 μ M) decreased it (2.3 ± 0.4 vs. $0.4 \pm 0.3\%$ BrdU⁺ cells, 804G-ECM - vs. + H89; $p=0.004$).

Conclusion: Our results suggest that calcium entry which is necessary for 804G-ECM increased beta-cell proliferation is also involved in 804G-ECM induced NF- κ B activity that is required for beta-cell proliferation. IL-1 β may amplify this process by feed-forward activation of NF- κ B. These results also indicate a role for NFAT signalling in 804G-ECM induced beta-cell proliferation, with possible modulation via both calcineurin and non-calcineurin-dependent pathways.

The protein tyrosine phosphatase, PTP-BL, regulates pancreatic beta cell proliferation by interacting with components of the Wnt signalling pathway

A.R. Oknianska¹, H.J. Welters¹, K.S. Erdmann², G.U. Ryffel³, N.G. Morgan¹

¹Institute of Biomedical and Clinical Science, University of Plymouth, United Kingdom, ²Department of Biochemistry II, Ruhr-University Bochum, Germany, ³Institut fuer Zellbiologie, University of Duisburg-Essen, Germany

Introduction: In pancreatic beta-cells, increased expression of the MODY5 gene product, HNF1 β , leads to enhanced rates of apoptosis and altered regulation of the cell cycle, suggesting that control of HNF1 β expression may be important for the control of β -cell proliferation and viability. It is unclear how these effects of HNF1 β are mediated but previously we identified a protein tyrosine phosphatase, PTP-BL, as an HNF1 β -regulated protein in β -cells and we have now studied the role of this protein in INS-1 β -cells.

Methods: The rat β cell line INS-1 was used to generate clones stably expressing either wild type (WT) PTP-BL or a tyrosine phosphatase deficient mutant (PTP-BL-CS) under the control of an inducible promoter. Cell proliferation was measured with the CellTiter 96[®] AQueous One Solution Cell Proliferation Assay (Promega). For routine determination of cell viability, trypan blue staining was used. Insulin secretion was measured by radioimmunoassay. Whole cell protein extracts were analysed by immunoprecipitation and Western blotting.

Results: Stably transfected INS-1 cells were generated that express either wild type (WT) or the phosphatase-deficient mutant (PTP-BL-CS) of PTP-BL conditionally under the control of a tetracycline-regulated promoter. Enhanced expression of WT PTP-BL inhibited INS-1 cell growth dose-dependently (uninduced: $0.30 \pm 0.02 A_{490}$ units at 72h; 20ng/ml tetracycline: 0.18 ± 0.01 ($p<0.001$); 1 μ g/ml tetracycline: 0.14 ± 0.01 units; ($p<0.001$)) but this effect was not observed when PTP-BL-CS was expressed. Neither construct altered the rate of apoptosis. PTP-BL has been reported to interact with components of the Wnt signalling pathway and addition of exogenous Wnt3a resulted in an increase in cell proliferation ($120 \pm 5\%$ vs control; $P<0.01$) and a rise in β -catenin levels, consistent with the operation of this pathway in INS-1 cells. Up-regulation of WT PTP-BL antagonised Wnt3a-induced cell growth ($85 \pm 5\%$ vs control; $p<0.001$) and the rise in total β -catenin levels. By contrast, PTP-BL-CS failed to inhibit Wnt3a-induced proliferation. Induction of PTP-BL caused a decrease in the expression of active (dephosphorylated) β -catenin in INS-1 cells consistent with the involvement of the phosphatase in the direct regulation of β -catenin functionality. The rise in β -catenin caused by Wnt3a was also suppressed by over-expression of HNF1 β , suggesting that HNF1 β may regulate the Wnt signalling pathway via an increase in PTP-BL levels.

Conclusion: We conclude that PTP-BL plays an important role in regulation of cell cycle progression in pancreatic β -cells and that it interacts functionally with components of the Wnt signalling pathway.

PTB1 regulates the expression of VEGF-A in rat insulinoma INS1 cells
K.-P. Knoch¹, K. Kratz¹, F. Ehehalt², C. Wegbrod¹, A. Altkrueger¹, M. Solimena¹

¹Experimental Diabetology, ²Dept. of Surgery, Dresden University of Technology, Dresden, Germany

Background and aims: PTB1 plays a key role in the biogenesis of insulin secretory granules (ISGs) induced by glucose and GLP-1 shortly after their stimulation of pancreatic beta-cells. Stimulation by these agents results in the nucleocytoplasmic translocation of PTB1 through independent mechanisms and its binding to polypyrimidine-rich motifs in the 3'- and/or 5'-untranslated region (UTR) of mRNAs encoding ISG components. This, in turn, increases the stability of these mRNAs and promotes their translation in a concerted fashion, thereby enhancing ISG biogenesis. In this study we focused on the potential role of PTB1 in the expression of VEGF-A. Release of VEGF-A by beta-cells promotes islet angiogenesis, stimulates endothelial cells to produce extracellular matrix components and favors the vascularization of transplanted islets. The 5'-UTR of the VEGF-A mRNA is unusually long (>900 bp) and contains several PTB1 binding sites.

Materials and methods: We investigated therefore whether the expression of VEGF-A in rat insulinoma INS-1 cells is regulated by PTB1 by RT/PCR and reporter gene assays.

Results: We found that INS1 cells express primarily VEGF-A₁₆₄ and that glucose stimulation induces a rapid increase of VEGF-A₁₆₄ mRNA levels because of post-transcriptional mechanisms. This up-regulation was prevented upon knockdown of PTB1 by RNA interference, while over-expression of PTB1 increased the levels of VEGF-A₁₆₄ mRNA. Sequential truncation of VEGF-A 5'-UTR progressively reduced its in-vitro binding to PTB1, while inclusion of PTB1 binding sites found in the VEGF-A 5'-UTR enhanced the expression of luciferase reporter constructs in glucose-stimulated INS-1 cells. This enhanced expression, however, was abolished by knockdown of PTB1.

Conclusion: Taken together, these data suggest that in addition to promoting ISG biogenesis, PTB1 is required for the rapid up-regulation of VEGF-A₁₆₄ in glucose-stimulated beta cells.

Ufm1, a new ubiquitin-like protein, is required for glucose-induced insulin secretion from pancreatic beta cells

K. Lemaire¹, M. Granvik¹, T. Becker², C. Newgard², E. Waelkens³, F. Schuit¹

¹Molecular Cell Biology, Gene Expression Unit, KULeuven, Belgium,

²Department of Pharmacology and Cancer Biology, Duke University Medical Center and Sarah W. Stedman Nutrition and Metabolism Center, Durham, United States, ³Molecular Cell Biology, Promega, KULeuven, Belgium

Background and aims: Ufm1 is a ubiquitin-like protein with an unknown function. Generally, ubiquitin-like proteins affect very diverse cellular processes via post-translational modification of their targets. We studied the expression and function of Ufm1 in pancreatic islets.

Materials and methods: Ufm1 mRNA levels were measured via quantitative RT-PCR. Insulin release and content were measured in Ufm1-silenced INS1-832/13 cells via ELISA. Identification of Ufm1 targets was performed using affinity purification and mass spectrometry analysis.

Results: Knockdown of Ufm1 in INS1-832/13 cells resulted in a drastic decrease in glucose-induced insulin release and in insulin content. Further, we identified the first two target proteins of Ufm1, namely Ufbp1 and Cdk5Rap3. Ufbp1 is an uncharacterised protein with an unknown function. Via detailed computational protein analysis and fluorescence microscopy, we showed that Ufbp1 is a component of the secretory pathway and that it influences the distribution of Ufm1 in the cell between the nucleus and the ER.

Conclusion: Together, our data shows that Ufm1 specifically plays a role in glucose stimulated insulin release in the pancreatic beta cell and we propose that it plays a role in regulating the protein secretory pathway via Ufbp1.

Pax6 and Pax6(5a) in pancreatic beta cells

G. Wolf, A. Karkour, U. Henrion, R. Walther

Department of Medical Biochemistry and Molecular Biology, University of Greifswald, Germany

Background and aims: The transcription factor Pax6 is known as an important insulin-dependent regulator of the glucagon gene expression in pancreatic alpha cells, while in beta cells the influence of this transcription factor on insulin gene expression is discussed controversially. Moreover the impact of Pax6(5a), an alternative splice product, has not been investigated so far. We already identified Pax6 as an inhibitor of the rat insulin gene 2. Using starved and high glucose conditions we studied posttranslational modifications by kinases and glycosyl-transferases of both isoforms in pancreatic beta cells.

Materials and methods: Microscopical analyses of overexpressed fluorescent fusion proteins or immunostained endogenous transcription factors were done to study its intracellular localization in dependence on glucose. Glycosylation of these proteins was investigated using specific antibodies after immunoprecipitations and Western Blots. Several mutant GST fusion proteins were generated and subjected to *in vitro* kinase assays to detect phosphorylation sites.

Results: Under low glucose conditions Pax6 is localized in the nucleus, whereas high glucose leads to cytoplasmic localization. Translocation was conducted by phosphorylation of Pax6. *In vitro* both Pax6 isoforms are phosphorylated by CaMK2 and CK2, but not by PKB. The mutation of Threonin 48, which is phosphorylated by CK2 in Pax6(5a), but is absent in Pax6, caused nuclear remaining of Pax6(5a) even under high glucose. Although glycosylation has been reported to be involved in translocation, Pax6 has not been found to be glycosylated.

Conclusion: Pax6 and Pax6(5a) are posttranslational modified by phosphorylation through CaMK2 and CK2, but not PKB, which may influence its functional activities.

Background and aims: Hepatocyte nuclear factor 4a (HNF4a) is a key promoter of gene expression leading to insulin secretion in pancreatic β cells. A number of heterozygous HNF4a mutations causing MODY type 1 (MODY1) have been reported. HNF4a protein functions only as homodimers and usually locates in the nucleus. We focused Q268X, the first reported HNF4a mutation responsible for. Q268X is a C-terminal truncated mutant up to the 269th amino acid, lacks transactivation function, and causes diabetes phenotype with remarkable penetration, unlike point mutations such as R127W HNF4a. Q268X has been shown to bind with wild-type HNF4a in biochemical assay *in vitro*. However, since the nuclear distribution pattern differs between Q268X and wild-type, they might be not associated in living cells.

Results: Expressed wild-type HNF4a tagged with EYFP was predominantly located in the nucleus except the nucleoli in COS7. The localization in the nucleoplasm was confirmed in CHO cells and MIN6 cells. The similar distribution was observed for point mutation R127W which has been found as a heterozygous mutation in MODY1 patients. In contrast, a truncated mutant Q268X tagged with EYFP was predominantly localized in the nucleoli in COS7 and CHO cells. In MIN6 cells, however, expressed Q268X-YFP was located in the nucleoplasm as well as the nucleolus. We thought that Q268X should be precisely examined in nuclear localization and dimerization with wild-type HNF4a in living cells. We found that Q268X binds with wild-type HNF4a in living COS7 and CHO cells, whose cells are not express HNF4a naturally, as visualized by co-transfecting the cells with genes encoding Q268X or HNF4a tagged with yellow or cyan variants of green fluorescent proteins (GFPs), respectively, and by utilizing fluorescence resonance energy transfer (FRET) between the two GFP variants. Q268X was also found to interact with small heterodimer partner (SHP), a negative regulator of nuclear receptors including HNF4a. Mutational analysis by deletion from the C terminus of HNF4a showed that the predominant nucleoplasm localization

of HNF4 α was conserved up to I338X mutant, and the nucleolus-targeting activity appeared from S337X. The even smaller mutant such as R154X seems to be accessible to the nucleolus but not anchored there. R154 distributed in the whole nucleus without preferential localization to the nucleoli.

Conclusion: When expressed simultaneously, Q268X was capable of accumulating HNF4 α or SHP in the nucleoli, exhibiting enhanced FRET there. Altered intra-nuclear localization to nucleoli as heterodimers with Q268X could perturb normal function of HNF4 α and/or SHP. HNF4 α has been shown to bind with SHP at AF-2 domain. The present results indicate that there is another binding site than AF-2 domain, as suggested by previous study. The binding site for SHP is thought to be located between A250 and R150. A variety of phenotypes of MODY1 may have another possible functional modification; that is, intra-nuclear localization change of HNF4 α and its repressor SHP caused by binding of the mutant.

CREBP is involved in glucagon-stimulated glucagon gene transcription

T. Moede, D. Kaiser, I.B. Leibiger, P. Vaca-Sanchez, P.-O. Berggren, B. Leibiger

The Rolf Luft Research Center for Diabetes and Endocrinology, Karolinska Institutet, Stockholm, Sweden

Background and aims: We have previously demonstrated that glucagon gene transcription can be up-regulated by secreted glucagon through a molecular mechanism involving the glucagon receptor and multiple protein kinases, namely protein kinase A, protein kinase C and CaM-kinase II. It has been shown that these signalling pathways can converge at the level of the transcription factor CRE-binding protein (CREBP). Because the glucagon promoter is known to contain a CREBP-binding site at -308 bp to -280 bp, the aim of this study was to investigate the involvement of transcription factor CREBP binding in the positive feedback regulation of glucagon gene transcription.

Materials and methods: Glucagon mRNA levels were analysed by QPCR and normalized to cyclophilinA. Online monitoring of glucagon promoter (-775 to +7 bp) driven DsRed expression was used as a readout for glucagon-stimulated gene transcription, while glucagon promoter-driven firefly luciferase expression was used to assess basal promoter activity. Electrophoretic mobility shift assay (EMSA) in combination with supershift using a CREBP-specific antibody and wild type and mutant variants of the CRE *cis*-elements, were employed to study the *in vitro* binding of CREBP to the glucagon promoter CRE. Functional expression studies using wild type and mutant glucagon promoter variants in combination with pharmacological inhibitors of PKC, PKA and CaMKII were performed to test the involvement of CREBP in glucagon-mediated glucagon transcription.

Results: Stimulation of alphaTC1-9 cells with 200 pmol/ml glucagon led to a 1.56 \pm 0.1 (n=10) fold increase in glucagon-promoter driven DsRed fluorescence in alphaTC1-9 cells. This treatment also resulted in 2.2 \pm 0.1 (n=3) and 2.5 \pm 0.2 fold (n=3) increased mRNA levels in alphaTC1-9 and isolated islets respectively. The increase in either mRNA levels or DsRed fluorescence were abolished by treatment with inhibitors of protein kinase A (100 μ M Rp-cAMPs), protein kinase C (150 nM bisindolylmaleimide) and CaM-kinase II (400 nM autocalmitide). Since these signalling pathways can all converge at the CREBP-CRE system, we studied the effect of a CRE-mutation, which does not allow CREBP binding, on rat glucagon promoter activity. Electrophoretic mobility shift assay in combination with a supershift assay, utilizing a CREBP-specific antibody revealed that CREBP is present in nuclear extracts of alphaTC1-9 cells and that CREBP binds to the previously identified CRE-element of the glucagon promoter at -308 to -280 bp. Mutation in the core of the CRE-element (TGACGTCA to TGtGTCA) abolished the *in vitro* binding of CREBP as observed in the EMSA. When this mutation was introduced into the expression constructs for the luciferase reporter system, it resulted in 75 \pm 5% reduction of luciferase expression (n=5), indicating a reduced basal promoter activity. Finally, the mutation in the CRE-element completely abolished the stimulatory effect of 200 pmol/ml glucagon on glucagon promoter driven DsRed expression.

Conclusion: Our findings suggest that CREBP binding to the CRE element of the glucagon promoter is critically important for both basal and glucagon stimulated glucagon gene transcription. The transcription factor CREBP appears to be the target of the signalling events underlying the positive feedback regulation of glucagon on the transcription of its own gene in the pancreatic alpha-cell.

Gene expression profiling of various sulfonylureas in insulin producing INS-1E cells

N.E. Magnusson, A.B. Petersen, K. Smidt, B. Brock, O. Schmitz, J. Rungby
Pharmacology, University of Aarhus, Denmark

Background and aims: Sulfonylurea derivatives (SUs) are used in the management of type 2 diabetes. They act by stimulating insulin secretion by binding to the ATP-sensitive potassium channel (K-ATP) subunit SUR1 in beta-cells. SU-receptors are found in other cell types where K-ATP channels are thought to be involved in protective physiological responses to metabolic stress. Previous studies have shown that glimepiride and glibenclamide interact with SUR subunits in other cell types. To identify SU responsive genes in the beta-cell we investigated the transcriptional regulation of gliclazide, glimepiride, and glibenclamide by microarray analyses in INS-1E cells.

Materials and methods: INS-1E cells were exposed to 10 μ M of each compound for 24h. Control groups received vehicle. Each experiment was performed as three independent replicates. Gene expression profiles were analyzed using Affymetrix GeneChip arrays. Low intensity data was reduced using the following criteria: Genes with log fold changes >0 and absolute signal values < 100 for the test sample were omitted. Similarly log fold changes <0 and absolute signal intensities < 100 for the control sample were omitted. Pathways were analyzed with Ingenuity Pathway analysis software using a cut-off limit of fold change > 1.5 and p<0.05 (test vs control). Significant biological functions and canonical pathways were identified using Fishers exact test.

Results: A number of networks were identified for glibenclamide and glimepiride and none for gliclazide. 5 and 4 networks at various levels of significance were found for glimepiride (p=0.2-1E-26) and glibenclamide (p=0.2-1E-22), respectively. The functional categories of these networks primarily related to cancer, immunological disease, cell death, and cell cycle. Toxicological analyses identified signalling pathways for glimepiride relating to oxidative stress and hypoxia via the NAD(P)H dehydrogenase system involved in free radical production. Also, down-regulation of AMP-activated protein kinase was identified as a function for cardiac damage. AMPK lacking the kinase activity increases the heart injury via alteration of the myocardial ischemia-reperfusion protective mechanism. Cell death signalling pathways comprised the second largest functional group for glimepiride and glibenclamide including pro-apoptotic IFN-gamma, MYC, TNF, and leptin pathways. The effect of gliclazide was analysed with reduced stringency allowing genes varying by 1.4 fold. A single network involving the beta-catenin pathway was identified. Activated beta-catenin has been shown to increase beta-cell expansion in mouse islets. In contrast to glimepiride and glibenclamide, no evidence of genes regulating beta cell apoptosis was found for gliclazide.

Conclusion: This study demonstrates that SU's affect the gene expression in INS-1E cells. Glibenclamide and glimepiride altered several transcription factors and signalling pathways involved in cell homeostasis and cell death. In contrast, a lower level of gene-regulation was found for gliclazide which may correspond to a higher specificity for SUR1 subunits of this compound. Regulation by gliclazide revealed changes compatible with beta-cell preserving networks (beta-catenin). This is in agreement with previous findings suggesting gliclazide as a general scavenger of radicals. SUs affect both beta-cell function and survival. This genome-wide scan suggests a differential profile among SUs on beta cell function and survival.

Effects of AMP-activated protein kinase on peroxisome proliferators-activated receptors α / γ and pancreatic duodenal homeobox-1 in INS-1 cells

H. Guo^{1,2}, X.X. Lv¹, X.J. Zhang¹, Q.B. Guan¹, L. Gao¹, J.J. Zhao¹

¹Scientific Centre, Provincial Hospital affiliated to Shandong University,

²Department of Pharmacology, Shandong University School of Medicine, Jinan, China

Background and aims: AMP-activated protein kinase (AMPK) is an energy sensor that regulates cellular metabolism and controls whole-body glucose homeostasis in multiple tissues. Although large numbers of studies have reported AMPK exerts action in several tissues, effects of AMPK on its target molecules in pancreatic β cells remain largely elusive. One of the main purposes here was to detect the PDX-1 expression when AMPK activity changes. Pancreatic duodenal homeobox-1 (PDX-1) plays a pivotal part both in embryonic Pancreas development and in regulating pancreatic islet β -cell-spe-

cific gene expression. Whether AMPK can affect PDX-1 expression has not previously been described. If so, accompanying with the changes of PDX-1, whether the expression changes also occurred simultaneously in PPAR α and PPAR γ , which are two members of the peroxisome proliferators-activated receptors (PPARs) subfamily. Owing to the more beneficial and effective function in antidiabetes of dual PPAR α / γ agonist. Another emphasis, thus, of our aims here was to investigate whether AMPK could affect synchronously PPAR α / γ expression in β cells.

Materials and methods: INS-1 cells, a rat insulin-secreting cell line, were cultured in RPMI 1640 medium, and treated with or without 0.5 mM AICAR (an AMPK agonist) in the presence or absence of 10 μ M Compound C (an AMPK inhibitor). Treatment for 8 hours, total RNA was extracted for determining the contents of PPAR α / γ and PDX-1 mRNA by real-time PCR (normalized to GAPDH), total proteins were extracted for analysis of PPAR α protein expression by immunoprecipitation, while nuclear and cytoplasmic proteins were respectively gained for detecting PDX-1 by western blot (normalized to β actin).

Results: Treatment with AICAR increased the PDX-1 mRNA levels approximately 2-fold ($p < 0.05$) compared to control. But, the AICAR-mediated increase was restored to the normal levels when Compound C prior to AICAR added. There are no significant difference between control and Compound C alone groups. Accordingly, compared to control, the nuclear PDX-1 proteins of the cells treated with AICAR alone were increased 1.8-fold ($p < 0.05$). When cells were treated with AICAR and Compound C together, the nuclear PDX-1 protein expression was reduced by 33.3% ($p < 0.05$ vs AICAR alone). However, in cytoplasmic proteins, PDX-1 expression in both AICAR group and Compound C/AICAR co-treated group was obviously higher than that in the control ($p < 0.05$). The PPAR α and PPAR γ mRNA contents were respectively increased about 1.68-fold ($p < 0.05$) and 2.66-fold ($p < 0.05$) in the cells treated with AICAR alone compare to control, but this increase was oppressed and was respectively reduced by 33.88% ($p > 0.05$) and by 34.89% ($p < 0.05$) in the cells treated with AICAR and Compound C together. Consistent with the changes of PPAR α mRNA contents, IP experiment showed a strong stained band ($p < 0.05$) representing PPAR α protein in the cells treated with AICAR alone, while the weakest band ($p < 0.05$) was obtained in the presence of AICAR and compound C together.

Conclusion: AMPK activation increases PPAR α , PPAR γ and PDX-1 expression both in gene transcriptional level and in protein level in INS-1 cells under “physiological” conditions. Our knowledge concerning the effects of AMPK on its downstream targets may be useful for its involvement in islet β cells protection.

Promoter activity of microsomal triglyceride transfer protein (MTTP) affected by lipids

I. Kraus-Stojanowic¹, F.-A. Heinsen¹, A. Schneider-Muntau¹, F. Döring², D. Rubin¹, J. Schrezenmeir¹

¹Department of Physiology and Biochemistry of Nutrition, Max-Rubner Institute, ²Institute of Human Nutrition and Food Science, Christian-Albrechts-University, Kiel, Germany

Background and aims: MTTP is involved in the assembly and secretion of VLDL by liver and of chylomicrons by intestine. Subjects homozygous for -493T polymorphism have fewer but more lipid-rich VLDL particles, lower cholesterol levels and therefore a less atherogenic lipoprotein profile. There is a nearly complete linkage disequilibrium in the common -493G/-400A/-164T and the rare allele -493T/-400T/-164C. The common haplotype has an almost twofold lower promoter activity than the rare haplotype. Mutagenesis experiments of our group revealed that instead of -493G>T as described in the literature, polymorphism at position -164 is responsible for different activity of MTTP promoter haplotypes, which seems to be mediated via SREBP1a. Further on allele specific binding sites for the SREBP cofactor NFY at -164T and for HNF1 at -400A are indicated *in silico*. To verify the putative transcription factor binding sites mobility shift assays (EMSA) were performed. Since there transcription factors are known to bind lipid ligands the effect of lipids on the allele specific promoter activity was studied in reporter gene assays and by qRT-PCR.

Materials and methods: For EMSA biotinylated complimentary oligos of allelic variants at position -400 and -164 were incubated with nuclear extracts of HeLa cells transfected with either NFY or HNF1a. Unlabeled oligos were used as competitors, for super shift antibodies against NFY-A and HNF1a

were added. For reporter gene assay HuH7 liver carcinoma cells were transfected with pGL4.10 vector containing different functional 966-bp segments of the MTTP promoter. Cells were incubated with 50 μ M palmitic, oleic, linoleic, eicosapentaenoic acid or cholesterol for 24 h before analysis of luminescence. MTP expression of untransfected HuH7 cells was determined by qRT-PCR after treatment.

Results: EMSA indicated specific binding of NFY to -164T. Binding was competed by unlabeled -164T but not -164C oligos. Antibody against NFY lead to a supershift only of the -164T variant. Reporter gene assay demonstrated a nearly twofold decrease in promoter activity of -164T compared to -164C, indicating an inhibitory effect of SREBP1a or NFY. EMSA identified a specific binding of HNF1a to the -400T allele, that is reduced by displacement reaction and shows a supershift with an antibody against HNF1a. In reporter gene assay there was no significant difference between the activity of promoter constructs -400T and -400A. Palmitic acid slightly increased and oleic, linoleic and eicosapentaenoic acid decreased MTTP promoter activity, irrespective of the genotype. Multifactor ANOVA indicates a lacking interaction between fatty acids and promoter constructs. Cholesterol had no significant influence on the promoter activity of the different constructs. MTTP expression in HuH7 cells after incubation with fatty acids or cholesterol showed a ranking: eicosapentaenoic acid > palmitic acid > cholesterol > untreated control > oleic acid > linoleic acid.

Conclusion: Binding of NFY to -164T could reduce MTTP promoter activity as a cofactor for SREBP. Binding of HNF1a to -400T is of minor relevance. The impact of fatty acids is not dependent on the influence of the examined genotypes.

New strategy for generation of a mouse inducible model of protein expression in pancreatic beta cells

N. Bulat, C. Widmann

Physiology, University of Lausanne, Switzerland

Background and aims: RasGAP is a GTPase-activating protein specific for Ras. RasGAP is also a substrate of the caspase family of proteases. Under mild stress conditions RasGAP is cleaved by caspases into two fragments, fragment C (C-terminal part) and fragment N (N-terminal part). Fragment N expressed in cells, including insulinoma cell lines, induces potent survival signals that depend on the activation of Akt and the repression of NF κ B. Transgenic mice expressing fragment N under the control of the rat insulin promoter (RIP-N mice) are more resistant to streptozotocin-induced diabetes. Islet cells isolated from this transgenic mouse are also more resistant to a series of pro-apoptotic stimuli, including inflammatory cytokines, palmitate, hypoxia and high glucose concentrations. The RIP-N mice however constitutively express fragment N. An inducible model of fragment N expression in beta cells would represent a better system to assess the therapeutic potential of fragment N at the onset of diabetes. Generation of such a model requires that a targeting DNA sequence allowing a tight and specific regulation of fragment N expression in beta cells be constructed.

Materials and methods: We developed a strategy based on the ability of a fusion protein (called tTRKRAB) between KRAB (Krüppel-associated box protein) and the tetracycline repressor to block gene expression. Upon addition of tetracycline (or the doxycycline analogue), the fusion protein detaches from TREs allowing transcription to resume. We have constructed a targeting vector containing fragment N, RIP, tTRKRAB, and TRE sequences that allows specific expression in beta cells upon doxycycline addition *in vitro*.

Results: This vector was used to generate mice that can be turned on and off at will for the expression of fragment N specifically in pancreatic beta cells. The transgenic mice line is created and is under the process of testing and will be used for possible ameliorating transplantation procedure.

Conclusion: Inducible expression of proteins in tissue specific manner by using one vector system is a much needed tool in molecular biology research. With this newly developed system we hope to generate such a mice line that will need no further backcrossing since it contain all the needed elements in one vector. This will hopefully bring us closer to the improvement of treatments for diabetic patients of both type I and type II.

Beta cell specific silencing of the plasma membrane monocarboxylate transporter *MCT1* (*SLC16A1*) is not effected through methylation of its promoterT.J. Pullen¹, G. da Silva Xavier¹, G. Kelsey², G.A. Rutter¹¹Cell Biology, Imperial College, London, ²Developmental Genetics and Imprinting, Babraham Institute, Cambridge, United Kingdom

Background and aims: Glucose metabolism in pancreatic β -cells is specialised to efficiently couple glucose oxidation to an increase in ATP:ADP ratio, critical for stimulating insulin secretion. Alternative metabolic pathways that could interfere with glucose sensing are suppressed by specifically “disallowing” expression of certain genes in β -cells. For example, *MCT1* (*SLC16A1*) encodes a plasma membrane monocarboxylate (pyruvate/lactate) transporter and is widely expressed in other tissues but not in β -cells. The effects of inappropriate expression of *MCT1* are shown in the rare genetic disorder, Physical Exercise-Induced Hypoglycaemia, caused by mutations within the *MCT1* promoter. In affected patients, during strenuous physical exercise the presence of the transporter allows circulating pyruvate/lactate to enter β -cells, resulting in inappropriate insulin release, and consequent hypoglycaemia. We aimed here to identify the mechanisms by which expression of *MCT1* is specifically disallowed in β -cells. Methylation of CpG islands associated with promoters is an epigenetic modification associated with gene silencing in development and disease. Both human and mouse *MCT1* promoters contain CpG islands. We therefore investigated whether methylation of the *MCT1* promoter may contribute to β -cell-specific silencing of this gene.

Materials and methods: The mouse pancreatic β -cell line, MIN6, was treated with a methylation inhibitor, 5-azacytidine, then *MCT1* expression was quantified by RT-PCR. The methylation status of the *MCT1* promoter was analysed by bisulphite sequencing in MIN6 cells, a mouse liver cell line mhAT3F which expresses high levels of *MCT1*, and isolated mouse islets. Methylated DNA immunoprecipitation was used as an independent technique to analyse the methylation status of the *MCT1* promoter. Sheared genomic DNA prepared from MIN6 and mhAT3F cells was immunoprecipitated with an antibody against methylated cytosine. Pulled-down DNA fragments were detected by PCR.

Results: Treatment of MIN6 cells with 5-azacytidine led to a 1.7-fold increase in the level *MCT1* mRNA ($p < 0.01$). However, bisulphite sequencing of the entire *MCT1* promoter CpG island in MIN6 and mhAT3F cells revealed very low levels of methylation ($< 5\%$) in both cell types. The *MCT1* promoter was also found to be hypomethylated ($< 5\%$) in isolated mouse islets. The quality of the bisulphite sequencing was verified by successfully analysing a normally methylated region. The hypomethylation of the *MCT1* promoter was confirmed as it was not pulled-down in a methylated DNA immunoprecipitation from MIN6 or mhAT3F cells. Selective pull-down of methylated promoters by this technique was confirmed using *FTMT* and *GAPDH* as positive and negative controls respectively.

Conclusion: Although global inhibition of DNA methylation in β -cells increased expression of *MCT1*, we have discovered that the *MCT1* promoter has very low levels of methylation in both MIN6 cells and in isolated islets. Therefore while methylation may be involved in upstream events, we show that *MCT1* is not transcriptionally regulated through methylation of its promoter in β -cells. We are currently investigating alternative mechanisms by which *MCT1* expression is specifically disallowed in β -cells, including post-transcriptional regulation by microRNAs.

Adenosine A_1 receptors modulate glucose-induced pulses of islet hormone releaseA. Salehi¹, F. Parandeh¹, B. Fredholm², E. Grapengiesser³, B. Hellman³¹Clinical Sciences, University of Lund, Malmö, ²Physiology & Pharmacology, Karolinska Institute, Stockholm, ³Medical Cell Biology, University of Uppsala, Sweden

Background and aims: Evidence has been provided that extracellular ATP stimulates the pulsatile component of insulin, glucagon and somatostatin release by activating P2Y₁ receptors. The present investigation examines if the purine adenosine, via A₁ receptors (A₁R) interferes with the pulsatile islet hormone release.

Materials and methods: Ratiometric Fura-2 technique was used for measuring cytoplasmic Ca²⁺ in individual mouse β -cells. Insulin, glucagon and somatostatin were measured by radioimmunoassay in perfusate from pancreas.

Results: Addition of 10 μ M adenosine to isolated mouse β -cells rapidly suppressed IP₃-induced Ca²⁺ transients supposed to co-ordinate the insulin release pulses. This process was reversed by 100 nM of the A₁R antagonist DPCPX. In situ perfusion of mouse pancreas indicated two phases of islet hormone response when glucose was raised from 3.3 to 16.7 mM. Typically, the first phase response was characterized by a small initial dip followed by a peak, which was more pronounced for insulin and somatostatin than for glucagon. The second phase was markedly affected by knockout of A₁R. Wild type of mice (A₁R +/+) usually lacked statistically verified insulin pulses but generated 8–9 min pulses of glucagon and somatostatin appearing in antisynchrony. In the A₁R (-/-) mice the secretory rate of insulin was almost three times higher due to distinct pulses, which appeared in periods of 8 min. There was no corresponding increase of average glucagon and somatostatin secretory rate, but a prolongation of the pulses of both hormones with 50 %.

Conclusion: The results indicate that A₁R receptor is important both for the amplitude (insulin) and duration (glucagon and somatostatin) of islet hormone pulses.

Molecular mechanisms controlling the activation and function of the RalA GTPase in pancreatic beta cells

S. Ljubicic, P. Bezzi, R. Regazzi

Department of Cellular Biology and Morphology, University of Lausanne, Switzerland

Background and aims: RalA is a Ras-like monomeric GTPase implicated in the modulation of a variety of cellular processes including exocytosis and endocytosis. We previously found that RalA GTPase is expressed in pancreatic beta cells and is activated by insulin secretagogues. In addition, we discovered that silencing of RalA leads to impaired insulin secretion. In the present study, we investigated the pathways leading to RalA activation as well as the molecular mechanisms through which the GTPase controls insulin release from pancreatic beta cells.

Materials and methods: The experiments were performed in the insulin-secreting cell line INS-1E. Activation of RalA in living cells was assessed by Fluorescence Resonance Energy Transfer (FRET) using a construct including a YFP-labeled RalA and a CFP-labeled Ral effector. The role of RalA in the docking step was assessed by TIRF microscopy. The implication of the GTPase in phospholipase D activation was determined by measuring the generation of phosphatidic acid in cells lacking RalA.

Results: We previously demonstrated that insulin secretagogues activate RalA. Here, we found that activation of RalA requires RalGDS, a specific Ral exchange factor. Indeed, RalGDS silencing by RNA interference reduced hormone release induced by secretagogues by more than 50%, whereas overexpression of RalGDS did not alter hormone secretion. To precisely define the molecular mechanisms through which RalA controls the secretory process of beta cells we analyzed the impact of RalA silencing on docking and fusion on insulin-containing granules. We found that the reduction in RalA expression is associated with a small but significant decrease (20%) in the number of granules recruited to the plasma membrane. Moreover, RalA silencing in INS-1E cells led to a strong decrease in secretagogues-evoked phospholipase

D activity, indicating that this small GTPase is not only involved in the docking process but participates also in the regulation of late events leading to insulin exocytosis.

Conclusion: Taken together our data indicate that the exchange factor Ral-GDS plays an important role in secretagogue-induced RalA activation and insulin secretion. We also demonstrate that once activated RalA can regulate two key events in the insulin secretory pathway: the docking of secretory granules at the plasma membrane and their subsequent fusion.

Presence and role of an electrogenic Na-HCO₃-cotransporter in insulin-producing cells

N. Bulur¹, P. Lybaert¹, E. Hupkens¹, K. Louchami¹, Y. Zhang¹, A.P. Yates², L.C. Best², R. Beauwens³, W.J. Malaisse¹, A. Sener¹

¹Laboratory of Experimental Hormonology, Université Libre de Bruxelles, Belgium, ²Departements of Clinical Biochemistry and Medicine, University of Manchester, United Kingdom, ³Laboratory of Cell and Molecular Physiology, Université Libre de Bruxelles, Belgium

Background and aims: We have recently documented the presence of the electrogenic Na-HCO₃-cotransporter NBCe1-A in rat islet beta cells by immunohistochemistry, western blotting and RT-PCR. The participation of this cotransporter in sodium handling by insulin-producing cells was also recently examined. The present study deals mainly with the possible role of this cotransporter in insulin release.

Materials and methods: Rat pancreatic islets, isolated by the collagenase procedure, were incubated for 90 min in the absence or presence of tenidap, an inhibitor of NBCe1-A in kidney proximal tubule cells. Intracellular pH measurements were carried out in dispersed rat islet cells. Beta-cell membrane potential was recorded using the perforated patch technique.

Results: In the 3 to 100 µmol/l range, tenidap cause a concentration-related inhibition of insulin release from islets exposed to 16.7 mmol/l glucose, with a half-maximal suppressing effect at about 50 µmol/l. Further experiments conducted in the absence or presence of 100 µmol/l tenidap indicated that it failed to affect significantly the basal release of insulin release recorded at 5.6 mmol/l glucose, abolished the secretory response to 8.3 mmol/l glucose and severely decreased the insulinotropic action of 16.7 mmol/l glucose. Tenidap also decreased insulin secretion evoked by 10.0 mmol/l 2- ketoisocaproate, the relative extent of such an inhibition (42±8 %) not being significantly different from that found a 8.3 mmol/l glucose (57±10 %). The secretory response to 20.0 mmol/l L-leucine, which was comparable to that evoked by 8.3 mmol/l glucose was decreased by no more 24±10%, however, in the presence of tenidap. Last, the enhancing action of glibenclamide (5 µmol/l), theophylline (1.4 mmol/l), forskolin (5 µmol/l) and cytochalasin B (0.2 mmol/l) upon insulin release evoked by 8.3 mmol/l glucose was also abolished by tenidap. At all glucose concentrations (4 to 16 mmol/l), tenidap (50–100 µmol/l) provoked an immediate lowering of intracellular pH, this effect slowly fading out over the ensuing 7–8 min, and promoted pronounced hyperpolarisation of the plasma membrane potential.

Conclusion: The concentration-response relationship for the inhibitory action of tenidap on glucose-stimulated insulin release and its effect upon intracellular pH in dispersed islet cells are comparable to observations made in other cell types. The latter effect may account for the lower sensitivity of leucine-stimulated islets to the inhibitory action of tenidap. With due reservation on the specificity of tenidap inhibition of NBCe1-A, the present results are compatible with a key role for bicarbonate efflux via this cotransporter in the insulinotropic action of nutrient secretagogues.

474

NADPH as a putative regulator of voltage-gated Ca²⁺ channels in pancreatic beta cells

T.M. Reinbothe, U. Fransson, E. Renström

Islet Pathophysiology, Lund University, Malmö, Sweden

Background and aims: The pyridine nucleotide NADPH is formed by mitochondrial shuttles during glucose metabolism and we have previously demonstrated that it influences Ca²⁺-induced insulin release. NADPH also serves as a reducing equivalent in many cellular processes instrumental in the regulation of beta-cell's redox state. The aim of the present study was to further investigate the role of NADPH in stimulus-secretion coupling focusing on voltage-gated Ca²⁺ channels in individual beta-cells.

Materials and methods: Islets were isolated from adult Wistar rats by collagenase digestion and dissociated into single cells. Whole-cell Ca²⁺ currents were recorded using the patch-clamp technique in standard whole cell configuration. In order to investigate the effect of NADPH on Ca²⁺ channel subtypes, Ca²⁺ channel blockers were used as specified below. RNA interference with siRNA targeting the NADPH effector glutaredoxin (GRX) was used to determine its effect on insulin secretion which was detected using an insulin radioimmunoassay (RIA). Furthermore, cellular thiol concentration was measured after knockdown of GRX with an Ellman's assay.

Results: After the addition of 100 µM NADPH to the pipette solution we could observe an inhibition of averaged Ca²⁺ current amplitudes at 0 mV by 36% (50 pA; SE=4.6 pA; n=15) compared to patches containing no NADPH (78.8 pA; SE=13.4 pA; n=11). Isradipine (2 µM) was then used in the bath solution to determine the effect of NADPH on the non L-type current component of measured Ca²⁺ currents. In control cells without NADPH, isradipine reduced whole cell Ca²⁺ current amplitudes by 52% (38 pA; SE=10 pA; n=8) as compared with non-treated cells (78.8 pA; SE=13.4 pA; n=11). Interestingly, NADPH stimulated the non L-type Ca²⁺ current component by 61.5% (61.7 pA; SE=10.3 pA, n=8). By contrast, in the presence of the R-type Ca²⁺ channel blocker SNX482 (100 nM), NADPH was without effect. The down-regulation of GRX (KO) suppressed insulin secretion by 62% in high glucose (16.7 mM Glucose; 7.09 ng/mg/h vs. 18.65 ng/mg/h KO vs. control; p<0.04; n=3) and had no effect on basal insulin secretion (2.8 mM Glucose; 5.69 ng/mg/h vs. 5.14 ng/mg/h KO vs. control; p>0.6; n=3). We could not detect an influence of GRX down-regulation on cellular thiol concentration (0.59 µM vs. 0.51 µM KO vs. control; p>0.4; n=3).

Conclusion: Our results demonstrate a Ca²⁺ channel subtype specific effect of the pyridine nucleotide NADPH. It inhibits L-type Ca²⁺ current components whereas non L-type components are stimulated. The NADPH effector glutaredoxin can also influence insulin secretion. We hypothesize that this mechanism is involved in differential regulation of the attributed roles of Ca²⁺ subtypes in biphasic insulin secretion.

Kv2.1 channel blockers potentiate glucose-induced insulin release in islets of type 2 diabetic rats

K. Dezaki¹, B. Damdindorj¹, M. Kakei², T. Yada¹

¹Physiology, Jichi Medical University, Tochigi, ²Saitama Medical Center, Jichi Medical University, Saitama, Japan

Background and aims: Voltage-dependent potassium channels are involved in repolarization of excitable cells. In pancreatic β-cells, activation of delayed rectifier K⁺ (Kv) channels might repolarize cells and attenuate glucose-stimulated action potentials to suppress insulin secretion. Inhibition of the β-cell Kv current would be expected to prolong action potentials and enhance glucose-stimulated insulin secretion. Among Kv channel families, Kv2.1 is reportedly expressed in islet β-cells as the major component of Kv currents in rodents. This study aimed to determine the effects of specific blockers of Kv2.1 channels on the glucose-induced insulin release in islet β-cells of diabetic rats.

Materials and methods: Islets were isolated from male Wistar and type 2 diabetic Goto-Kakizaki (GK) rats by collagenase digestion, and insulin release was determined by ELISA. In rat single β-cells, cytosolic Ca²⁺ concentration ([Ca²⁺]_i) was measured by fura-2 microfluorometry, while whole cell currents were measured in the presence of tolbutamide by nystatin-perforated patch-clamp technique.

Results: In isolated islets of Wistar rats, tetraethylammonium (TEA), a non-selective blocker of Kv channels, increased glucose (8.3 mM)-induced insulin release. Moreover, Kv2.1 channel blockers, stromatotoxin (ScTx) and guangxitoxin-1E (GxTx), significantly increased glucose-induced insulin release. The basal insulin release at 2.8 mM glucose was not altered by these Kv channel blockers. In contrast, margatoxin, a Kv1.3 channel blocker, affected insulin release neither at stimulated nor at basal glucose. TEA and ScTx markedly attenuated Kv currents in β-cells. ScTx and GxTx concentration-dependently potentiated glucose (8.3 mM)-induced [Ca²⁺]_i increases in rat β-cells, whereas basal [Ca²⁺]_i levels at 2.8 mM glucose were not affected by these Kv2.1 channel blockers. In type 2 diabetic GK rats, Kv2.1 channel blockers increased glucose (8.3 mM)-induced insulin release from islets and potentiated [Ca²⁺]_i increases in β-cells, to similar extents to those observed in Wistar rats.

Conclusion: Kv2.1 channels may physiologically limit glucose-induced Ca²⁺ entry to suppress insulin secretion in β-cells. Blockade of Kv2.1 channels can promote glucose-induced insulin release in diabetic GK rats as well as normal rats, providing a potential therapeutic tool to treat type 2 diabetes.

476

ADP mediates inhibition of insulin secretion by activation of P2Y₁₃ receptorsS. Amisten¹, S. Meidute-Abaraviciene², A.S. Salehi², D. Erlinge¹¹Cardiology, Lund University, ²Clinical Science, Lund University, Malmö, Sweden

Background and aims: Several studies have previously suggested that extracellular nucleotides such as ATP and ADP play an important role in the regulation of insulin secretion from pancreatic beta-cells. The aim of this study was to determine which ADP sensitive P2Y receptors are present in mouse islets and pancreatic beta-cells and to investigate their role in insulin and glucagon secretion.

Materials and methods: Quantitative real-time PCR (qPCR) was used to quantify the expression of the ADP receptors P2Y₁, P2Y₁₂ and P2Y₁₃ in mouse islets and isolated beta-cells. The non-biodegradable ADP-analogue 2-MeS-ADP was used in combination with either the P2Y₁ antagonist MRS2179 or the P2Y₁₃ antagonist MRS2211 to study the influence of P2Y₁ and P2Y₁₃ receptors on insulin and glucagon release. The effects of endogenously released ADP on insulin and glucagon secretion were also studied by co-incubation of islets with the nucleotide degrading enzyme apyrase at different glucose concentrations.

Results: Both P2Y₁ and P2Y₁₃ were found to be expressed in mouse islets and beta-cells, but only trace amounts of P2Y₁₂ could be detected. The relative expression of P2Y₁₃ was 19% of the P2Y₁ expression in islets and 45% of the P2Y₁ expression in beta cells. Incubation of mouse islets with 2-MeS-ADP (10 μM) and the selective P2Y₁ antagonist MRS2179 (10 μM) in the presence of 8.3 mM glucose resulted in a marked decrease in insulin secretion (-70%, $p < 0.001$). This indicates an inhibitory effect on insulin secretion mediated by the unblocked P2Y₁₃ receptor. In contrast, pre-treatment of islets with the selective P2Y₁₃ receptor antagonist MRS2211 strongly increased insulin secretion (+112%, $p < 0.001$), indicating a stimulatory effect on insulin secretion by the unblocked P2Y₁ receptor. The effect of P2Y₁₃ receptor blockade by MRS2211 on insulin and glucagon secretion was tested at both sub-stimulatory (8.3 mM) and high (20 mM) glucose concentrations. Inhibition of P2Y₁₃ mediated signaling resulted in elevated secretion of both insulin (8.3 mM glucose: +92%, $p < 0.001$; 20 mM glucose: +38%, $p = 0.005$) and glucagon (8.3 mM glucose: +76%, $p < 0.05$; 20 mM glucose: +69%, $p = 0.005$). The ADP degrading enzyme apyrase was found to increase both insulin (+122%, $p < 0.001$) and glucagon (+45%, $p < 0.001$) secretion at low (1 mM) glucose, whereas at high glucose (20 mM), insulin secretion was inhibited (-45%, $p = 0.003$) and glucagon secretion was promoted (+118%, $p < 0.001$).

Conclusion: In this study we have found that the ADP receptors P2Y₁ and P2Y₁₃ are expressed in islets and isolated beta-cells from the mouse and that P2Y₁₃ mediated signaling has an inhibitory effect on both insulin and glucagon secretion in the mouse. We have also shown that inhibition of the P2Y₁₃ receptor results in an increased secretion of both insulin and glucagon, and that administration of the ADP degrading enzyme apyrase affects islet hormone release, suggesting that endogenous ADP is a mediator of both insulin and glucagon secretion in mouse islets. We conclude that inhibition of the P2Y₁₃ receptor might be an interesting novel therapeutic approach aimed at increasing the natural insulin secretion from pancreatic islets.

Induction of cyclic AMP responsiveness in pseudoislets constituted from beta cell-beta cell interactionM. Iwasaki¹, K. Minami¹, T. Shibasaki¹, T. Miki², J.-I. Miyazaki³, S. Seino^{1,4}

¹Divisions of Cellular and Molecular Medicine, Kobe University Graduate School of Medicine, Kobe, ²Department of Autonomic Physiology, Chiba University Graduate School of Medicine, ³Department of Nutrition and Physiological Chemistry, Osaka University Graduate School of Medicine, ⁴Diabetes, Metabolism and Endocrinology, Kobe University Graduate School of Medicine, Japan

Background and aims: Cell-cell interactions are involved in the regulation of cellular functions. It has been shown that insulin secretion from intact pancreatic islets is greater than that from dispersed β-cells, and that reaggregation of the dispersed β-cells improves the secretory response. Thus, cell-cell interactions may well have a role in pancreatic β-cell function. However, the

effect of cell-cell interaction on insulin secretion is little understood. We have addressed the role of β-cell-β-cell interaction on insulin secretory properties and intracellular signals by comparing monolayer-cultured clonal β-cells (MCCs) and three-dimensional islet-like structure or pseudoislets (PIs) constituted from clonal β-cells.

Materials and methods: PIs were formed from clonal β-cells (termed MIN6-K20 cells) by culture on gelatin-coated dishes for seven days. Insulin secretion was measured by batch incubation method with stimulation of glucose, glucagons-like peptide-1 (GLP-1), or 8-Br-cyclic AMP, and cellular insulin was extracted with acid ethanol. Cellular cyclic AMP was also measured. Data were normalized by DNA content.

Results: The newly established β-cell line MIN6-K20 secretes insulin in a regulated manner, but the cells do not respond to GLP-1, an incretin hormone that potentiates insulin secretion through cyclic AMP signaling. We found that insulin content in MCCs of MIN6-K20 cells was much lower than that in native islets, formation of PIs increased insulin content (0.95 ± 0.02 ng/ng DNA in MCCs vs. 6.88 ± 0.57 ng/ng DNA in PIs) in MIN6-K20 cells to a level comparable to that in native mouse islets (6.81 ± 0.47 ng/ng DNA). In contrast, mRNA expression levels of insulin 1 and insulin 2 were not changed by formation of PIs. In addition, formation of PIs in the cells induced GLP-1 responsiveness of insulin secretion. While cyclic AMP content was only slightly increased by GLP-1 in MCCs (2.6-fold), it was drastically increased in PIs (11.2-fold). Even in the presence of phosphodiesterase inhibitor, cyclic AMP content in PIs (15.16 ± 3.06 fmol/ng DNA) was significantly higher than that in MCCs (0.69 ± 0.09 fmol/ng DNA), indicating that cyclic AMP production is increased in PIs. Moreover, potentiation of insulin secretion by 8-Br-cyclic AMP was significantly higher in PIs (0.09 ± 0.01 ng/ng DNA) than in MCCs (0.06 ± 0.01 ng/ng DNA), suggesting that signals downstream of cyclic AMP are enhanced in PIs.

Conclusion: Our data show that cyclic AMP signaling and insulin secretory response are induced by constitution of PIs. Thus, the three dimensional structure formed by β-cell-β-cell interaction is critical for normal regulation of insulin secretion.

478

K_{ATP}-channel independent insulinotropic effect of the imidazolines: an exception to the rule?K. Hatlapatka¹, A. Wienbergen¹, A. Jörns², M. Willenborg¹, I. Rustenbeck¹¹Institute of Pharmacology and Toxicology, University of Braunschweig,²Institute of Anatomy, Hannover Medical School, Germany

Background and aims: The marked glucose-dependency of the imidazoline-induced insulin secretion has been ascribed to K_{ATP} channel-independent effects. This hypothesis was tested using islets from SUR1 KO mice which have no functional K_{ATP} channels.

Materials and methods: Insulin secretion was measured by perfusion of NMRI and SUR1 KO mouse islets, K_{ATP} channel activity and plasma membrane potential by patch clamping and cytosolic free calcium concentration [Ca²⁺]_i by microfluorimetry.

Results: 100 μmol/l efaroan enhanced insulin secretion when the glucose concentration was stimulatory (10 mmol/l) but not when it was basal (5 mmol/l). The secretory pattern elicited by 10 μmol/l RX 871024 closely resembled that of 100 μmol/l efaroan, consistent with a K_{ATP} channel block of comparable magnitude (reduction by 85%). Consequently, all of the named imidazoline compounds induced a rise in [Ca²⁺]_i in NMRI mouse islets, even in the presence of a basal glucose concentration. In contrast to 10 μmol/l RX871024, 100 μmol/l RX massively stimulated insulin secretion at basal glucose. The insulin secretion by SUR1 KO islets was neither increased by efaroan, nor by alinidine nor by phentolamine. Again, RX871024 was different in that 100 but not 10 μmol/l RX871024 stimulated secretion by SUR1 KO islets both at 5 and 10 mmol/l glucose. This was confirmed by electron microscopy of the granule content.

Conclusion: Only RX871024 at a high concentration, but not the other K_{ATP} channel blocking imidazolines, exerts a K_{ATP} channel-independent insulinotropic effect. This effect, however, does not seem to be responsible for the marked glucose dependency.

Employing genetically encoded Ca^{2+} indicators to assess beta cell Ca^{2+} homeostasis

S. Speier, T. Moede, B. Leibiger, D. Kaiser, I.B. Leibiger, P.-O. Berggren
The Rolf Luft Research Center for Diabetes and Endocrinology, Karolinska Institutet, Stockholm, Sweden

Background and aims: Changes in cytoplasmic free Ca^{2+} concentration ($[\text{Ca}^{2+}]_i$) are a key mechanism in beta-cell signal transduction, being involved in the regulation of insulin secretion, gene transcription and cell death, respectively. To investigate these mechanisms, Ca^{2+} imaging experiments in beta-cells have so far mainly employed synthetic Ca^{2+} indicators. However, genetically-encoded Ca^{2+} indicators (GECIs) serve several advantages over synthetic sensors. Employing GECIs enables monitoring Ca^{2+} in a genetically-defined cell population or specific subcellular compartments. Furthermore, the use of GECIs would allow long-term Ca^{2+} imaging of beta-cells *in vivo*. We tested several GECIs to evaluate suitable GECIs for assessing beta-cell Ca^{2+} homeostasis with the aim to establish a system that enables assessment of beta-cell physiology non-invasively *in vivo*.

Materials and methods: Three different GECIs, YCAM2.3, Design3 and GCAMP2, were first tested in MIN6 cells and isolated islets *in vitro*. For the transfection of beta-cells in islets the constructs were incorporated into adenoviral vectors. Islets transduced with the GECI containing adenovirus were tested *in vitro* or transplanted into the anterior chamber of the eye of mice via injection through the cornea to enable *in vivo* studies. For measurements of changes in fluorescence of the GECIs widefield fluorescence microscopy, confocal and two-photon laser scanning microscopy were used.

Results: For stimulation, transfected MIN6 cells were perfused with 16 mM glucose, 30 mM KCl or 100 μM glibenclamide. The Fluorescence resonance energy transfer (FRET) based GECIs YCAM2.3 and Design3 showed an increase in the yellow fluorescent protein (YFP) / cyan fluorescent protein (CFP) ratio of at least 50% after stimulation. The green fluorescent protein (GFP) based GECI GCAMP2 showed an increase in single wavelength fluorescence of more than 2-fold. Stimulation of changes in $[\text{Ca}^{2+}]_i$ by perfusion of transduced islets with 30 mM KCl and 100 μM glibenclamide lead to increases in GFP fluorescence or the YFP / CFP ratio comparable to the results obtained in MIN6 cells. In response to elevated glucose levels all three GECIs showed oscillatory changes in fluorescence. First transplantations of transduced islets into the anterior chamber of the eye displayed no changes in engraftment compared to non-transduced islets and the fluorescent constructs were detectable for several months.

Conclusion: We showed that the GECIs YCAM2.3, Design3 and GCAMP2 are useful indicators to assess beta-cell physiology *in vitro* by measuring changes in $[\text{Ca}^{2+}]_i$. Future experiments will evaluate the use of these GECIs in an *in vivo* system by transplanting islets transduced with GECIs into the anterior chamber of the eye. This will enable non-invasive long-term studies of beta-cell signal transduction in vascularized and innervated islets and will help to reveal function of the endocrine pancreas in health and disease.

Expression analyses of type 2 diabetes mellitus associated genes in clonal and primary beta cells and functional characterisation of INS-1E cells overexpressing the beta cell specific zinc transporter ZnT-8

M. Elsner, E. Knoche, S. Lenzen

Institute of Clinical Biochemistry, Hannover Medical School, Germany

Background and aims: The recent identification of new gene loci, which are associated with T2DM, opens new perspectives in the analyses of the pathomechanisms leading to the manifestation of the disease. In genome wide association studies (GWA) SNPs were discovered in the non-coding regions of several genes with so far unknown consequences for the expression of the respective gene. In the present study the gene expression of the most significant T2DM associated genes TCF7L2, SLC30A8 (ZnT-8), IGF2BP2, CDKAL1, CDKN2A and CDKN2B were analysed by quantitative real time PCR in the β -cell lines RINm5F, INS-1 and MIN-6 compared with primary islets and pancreas tissue.

Materials and methods: The expression of the genes was determined by absolute quantitative real time RT-PCR using a SYBR Green I assay. RNA was isolated from the cells and reverse transcribed into cDNA. For preparation of specific DNA standard cDNA fragments of the analysed genes were cloned into the pCR2.1 plasmid. The amount of specific mRNA per cell was calculated with the determined efficiency of the PCR reaction (1.8 to 1.96) using the software qPCR. For the expression study the coding region of the ZnT-8 was cloned into a lentiviral gene expression system. ZnT-8 overexpressing INS-1E cells were selected after viral transduction with the antibiotic blasticidin. The viability of the cells in dependence on the zinc content of the medium was determined by the MTT assay. Insulin secretion and content of the INS-1E-ZnT-8 cells was measured after static incubation by RIA.

Results: TCF7L2 was expressed in all cell types without significant differences. The expression of IGF2BP2 was significantly higher in human pancreas than in rat and mouse cells, which indicates a particular impact for the human system. In contrast the expression of CDKAL1 at relatively low levels in comparison to rodent cells seems to be of less importance for the examined human cells. An expression of the genes CDKN2A/B which were probably involved in the regulation of cell cycle and β -cell mass could not be detected in the human pancreas. The highest expression was measured in the MIN-6 cell line. The highest expression level for the SLC30A8 gene, which encodes for the β -cell specific zinc transporter ZnT-8, was detectable in MIN-6, INS-1E cells and human pancreas. An overexpression of the ZnT-8 transporter in INS-1E cells led to a more than 2 fold increase in glucose-stimulated insulin secretion (GSIS) at glucose concentrations $> 3 \text{ mmol/l}$ in comparison to non-transduced control cells. Interestingly, this increase of GSIS was independent from the zinc concentration of the culture medium indicating that the enhancement of the GSIS might be independent on the accumulation of zinc in the insulin granules.

Conclusion: The present study provides important data for further *in vitro* investigations on established beta cell lines to clarify the role of T2DM candidate genes for the physiology of β -cells. The β -cell specific zinc transporter ZnT-8 has the ability to enhance glucose-stimulated insulin secretion and may thereby represent a novel pharmacological target for the treatment of diabetes.

Glucokinase activators modulate glucose metabolism and glucose-induced insulin secretion in islets from GK/Par rats

M. Fradet¹, M.-H. Giroix¹, D. Bailbe¹, S. El Bawab², V. Autier², M. Kergoat², B. Portha¹

¹Physiopathol. Nutrition, CNRS UMR7059, Paris, ²Biochemistry Group, Merck-Serono, Chilly-Mazarin, France

Background and aims: Recently, the discovery and development of small-molecule glucokinase activators (GKAs) have been reported. The activators stimulate glucokinase activity via binding to an allosteric site on the enzyme and have been shown to decrease plasma glucose levels in healthy and diabetic animals. GKAs stimulate glucose phosphorylation in isolated hepatocytes and pancreatic beta-cells and it is considered that the increased glucose metabolism in these *in vitro* systems is accompanied by the expected

downstream effects. Thus, in rat hepatocytes GKAs stimulate glycolysis and glycogen synthesis whilst inhibiting gluconeogenesis and glycogenolysis. In beta-cell lines and in pancreatic islets isolated from normal rodents or human, GKAs amplify glucose-stimulated insulin secretion (GSIS). However, it has never been shown so far that this is also the case in diabetic islets, as it is unknown to what extent the beta-cell glucose metabolism is modulated by GKAs. In this respect, it was considered of interest to compare the metabolic and secretory responses to GKAs in islets freshly isolated from either normal Wistar (W) or spontaneously diabetic GK/Par rats.

Materials and methods: The two compounds Ro-28-1675 (C1) and GKA50 (C2) were tested at maximally effective dosage *in vitro* (10 μ M). The rates of appearance of $^3\text{H}_2\text{O}$ and $^{14}\text{CO}_2$ formed from $[5\text{-}^3\text{H}]\text{glucose}$ and $[6\text{-}^{14}\text{C}]\text{glucose}$ during 120 min islet incubations at 37°C, were measured and taken as evaluations of the islet glucose utilisation and glucose oxidation respectively. Insulin release was determined under similar conditions in parallel experiments.

Results: In normal W islets, both C1 and C2 markedly increased the glycolytic flux and the glucose oxidation rate, at low (G 2.8 mM) and intermediate glucose (G 8 mM) concentrations, while at G 16 mM, they were far less efficient. Concerning stimulation of insulin release, both activators were more efficient at low and intermediate glucose concentrations shifting the dose-response curve for glucose to the left with no effect on the maximal increase in GSIS. The fact that the activators did not further increase insulin secretion stimulated by G 16 mM is consistent with the observation that at high G concentrations, other metabolic enzymes downstream of glucokinase become rate limiting and insulin secretion no longer parallels glucokinase activity. In the absence of G, C1 and C2 did not affect insulin release. In diabetic GK/Par islets, both compounds promoted a pattern of activation of glucose metabolism and insulin secretion very similar to that reported in W islets, resulting in a notable potentiation of G 8 mM-induced insulin secretion (1.6 fold and 1.8 fold, in response to C1 and C2 respectively).

Conclusion: We have shown for the first time that GKAs cause in diabetic islets (as in normal islets) an increase in glucose-induced insulin secretion correlated with an increased glucose oxidation rate. This associated with a leftward shift of the glucose dose-response profile seen in these islets, while the maximal response remains unaffected. These data further document a role for GKAs as novel utilities in the therapeutic management of mild diabetes.

Adaptative secretory changes to a fructose-induced insulin resistance state: role of glucokinase and glucose metabolism in the islets

B. Maiztegui, M.I. Borelli, J.J. Gagliardino

Cenexa (UNLP-CONICET), National University of La Plata School of Medicine, Argentina

Background and aims: The role of glucokinase (GK) in the compensatory increased secretion of insulin observed in rats with normoglycemia and dietary-induced insulin resistance (IR) was studied.

Materials and methods: Normal male Wistar rats received a standard commercial diet and tap water without (control, C) or with (FRD) 10% fructose for 3 weeks. Blood glucose (strips), triglyceride (commercial kit) and insulin (radioimmunoassay) levels were measured at the time of sacrifice. Islets were isolated by collagenase digestion to study glucose-induced insulin release, glucose metabolism ($^{14}\text{CO}_2$ and $^3\text{H}_2\text{O}$ production from labeled glucose), hexokinase (HK) and GK transcription (RT-PCR), protein expression (Western blot), compartmentalization (cytosol and particulate fractions) and activity (bioassay).

Results: C and FRD rats had similar body weights. FRD rats presented normoglycemia, hypertriglyceridemia, hyperinsulinemia and increased HOMA-R index. FRD islets released significantly more insulin and produced higher amounts of $^{14}\text{CO}_2$ and $^3\text{H}_2\text{O}$ in response to high glucose. While no differences were found in HK transcription, protein expression and activity between groups, GK total and cytosolic fraction activity and protein expression were significantly higher in FRD rat islets. FRD did not induce significant changes in GK transcription rate.

Conclusion: Our results demonstrate that in rats with sustained induced IR and normoglycemia, GK activity increased due to a combination of post-translational mechanisms of increased GK protein amount and compartmentalization, which resulted in increased glucose metabolism and insulin secretion. These data demonstrate that GK plays a pivotal role in functional islet adaptation to maintain normal glucose homeostasis.

Insulin resistance modifies plasma membrane calcium-ATPase activity and isoform expression in rat pancreatic islets

M.E. Alzugaray¹, M.E. García¹, H.H. Del Zotto¹, J.P.F. Rossi², J.J. Gagliardino¹, L.E. Flores¹

¹Endocrinology, Cenexa (UNLP-CONICET), La Plata, Argentina, ²IQUIFIB, UBA-CONICET, Buenos Aires, Argentina

Background and aims: Despite the extensive knowledge about the patterns of Plasma Membrane Calcium-ATPase (PMCA) and their regulatory role upon insulin secretion under normal conditions, there are scarce reports on their possible changes and their participation in the pathogenesis of diseases that affect islet function, such as type 2 diabetes. Insulin resistance (IR) is an early abnormality present in such disease, so the knowledge of PMCA state in that condition could help to understand their possible participation in the pathogenesis of type 2 diabetes. The aim of the present study is to study the effects of IR induced by dietary manipulation upon islet PMCA activity and expression, insulin secretion, glucose metabolism and morphometric parameters of β -cells.

Materials and methods: Normal male Wistar rats were fed for 21 days with a commercial diet and water without (control) or with 10% fructose (FRD). After 21 days the animals were sacrificed and blood samples were used to determine plasma glucose, triglyceride and insulin levels, and whole pancreas were removed for immunocytochemical studies and islets isolation to measure insulin release, glucose metabolism, PMCA activity and transcription/expression of PMCA isoforms.

Results: Body weight and plasma glucose levels were similar in both groups, but FRD rats have significantly higher levels of triglyceride and insulin, insulin:glucose ratio and HOMA-R index as shown in the table. FRD islets released *in vitro* more insulin in response to glucose and metabolized more glucose than control islets. On the other hand, they showed a significant decrease in protein content of PMCA2 ($p < 0.001$), an increase of PMCA3 ($p < 0.01$), and no significant changes in PMCA1 and 4. PMCA activity was significantly lower in FRD islets (1.22 ± 0.09 vs. 1.57 ± 0.11 pmol Pi/ug/h; $p < 0.02$), but this difference disappeared when calmodulin activity was blocked with calmidazolium. β -cell mass decreased significantly in FRD rats (6.22 ± 1.00 vs. 3.89 ± 0.40 mg, $p < 0.05$), with no significant differences in the pancreatic PMCA cellular distribution pattern.

Conclusion: FRD simultaneously induced IR, a decrease in β -cell mass, a decrease in PMCA activity, and an increase in glucose metabolism of the islets. Functional changes favor the compensatory greater release of insulin necessary to cope with the IR state, maintaining glucose homeostasis within normal range. Thus, changes in PMCA activity and in its isoforms expression play a modulatory role upon insulin secretion during long-term adaptation to an increased hormone demand.

	Control	FRD	P Value
Body weight gained during treatment (g)	69.2 \pm 0.71	72.3 \pm 0.85	NS
Glucose (mg/dl)	130.1 \pm 4.4	131.6 \pm 3.2	NS

Changes in neuronal NO synthase dimerisation state but not catalytic activity are involved in the hypersecretion of insulin in obese Zucker fa/fa rats

K. Mezghenna, M. Manteghetti, C. Jahannault, P. Petit, R. Gross, A.-D. Lajoix

UMR 5232, CNRS, Montpellier, France

Background and aims: In rat pancreatic β -cell, we have previously shown the expression of an isoform of neuronal NO synthase (nNOS), that controls insulin secretion through metabolic and non-metabolic activities. This latter activity is related to the interaction of nNOS with its protein inhibitor

PIN at the level of insulin secretory granules. PIN is also the light chain of cytoskeletal motors like myosin V. Zucker fa/fa rats are hyperphagic, obese, insulin-resistant and hyperinsulinic animals, due to a mutation in the leptin receptor. In these animals, the hypersecretion of insulin is persistent even if islets are maintained in culture for a long period, suggesting a constitutive defect of pancreatic β -cell. Our aim is thus to search if nNOS abnormalities could be involved in β -cell dysfunction observed at early stages of diabetes, using the Zucker fa/fa rat model.

Materials and methods: nNOS and PIN expression was studied by quantitative RT-PCR and Western blotting using monoclonal antibodies. Dimerization of nNOS was analyzed by low temperature SDS-PAGE without boiling the samples, followed by a Western blotting. nNOS catalytic activity was measured by the production of citrulline from radiolabeled arginine. Immunofluorescence studies were performed on isolated β -cells with specific polyclonal antibodies against nNOS, PIN and myosin V.

Results: In islets of Zucker fa/fa rats, we first observed a 7-fold increase in nNOS proteic expression. We also analyzed the monomer/dimer equilibrium of nNOS and found higher amounts of nNOS dimers in fa/fa rats as compared to the fa/+ rats. Surprisingly, nNOS catalytic activity was diminished by 25% in the fa/fa rats, suggesting the presence of inactive nNOS dimers. We analyzed the presence of nNOS phosphorylation at Ser 847, known to inactivate the enzyme through inhibition of calmodulin binding. An enhanced phosphorylation of both nNOS monomers and dimers could be observed in the fa/fa rats. Using confocal microscopy, nNOS displayed a greater colocalization with insulin secretory granules and its protein inhibitor PIN, which is also overexpressed in fa/fa rats and strongly associated with myosin V.

Conclusion: As pharmacologically-induced nNOS dimers account for a monophasic enhanced insulin response to glucose, the increased nNOS dimerization state observed could be involved in the hypersecretion of insulin present in the Zucker fa/fa rats, through interactions of nNOS with PIN and myosin V at the insulin secretory granules rather than through an increased catalytic activity.

Roles of islet glucose 6 phosphatase related protein in islet function *in vivo* and *in vitro*

P.G. Pirot¹, S.I. Hackl¹, S.A. Sarkar¹, R.M. O'Brien², H.W. Davidson¹, J.C. Hutton¹

¹Barbara Davis Center for Childhood Diabetes, University of Colorado Denver, Aurora, ²Barbara Davis Center for Childhood Diabetes, Vanderbilt University, Nashville, United States

Background and aims: Islet glucose 6-phosphatase catalytic subunit related protein (IGRP) is a major autoantigen in type 1 diabetes and a candidate gene in type 2 diabetes. It was originally identified on the basis of its sequence similarity to the catalytic subunit of liver glucose 6-phosphatase (G6Pase), and like G6Pase is localized to the endoplasmic reticulum. However, it is a pseudogene in the rat, and its precise role in pancreatic beta cell function in humans and mice remains unclear. The aim of this study was to address this issue by determining the catalytic properties of IGRP.

Materials and methods: G6P assays were conducted using isolated islets from Balb/c mice, and Cos-7 cells transfected with mouse G6Pase, IGRP, or G6Pase/IGRP chimeras. Cell lysates were prepared by freeze-thawing and/or sonication and incubated for 2 h at 30°C with 0.5 μ Ci [¹⁴C] G6P. After precipitation with a mixture of zinc sulfate and barium hydroxide to remove unreacted substrate the product was measured by liquid scintillation counting. Protein concentrations were measured by BCA assay, and IGRP expression analyzed by western blotting using a rabbit polyclonal antibody. In some experiments islets were cultured overnight prior to analysis.

Results: Freshly isolated islets hydrolyzed G6P at 21 ± 3 nmol/min/mg. This activity was maintained after overnight culture in 11.1 mM glucose. In contrast, culture in low glucose (5.6 mM) resulted in an ~66% reduction in G6Pase activity (7 ± 2 nmol/min/mg), suggesting that IGRP may be involved in the regulation of insulin secretion. The decreased activity resulted from turnover of the protein as evidenced by semi-quantitative western blotting. Cos-7 cells transfected with vector alone had an apparent basal G6Pase activity of 2 nmol/min/mg. A 4.3-fold increase (8.6 nmol/min/mg) was observed after transfection with wild-type IGRP, which was not seen with a mutant (R79A) in the presumptive catalytic domain. In contrast, transfection with liver G6Pase resulted in an activity of 2900 ± 150 nmol/min/mg. To investigate the structural features that resulted in the ~330 fold greater activity of the liver enzyme we created a series of chimeras. Substitution of the final 3 transmembrane domains (TMDs) of G6Pase with the equivalent regions of IGRP

had no significant effect on activity. In contrast, chimeras containing only the first 3 TMDs of G6Pase had a similar activity to IGRP, which was also true of chimeras containing the first IGRP TMD and the final 8 TMDs of G6Pase.

Conclusion: IGRP appears to be the principal enzyme responsible for the low level G6Pase activity in mouse islets. It undergoes rapid changes in expression in response to glucose, consistent with a role in regulating insulin secretion. Chimeras with liver G6Pase that do not involve regions predicted to form the catalytic site have no effect, suggesting that the overall topology of the 2 proteins are equivalent. In contrast, introduction of elements of the IGRP catalytic site into G6Pase significantly decreases activity. Although IGRP conceivably forms a substrate cycle with glucokinase, it appears not to be simply a regulator of glycolysis.

Rosiglitazone prevents fatty acid induced increases in uncoupling protein 2 gene expression and protects pancreatic beta cells from lipotoxicity

T. Ali¹, C. Landy¹, C.E. Marriott¹, R. Crawford², A. Woollhead¹, M. Harrison¹, W.M. Macfarlane¹

¹School of Pharmacy & Biomolecular Sciences, University of Brighton, ²Bute Medical School, University of St Andrews, United Kingdom

Background and aims: A wealth of recent evidence implicates increasing obesity levels in the rising global epidemic of type 2 diabetes. At a cellular level, high fatty acid concentrations contribute to increasing beta-cell dysfunction and the eventual loss of beta-cell viability. The free fatty acid palmitate has been shown to act in part through elevation of uncoupling protein 2 (UCP2) mRNA levels within the beta-cells. We have recently shown that the thiazolidinedione rosiglitazone has direct effects on pancreatic beta-cell gene expression. The aim of the present study was to test the hypothesis that rosiglitazone can protect beta cells from lipotoxicity, and to determine the specific effect of this drug on UCP2 gene expression.

Materials and methods: Utilizing the mouse beta cell line Min6, real time PCR was employed to determine the effects of palmitate and rosiglitazone on UCP2 gene expression. MTT viability assays were used to determine the effects of these agents on Min6 cell viability. These methods were combined with selected inhibitors of AMPK, CK2 and PPAR γ activity to investigate the signaling events mediating these effects.

Results: MTT assays showed that addition of 0.5 mM palmitate for 72 hours resulted in a 70% loss of Min6 cell viability ($P < 0.01$). However, the presence of 10 μ M rosiglitazone completely abolished the detrimental effect of palmitate, protecting beta cell viability. At a gene expression level, palmitate exposure significantly increased UCP2 mRNA levels ($p < 0.05$). In contrast, rosiglitazone alone had no significant effect on UCP2 gene expression. However, addition of rosiglitazone prior to palmitate completely abolished the effect of palmitate on UCP2 expression ($p < 0.05$). The ability of rosiglitazone to block palmitate-induced increases in UCP2 gene expression was abolished by addition of the PPAR γ antagonist GW9662, suggesting that the effects of rosiglitazone on UCP2 expression under these conditions are mediated through the modulation of PPAR γ activity. At the level of individual kinase activities, addition of 10 μ M rosiglitazone significantly increased the activity of both AMPK ($p < 0.05$) and casein kinase 2 (CK2) ($p < 0.01$) in Min6 cells. The AMPK inhibitor compound C was able to completely block the protective effect of rosiglitazone on cell viability ($p < 0.01$). CK2 inhibitor TBB was able to partially block the effects of rosiglitazone on cell viability ($p < 0.05$), suggesting that AMPK lies upstream of CK2 in the cell signaling events being stimulated by rosiglitazone. Neither inhibitor was able to block the ability of rosiglitazone to suppress palmitate-induced increases in UCP2 expression.

Conclusion and interpretation: The results of the present study indicate that rosiglitazone modulates multiple signaling pathways in pancreatic beta cells, protecting Min6 cells from the detrimental effects of palmitate and blocking palmitate-induced increases in UCP2 gene expression. The present study adds to a growing body of evidence indicating that rosiglitazone can have direct protective effects on beta-cell viability and function, and that these effects occur through both PPAR γ -dependent and PPAR γ -independent signaling pathways.

Pyruvate dehydrogenase kinase 1 knock down in INS-1 832/13 Cells enhances insulin secretion and the cellular NADPH/NADP⁺ ratioO.V. Kotova¹, U. Fransson¹, M.C. Sugden², H. Mulder¹¹Clinical Science, Unit of Molecular Metabolism, Lund University, UMAS, Malmö, Sweden, ²Centre for Diabetes and Metabolic Medicine, Barts and London School of Medicine and Dentistry, United Kingdom

Background and aims: While it is widely agreed that fuel metabolism in the pancreatic β -cell controls glucose-stimulated insulin secretion (GSIS), it has become increasingly clear that the precise ways in which carbons enter and exit the TCA-cycle are key regulatory events. Two major pathways for entry of carbons into the TCA-cycle are the reactions catalyzed by pyruvate dehydrogenase (PDH) and pyruvate carboxylase (PC), respectively; the latter has received a great deal of attention because it is remarkably prominent in the pancreatic β -cell. PC controls the major anaplerotic pathway in β -cells, and we and others have shown that its inhibition results in impaired GSIS. Here, we took an alternative approach and examined the effect of silencing PDH kinase 1 (PDK1) on GSIS and metabolism in INS-1 832/13 clonal β -cells. PDK1 is known to inhibit activity of PDH via phosphorylation, and the manipulation is envisaged to enhance TCA-cycle flux through PDH.

Materials and methods: PDK1 was knocked down in INS-1 832/13 cells by RNA interference (RNAi). After 72 h, insulin secretion, glucose oxidation, ATP/ADP ratio, PDH activity and the NADPH/NADP⁺ ratio were determined.

Results: PDK1 mRNA was reduced by 80% ($P < 0.001$), and PDK1 protein expression was decreased, as assessed by Western Blot. Knock down of PDK1 did not affect basal insulin secretion. Remarkably, cells treated with siRNA to PDK1 increased insulin secretion 5-fold ($P < 0.01$) in response to 16.7 mM glucose, while cells transfected with the negative control increased insulin secretion by only 3.1-fold. Insulin secretion provoked by two other metabolic fuels, leucine and succinate, was not influenced by knock down of PDK1. Knock down of PDK1 led to a 1.7-fold increase in PDH activity, but surprisingly, did not affect either glucose oxidation or the glucose-induced rise in ATP/ADP ratio. After stimulation with 16.7 mM glucose for 3 min, the NADPH/NADP⁺ ratio rose in both silenced and control cells. However, the ratio was 1.8-fold higher in 832/13 cells where PDK1 was silenced compared to control cells.

Conclusion: We suggest that maintenance of low PDK1 expression, keeping PDH in a dephosphorylated and active state, is an important factor in GSIS in pancreatic β -cells. Since secretion in response to leucine and succinate, which act distally to the exit of citrate and/or isocitrate from the TCA-cycle, was unaffected, it is possible that cycling of citrate and/or isocitrate to pyruvate accounts for enhanced GSIS. This agrees both with the observed exaggeration of the NADPH/NADP⁺ ratio in the cytosol, while neither glucose oxidation nor the ATP/ADP ratio was increased.

Assessment of the AstraZeneca glucokinase activator GKA50 on pancreatic beta cell function and viability in the clonal beta cell line BRIN-BD11N. Mullooly¹, P. Newsholme¹, D. Smith²¹School of Biomolecular and Biomedical Science, University College Dublin, Ireland, ²AstraZeneca, Alderly Park, Macclesfield, Cheshire, United Kingdom

Background and aims: Pancreatic beta cells fail to secrete appropriate amounts of insulin for glycaemic control in type 2 diabetes. Therapeutic strategy for type 2 diabetes includes increasing the insulin secretory capacity of the beta cells. Glucokinase has emerged as a promising target for an anti-diabetic agent. This enzyme has been designated the “glucose sensor” due to its concentration dependent control over glucose metabolism and thus insulin secretion. Genetic analysis and structural studies reveal the enzyme possesses an allosteric activation site. Molecular compounds which bind to this site stabilize glucokinase in its closed conformation increasing its affinity for glucose and should enhance glucose stimulated insulin secretion in the pancreatic beta cell. We have tested the glucokinase activator GKA50 with respect to clonal beta cell (BRIN-BD11) metabolism, insulin secretion and cellular integrity. This bioengineered cell line has a high glucokinase-hexokinase ratio compared to other beta cell lines, and exhibits bi-phasic glucose stimulated insulin secretion, consistent with normal beta cells.

Materials and methods: The metabolic and insulin secretory action of GKA50 was determined using basal (1.1mM) and stimulatory (16.7mM) glucose + alanine (10mM) static incubation conditions. Insulin secretion was determined by ELISA. The effects of GKA50 on cell growth and viability was assessed using the WST-1 cell viability assay.

Results: We have shown that micromolar concentrations of GKA50 are potent activators of glucokinase and increase glucose stimulated insulin secretion in BRIN-BD11 cells in a dose dependent manner, becoming significant at 10 μ M GKA50 ($p < 0.05$). GKA50 stimulated insulin secretion was further enhanced by the presence of 10mM alanine. No significant difference in viability was found between cells incubated in the absence or presence of GKA50, even at concentrations of 100 μ M.

Conclusion: Increased activation of glucokinase increases cellular glucose metabolism and insulin secretion. Our results highlight the importance of glucokinase in metabolic regulation and stimulus secretion coupling in pancreatic beta cells. Glucokinase activator drugs offer the possibility of effective pharmacological control over glycaemia and may be a novel therapeutic approach to the treatment of defective glucose stimulated insulin secretion in type 2 diabetes mellitus.

Over-expression of constitutively-activated or dominant-negative forms of AMP-activated protein kinase (AMPK) selectively in the beta cells of transgenic mice exerts opposing effects on glucose tolerance

G. Sun, G. da Silva Xavier, A. Riboulet-Chavey, T. Taneja, I. Leclerc, G.A. Rutter

Cell biology, Imperial college London, United Kingdom

Background and aims: Defective insulin secretion from pancreatic β cells underlies the progression towards type 2 diabetes. Whilst stimulation of AMP-activated protein kinase (AMPK) in insulin-sensitive tissues is an important mode of action of anti-hyperglycemic agents including metformin, the role of this enzyme in the β -cell is less clear. In order to address this question we have generated transgenic mice over-expressing constitutively-active (CA) or dominant-negative (DN) forms of AMPK under the rat insulin II (RIP) promoter.

Materials and methods: cDNAs encoding the truncated N-terminal domain common to AMPK α 1 and α 2 (residues 1–312) and carrying an activating mutation (T172D; AMPK CA) was fused downstream of a 0.6 kb proximal fragment of the RIP promoter. AMPK DN was generated similarly using full length AMPK α 1 cDNA (D157A), and the purified fragments were injected into oocytes from C57BL6 mice before re-implantation. The offspring of founders carrying 10 copies of the AMPK CA, or 2–5 copies of the AMPK DN transgenes, were characterized. Both RIP-AMPK CA C57BL6 mice and their wild type littermates were kept on normal chow diet, while DN mice and their wild type littermates were kept on high fat (60 %) diet from six weeks of age. Transgenic mice or littermates were fasted 16 h prior to intraperitoneal injection of glucose (1 g/kg body weight) for measurement of blood glucose (Roche, Accucheck glucometer), or 3 g/kg body weight for measurement of plasma insulin (Merchodia, ultrasensitive rat insulin ELISA). Insulin secretion from isolated islets was measured after batch incubation with 3 or 16.7 mmol/l glucose. Secreted and total insulin were quantified by radioimmunoassay using I^{125} -labeled insulin. All experiments were approved by UK Home Office according to Animals (Scientific Procedures) Act, 1986.

Results: RIP-AMPK CA (10 copies) female transgenic mice developed glucose intolerance at 24 weeks (peak glucose \pm SEM: transgenic = 14.76 ± 0.3 mmol/l, littermate controls = 12.45 ± 0.65 mmol/l; $n=4$; $p=0.039$) and male mice at 12 weeks (Peak glucose \pm SEM: transgenic = 16.78 ± 0.27 mmol/l, littermate controls = 15.33 ± 0.037 mmol/l; $n=2$). Both male and female transgenic mice showed a small decrease of plasma insulin levels (Male: transgenic = 0.38 μ g/l, littermate controls = 0.72 μ g/l; Female: transgenic = 0.53 μ g/l, littermate controls = 0.55 μ g/l) 15 min after glucose challenge, and reduced insulin secretion in islets from RIP-AMPK CA mice (transgenic = 0.25 ± 0.05 %/30 min., littermate controls = 0.57 ± 0.16 %/30 min; $n=2$, $p=0.044$) when stimulated by 16.7 (vs 3.0) mmol/l glucose. Male RIP-AMPK DN (2–5 copies) displayed unaltered glucose tolerance on a normal chow diet but significantly improved tolerance (Peak glucose \pm SEM: transgenic = 19.09 ± 0.8 mmol/l, littermate controls = 21.12 ± 0.97 mmol/l; $n=8$; $p=0.024$) after 12 weeks exposure to a high fat (60 %) diet.

Conclusion: Over-expression of AMPK in β cells impairs insulin secretory function *in vivo*, whereas this parameter is improved under conditions of β cell stress when AMPK activity is suppressed. The development of agents selective for AMPK complexes in β cells may provide a new therapeutic approach towards type 2 diabetes.

Deletion of protein kinase C epsilon in mice enhances glucose stimulated insulin secretion following lipid exposure by up-regulation of the amplifying pathways of insulin secretion

J. Cantley, G.L. Pearson, J.G. Burchfield, C. Schmitz-Peiffer, T.J. Biden
Diabetes and Obesity Research Program, Garvan Institute of Medical Research, Sydney, Australia

Background and aims: Deletion of protein kinase C epsilon (PKC ϵ) has been shown to protect mice from high fat diet induced glucose intolerance by enhancing glucose stimulated insulin secretion (GSIS). Islets isolated from PKC ϵ

knock-out (PKC ϵ KO) mice showed enhanced GSIS, relative to wild type (wt) islets, following lipid pre-treatment, although the mechanisms responsible for this are unknown. The amplifying pathways of GSIS allow glucose to dose dependently increase insulin secretion in a depolarised β -cell, independently of the canonical triggering pathway of GSIS. It has been demonstrated that the amplifying pathways function, in part, by increased partitioning of long-chain fatty acyl CoAs (LC-CoAs) into esterification pathways by inhibition of β -oxidation by glucose. Malonyl CoA production by acetyl CoA carboxylase (ACC) has been shown to regulate this partitioning in β -cells. Therefore, the aim of this study was to investigate the mechanisms of lipid dependent up-regulation of GSIS in PKC ϵ KO islets.

Materials and methods: Islets were isolated from 12 week old male mice and cultured for 48 hours in DMEM containing either 0.92% BSA alone (control), or 0.92% BSA coupled to 0.4mmol/l palmitate (lipid). Secretion experiments were performed using KRB with 10mmol/l HEPES and 0.1% BSA, containing either 2mmol/l or 20mmol/l D-glucose. Diazoxide (DZX 100 μ mol/l) was used to maintain open KATP channels and KCl (25mmol/l) to depolarise cell membranes. Insulin was assayed by RIA. Intracellular free calcium was measured by fluorescence microscopy. Phosphorylation of ACC and AMP activated protein kinase (AMPK) was determined by immunoblot. Data is presented as mean \pm SEM with statistical analysis using ANOVA and bonferroni post test.

Results: GSIS in response to 20mmol/l glucose was diazoxide sensitive in wt and PKC ϵ KO islets pre-treated with control BSA or lipid. To study amplifying GSIS, DZX and KCl were combined to initiate insulin secretion by depolarising cell membranes independently of KATP channel closure. Under these conditions (DZX+KCl), PKC ϵ KO lipid pre-treated islets showed a significant enhancement of amplifying GSIS in response to 20mmol/l glucose (wt control 1.39 ± 0.16 , wt lipid 1.76 ± 0.22 , PKC ϵ KO control 2.12 ± 0.23 , PKC ϵ KO lipid 3.55 ± 0.40 ; ng insulin secreted/islet/hour; $n=3$ experiments; PKC ϵ KO lipid vs other groups $P<0.01$). Glucose and KCl induced calcium influx was normal in PKC ϵ KO β -cells (wt control 17.4 ± 2.0 ; wt lipid 16.15 ± 1.89 ; PKC ϵ KO control 14.84 ± 1.3 ; PKC ϵ KO lipid 15.73 ± 1.92 ; AUC of calcium trace, $n=4$ experiments, NS) indicating that enhanced secretion was not due to altered calcium influx. Immunoblots showed decreased phosphorylation of AMPK threonine 172 and ACC serine 79 in PKC ϵ KO islets during culture with lipid.

Conclusion: These data show up-regulation of the amplifying pathways of GSIS in lipid pre-treated PKC ϵ KO islets, following a depolarising stimulus. Reduced phosphorylation of ACC and AMPK suggests altered lipid partitioning. PKC ϵ KO islets are therefore a model of enhanced amplifying GSIS, and may allow further elucidation of signalling mechanisms governing the amplification pathways. As PKC ϵ KO mice are protected from high fat diet induced glucose intolerance, up-regulation of amplifying GSIS by inhibition of PKC ϵ in humans represents a potential novel treatment for type 2 diabetes.

Insulin-stimulated PI(3,4)P₂ production by PI3K-C2 α and activation of glucokinase gene transcription in pancreatic beta cells

B. Leibiger¹, T. Moede¹, C.J. Barker¹, S. Uhles¹, J. Domin², P.-O. Berggren¹, I.B. Leibiger¹

¹The Rolf Luft Research Center for Diabetes and Endocrinology, Karolinska Institutet, Stockholm, Sweden, ²Renal Section, Imperial College School of Medicine, London, United Kingdom

Background and aims: Pancreatic β -cells are targets for positive feedback action by secreted insulin. We have shown that insulin activates the transcription of the β -cell glucokinase transcription unit (BGK) via the insulin receptor B-type (IR-B) and signalling via a class II PI3K-C2 α -like activity and PKB. The present study aimed at identifying the actual PI3K activity involved as well as the molecular mechanisms mediating this activation.

Materials and methods: BGK promoter-driven GFP expression in transfected HIT-T15, MIN6 and primary mouse β -cells served as the readout for BGK transcription. By combining the use of pharmacological inhibitors with transient over-expression of PI3K-C2 α and PKB variants, siRNA based knockdown of PI3Ks and PKB isoforms, PI-lipid profiling and co-localization analysis using life-cell confocal and TIRF microscopy, we now show that IR-B-mediated activation of BGK transcription involves the generation of PI(3,4)P₂ by PI3K-C2 α and the subsequent activation of the α -isoform of PKB.

Results: Because 100 μ M LY294002 or 150 nM Wortmannin was needed to block insulin-stimulated BGK promoter activity, i.e. concentrations similar to those that inhibit PI3K class II C2 α , we studied the involvement of PI3K-C2 α

in BGK transcription. Over-expression of both wild type PI3K-C2α as well as plasma-membrane-targeted PI3K-C2α-CAAX increased BGK promoter activity, while expression of the kinase-dead mutant PI3K-C2α-R1251P had no stimulatory effect. Vice versa, siRNA-mediated knockdown of PI3K-C2α abolished insulin-stimulated BGK activation without any effect on IR-A/PI3K class Ia-mediated insulin promoter activity. siRNA-mediated knockdown of PKB isoforms identified PKBα to be involved in insulin-stimulated BGK transcription. siRNA-mediated knockdown of PI3K-C2α abolished insulin-stimulated PKBα activation. PI-lipid profiling, combining LY294002-mediated inhibition of class Ia PI3K and siRNA-mediated knockdown of PI3K-C2α, identified PI(3,4)P₂ as the lipid product of PI3K-C2α in insulin-stimulated MIN6 cells. Life-cell confocal and TIRF microscopy demonstrated the colocalization of both PI3K-C2α and PKBα with IR-B at the plasma membrane of HIT and MIN6 cells.

Conclusion: Our data suggest that IR-B-mediated activation of PI3K-C2α results in the generation of PI(3,4)P₂, which activates PKBα and subsequently the transcription of BGK in the pancreatic β-cell.

Mediators of cyclic AMP action in glucose-stimulated pulsatile insulin secretion from single beta cells

O. Idevall-Hagren, E. Gylfe, A. Tengholm
Medical Cell Biology, Uppsala University, Sweden

Background and aims: Glucose stimulation of β-cells evokes synchronized oscillations of the cytoplasmic Ca²⁺ ([Ca²⁺]_i) and sub-membrane cAMP ([cAMP]_m) concentrations, which underlie pulsatile insulin release. However, it is not known how cAMP oscillations contribute to pulsatile insulin release. In the present study, we investigated the involvement of protein kinase A (PKA) and exchange protein directly activated by cAMP (Epac) for glucose-induced pulsatile insulin release from individual β-cells.

Materials and methods: Evanescent wave fluorescence imaging was used to record [cAMP]_m or [Ca²⁺]_i in parallel with phosphatidylinositol-3,4,5-trisphosphate (PIP₃). This membrane lipid is formed by autocrine insulin receptor activation and was used as readout for insulin secretion from single MIN6 β-cells.

Results: Elevation of the glucose concentration from 3 to 11 mM induced oscillations of [cAMP]_m, followed after a 14 s delay by PIP₃ oscillations reflecting pulsatile insulin release. Inhibition of cAMP formation with the adenylyl cyclase inhibitor 2',5'-dideoxyadenosine markedly reduced this PIP₃ response. Also the PKA inhibitors Rp-8-CPT-cAMPS (100 μM) or KT5720 (2 μM) diminished the time-average PIP₃ response to 72±7 % (n=35, P<0.02) and 41±10% (n=12, P<0.001) of control, respectively, when applied before glucose stimulation. In contrast, the PKA inhibitors had only a modest effect on already manifested PIP₃ oscillations. The reduction of the early PIP₃ response was accompanied by a temporal dissociation between the initial [Ca²⁺]_i and [cAMP]_m elevations due to a selectively shortened time lag between glucose stimulation and elevation of [Ca²⁺]_i from 164±5 s (n=11) to 134±7 s (n=20; P<0.01). Although insensitive to PKA inhibition, manifested PIP₃ oscillations in response to glucose were amplified by specific activators of both PKA and Epac.

Conclusion: The data indicate that coordination of [Ca²⁺]_i and [cAMP]_m signals are important for glucose-induced insulin secretion. Whereas PKA is important for the establishment of proper pulsatile insulin release, maintenance of secretion seems to involve a PKA-independent cAMP effector.

493

Zinc mediates feedback inhibition of cyclic AMP signalling and insulin secretion in beta cells

O. Dyachok, O. Idevall, A. Tengholm, E. Gylfe
Department of Medical Cell Biology, Uppsala University, Sweden

Background and aims: Glucose is the principal regulator of insulin secretion from pancreatic β-cells. Glucose increases the cytoplasmic Ca²⁺ and cAMP concentrations in β-cells, and it is well documented that cAMP is an important amplifier of Ca²⁺-triggered insulin release. Insulin is stored in secretory vesicles as a crystalline zinc complex and Zn²⁺ co-released with insulin has been proposed to exert a negative feedback on secretion by inhibiting Ca²⁺ influx after activation of hyperpolarizing K⁺ channels. Since Zn²⁺ has been

found to interfere with cAMP turnover in some cells, we tested the effects of Zn²⁺ on the kinetics of cAMP and Ca²⁺ signaling as well as insulin secretion from individual glucose-stimulated β-cells.

Materials and methods: MIN6 β-cells were transfected with a fluorescent translocation biosensor reporting phosphatidylinositol-3,4,5-trisphosphate (PIP₃). This membrane lipid is formed by autocrine insulin receptor activation and was used as readout for insulin secretion from single cells. The cytoplasmic cAMP concentration beneath the plasma membrane ([cAMP]_i) was detected by another translocation biosensor based on fluorescence-labeled protein kinase A subunits. Measurements of intracellular Ca²⁺ ([Ca²⁺]_i) and Zn²⁺ ([Zn²⁺]_i) concentrations were performed in cells loaded with the fluorescent indicators fura-2 and FluoZin-3, respectively. Changes in PIP₃ in the plasma membrane and [cAMP]_i and [Zn²⁺]_i in the sub-membrane space were recorded with evanescent wave microscopy.

Results: MIN6 β-cells reacted to glucose stimulation with pronounced oscillations of [Ca²⁺]_i and [cAMP]_i, as well as with pulsatile insulin release. The oscillatory patterns varied among cells and the responses sometimes faded with time. Glucose also induced elevation of [Zn²⁺]_i and oscillations were apparent in some cells. Addition of 30 μM Zn²⁺ markedly inhibited or even abolished the glucose-induced [cAMP]_i and insulin responses, but had a less pronounced effect on [Ca²⁺]_i oscillations. The inhibitory effects of added Zn²⁺ were not reversed by omission of the cation and chelation of residual extracellular Zn²⁺ with Ca-EDTA. In contrast, the membrane permeable heavy metal chelator TPEN (50 μM) readily restored the Zn²⁺-inhibited [cAMP]_i oscillations and insulin release. Moreover, TPEN immediately rescued spontaneously faded [cAMP]_i oscillations and pulsatile insulin release. Extracellular Zn²⁺ concentration-dependently suppressed basal cAMP production in the presence of the phosphodiesterase inhibitor IBMX and this effect was reversed by TPEN.

Conclusion: These data reveal a novel regulatory role for Zn²⁺ in β-cells by showing that Zn²⁺ co-released with insulin feedback inhibits cAMP formation and insulin secretion.

A metabolic comparison of glucose-responsive INS-1 832/13 and glucose-nonresponsive INS-1 832/2 cells

V.V. Sharoyko¹, K. Bacos¹, A. Abhyankar², C.L.F. Nagorny¹, H. Mulder¹, H. Luthman²

¹Unit of Molecular Metabolism, Department of Clinical Sciences in Malmö, Lund University; ²Unit of Medical Genetics, Department of Clinical Sciences in Malmö, Lund University, Malmö, Sweden

Background and aims: The biochemical mechanisms underlying glucose-stimulated insulin secretion (GSIS) from pancreatic beta-cells are not completely understood. Specifically, mitochondrial metabolism plays a key role in GSIS. In fact, several different mutations in mitochondrial DNA (mtDNA) cause a maturity-onset form of diabetes. In order to investigate putative mitochondrial disturbances in beta-cells that impact GSIS, we employed the two clonal isolates of INS-1 cells the glucose-responsive 832/13 and glucose-nonresponsive 832/2 cells. These clones are characterized by similar insulin content but exhibit specific differences in TCA-cycle fluxes. The anaplerotic pyruvate cycling pathway is more active in the glucose-responsive 832/13 cells. We examined the rate of glucose oxidation, which reflects TCA-cycle activity. We also sequenced mtDNA, which encodes transfer and ribosomal RNAs (rRNA) as well as 13 of the proteins in the multi-subunit enzyme complexes responsible for oxidative phosphorylation in mitochondria.

Materials and methods: Glucose oxidation and mitochondrial DNA sequencing in INS-1 832/13 and INS-1 832/2 cells were performed.

Results: The rate of glucose oxidation under basal conditions (2.8 mM glucose) was significantly higher in 832/2 cells than in 832/13 cells (2.7±0.5 versus 0.7±0.1 nmol glucose/mg protein/h, respectively; P<0.01). Upon stimulation with 16.7 mM glucose, the rate of glucose oxidation in 832/2 and 832/13 cells increased to 10.3±0.8 and 2.5±0.3 nmol glucose/mg protein/h, respectively (P<0.01). However, whereas the absolute rates of glucose oxidation were different in the two cell lines, the increment of glucose oxidation was similar in both clones (3.6-fold versus 3.8-fold in 832/13 and 832/2 cells, respectively). Moreover, mitochondrial DNA sequencing revealed a DNA sequence variant (1242 T/C) in the gene encoding 16S rRNA. T is the common allele in the rat and is found in the superior INS-1 832/13 cell line.

Conclusion: Glucose-nonresponsive INS-1 832/2 cells are characterized by a higher absolute rate of glucose oxidation compared to glucose responsive INS-1 832/13 cells, while the increment due to an increase in glucose concentration is similar. 16S rRNA is involved in the synthesis of mitochondrial

proteins found in the respiratory chain, and we suggest that the mutation in 16S rRNA may be one of the factors leading to impaired GSIS in INS-1 832/2 cells.

Islet GABA plays a dual role in the mechanism of stimulation of insulin secretion by α -ketoisocaproic acid

J. Pizarro-Delgado¹, I. Hernández-Fisac¹, R. Martín-del-Río², J. Tamarit-Rodríguez¹

¹Biochemistry, Complutense University, ²Research Department, Hospital "Ramón y Cajal", Madrid, Spain

Background and aims: We have previously found that α -ketoisocaproic acid (KIC) decreases strongly islet GABA content by promoting its metabolism in the "GABA shunt". Now, we have investigated whether GABA-decrease is necessary for the stimulation of insulin secretion.

Materials and methods: Hormone release was studied in rat perfused islets and insulin radioimmunologically measured every minute in the perfusate. Islet amino acids contents were quantified measuring their fluorescence after being derivatized with o-phthalaldehyde and separated by reverse-phase HPLC.

Results: 10 mM KIC stimulated a biphasic secretion of insulin whose magnitude was approximately one third lower than the one triggered by 20 mM glucose. Addition of a plasma membrane permeable precursor of GABA (ethyl-GABA = eGABA) at 1 mM clamps the intracellular GABA content at the values recorded at the plasma concentration of glutamine (close to 1 mM): it did not modify significantly first phase (13.1 ± 3.8 , $n=4$ vs. 23.8 ± 6.2 ng/10 min. \times 40 islets, $n=6$; N.S.) but suppressed second phase of KIC-induced release within 52 % (16.2 ± 3.0 , $n=4$ vs. 33.5 ± 3.0 ng/20 min. \times 40 islets, $n=6$; $p<0.005$). 30 mM KCl depolarization did not prevent eGABA-induced decrease. Surprisingly, a further reduction of the K^+ -electrochemical potential with 70 mM KCl induced *per se* a non significant decrease of the first phase (14.2 ± 2.2 , $n=6$ vs. 23.8 ± 6.2 ng/10 min. \times 40 islets, $n=6$; N.S.) and markedly suppressed by 52.5 % (15.9 ± 2.4 , $n=6$ vs. 33.5 ± 3.0 ng/20 min. \times 40 islets, $n=6$; $p<0.001$) the 2nd phase of KIC-induced release to a similar extent than 1 mM eGABA. No further reduction of 2nd phase insulin secretion was obtained by eGABA (5 or 10 mM) addition to 70 mM KCl but it was prevented by 10 mM glutamine (14.6 ± 2.3 , $n=6$ vs. 6.3 ± 1.1 ng/20 min. \times 40 islets, $n=6$; $p<0.008$). Amino acid analysis showed that 70 mM KCl decreased islet GABA content (752.5 ± 77.4 , $n=7$ vs. $1,109.1 \pm 74.2$ pmol/25 islets, $n=7$; $p<0.006$) to the same extent as 10 mM KIC (644.4 ± 65.6 , $n=7$ vs. $1,109.1 \pm 74.2$ pmol/25 islets, $n=7$; $p<0.0005$). However, at variance with KIC, 70 mM KCl induced a strong release of GABA (619.6 ± 106.5 , $n=8$ vs. 305.0 ± 22.9 pmol/25 islets, $n=6$; $p<0.01$) and taurine (227.0 ± 41.5 , $n=8$ vs. 110.4 ± 11.2 pmol/25 islets, $n=8$; $p<0.017$) and this pattern was not modified by the simultaneous application of KIC and KCl. Taurine content was not modified by KIC but it was decreased by 70 mM KCl (197.8 ± 20.7 , $n=8$ vs. 327.8 ± 24.9 pmol/25 islets, $n=8$; $p<0.001$).

Conclusion: KIC-induced reduction of the intracellular GABA concentration is necessary for the stimulation of insulin secretion because clamping it at "physiological" levels suppressed the second phase of release. Intracellular GABA depletion induced by its increased efflux at 70 mM KCl did not allow a normal stimulation of insulin secretion by KIC. GABA seems to play a dual role in the regulation of KIC-induced insulin release: maintaining its resting concentration suppresses secretion stimulation but the latter is favoured when GABA is lowered by increasing its metabolism.

Molecular mechanisms of nutrient stimulated insulin-containing vesicle transport in pancreatic beta cells - identification of secretory vesicle-specific motor protein receptors

S. Lajus, A. Varadi

Faculty of Applied Sciences, University of the West of England, Bristol, United Kingdom

Background and aims: Pancreatic beta-cells synthesize insulin and store it in large dense core vesicles (LDCVs). When the blood-glucose concentration increases, a biphasic secretion of insulin occurs. The first phase is rapid and transient whereas the second phase is slower and more sustained. Our pre-

vious studies have demonstrated that transport of LDCVs driven by motor proteins, kinesin 1 and myosin Va, from reserve pool to plasma membrane is important for the second phase of secretion. The recruitment of these motor proteins to LDCVs requires specific receptors. However, the molecular components of the motor protein - LDCV complex and their direct regulators have not been identified in pancreatic beta-cells.

Materials and methods: We used reverse transcription polymerase chain reaction (RT-PCR) to identify the beta-cell specific splice variants of the globular tail domain of myosin Va heavy chain which is known to be involved in cargo binding. We used immunoprecipitation with a myosin Va and a kinesin 1 specific antibody, GST pull-down experiments, followed by MALDI-TOF method in order to identify kinesin 1 and myosin Va-specific receptors and interacting partners on LDCVs.

Results: Myosin Va-organelle receptor is well characterised in melanocytes where exons ABCDEF are co-expressed. Exons F and D are essential for cargo binding and interaction with MyRIP. However, in beta-cells these exons are absent suggesting that the putative interaction partners of myosin Va in this cell type are different than that of in melanocytes. Immunoprecipitation experiments revealed that myosin Va and kinesin 1 are part of the same protein complex in beta-cells. To confirm the specific interaction as expected neither of these proteins form complex with the mitochondrial resident cytochrome C.

Conclusion: We now use the natural splicing variants of myosin Va and kinesin 1 to identify the novel secretory vesicle-specific motor protein receptors in beta-cells. Furthermore, the nutrient-induced signalling pathway implicated in the recruitment of these motors to LDCVs will be addressed. This study provides fundamental information on the molecular basis and regulation of insulin-granule mobilisation which is essential for the sustained phase of insulin release.

Down regulation of the mitochondrial malate-aspartate shuttle by knockdown of its key component Aralar1 in INS-1E beta cells

M. Casimir, P. Maechler

Department of Cell Physiology and Metabolism, University of Geneva, Switzerland

Background and aims: The NADH shuttle system transports reducing equivalents from the cytosol to the mitochondrial matrix and is essential for efficient coupling of glucose metabolism to insulin secretion. Among the NADH shuttles identified, the malate-aspartate has been shown to play the major role in pancreatic beta-cells. A key component of the malate-aspartate shuttle is Aralar1, also referred to as aspartate-glutamate carrier 1. We previously demonstrated that over-expression of Aralar1 increases glucose derived products into mitochondria and results in potentiated metabolism secretion coupling. In the present study, we addressed the reverse question by decreasing expression of Aralar1 by means of siRNA approach. This way, we aimed at evaluating the contribution of the malate-aspartate shuttle in insulin secreting cells along with possible compensatory mechanisms.

Materials and methods: We first identified siRNA construct down-regulating Aralar1. The selected construct was cloned into a recombinant adenovirus. Expression levels were assessed by immunoblotting. The most efficient titer (0.1 μ l per well of 24-well plates) was used to transduce INS-1E beta-cells for 1 hour and cells were subsequently cultured for 4 days before analyses. An empty adenovirus construct was used in control cells. Then, we measured parameters of the metabolism secretion coupling: cellular ATP concentrations, glucose oxidation, glucose utilization, lactate production, and NADH levels. Insulin secretory responses (analysed by RIA) to stimulatory glucose concentrations were also tested.

Results: Immunoblotting revealed that 4 days after transduction with anti-Aralar1 siRNA adenovirus, expression of Aralar1 was decreased by about 50%. The reduction in Aralar1 expression dramatically decreased glucose induced NADH generation. In parallel, depletion of Aralar1 decreased glucose oxidation by 20% compared to control cells ($p<0.01$). ATP measurements showed a typical 20% increase in control cells stimulated with 15 mM versus basal 2.5 mM glucose ($p<0.01$). Glucose-evoked ATP generation was only 50% of controls in Aralar1 knockdown INS-1E cells ($p<0.05$). Parameters reflecting pathways up-stream of mitochondrial metabolism, such as glucose utilization and lactate production, were not modified by Aralar1 knockdown. Despite the observed impairment in glucose induced mitochondrial activation, glucose stimulated insulin secretion was not significantly affected in Aralar1 knockdown INS-1E cells compared to controls.

Conclusion: Down regulation of the malate-aspartate shuttle by knockdown of Aralar1 resulted in marked reduction in glucose induced mitochondrial activation. Unexpectedly, such impairment was not accompanied by decreased glucose stimulated insulin secretion. Ongoing experiments investigate possible compensatory mechanisms.

Effects of diazoxide on beta cell mitochondrial function and mass are glucose-dependent

G. Larsson-Nyrén¹, Z. Ma², V. Grill^{3,2}, A. Björklund²

¹Integrative Medical Biology, Histology and Cell Biology, Umeå, Sweden,

²Dept. of Molecular Medicine and Surgery, Karolinska Institutet, Karolinska Hospital, Sweden, Rolf Luft Center of Diabetes Research, Stockholm, Sweden, ³Dept. of Cancer Research and Molecular Medicine, Trondheim, Norway, Norwegian University of Science and Technology, Trondheim, Norway

Background and aims: Diazoxide protects insulin secretion during chronic hyperglycemia and the drug has been considered for therapy. Beneficial effects could be secondary to opening effects of the drug on K-ATP channels in the plasma membrane. Also effects on beta cell mitochondria could potentially be important but are insufficiently clarified. Here we tested for effects of diazoxide on beta cell mitochondrial function and mass during culture conditions

Materials and methods: Rat pancreatic islets were used to investigate effects of diazoxide on mitochondrial membrane potential (MMP). Islets were cultured for 48 h at 5.5 or 27 mM glucose with and without diazoxide (325 µM). Islets were then loaded with Rhodamine123 (32 µM) for 10 min at 37° C. Measurements were carried out with a SPEX fluorolog-2 system coupled to an inverted microscope. Results were standardized by reference to the fluorescence obtained after the addition of 10 µM FCCP during the process of measurement.

Mitochondrial mass was assessed in isolated beta cells from *ob/ob* islets. Cells were cultured for 48 h in 5.5 or 27 mM glucose with or without diazoxide. After culture the distribution of the probe MitoTracker Red, which accumulates in active mitochondria, was measured using a Leica SP2 spectral laser scanning confocal microscopy equipped with a 250 mW argon/krypton laser.

Results: Culture of rat islets in 27 mM vs. 5.5 mM glucose expectedly increased (hyperpolarized) MMP (62 ± 2.9 vs. 68 ± 2.3 % of max FCCP, $p < 0.001$, $n = 23$). Pre-exposure of rat islets to diazoxide during the culture period (48 h) affected MMP in an opposite fashion when co-cultured with the high compared with the low glucose concentration. Thus, hyperpolarization was seen after co-culture with 27 mM glucose (-6 ± 4.2 % of max FCCP, $n = 7$) but depolarization after co-culture at 5.5 mM glucose ($+4 \pm 1.4$ % of max FCCP, $n = 10$). The difference between the MMP effect of diazoxide when co-cultured with 27 mM vs. when co-cultured with 5.5 mM glucose was highly significant, $p < 0.001$. Culturing beta cells from islets of *ob/ob* mice at elevated glucose (27 mM) increased the total area of each beta cell (from 132 ± 4 , $n = 29$ to 160 ± 6 arbitrary units, $n = 34$, $p < 0.005$). The mitochondrial area increased in proportion to the total cell area (from 95 ± 5 , $n = 29$ to 110 ± 6 arbitrary units, $n = 34$, $p < 0.1$). Both total cell and mitochondrial areas were significantly reduced by previous diazoxide (to 132 ± 6 , $n = 26$, $p < 0.001$ and 88 ± 4 , $n = 26$, $p < 0.019$ vs. 27 mM glucose only). In contrast, pre-exposure to diazoxide during co-culture with 5.5 mM glucose neither affected the total, nor the mitochondrial area.

Conclusion: The glucose concentration during culture determines the impact of diazoxide on MMP, indicating that diazoxide effects are governed by the degree to which mitochondria are energized. The glucose-dependent inhibitory effects by diazoxide on total and mitochondrial mass could reflect reduced demands for insulin biosynthesis and secretion. The glucose dependencies demonstrated here are in line with, and may be linked to the beneficial effects of diazoxide on insulin secretion which are restricted to sustained hyperglycemia.

On the urotensin II inhibition of insulin release, study in the perfused rat pancreas

R.A. Silvestre, E.M. Egido, R. Hernández, J. Marco

Exp. Endocrinology, Hospital Universitario Puerta de Hierro, Madrid, Spain

Background and aims: Urotensin-II (UII), a somatostatin-like peptide, has been found to be a highly potent vasoactive peptide in some vascular beds. We have previously demonstrated that UII is present in the pancreas and, in the perfused rat pancreas, it exerts a dose-response inhibition of glucose-induced insulin secretion. Furthermore, specific UII antagonists (urantide and palosuran) potentiate glucose-induced insulin secretion, thus supporting the concept that endogenous UII is an insulinostatic peptide. To gain further insight into the insulinostatic effect of UII, we have investigated the effect of this peptide on glucose-induced insulin secretion in the rat pancreas perfused at normal and high glucose concentrations, as well as its effect on the insulin release elicited by non-glucose secretagogues (tolbutamide, KCl and exendin-4).

Materials and methods: The study was performed in the isolated perfused rat pancreas. Rat UII (Peptide Institute Inc., Japan) was infused at 1 and 10 nM. Insulin secretion was stimulated by increasing perfusate glucose concentration (from 5.5 to 9 mM and from 9 to 13 mM), by increasing perfusate K⁺ concentration (from 5 to 11 mM), and by infusing tolbutamide (100 mg/l) or exendin-4 (1 nM). The effect of UII on exendin-4-induced insulin secretion was also studied in rats pretreated with pertussis toxin (*Bordetella pertussis*; Sigma-Aldrich, St. Louis, MO, USA; 3 µg/100 g b.w., i.p., 3 days before experiments). Insulin was analyzed by RIA.

Results: 1 nM UII significantly reduced the insulin secretion elicited by an increase in perfused glucose level from 5.5 to 9 mM, but not the insulin response induced by increasing glucose concentration from 9 to 13 mM. The insulin response to the latter glucose stimulus was reduced by a higher UII concentration (10 nM) (). UII, at 1 nM, significantly blocked the insulin response elicited by tolbutamide (incremental area: 377 ± 73 vs. 665 ± 72 ng/15 min in controls; $p < 0.05$) but not by KCl (44.8 ± 10.7 vs. 55.5 ± 9.8 ng/15 min in controls; $p = 0.486$). The insulin response to exendin-4, a GLP-1 analogue, was also reduced by 1 nM UII (34 ± 6 vs. 76 ± 9 ng/15 min; $p < 0.01$). The insulinostatic effect of UII on exendin-4-induced insulin secretion, observed in control rats, was not observed in Pertussis toxin-pretreated rats (exendin-4+UII: 242 ± 79 vs. 198 ± 75 ng/15 min in exendin-4 experiments; $p = 0.697$).

Conclusion: Our results confirm the insulinostatic effect of UII on glucose-induced insulin release at low glucose levels, and indicate that, at a high glucose concentration, the B cell is less sensitive to UII than at a low glucose level. Furthermore, UII inhibits tolbutamide-induced insulin secretion and does not affect the insulin response elicited by K⁺ depolarization, thus suggesting that ATP-dependent K⁺ channels might be implicated in its insulinostatic effect. Finally, UII also reduced exendin-4-induced insulin secretion, an effect not observed in Pertussis toxin-treated rats. Thus, the insulinostatic effect of UII can be accounted for, at least in part, by its inhibitory action on the adenylyl cyclase/cAMP system via a Pertussis toxin-sensitive Gi protein.

Role of cb1 and cb2 cannabinoid receptors on insulin secretion and glucose metabolism

R. Maldonado, C. Touriño, M.A. Martín, B. Rubi

Neurophar, Universitat Pompeu Fabra, Barcelona, Spain

Background and aims: Overactivation of the endocannabinoid system is linked to the development of abdominal obesity and associated metabolic disorders, contributing to a high risk of cardiovascular disease and type II diabetes. However, the specific role of CB1 and CB2 receptors on glucose homeostasis and pancreatic endocrine function is still controversial. Here, we analyzed the role of cannabinoid receptors on glucose homeostasis *in vivo* by using the mixed CB1-CB2 agonist CP55,490, the CB1 antagonist rimonabant and the CB2 antagonist SR144528 in C57BL/6J mice. In addition, we tested the effects of CB1-CB2 receptor activation on glucose-stimulated insulin secretion *ex vivo* in isolated mouse pancreatic islets.

Materials and methods: *In vivo experiments:* Overnight (15 h) fasted C57BL/6J mice were treated i.p. with 3 mg/kg rimonabant, 3 mg/kg SR144528 and/or 0.1 mg/kg CP55,490, at t=-25, -20 and -15 min respectively. At t=0 mice were administered glucose (2 g/kg). Blood samples were collected from the tail vein at t=0, 15, 30, 45, 60 and 120 min. Blood glucose was measured with Glucometer Elite device (Bayer, Leverkusen, Germany). *Ex vivo experiments:* Mouse pancreatic islets were isolated by collagenase digestion and cultured free-floating for 24 h in RPMI-1640 medium before use. For static incubations, islets were washed and preincubated in 2.8 mM glucose Krebs-Ringer bicarbonate HEPES buffer (0.1% bovine serum albumin). After 30 min preincubation, islets were washed in the same buffer. Batches of 3 islets were hand-picked and incubated for 60 min at 37°C in 200 µl at basal (2.8 mM) or stimulatory (11 mM) glucose concentrations in the presence or absence of CP55,490 (5 nM, 50 nM, 500 nM, 5 µM). Insulin was measured with Ultrasensitive mouse insulin ELISA (Mercodia AB, Uppsala, Sweden).

Results: Simultaneous activation of CB1 and CB2 receptor by CP55,940 did not affect glucose tolerance *in vivo*. Accordingly, insulin secretion in mouse islets stimulated with 11 mM glucose (5.2 fold vs. 2.8 mM glucose, $p < 0.05$) was not modified by the administration of CP55,940 at concentrations up to 500. A higher concentrations of CP 55,940, 5 µM, was required to inhibit glucose stimulated insulin secretion ($\sim 38\%$ $p < 0.05$). The selective activation of CB1 receptor *in vivo* by the co-administration of CP55,490 and the CB2 antagonist SR144528 induced a right shift on the glucose tolerance curve, indicating glucose intolerance. This effect was suppressed by the CB1 antagonist rimonabant.

Conclusion: CB1 AND CB2 receptor modulate glucose metabolism *in vivo* and insulin release in pancreatic islets *ex vivo*. CB1 activation *in vivo* impairs pancreatic function and glucose homeostasis in mice and this effect is reverted by the CB1 antagonist rimonabant.

Zinc transporter ZnT-8 regulates insulin and glucagon secretion in Min6 and α TC1-9 pancreatic cell lines

S.C. Souza, L. Qiu, K.E. Inouye, J.J. Roix, H. Chen

Cardiovascular and Metabolic Diseases, Novartis Institutes for BioMedical Research, Cambridge, United States

Background and aims: Alterations in zinc homeostasis are involved in the pathology of diabetes. In pancreatic islets, zinc plays an important role in insulin processing, storage, and secretion. Specifically, zinc is required for the formation of zinc-insulin hexamers within the secretory granules and packaging of insulin in this format is necessary for its efficient secretion. Control of zinc uptake and efflux is achieved through the action of specialized zinc transporter proteins. Recently, ZnT-8 (SLC30A8) was cloned and found to be, predominantly expressed in pancreatic β cells. Over-expression of human ZnT-8 in INS1 cells increased the intracellular zinc content and glucose-stimulated insulin secretion (GSIS) (J.Cell.Sci., 2006,119:4199). Of particular interest, whole-genome association studies have linked a non-synonymous variation of the ZnT-8 gene, R325W, with an increased risk of human type 2 diabetes (T2D) (Nature, 2007, 445:881). This study aimed to further explore the role of ZnT-8 in pancreatic clonal cells, and to understand how genetic variations in ZnT-8 affect the disease risk at cellular levels.

Materials and methods: Adenoviruses expressing human ZnT-8 variants W325 and R325 (the risk allele) were used to transduce Min6 insulinoma and α TC1-9 glucagonoma cells. Mouse ZnT-8 shRNAs were used to generate Min6 or α TC1-9 pancreatic stable cell lines with reduced ZnT-8 expression. Concentration of insulin and glucagon was determined using an Elisa assay. Sub-cellular localization of ZnT-8 variants proteins were assessed by confocal microscopy.

Results: In Min6 cells, over-expressed ZnT-8 W325 or R325 were co-localized with insulin. Moreover, over-expression of both variants resulted in a glucose dose-dependent stimulation of insulin secretion (up $\sim 80\%$ at 20 mM of glucose). There was no change in cellular insulin content and mRNA levels. Conversely, 50% knockdown of ZnT-8 in Min6 cells reduced basal insulin secretion by $\sim 40\%$. This reduction was accompanied by a ~ 1.7 fold increase in intracellular insulin content. α TC1-9 cells expressed high levels of endogenous ZnT-8. Over-expression of ZnT-8 W325 or R325 in α TC1-9 cells decreased glucagon secretion by $\sim 50\%$ and its cellular content by $\sim 30\%$. mZnT-8 knockdown in α TC1-9 cells, on the other hand, led to an increase of glucagon mRNA ($\sim 50\%$) and secretion ($\sim 69\%$).

Conclusion: The present study demonstrates that ZnT-8 is not only critical for insulin secretion in β cells, but also plays a complementary role in inhibit-

ing glucagon secretion directly in α cells. Although we have yet to determine the differential effects of the wild type and risk allele of ZnT-8 on islet secretory functions, our data provides evidence that ZnT-8 deficiency could adversely affect both insulin and glucagon metabolism, potentially contributing to an increased risk of T2D.

502

ZnT-3 knockout effects expression and glucose-mediated secretion of insulin in INS-1E cells

A.B. Petersen, K. Smidt, N.E. Magnusson, L. Egefjord, B. Brock, O. Schmitz, J. Rungby

Department of Pharmacology, University of Aarhus, Denmark

Background and aims: Insulin secreting β -cells contain large amounts of zinc which is necessary for the formation of stable insulin hexamers in secretory vesicles. Rising evidence points to a connection between zinc transporters (ZnTs) and diabetes. It has recently been shown that ZnT-8 functions as an antigen in the development of Type 1 diabetes and that mutations in the same gene is associated with Type II diabetes. Transporters of the Slc30A-family (ZnT-1 to 10) regulate zinc efflux from the cytoplasm. ZnT-3 has been identified in β -cells, the expression of ZnT-3 is glucose sensitive and ZnT-3 KO mice have decreased glucose tolerance. In this study we used siRNA-mediated knockdown to further investigate the role of ZnT-3 in insulin secretion from β -cells.

Materials and methods: 100 nM siRNA concentration was used to perform ZnT-3 knockdown in INS-1E cells. Knockdown of ZnT-3 and insulin expression at mRNA level was detected using Q-PCR. Following transfection and 48 hours of recovery the knockout and control cells were stimulated with various concentrations of glucose (2.0; 6.6; 16.7 and 24.6 mM) for 2 hours. Intracellular and secreted insulin following stimulation was then measured.

Results: Following transfection the expression of ZnT-3 was reduced to 57,86 % ($p < 0,05$) compared to mock-transfected controls. Insulin expression in cells transfected with ZnT-3 siRNA showed a fold change of -1,796 ($p < 0,05$) compared to mock-transfected samples. Insulin secretion data was analysed using 2-way ANOVA. ZnT-3 knockdown had a negative effect on the secretion of insulin at 16,7 mM glucose (figure) . At 25 mM the difference was abolished. The intracellular insulin content was unchanged in ZnT-3 transfected cells compared to the mock-transfected after the 2 hour glucose stimulation.

Conclusion: The influence of ZnT-3 on insulin expression and secretion has until now not been described. It has been shown that ZnT-3 is glucose-sensitive. The gene is up-regulated at high glucose levels when increased amounts of secreted insulin are needed. In this study we have shown that siRNA mediated knockdown of the ZnT-3 zinc-transporter in INS-1E cells results in decreased expression and glucose-mediated secretion of insulin at high glucose levels, although at 24,6 mM we found no difference, most likely due to glucose-toxicity. These findings add to the rising evidence demonstrating a connection between ZnTs and insulin secretion.

Dopamine transporter modulates glucose-stimulated insulin secretion in mouse pancreatic islets

B. Rubí, R. Maldonado

Departament de Ciències Experimentals i de la Salut, Laboratori de Neurofarmacologia, Barcelona, Spain

Background and aims: Recent studies highlight the relevance of widely known neurotransmitters, such as dopamine, in the modulation of various physiological functions outside of the CNS. In pancreatic islets, dopamine inhibits insulin secretion. Dopamine receptors are present in insulin granules of rodent and human beta cells. Dopamine D2 receptor polymorphisms are associated with obesity and type 2 diabetes and are predictive of body mass index categories. However, the origin and mechanism of action of dopamine acting in pancreatic islets is not yet fully understood. Here, we investigated whether dopamine transport into pancreatic islets is necessary for the inhibitory actions of dopamine. For this purpose, we analyzed the effects of the dopamine transporter inhibitor nomifensine on glucose stimulated insulin secretion in isolated mouse islets.

Materials and methods: Mouse pancreatic islets were isolated by collagenase digestion and cultured free-floating for 24 h in RPMI-1640 medium before use. For static incubations, islets were washed and preincubated in 2.8 mM glucose Krebs-Ringer bicarbonate HEPES buffer (0.1% bovine serum albumin). After the 30 min preincubation, islets were washed in the same buffer. Batches of 3 islets were hand-picked and incubated for 60 min at 37°C in 200 microl at basal (2.8 mM) or stimulatory (11 mM) glucose concentrations in the presence or absence of 10 microM dopamine and/or 10 microM nomifensine. Insulin secretion was determined using an ultrasensitive mouse insulin ELISA (Mercodia AB, Uppsala, Sweden).

Results: Mouse islets were washed after the 30 min low glucose preincubation and insulin secretion was stimulated with 11 mM glucose (7.5 fold vs. 2.8 mM glucose, $p < 0.05$). Ten microM dopamine resulted in inhibition of glucose-stimulated insulin secretion (56% inhibition vs. 11 mM glucose control, $p < 0.05$). Blockade of dopamine uptake by 10 microM nomifensine rescued the response to glucose (132% increase vs. dopamine alone, $p < 0.05$), whereas 10 microM nomifensine alone had no effect on glucose-stimulated insulin secretion in mouse islets. Intriguingly, we observed that islets that were not washed after the 30 min low glucose preincubation were much less responsive to glucose (3.6 fold increase vs. 2.8 mM glucose, $p < 0.05$). The same islets responded potently to glucose in the presence of 10 microM nomifensine (11.5 fold increase vs. 2.8 mM glucose, $p < 0.05$). Therefore nomifensine was able to rescue the basal dopamine dependent inhibition of glucose response.

Conclusion: Our results show that dopamine requires to be taken up by pancreatic islet cells in order to inhibit insulin secretion. Additionally, our data suggest that uptake of pancreatic tissue-derived dopamine decreases islet glucose-response. The drug of abuse cocaine and several pharmacological compounds, such as methylphenidate and bupropion, are inhibitors of DAT. Knowledge of the role of DAT on pancreatic endocrine function might help to understand some of the metabolic effects of these substances.

SK4 channel knock-out improves glucose homeostasis by influencing the function of pancreatic beta cellsM. Düfer, B. Gier, D. Wolpers, P. Ruth, P. Krippeit-Drews, G. Drews
Pharmazeutisches Institut, Universität Tübingen, Germany

Background and aims: Besides ATP-dependent K⁺ channels, the key regulators of glucose-stimulated insulin secretion, pancreatic beta-cells express voltage- and Ca²⁺-regulated K⁺ channels. To elucidate the significance of Ca²⁺-activated K⁺ channels of intermediate conductance (SK4, IK1) for stimulus-secretion coupling we investigated whether SK4 channel knock-out mice (SK4-KO) show alterations in beta-cell function and/or glycemic control.

Materials and methods: Glucose tolerance and insulin sensitivity were measured in male wildtype (WT) and SK4-KO mice at an age of 12 and 24 weeks by intraperitoneal (i.p.) injection of 2 g/kg BW glucose and 0.7 I.U./kg BW insulin, respectively. Membrane potential and ion current recordings were performed in the perforated-patch configuration and [Ca²⁺]_i was determined using fluorescence techniques.

Results: Blood glucose concentrations in the fed and fasted state were similar in SK4-KO and WT mice at an age of 12 and 24 weeks (fasted: 6.6±0.5 vs.

5.8±0.6 mM, fed: 10.4±0.8 vs. 11.1±1.1 mM, n=5-6, 12 weeks, respectively). However, SK4-KO animals showed a significantly lower increase in blood glucose concentration after i.p. glucose challenge (2-hour plasma glucose concentration of 6.2±0.5 mM in SK4-KO vs. 9.5±1.2 mM in WT animals, 12 weeks, n=5, $p < 0.05$). As the improved glucose tolerance was not accompanied by an increased insulin sensitivity (n=5-6) we investigated whether SK4-KO influences beta-cell function. SK4-KO did not alter the resting membrane potential in 0.5 mM glucose (SK4-KO: -66±2 mV, n=6, WT: -68±1 mV, n=3). In the presence of 15 mM glucose the frequency of Ca²⁺ action potentials was significantly elevated in SK4-KO beta-cells (SK4-KO: 97±5/min, n=53 vs. WT: 74±12/min, n=18, $p < 0.05$). In addition, the threshold for glucose-induced membrane depolarization and Ca²⁺-influx was shifted to lower glucose concentrations. The glucose concentration at which 50 % of all cells tested showed a rise in [Ca²⁺]_i was 6.37 mM (95 % confidence interval CI: 6.09 to 6.68 mM) for WT beta-cells and was reduced to 5.67 mM (95 % CI: 5.29 to 6.05 mM) for SK4-KO beta-cells. Importantly, in WT beta-cells that were stimulated with 15 mM glucose [Ca²⁺]_i was increased by addition of the SK4 channel blocker TRAM-34 (1 μM, n=5).

Conclusion: These data implicate that SK4 channels participate in the regulation of beta-cell stimulus-secretion coupling. The ablation of SK4 channels increases beta-cell responsiveness to glucose stimulation and improves glucose tolerance in vivo without alterations in insulin sensitivity. As [Ca²⁺]_i of WT beta-cells could be augmented by blocking SK4 channels pharmacologically, SK4 channels might provide a target to improve beta-cell function in patients with impaired glucose homeostasis.

Chronic exposure to high leucine decreases glucose-stimulated insulin secretion probably by AMP-activated protein kinase mediating pathway in INS-1 cellsX.J. Zhang¹, Y.T. Li², W. Xin³, L. Gao³, J.J. Zhao¹¹Endocrinology, ²Clinical Laboratory, Provincial Hospital affiliated to Shandong University, Jinan, China, ³Scientific Center, Jinan, China

Background and aims: AMP-activated protein kinase (AMPK) reacts in modulating insulin secretion. Glucokinase (GCK) plays a key role in glucose metabolism, particularly glucose-stimulated insulin secretion (GSIS). Studies have shown AMPK regulates GCK at high glucose circumstance. Based on that, we supposed that there existed a regulatory effect of AMPK on GCK under physiological condition. Furthermore, how AMPK regulating GCK exposed to high leucine was our interest as well. Pancreatic duodenal homeobox (PDX) -1 can transactivate the expression of β-cell-specific genes, such as GCK, GLUT2. We assumed that AMPK regulated GCK/GLUT2 via PDX-1. It is reported that chronic exposure of pancreatic β-cells to high concentration of leucine impairs GSIS *in vitro*. However, the exact mechanism is unclear. Some studies showed that exposure to leucine related with the expression of AMPK and GCK/GLUT2. Hence, we hypothesized that chronic exposure to leucine decreased GSIS associated with the assumed pathway above. In the present study, we firstly tested if AMPK regulated GCK/GLUT2 via PDX-1 in beta cells under physiological condition, then studied if chronic exposure to leucine decreased GSIS associated with the pathway.

Materials and methods: INS-1 cells were cultured in RPMI 1640 with and without 0.5 mM AICAR (an AMPK activator) or 10 μM Compound C (an AMPK inhibitor) for 48 hours. In addition, DN-Pdx-1²⁸ cells, another INS-1 stable cell line, allowing the absent expression of PDX-1 inducing with 500 ng/ml doxycycline, were treated with and without 0.5 mM AICAR or 10 μM Compound C for 48 hours as well. Then INS-1 cells were treated with and without the elevated concentrations of leucine (10 mM, 20 mM or 40 mM) for 48 hours. After that, the GSIS and intracellular insulin contents were determined by radioimmunoassay. AMPK, PDX-1, GCK and GLUT2 protein expression was detected by Western blotting.

Results: (1) In INS-1 cells, relative to the control, AICAR treatment decreased the expression of PDX-1 and its downstream targets, GCK and GLUT2 ($p < 0.05$). While Compound C treatment had the opposite effects. (2) In DN-Pdx-1²⁸ cells, we observed that there was nearly no PDX-1 protein band occurrence under induced condition. In agreement with this, weaker bands ($p < 0.05$) were seen in GLUT2 and GCK expression compared with those under non-induced condition. Under non-induced condition, AICAR or Compound C had the same effects as those observed in the INS-1 cells above, however, under induced condition, whatever AICAR or Compound C could not affect the expression of GCK and GLUT2. (3) When the INS-1 cells were exposed to leucine, there was no difference of the GSIS levels and insu-

lin content between control and 10 mM or 20 mM leucine. However, exposed to 40 mM leucine decreased the GSIS levels by 45% ($p < 0.01$) at high glucose stimulation and diminished the intracellular insulin contents by 32% ($p < 0.01$). It also increased p-AMPK activation ($p < 0.05$) and decreased PDX-1, GLUT2 and GCK expression ($p < 0.05$).

Conclusion: In conclusion, the present study demonstrates that in pancreatic β -cells, AMPK regulates GCK/GLUT2 via PDX-1 and chronic exposure to leucine for 48h decreases GSIS and insulin content probably associated with the changes of the signaling pathway.

STAT3 is the primary signalling pathway used by CNTF in rat pancreatic islets

L.F. Rezende¹, A. Negro², F. Langone¹, A.C. Boscherio¹

¹Physiology and Biophysics, UNICAMP, Campinas, Brazil, ²Department of Biochemistry, Università di Padova, Padova, Italy

Background and aims: CNTF is a cytokine that promotes survival and/or differentiation in many cell types, including pancreatic islet-cells, but until now, the signaling mechanisms of CNTF effects in pancreatic islets are not known. In this work, we elucidated the underlying mechanisms of CNTF signaling in cultured neonatal pancreatic islets.

Materials and methods: Pancreatic islets from neonatal rats were isolated by the collagenase method and cultured for 3 days in RPMI medium without (CTL) or with 1nM of CNTF (CNTF). The medium also contained, when required, specific inhibitors of the PI3K, MAPK and JAK/STAT3 pathways. mRNA expression (RT-PCR) and protein phosphorylation (Western blot) of Akt, ERK1/2 and STAT3, and SOCS-3 (RT-PCR and Western-blot), as well as glucose-stimulated insulin secretion (GSIS) (Radioimmunoassay), were analysed.

Results: Results: Akt, ERK1 and STAT3 mRNA expression, as well as phosphorylated Akt and ERK1/2, was not affected by CNTF treatment. CNTF increased cytoplasmatic and nuclear phosphorylated STAT3, and the mRNA and protein expression of SOCS3 (target-gene of STAT3 activation). These effects were blocked by the STAT3 inhibitor, curcumin. Finally, GSIS was lower in CNTF-treated islets and this inhibitory effect was counteracted by curcumin, but not by the MAPK inhibitor, PD98059, nor by the PI3K inhibitor, wortmannin.

Conclusion: CNTF chronically affects pancreatic islets, activating STAT3, but not, MAPK and PI3K pathways, increasing SOCS3 expression and impairing GSIS. These findings demonstrate that STAT3 is the primary signaling pathway activated by CNTF in rat pancreatic islets.

Identification of putative prion protein interacting proteins in islet beta cells

A. Strom¹, G.-S. Wang¹, A.W. Stuke², F.W. Scott¹

¹Chronic Disease Program, Ottawa Health Research Institute, Ottawa, Canada, ²Virology and Immunology, German Primate Centre, Göttingen, Germany

Background and aims: Cellular prion protein (PrP^C) is a glycoprotein ubiquitously expressed in neuronal and neuroendocrine cells. In the pancreas, PrP^C is specifically and abundantly expressed in islets. However, the function of PrP^C in pancreatic islets and specifically in β -cells is not known. We recently investigated expression of PrP^C in the pancreas of diabetes-prone Bio-Breeding (BBdp) rats compared with control strains. There was strong PrP^C expression in all hormone secreting cells within the islets of Langerhans and cytosolic PrP^C aggregates, found exclusively in β -cells, were more frequent in BBdp rats compared with the BB control strain ($P < 0.0001$, at 100 days of age). Furthermore, PrP^C expression was suppressed in β -cells of Sprague Dawley rats under hyperglycemic conditions and a pronounced PrP^C aggregation was observed while the blood glucose returned to physiological level. These results suggested that the function of PrP^C in β -cells is closely related to glucoregulation and/or insulin secretion. The aim of the present study was to identify potential PrP^C binding proteins in β -cells that might reveal PrP^C related pathways.

Materials and methods: Extracts of soluble (cytosolic) and insoluble (membrane) proteins from rat insulinoma INS-1E cells (kind gift of Dr. P. Maechler; Geneva, Switzerland) were separated by SDS-PAGE and immunoblotted onto

nitrocellulose membranes. Far-Western immunoblotting, also referred to as protein overlay assay, was performed in which membranes were blocked, then probed with 200 ng/ml of recombinant PrP^C (rPrP^C) (Prionics, Switzerland), followed by incubation with primary anti-PrP^C 4F2 antibody and secondary anti-mouse/HRP antibody. Candidate rPrP^C interacting proteins were excised and analyzed by MALDI-TOF mass spectrometry. Full length and C-terminally truncated constructs of H1⁰ (kind gift of Dr. J. Hansen; Colorado State University) were expressed in BL21(DE3)LysS *E.coli* strain.

Results: Probing protein extracts of INS-1E cells with rPrP^C revealed several candidate interacting proteins. One of the candidate PrP^C interacting proteins was identified by mass spectrometry as histone H3. To confirm the specificity of rPrP^C binding to H3 we immunoblotted purified recombinant histones H1⁰, H2A, H2B, H3 and H4 (New England BioLabs) and probed the blot with rPrP^C. Recombinant PrP^C showed strong binding to the histone H3 and also to the linker histone H1⁰. Using different C-terminal truncation mutants of histone H1⁰ expressed in *E.coli* we demonstrated by far-Western immunoassay that rPrP^C binds to the C-terminal domain of H1⁰ (aa 163-193).

Conclusion: Recombinant PrP^C interacts *in vitro* with two different structural proteins from chromatin. These findings raise the possibility that PrP^C participates in epigenetic gene silencing or activation in β -cells. Further investigations must confirm these interactions and evaluate their physiological effects. The elucidation of the function of PrP^C in β -cells may provide new mechanisms through which this unique cell type responds to and maintains blood glucose levels.

The monounsaturated fatty acid, palmitoleate, attenuates the PERK signalling pathway of ER stress by regulating the phosphorylation of eIF2 α

E. Diakogiannaki, N.G. Morgan

Endocrine pharmacology, Peninsula Medical School, Plymouth, United Kingdom

Background and aims: Among the various factors which have been implicated in the loss of beta-cell mass in type 2 diabetes are the elevated levels of free fatty acids (FA). FA species differ considerably in their ability to regulate beta-cell viability, with long chain saturated FA (such as palmitate (C16:0)) being cytotoxic whereas long chain monounsaturated species (e.g. palmitoleate (C16:1)) are well tolerated. The most striking effect occurs during exposure to combinations of palmitate and palmitoleate. Under these conditions, the cytotoxicity of palmitate is prevented and the beta-cells remain viable and proliferate normally. Studies of cell morphology have revealed that palmitate causes alterations to the cellular architecture and, in particular, to the morphology of the endoplasmic reticulum (ER). By contrast, palmitoleate is much less disruptive. The combination of the two FA results in changes that are less extensive than those seen with palmitate alone. These results suggest that alterations to ER homeostasis could be involved in the differential effects of FA on cell viability. Therefore, the aim of this study was to investigate whether the cytoprotective effect of palmitoleate is associated with an amelioration of the beta-cell ER stress response.

Materials and methods: The rat pancreatic beta-cell line BRIN-BD11 was employed and the expression of markers associated with ER stress was detected by Western blotting following exposure to fatty acids.

Results: Palmitate dose-dependently (0.05–0.25 mM) induced apoptosis of BRIN-BD11 cells and it augmented the expression of the ER associated pro-apoptotic factor CHOP-10 over the same concentration range. By contrast, palmitoleate (either alone or in combination with palmitate) was not toxic and did not up-regulate CHOP-10. Markers of the PERK signalling pathway, such as the transcription factor ATF4 and the phosphorylated form of eIF2 α , were highly expressed in palmitate treated cells while the addition of palmitoleate minimised this response. Surprisingly, the major ER chaperone GRP78 and the phosphorylated form of PERK were not induced in FA treated cells although both proteins were increased after exposure to the established ER stress inducer tunicamycin. Similar to its actions in palmitate-treated cells, palmitoleate attenuated the induction of CHOP-10, ATF4 and phospho-eIF2 α in cells exposed to tunicamycin. However, it failed to alter the levels of GRP78 in response to tunicamycin. Palmitoleate also significantly improved the viability of cells treated with tunicamycin. Based on these observations it was hypothesised that the protective effect of palmitoleate may derive from its ability to regulate the level of eIF2 α phosphorylation either by inhibiting a relevant kinase or by enhancing the activity of an eIF2 α phosphatase. When cells were exposed to the phosphatase inhibitor salubrinal, the extent of eIF2 α phosphorylation was increased. Palmitoleate minimised this effect, consistent with the possibility that it may regulate the activity of an eIF2 α kinase.

Conclusion: Palmitoleate prevents the expression of markers of ER stress stimulated by palmitate and tunicamycin in beta-cells. This cytoprotection may be attributable to the inhibition of an eIF2 α kinase(s).

Effects of exendin-4 on free fatty acid-induced endoplasmic reticulum stress and apoptosis in pancreatic beta cells

D.A. Cunha, L. Ladrère, F. Ortis, M. Igoillo-Estève, D.L. Eizirik, M. Cnop
Laboratory of Experimental Medicine, Université Libre de Bruxelles, Belgium

Background and aims: Chronic exposure of pancreatic beta cells to saturated free fatty acids (FFA) causes endoplasmic reticulum (ER) stress and apoptosis, and may contribute to beta cell loss in type 2 diabetes. It has been suggested that GLP-1 receptor agonists, such as exendin-4, preserve beta cell function and mass in part by protecting beta cells against ER stress via up-regulation of ATF4-CHOP-GADD34 and consequent dephosphorylation of eIF2 α . We have previously shown that salubrinal (sal), a selective inhibitor of eIF2 α dephosphorylation, is deleterious to beta cells by potentiating FFA in-

duction of ATF4 and CHOP. The aim of this study was to evaluate the effects of exendin-4 on FFA \pm sal-induced ER stress in beta cells.

Materials and methods: INS-1E or FACS-purified rat beta cells were exposed to the chemical ER stressors thapsigargin (thap, 1 μ M) and the FFA oleate or palmitate (0.5 mM, 1% BSA) in the presence or absence of exendin-4 (Ex, 10–50 nM) or the cAMP generator forskolin (Fo, 20 μ M). Apoptosis was detected by Hoechst/propidium iodide staining and by Cell Death Detection ELISA-PLUS assay. mRNA expression was analyzed by real time RT-PCR, and protein expression and eIF2 α phosphorylation by Western blot. CHOP knockdown was achieved by siRNA transfection.

Results: Ex or Fo protected primary beta cells against thapsigargin (thap 26 \pm 1%, thap + Ex 17 \pm 1%, thap + Fo 13 \pm 3% apoptotic cells after 24 h, n=3–4, p<0.05 vs thap alone; apoptosis in control condition 9 \pm 2%), and against oleate (oleate 23 \pm 2%, oleate + Ex 15 \pm 3%, oleate + Fo 15 \pm 3% apoptosis after 3 days, n=10, p<0.05) but not palmitate. Ex or Fo also protected primary beta cells against the combination of oleate + sal (oleate + sal 55 \pm 6%, oleate + sal + Ex 43 \pm 6%, oleate + sal + Fo 30 \pm 5 %, n=7–9, p<0.05) or palmitate + sal (palmitate + sal 65 \pm 7%, palmitate + sal + Ex 43 \pm 6%, palmitate + sal + Fo 43 \pm 8%, p<0.05). Findings were similar in INS-1E cells (24 h) and also when evaluating apoptosis by ELISA. Fo tended to increase ATF4 and CHOP mRNA and protein expression in INS-1E cells exposed to FFA + sal for 7–14 h, and it increased GADD34 mRNA after 14 h (respectively 2.2- and 2.4-fold for oleate + sal and palmitate + sal compared to FFA + sal alone, n=5–6, p<0.05) whereas the increase by Ex did not reach significance. Sal augmented eIF2 α phosphorylation (oleate + sal 1.6-fold of control compared to 0.9-fold for oleate, palmitate + sal 3.6-fold of control compared to 1.5-fold for palmitate at 6 h, n=4, p<0.05) and this was decreased by Ex or Fo. To examine whether Ex or Fo dephosphorylated eIF2 α via enhanced ATF4-CHOP-GADD34 signaling, we knocked down CHOP. CHOP inhibition decreased palmitate + sal-induced apoptosis (from 30 \pm 3% to 17 \pm 1% apoptotic INS-1E cells after 14 h, n=5, p<0.05), but it did not alter the protective effects of Fo against palmitate + sal. Fo prevented sal-mediated eIF2 α phosphorylation very early on (20 min–6 h), confirming that Ex and Fo do not protect beta cells against lipotoxic ER stress via enhanced negative feedback through CHOP.

Conclusion: Ex and Fo partially decrease FFA \pm sal-induced apoptosis in beta cells. This anti-apoptotic effect is not due to enhanced CHOP signaling, as previously proposed. Activation of the GLP-1 receptor may instead directly modulate eIF2 α phosphorylation and thereby improve beta cell viability.

Mono-oleoyl-glycerol acutely stimulates basal insulin secretion and rapidly inhibits glucose-induced insulin secretion from rat pancreatic islets

J.T. Deeney¹, M. Saadeh², T.C. Ferrante², A. Kane², B.E. Corkey¹¹Department of Medicine, Boston University School of Medicine, United States, ²Department of Medicine, Boston Medical Center, United States

Background and aims: Chronic exposure (24–72 hrs) of pancreatic islets to elevated glucose and fatty acid (FA) leads to glucolipotoxicity (GLT) characterized by basal insulin hypersecretion and impaired glucose-stimulated insulin secretion (GSIS) mimicking type 2 diabetes. The aim of this study was to study the effects of an acute increase in lipids on insulin secretion from pancreatic β -cells.

Materials and methods: Insulin secretion was measured from batch incubated and perfused rat pancreatic islets as well as batch incubated INS-1 832/13 cells. Glycerol and long-chain acyl-CoA (LC-CoA) were measured enzymatically, intracellular Ca²⁺ was measured in single cells loaded with fura 2-AM and O₂ consumption was measured using a multi-well plate O₂ sensor.

Results: Mono-oleoyl-glycerol (MOG) (0.1–1 mM) acutely stimulated basal insulin secretion from rat pancreatic islets and INS-1 832/13 cells in a dose dependent manner without increasing intracellular Ca²⁺. Diazoxide (0.4 mM) did not prevent the acute stimulatory effect of MOG confirming that the effect was independent of the K_{ATP}-dependent (triggering) pathway of secretion. How MOG enhances insulin secretion is currently under investigation. MOG has been reported to increase diacylglycerol (DG) through inhibition of DG kinase (DGK). The DGK inhibitor R59949 (1–5 μ M) did not increase basal insulin secretion in INS-1 cells indicating that increasing DG through this pathway does not stimulate insulin secretion. MOG was however metabolized by INS-1 cells, which was indicated by increased glycerol

production and a 6-fold increase in LC-CoA within 30 min. The metabolism of MOG did not result in an increase in basal respiration in INS-1 cells, which was consistent with a non-triggering pathway for increased insulin secretion. Rat islets perfused with MOG (0.2 mM) exhibited a large transient increase in basal insulin secretion (peak value increased 10-fold over basal), which remained 2-fold elevated compared to the pre-MOG basal level. Glucose (11 mM) failed to stimulate insulin release from the same islets pre-exposed to MOG for 30 min. KCl (40 mM) stimulated insulin secretion was reduced by 90% after MOG exposure. Consistent with this inhibition of secretion 30 min of MOG exposure inhibited the glucose stimulated Ca^{2+} increase in dissociated rat pancreatic islets by 75% (average of 30 cells) and the KCl stimulated Ca^{2+} increases in dissociated rat pancreatic islets and INS-1 cells. The effects of MOG to inhibit insulin secretion were chain length dependent with monodecanoyl-glycerol having little inhibitory effect after 30 min preincubation. **Conclusion:** β -cell glucolipotoxicity characterized by basal hypersecretion and impaired GSIS can be rapidly mimicked by MOG exposure in the absence of elevated glucose and FA. The rapidity of the affects provide a model to examine the effects of elevated lipids on insulin secretion independent of genetic alterations that occur over the time required to achieve GLT by more conventional means. An acute increase in LC-CoA may lead to both increased basal insulin secretion and subsequent decreased GSIS in rat pancreatic islets.

The once-daily human GLP-1 analogue liraglutide preserves pancreatic beta cells in diabetic *db/db* mice through both acute and chronic action mechanisms

M. Shimoda, Y. Kanda, K. Tawaramoto, M. Hashiramoto, M. Matsuki, K. Kaku

Diabetes and Endocrine Division, Kawasaki Medical School, Okayama, Japan

Background and aims: GLP-1 increases the pancreatic beta-cell mass by stimulating cell proliferation and inhibiting apoptosis. In this study, we investigated the molecular mechanism for the proliferative effect of liraglutide on beta-cell mass in the obese diabetic animal model *db/db* mice.

Materials and methods: Ten week-old male *db/db* mice received liraglutide (0.2 mg/kg twice daily s.c.) or vehicle (control) for 2 days (*Study 1*) or 2 weeks (*Study 2*). Body weight (BW), fasted blood glucose (FBG), insulin (FIRI), and triglyceride (TG) were measured at before and after liraglutide intervention, and intraperitoneal insulin tolerance test (ipITT: 1 IU/kg BW) was performed at 12 weeks of age. The beta-cell mass and cell proliferation/apoptosis were assessed by histological analysis including proliferating cell number antigen (PCNA), 4-hydroxynonenal modified protein (4-HNE) immunostaining, and TUNEL assay of the islet tissue. Gene expressions specific for the core area of pancreatic islet were analyzed by Laser Capture Microdissection method and real time reverse transcriptase-polymerase chain reaction (RT-PCR). Primer pairs encoding genes associated with pancreatic hormones, cell proliferation, apoptosis, cell cycle, and oxidative stress were prepared, and real-time RT-PCR with SYBR Green was applied. Each gene expression was relatively quantified by the comparative CT method with each result in the 18 SrRNA as a control.

Results: *Study 1:* After 2 days' intervention with liraglutide, FBG and FIRI were readily lowered in liraglutide-treated mice. The pancreatic beta-cell mass was not affected by liraglutide treatment, but islet cell gene expressions of Cyclin D and Hlx-9, a marker of cell differentiation, were significantly up-regulated, and Hes-1, a marker of anti-cell differentiation, was down-regulated in mice treated with liraglutide. Gene expressions of catalase, GSHPx and XBP-1 related with oxidative stress and endoplasmic reticulum (ER) stress did not differ between groups. Immunohistochemical findings and TUNEL assay did not show any significant difference between groups. *Study 2:* After 2 weeks' intervention, BW was significantly lower in the liraglutide group than in the control (42.1 ± 0.5 g vs. 44.6 ± 0.6 g, mean \pm SE, $p < 0.01$, $n=10$ for each). FBG, FIRI, and TG levels were significantly lower in the liraglutide group than in the control (glucose: 189 ± 10.3 vs. 272 ± 26.0 mg/dl, $p < 0.05$, insulin: 4.3 ± 0.5 vs. 6.4 ± 0.7 ng/ml, $p < 0.05$, TG: 113 ± 2.4 vs. 133 ± 6.5 mg/dl, respectively, $p < 0.01$). The pancreatic beta-cell mass was higher in liraglutide-treated mice than in the control (7.7 ± 0.7 vs. 4.9 ± 0.5 mg, $p < 0.01$, $n=5$ for each). The islet TG content was reduced by liraglutide. PCNA-positive cells were increased and 4-HNE-positive cells were decreased by liraglutide treatment. TUNEL assay showed the less beta-cell apoptosis in liraglutide-treated mice. NeuroD, ERK-1 and cyclin D mRNA levels were significantly

higher in liraglutide mice than in the control. SREBP-1c, FAS, and XBP-1 gene expressions were down-regulated, and catalase and GSHPx genes were up-regulated by 2 weeks' intervention with liraglutide.

Conclusion: Liraglutide increased pancreatic beta-cell mass in diabetic *db/db* mice. The mechanism was both regulation of cell kinetics as an acute effect but also suppression of oxidative stress and ER stress by ameliorating glucolipotoxicity as a chronic effect.

High density lipoproteins protect pancreatic beta cells by targeting 4E-BP1

J. Petremand¹, A.-C. Butty¹, J.-Y. Yang¹, B. Natasa¹, C. Poussin¹, B. Thorens¹, G. Waeber², C. Widmann¹

¹Physiology, University of Lausanne, ²Medecine Interne, CHUV, Lausanne, Switzerland

Background and aims: Low level of HDL cholesterol is one of the lipid phenotype observed in diabetic patients. HDLs exert numerous protective effects on endothelial cells such as prevention of LDL oxidation, endothelial dysfunction and apoptosis. In the case of pancreatic beta cells, HDLs have been shown to protect against apoptosis elicited by various stress stimulus such as serum starvation, cytokines, or oxidized LDL. However, the molecular mechanisms of HDL-induced beta cells protection are not entirely identified and represent a promising way to discover new potential target for the treatment of diabetes.

Materials and methods: Affymetrix gene chip technology was used in stress or normal conditions to identify the target genes by which HDL exert their anti-apoptotic activities in insulin-secreting cells.

Results: One interesting target identified was the translational repressor 4E-binding protein (4E-BP1). This small protein regulates protein synthesis by sequestering eIF4E which is necessary for initiation of translation. 4E-BP1 expression is induced by starvation or hypoxia and has been demonstrated to induce apoptosis. In this study, stresses such as serum starvation or IL-1 beta treatment induced 4E-BP1 expression in insulin-secreting beta cell lines and in human islets. The induction of 4E-BP1 expression was significantly reduced by HDL, and this effect was correlated with prevention of apoptosis. Moreover, overexpression or lentiviral infection with 4E-BP1 constructs induced apoptosis, mimicking the starvation effect. Finally, the use of 4E-BP1 shRNA reduced the induction of 4E-BP1 expression by the stress and the stress-induced apoptotic response was also reduced showing that there is a direct link between stress conditions, increased 4E-BP1 levels and apoptosis in beta cells.

Conclusion: These data indicate that HDL block stress-induced expression of 4E-BP1 and prevent beta cell apoptosis, showing that 4E-BP1 is a possible target to prevent development of diabetes.

The importance of free fatty acid binding receptors and ER stress for lipotoxicity in insulin-producing cells

W. Gehrman¹, M. Elsner¹, A. Jörns^{1,2}, S. Lenzen¹

¹Institute of Clinical Biochemistry, ²Centre of Anatomy, Hannover Medical School, Hannover, Germany

Background and aims: Elevated levels of free fatty acids (FFA) can cause β -cell dysfunction and apoptosis in type 2 diabetes. Only saturated FFAs have toxic effects upon insulin-producing cells whereas unsaturated FFAs are protective. However, the molecular mechanisms of lipotoxicity are only partially understood. It is still under discussion if the FFA binding receptors GPR40 and GPR120 are involved and if ER stress is a crucial mechanism of lipotoxicity. Disturbed ER function lead to an accumulation of unfolded or misfolded proteins which activates a specific ER stress response. Therefore the aim of the present study was to analyse the gene expression of the GPR-receptors and different ER stress marker genes.

Materials and methods: To investigate the cytotoxic effects of palmitic acid (PA) upon different insulin-producing cell lines viability was measured by MTT assay after 24h exposure. The effect of PA and oleic acid (OA) on the mRNA expression levels of the ER stress marker genes Bip, CHOP, XBP-1 and XBP-1 spliced and the expression levels of GPR40 and GPR120 were determined by quantitative RT-PCR. The receptor mediated enhanced glucose

stimulated insulin secretion (GSIS) due to FFA treatment was measured by a static incubation. Electron microscopy analyses were performed to detect morphological changes due to FFA treatment in RINm5F and INS-1E cells.

Results: The cytotoxic effect of PA was much more pronounced in RINm5F ($EC_{50} = 113 \mu\text{M} \pm 6$) cells than in INS-1E ($EC_{50} = 1860 \mu\text{M} \pm 540$) and MIN6 ($EC_{50} = 993 \mu\text{M} \pm 123$) cells. Interestingly, in RINm5F cells, which showed the highest sensitivity for PA, the GPR40 and GPR120 receptors were not detectable by quantitative RT-PCR. By contrast the less sensitive cell lines INS-1E and MIN6 expressed both receptors. An enhanced GSIS due to FFA treatment was only detected in MIN6 and INS-1E cells. Palmitic acid led to a 5fold increased insulin secretion at 10 mM and 30 mM glucose in MIN6 cells and to 2fold increase in INS-1E cells. By contrast OA had a minor effect. The induction was only 3fold in MIN6 cells and 1.5fold in INS-1E cells. In electron microscopy analyses we found damage to the endoplasmic reticulum induced by PA in RINm5F cells whereas the endoplasmic reticulum was less damaged in INS-1E cells. The expression level of the ER stress marker gene CHOP was increased 21fold in RINm5F cells and 6fold in INS-1E cells after 12h incubation with PA. Furthermore the expression level of XBP-1 spliced was increased 10fold in RINm5F cells, whereas the expression level in INS-1E cells was unaltered. In both cell lines the expression level of Bip was only slightly increased and of XBP-1 unchanged after PA treatment. Incubation with OA did not affect the expression level of all analysed ER stress marker genes. Moreover, OA was able to prevent induction of CHOP and XBP-1 spliced due to PA treatment.

Conclusion: The presented data indicate that the toxicity of PA is probably not mediated through the FFA binding receptors GPR40 and GPR120, because the most sensitive cell line RINm5F did not express both receptors. The enhanced GSIS due to FFA in MIN6 and INS-1E cells showed the functionality of the GPR40 receptor. The different induction of ER stress marker genes in the analysed beta cell lines RINm5F and INS-1E cells after PA treatment which is also reflected by the results of the viability assay indicates that ER stress plays an important role for lipotoxicity.

Visfatin decreases cell viability, activates insulin receptor and alters expression of key genes in a clonal beta cell line

S.J. Dunmore¹, D. Onyango¹, J.E.P. Brown²;

¹Diabetes Research Group, University of Wolverhampton, ²Endocrinology and Metabolism Research Group, University of Warwick, Coventry, United Kingdom

Background and aims: The novel adipokine visfatin is reported to have insulin-like properties and to activate insulin signalling although there is some controversy as to whether this effect is genuine or whether the protein produces its effects through its nicotinamide phosphoribosyltransferase enzymic activity, the first step of the NAD synthetic pathway. Due to its high expression in visceral fat tissue and its insulin-like effects it has been suggested to be involved in the pathogenesis of type 2 diabetes, although this link has yet to be well established. Since insulin receptors are expressed in beta-cells, and a recent report has demonstrated progressive beta-cell failure with increased visfatin serum concentrations, we sought to evaluate the effects of visfatin on beta-cell viability and on the insulin signalling (insulin receptor (IR) phosphorylation) pathway. We also investigated the effect of incubation with visfatin on mRNA expression of a range of genes in the pancreatic beta-cell using a diabetes gene pathway specific PCR array.

Materials and methods: Beta-TC6 clonal mouse pancreatic beta-cells were cultured in RPMI-1640 before being treated for 24 hours with a range of recombinant visfatin concentrations (0 & 0.5 nmol/l for gene expression; 0, 1 & 10 nmol/l for IR phosphorylation; 0, 2, 4, 6, 8 & 10 nmol/l for cell viability), a positive control of 1 nmol/l insulin was used for the IR phosphorylation assay. Cell viability was measured by a modified MTS method and insulin signalling by Western blotting of protein extracts using an anti-IR phosphotyrosine (phospho Y972) antibody. Total RNA was extracted and PCR array technology was used to compare mRNA expression in treatment sample to control sample.

Results: Incubation with visfatin dose-dependently decreased beta cell viability with significant ($p < 0.05$) decreases of 24% and 40% at 8 and 10 nmol/l respectively. Visfatin increased insulin receptor phosphorylation by 5-fold compared to at 1 nmol/l (similar to the effect of insulin) and by 10 fold at 10 nmol/l. Visfatin caused changes in expression of a number of genes relevant to beta-cell function including greater than ten-fold increases in glucagon receptor, interleukin 12b, and transforming growth factor beta 1. Decreases of more than 50% were seen in FOXg1 and G6PD.

Conclusion: Pathologically relevant concentrations of visfatin decrease beta-cell viability and can activate early-stage insulin signalling in these cells as well as altering expression of a number of genes which may affect the function in these cells. This supports the suggestion that visfatin may have a role in loss of beta-cell function in obesity-related diabetes.

Loss of insulin synthesis and beta cell survival induced by oxidized LDL require activation of reticulum endoplasmic stress: a mechanism countered by HDL

D. Favre¹, S. Brajkovic¹, G. Niederhauser¹, G. Waeber², A. Abderrahmani¹

¹Dpt of Cell biology and Morphology, ²Dpt of Internal Medicine, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland

Elevated circulating concentrations in modified LDL-cholesterol particles (e.g. oxidised LDL) and low levels in HDL increase not only the risk for diabetic patients to develop cardiovascular diseases but also may contribute to development and progression of diabetes by directly having adverse effects on β -cells. Chronic exposure of β -cells to 2 mM human oxidised LDL-cholesterol (oxLDL) increases the rate of apoptosis, reduce insulin biosynthesis and the secretory capacity of the cells in response to nutrients. In line with the protective role, HDL efficiently antagonised the harmful effects of oxLDL, suggesting that low levels of HDL would be inefficient to protect β -cells against oxLDL attack in patients. Activation of endoplasmic reticulum (ER) stress is pointed out to contribute to β -cell dysfunction elicited by environmental stressors. In this study we investigated whether activation of ER stress is required for oxLDL to mediate detrimental effects on β -cells and we tested the potential antagonist properties of HDL: The mouse MIN6 insulin-secreting cells were cultured with 2 mM of LDL-cholesterol preparation (native or in vitro oxidized) in the presence or absence of 1 mM of HDL-cholesterol or the ER stress inhibitor 4-phenylbutyrate (4-PBA). Prolonged exposure of MIN6 cells to 2 mM oxLDL-cholesterol for 48 hours led to an increase in expression of ER stress markers such as ATF4, CHOP and p58 and stimulated the splicing of XBP-1 whereas, induction of these markers was not observable in the cells cultured with native LDL. Treatment of the cells with the 4-PBA chemical chaperone molecule efficiently blocked activation of the ER stress markers induced by oxLDL. The latter mediates β -cell dysfunction and apoptosis by diminishing the expression of islet brain 1 (IB1) and Bcl2. The levels of these two proteins were preserved in the cells that were co-treated with oxLDL and the 4-PBA. Consistent with this result we found that blockade of ER stress activation alleviated the loss of insulin synthesis and abolished apoptosis evoked by oxLDL. However incubation of the cells with 4-PBA did not prevent impairment of insulin secretion elicited by oxLDL, indicating that ER stress is not responsible for the oxLDL-mediated defect of insulin secretion. Co-incubation of the cells with HDL mimicked the effects of 4-PBA on the expression of IB1 and Bcl2 and thereby counteracted oxLDL attacks on insulin synthesis and cell survivals. We found that HDL efficiently inhibited activation of the ER stress mediated by oxLDL. These data highlight the contribution of the ER stress in the defects of insulin synthesis and cell survivals induced by oxLDL and emphasize the potent role of HDL to counter activation of the oxLDL-mediated ER-stress activation:

Influence of antioxidative enzyme overexpression and proinflammatory cytokines on Bcl-2 promoter activity and activation of caspase-9 in insulin-producing cells

I. Mehmeti, S. Lortz, S. Lenzen

Institute of Clinical Biochemistry, Hannover Medical School, Germany

Background and aims: Type 1 diabetes is caused by autoimmune destruction of pancreatic β -cells. This β -cell destruction process appears to result from proinflammatory cytokines, such as IL-1 β , IFN- γ and TNF- α , mainly by activation of intracellular signal cascades leading finally to apoptosis. One of the preferential target structures of these apoptosis pathways are mitochondria. Integrity and stability of mitochondria are critical for β -cell viability or initiation of apoptosis. In previous studies we have shown that overexpression of a mitochondrially located catalase (MitoCat) induced an increased gene and protein expression of the antiapoptotic acting Bcl-2 molecule. Therefore, the aim of this study was to characterise the influence of catalase overexpression and proinflammatory cytokines on the transcriptional regulation of Bcl-2 expression and to quantify caspase-9 activity before and after cytokine exposure.

Materials and methods: Quantification of Bcl-2 promoter activity was performed after transient transfection with firefly luciferase reporter gene constructs under the control of the Bcl-2 promoter (with intact or deleted cAMP-response element (CRE)) and exposure to IL-1 β or to a cytokine mixture (IL-1 β , TNF- α and IFN- γ) for 24 h. To examine the importance of the CRE site for the cytokine-mediated transcriptional regulation of Bcl-2 expression, we additionally transfected insulin-producing RINm5F cells with a reporter gene construct containing the luciferase reporter gene under the control of four tandem repeats of CRE. Caspase-9 activity of insulin-producing control cells and cells overexpressing either cytosolic catalase (Cat) or mitochondrially located catalase (MitoCat) was measured by a flow cytometry-based caspase-9 assay after 24 h cytokine exposure.

Results: RINm5F control cells transfected with a Bcl-2 promoter construct containing the intact CRE site showed a significantly decreased Bcl-2 promoter activity after cytokine treatment, whereas the CRE site deleted Bcl-2 promoter showed no significant changes of Bcl-2 promoter activity. This cytokine-mediated decrease of reporter gene activity was also seen with the CRE construct in RINm5F control cells. In MitoCat cells but not in CytoCat cells the CRE and Bcl-2 promoter activity was well preserved after cytokine exposure. Cytokine stimulation of control cells and cells overexpressing cytosolically localised catalase led to a significantly increased caspase-9 activity, whereas MitoCat overexpression prevented the increase of caspase-9 activity after cytokine treatment.

Conclusion: Cytokine-induced reduction of CRE and Bcl-2 promoter activity indicates that the CRE site within the Bcl-2 promoter is essential for the down-regulation in response to cytokines. These data correspond to the Bcl-2 expression in these cells. Cytokines significantly increased caspase-9 activity in control cells, suggesting that the mitochondrial apoptosis pathway is crucial for β -cell death. Overexpression of MitoCat could successfully avoid downregulation of Bcl-2 promoter activity and therefore maintain higher expression of Bcl-2 compared with control cells, resulting in a higher resistance against proinflammatory cytokines.

Identification of gene networks regulated by the cytokines IL-1 β and TNF α in primary rat beta cells

F. Ortis, N. Naamane, D. Flamez, F. Moore, D.L. Eizirik

Laboratory of Experimental Medicine, Université Libre de Bruxelles, Brussels, Belgium

Background and aims: Cytokines contribute to pancreatic beta cell death in type 1 diabetes. Cytokine induced beta cell apoptosis depends on the expression of hundreds of genes. To understand the regulation of these gene networks at its real level of complexity, we have performed array analysis of primary beta cells exposed to IL-1 β + IFN γ or TNF α + IFN γ using the new Affymetrix GeneChip containing more than 31.000 probe sets. This was followed by global analysis of gene expression using Ingenuity Pathway Analysis (IPA 5.5).

Material and methods: Primary rat beta cells were FACS-purified and exposed for 6 or 24h to control condition, IL-1 β (50 U/ml) + IFN γ (100 U/ml)

or TNF α (1000 U/ml) + IFN γ (100 U/ml) before array analysis (GeneChip® Rat Genome 230 2.0 Array). Results of 3 independent biological/array experiments were analyzed and mRNA expression considered modified by cytokines when $q \leq 0.025$ compared to control condition. These results were analyzed by the IPA 5.5 software to identify networks and pathways regulated by cytokines. Cell viability was evaluated by Hoechst 342 and propidium iodide and nitrite determined by the Griess method. NF- κ B translocation to the nucleus analyzed by immunostaining for p65.

Results: Cytokines induced beta cell death ($P \leq 0.001$ for cytokines vs control; 72 h), with $17 \pm 2\%$ apoptotic cells in the control, $44 \pm 2\%$ in IL-1 β + IFN γ and $41 \pm 2\%$ in TNF α + IFN γ treated cells. IL-1 β + IFN γ -induced higher NO production than TNF α + IFN γ (21 ± 4 vs 13 ± 3 pM/ 10^3 cells, respectively). The microarray analysis detected nearly 16.000 transcripts in control and cytokine-treated cells. Of these, 92 and 3.655 displayed significant changes in expression after respectively 6 and 24h treatment with IL-1 β + IFN γ . After TNF α + IFN γ exposure, 376 and 991 transcripts were modified after 6 and 24h, respectively. Among the top 5 canonical pathways significantly changed by cytokines, 2 were common for IL-1 β + IFN γ and TNF α + IFN γ , namely: "Antigen presentation" (p -value $\leq 5E-03$) and "Acute phase response" (p -value $\leq 2E-02$). The "Interferon signalling" pathway was identified as significantly changed only at 24h TNF α + IFN γ treatment. A total of 2 and 100 networks (representing key transcription factors and their interactions with more than 12 focus genes) were modified by IL-1 β + IFN γ after respectively 6 and 24h. Using the same criteria, we found 11 and 50 networks modified by the TNF α + IFN γ treatment after respectively 6 and 24h. The networks with higher scores for both treatments were regulated by Myc, NF- κ B and Jun. These networks, however, had a low agreement in the identity of the genes induced by IL-1 β or TNF- α : 21% (Myc), 17% (NF- κ B) and 11% (Jun). Additional experiments indicated that IL-1 β induced an earlier p65 translocation to the nucleus as compared to TNF- α ($84 \pm 2\%$ vs $10 \pm 3\%$ nuclear positive cells for respectively IL-1 β and TNF α ; $n = 4$, $p \leq 0.001$ at $10'$). There was also a more sustained p65 nuclear localization following IL-1 β exposure, with higher values at 1, 2, 8, 12, 24 and 48h as compared to TNF α .

Conclusion: There are major temporal differences between the effects of IL-1 β and TNF α in beta cells, with higher induction of gene networks by TNF α at 6h and by IL-1 β at 24h. IL-1 β and TNF α induce similar key transcription factor and gene networks, but there is a differential usage of genes involved in these networks. These different effects may be in part explained by a different temporal induction of key regulatory transcription factors, as presently shown for NF- κ B.

Liraglutide induces cell proliferation and protects from interleukin-1-beta induced beta cell apoptosis in human islets

R. Przak¹, S. Rütli¹, H. Ellingsgaard¹, L. Knudsen², M.Y. Donath¹¹Endocrinology, UniSpital Zürich, Switzerland, ²Novonordisk, Malov, Denmark

Background and aims: Glucagon-Like Peptide-1 (GLP-1) analogs induce beta-cell proliferation and have anti-apoptotic effects in rodent islets. However the effects in human islets are less studied. Interleukin-1 β (IL-1 β) production is increased in islets of patients with type 2 diabetes and induces beta-cell apoptosis. The aim of the study was to determine whether the once-daily human GLP-1 analog liraglutide affects proliferation and apoptosis in human islets.

Materials and methods: Mouse, and human islets from six organ donors were cultured on extracellular matrix-coated plates at 11mM, and 5.5mM glucose respectively, and exposed to liraglutide in the presence and absence of IL-1 β and of LDL particles.

Results: As previously shown, exposure to 300nM liraglutide for 4 days induced a 2.1-fold cell proliferation in mouse islets while human beta-cell proliferation remained unchanged as assessed by Ki-67 staining. However, detection of BrdU added throughout the culture period displayed an 1.74 ± 0.31 -fold increase in the number of positive endocrine cells in the liraglutide treated human islets ($n=5$). The quality of the insulin double staining did not allow for a clear characterization of the endocrine positive BrdU cells. Furthermore, liraglutide prevented beta-cell apoptosis induced by 2 ng/ml IL-1 β (2.77 ± 0.7 versus 0.81 ± 0.32 fold increase in TUNEL positive beta cells in IL-1 β alone versus IL-1 β and liraglutide, respectively, compared

to baseline; $n=3$). Moreover, liraglutide prevented the decrease in mouse β -cell proliferation (0.5 fold of control) caused by 3.1 mM LDL particles ($n=6$). **Conclusion:** Liraglutide induces endocrine cell proliferation in human islets detected by continuous BrdU exposure during prolonged incubation, but not by Ki-67 staining reflecting only the last 12 hours of proliferative activity. In analogy to the proliferative effect of liraglutide on rodent islets, it is likely that the BrdU positive human endocrine cells are replicating islet beta-cells and not non-beta-endocrine-cells. Finally, liraglutide prevents IL-1 β induced beta-cell apoptosis.

The contribution of different cytokines and nitric oxide to ER stress and cell death in insulin-producing cells

S.A. Kacheva, S. Lenzen, E. Gurgul-Convey

Institute of Clinical Biochemistry, Hannover Medical School, Germany

Background and aims: Proinflammatory cytokines and especially IL-1 β play a crucial role in beta cell damage and death during the development of type 1 diabetes mellitus (T1DM). But the underlying mechanisms are not fully understood. ER stress has been considered to play an important role in cytokine-mediated beta cell toxicity. Little is known, however, about the importance of the different cytokines as well as nitric oxide in this process. Therefore, we analyzed the role of various cytokine combinations and the contribution of nitric oxide in ER stress in insulin-producing cells.

Materials and methods: Insulin-producing INS1E cells were incubated for 72 h with IL-1 β , TNF α and IFN γ alone or in different combinations in the presence or absence of an iNOS blocker (5 mM L-nitro-arginine) and thereafter cell viability was measured (MTT assay). The expression of different ER stress markers was analyzed by Real-Time PCR. Caspase-3 activity was measured by a chemiluminescent method, NF κ B by a SEAP reporter gene assay and nitrite production by a Griess method.

Results: IL-1 β , TNF α and IFN γ showed a concentration-dependent toxicity in the MTT assay. The high concentrations of these cytokines (IL-1 β 600 U/ml, TNF α 1850 U/ml, IFN γ 140 U/ml) after 72 h decreased the viability to 40 %, 76 % and 43 %, vs. untreated controls, respectively. The combinations of lower concentrations of cytokines were more toxic than any cytokine used alone (viability after 72 h: IL-1+TNF 32 %, IL-1+IFN 13 %, TNF+IFN 33 %). The mixture of all three cytokines was the most toxic combination with 5 % viable cells after 72 h. The iNOS blocker prevented nitrite formation and this was accompanied by a partial protection against cytokine toxicity (viability after 72 h: IL-1 β 73 %, Mix 12 %, IL-1+TNF 73 %, IL-1+IFN 40 %, TNF+IFN 35 %). Cytokines affected the expression of ER stress markers with the maximal effects on CHOP and Bip after a 12 h incubation (CHOP: IL-1 630 %, Mix 733 %, IL-1+TNF 827 %, IL-1+IFN 593 %, TNF+IFN 362 %; Bip: IL-1 45 %, Mix, 40 % IL-1+TNF 60 %, IL-1+IFN 42 %, TNF+IFN 45 %). These effects were strongly counteracted in the case of CHOP (12 h iNOS blocker: IL-1 89 %, Mix 129 %, IL-1+TNF 62 %, IL-1+IFN 54 %, TNF+IFN 162 %, $p<0.05$) and to some extent in the case of Bip expression (12 h iNOS blocker: IL-1 83 %, Mix 54 %, IL-1+TNF 75 %, IL-1+IFN 67 %, TNF+IFN 92 %, $p<0.05$) by a use of the iNOS blocker. On the other hand, cytokines only slightly affected the expression of XBP-1 and XBP-1 spliced and this effect was NO-independent. IL-1 β and the three cytokine mixture induced caspase-3 activity (after 24 h: IL-1 140 %, Mix 163 %) and this was prevented by the iNOS blocker (IL-1 108 %, Mix 78 %, $p<0.05$). Cytokines induced the NF κ B activation after 6 h also in a NO-dependent manner (cytokines vs. cytokines with iNOS blocker: IL-1 269 vs. 126 %, Mix 317 vs. 148 %, IL-1+TNF 314 vs. 108 %, IL-1+IFN 195 vs. 150 %, TNF+IFN 121 vs. 92 %).

Conclusion: IL-1 β and the cytokine mixture, which show the highest toxicity in the MTT assay and caspase-3 activation have also the strongest effects on the expression of ER stress markers and this can be related to an increased production of nitric oxide. We postulate that the cytokine-induced NO production changes the unfolded protein response, which in turn leads to beta cell destruction and death.

Toxic cytokines interleukin-1 β , tumor necrosis factor- α and interferon- γ regulate zinc transporter gene expression in beta cells and Slc30A8 protects against cytokine-induced cell death

L. Egeford¹, A.B. Petersen¹, C.H. Bang-Berthelsen², F. Pociot², A.E.

Karlsen³, K. Schmidt¹, F. Chimienti⁴, B. Brock¹, O. Schmitz¹, J. Rungby¹, N.E. Magnusson¹

¹Pharmacology, University of Aarhus, Denmark, ²Steno Diabetes Center, Gentofte, Denmark, ³NovoNordisk, Copenhagen, Denmark, ⁴CEA, MELLITECH, Grenoble, France

β -cells depend on zinc influx to secretory vesicles for the crystallization of insulin since insulin is stored as a hexamer complexed with two zinc ions. Tight regulation of zinc homeostasis is ensured by zinc transporters (ZnTs and ZIPs). β -cell function and mass is severely affected by the presence of a number of cytokines, in particular interleukin-1 β (IL-1 β), in both type-1 and type-2 diabetes. Over-expression of the ZnT8, zinc transporter protein encoded by Slc30A8, which has been identified as a major risk gene for type-2 diabetes and an antigen associated with the development of type-1 diabetes, seems to protect β -cells from oxidative stress.

We therefore examined the expression profiles of ZnTs and ZIPs in cultured β -cells and islets after cytokine exposure and the survival of Slc30A8 over-expressing cells after cytokine treatment.

For the cell experiments, INS 1 cells were stimulated for 1 or 24 hours with 60–180 U IL-1 β /mL, 200 U TNF- α /mL, 200 U INF- γ /mL, or a mixture comprising 180 U IL-1 β /mL, 200 U TNF- α /mL and 200 U INF- γ /mL (PharMingen International, San Diego, CA, USA). Controls were stimulated with RPMI 1640 medium. Gene-expression was measured by Q-PCR. For islet experiments, rat neonatal islets were cultured at 11mM glucose. Stimulations were performed for 1, 2, 4, 6 and 24 h with 250 pg/mL IL-1 β /mL, 10 ng/mL INF- γ , or a mixture comprising 250 pg/mL IL-1 β and 10 ng/mL INF- γ . Controls were stimulated with RPMI 1640 medium. Gene-expression was measured by Q-PCR. For survival, INS 1E cells over-expressing Slc30A8 were compared to wild-type after exposure to a mixture of cytokines as above and survival was measured by MTT for cell death.

A number of cytokine-induced changes in Zn-transporter gene-expression were found. The figure shows significant changes in isolated INS 1 cells. Similar results were found in islets. Over-expression of Slc30A8 significantly reduced cytokine-induced apoptosis ($p<0.05$ when MTT activity was measured against wild type).

Our results indicate a dynamic response of genes responsible for β -cell zinc homeostasis to cytokines and provide clues for further exploration of the role of these proteins in both the development of diabetes and β -cell dysfunction during cytokine stress which is high in diabetes. Further, we demonstrate that high levels of Slc30A8 confer a protection against cytokines.

Test vs control, $p<0.05$, * $p<0.01$

An IKK β inhibitor protects against IL-1 β induced production of reactive oxygen species and beta cell death

J. Friberg¹, F. Pociot², M. Tonnesen², A.E. Karlsten¹

¹Diabetes biology, Novo Nordisk A/S, Maaloev, Denmark, Steno Diabetes Center, Gentofte, Denmark

Background and aims: Activation of inflammatory pathways has been reported in obesity, insulin resistance and both type 1 and type 2 diabetes. The notion that excess circulating nutrients stimulate an inflammatory response in the islets of Langerhans and its effect on insulin secretion from the β -cells has until now attracted little attention. The aim of the present work was to investigate the relationship between inflammatory pathways, induction of reactive oxygen species (ROS) and β -cell failure.

Materials and methods: ROS was measured with a fluorescent probe CM-H2DCFDA. Expression levels of genes were quantified using RT-PCR. NF κ B activity was defined by EMSA using a radioactively labeled NF κ B-binding oligonucleotide as probe. Reduced caspase-3 cleavage caused by DMT1 specific siRNA was detected by western blot. Mitochondrial activity was assessed by MTT assay and cell death was assessed as caspase 3/7 activity. Insulin concentrations were determined by LOCI assay.

Results: In newborn rat islets Interleukin-1 β (IL-1 β) induces ROS production with a maximal production after 24 hrs IL-1 β exposure (>200% of controls). IL-1 β exposure was accompanied by increased gene-expression of inflammatory markers like TNF α , IL6, iNOS and the macrophage specific marker CD68. Pre-treatment with an IKK β -inhibitor reduced IL-1 β mediated NF κ B activity, reversed the ROS production and normalized the expression levels of TNF α , IL6, iNOS and CD68. This could indicate that one beneficial effect of anti-inflammatory drugs is mediated through inhibition of the activity of passenger macrophages within the islets. Furthermore, in beta-cells IL-1 β exposure caused an even greater induction of ROS. This was time- and dose-dependent, with a maximal ROS production after 24 hrs IL-1 β exposure (>400% of controls) and accompanied by reduced insulin secretion, glucose intolerance and apoptosis. Pre-treatment with the IKK β -inhibitor reduced IL-1 β mediated NF κ B activity, reversed the ROS production and rescued cells from apoptosis. In addition IKK β -inhibition prevented IL-1 β mediated loss of accumulated and glucose stimulated insulin secretion.

To explore the mechanism behind IL-1 β induced ROS production, expression of NF κ B regulated genes was addressed. Expression of two NF κ B regulated genes, iNOS and Divalent Metal Transporter 1 (DMT1), were increased by IL-1 β and normalized by pre-treatment with the IKK β inhibitor. The production of ROS was reduced by an inhibitor of iNOS induced NO production (L-NAME), and by an iron chelator (DFO). Furthermore, siRNA-mediated DMT1 knockdown completely protected against IL-1-induced caspase-3 cleavage. This indicates that ROS is partly NO generated and in part depends on the reaction between hydrogen peroxide and iron, generating highly reactive hydroxyl radicals - known as the Fenton reaction.

Conclusion: IL-1 β exposure activates inflammatory pathways, including a significant increase in the production of ROS. In INS-1 cells the inflammatory response is followed by glucose intolerance and β -cell apoptosis. Glucose intolerance and β -cell apoptosis can be prevented by inhibition of IKK β activity. Our data suggest that this process depends upon the expression of the NF κ B-regulated genes DMT1 and iNOS, and thus the increased ROS production involve both NO and hydroxyl, resulting from the iron dependent Fenton reaction.

hibiting/stimulating agents e.g. clonidine, GLP-1 and forskolin in the absence and presence of A1AT were investigated and cytokine induced apoptosis was also measured.

Results: A1AT protected the apoptotic cell death induced by cytokines (TNF- α , IL-1- β , and IFN- γ) in INS-1 cells ($p < 0.001$). A1AT increased insulin secretion in dose dependent manner in response to a sub stimulatory glucose concentration (8.3 mmol/l) from both INS-1 cells and pancreatic islets. The insulin secretory response of pancreatic islets at different glucose concentrations was markedly potentiated in the presence of A1AT (0.5 mg/ml). The inhibitory effect of clonidine on insulin release was reversed by A1AT ($p < 0.001$) and the stimulatory effect of GLP-1 or forskolin was further increased in the presence of A1AT ($p < 0.001$). Preliminary data from INS-1 cells showed that A1AT has stimulatory effects on cyclic AMP generation. ($p < 0.01$).

Conclusion: Our data suggest that A1AT in addition to its anti inflammatory properties, has beneficial effects on potentiating insulin release by elevating cyclic AMP production which is a key player in different intracellular pathways.

Alpha 1 anti trypsin, modulates insulin secretion and prevents from cytokine mediated apoptosis

R. Kumar, M. Kallis, C. Cilio, S. Janciauskiene, A. Salehi

Clinical Sciences, Lund University, Malmö, Sweden

Background and aims: Alpha 1-anti trypsin (A1AT) is the prototypic member of the serine protease inhibitor (serpin) super family of proteins, which has a major role in inactivating neutrophil elastases and other proteases to maintain protease-antiprotease balance. Alpha 1-anti trypsin (A1AT) has been used as key suppressor of inflammatory process in different tissues. In the present study we investigated the effect of A1AT treatment on the beta cell function and survival.

Materials and methods: INS-1 cells and isolated murine pancreatic islets were used to study the dose dependent response of A1AT on the insulin secretion at different glucose levels. The modulating effects of cyclic AMP in-

High glucose-induced antiangiogenic environment impairs beta cells and microcapillary endothelial cells interactions

G. Cohen¹, N. Kaiser², S. Sasson¹

¹Pharmacology, Hebrew University School of Medicine, ²Endocrinology & Metabolism Service, Hadassah-Hebrew University Medical Center, Jerusalem, Israel

Background and aims: An intact and functional vascular microcapillary network in islets of Langerhans supports normal islet viability and function. Transplantation of pancreatic islets is emerging as a therapeutic option for type-1 diabetes. Upon isolation of islets from donors' pancreases their vasculature is severed. Thus, implanted islets must re-establish their vascular connection in the host. This revascularization process requires pro-angiogenic factors to induce the formation of new microvessels. Research efforts have been directed toward improving neovascularization of transplanted islets for developing better methods for successful engraftment and preservation of β -cell mass after implantation. However, it has not always been acknowledged that the efficiency of such approach is complicated by the presence in the graft and host of (i) anti-angiogenic factors and (ii) altered β -cell and endothelial cell-extracellular matrix (ECM) interactions within the islets. We aim at investigating these processes in a novel in vitro co-culture system.

Materials and methods: The newly developed co-culture system allows for a highly organised β -cell and capillary endothelial cell multicellular interaction: When plated on Matrigel- or 804G cell ECM-coated surfaces, capillary endothelial cells (bEnd3 of murine brain or MS-1 of murine islets of Langerhans) readily form distinct microcapillary-like network within a few hours (Panel A, Matrigel). The striking finding is that when β -cells (INS-1E) are added to such networks, they migrate, cluster and aggregate around and along the network, forming a unique three dimensional organization (Panel C), while in the absence of the network they remain uniformly spread (Panel B).

Results: Using this system we have found that high glucose levels impair the capacity of endothelial cells to form such well-organised microcapillary-like network. Moreover, it alters both β -cell and endothelial cell integrin-mediated interactions with Matrigel or 804G ECM. We have also discovered that high glucose levels augment the expression of the protein calreticulin and of its proteolytic product, vasostatin, in both cultured INS-1E and in microcapillary endothelial cells. Vasostatin is a potent endogenous anti-angiogenic factor. In addition to its anti-angiogenic potential, calreticulin also interferes with normal cell-matrix interactions by inhibiting integrin receptor-mediated cell adhesion. When added directly to microcapillary endothelial cell cultures calreticulin impeded their capacity to form organized microcapillary-like structures. It also blocked the migration and aggregation of INS-1E cells with pre-formed networks.

Conclusion: These data suggest that hyperglycaemia can induce antiangiogenic environment both in the host and in the graft and may contribute to a delayed revascularization of the transplanted islets in type 1 diabetic patients.

Proteomic profile of insulin producing INS-1E cells upon exposure to high glucose

M. Maris¹, L. Overbergh¹, W. D'Hertog¹, E. Waelkens², C. Mathieu¹

¹Catholic University of Leuven, Laboratory of Experimental Medicine and Endocrinology, ²Catholic University of Leuven, Laboratory of Protein Phosphorylation and Proteomics, Belgium

Background and aims: Type 2 diabetes is a dual disease that develops when the pancreatic β -cells can no longer compensate for insulin resistance in the target organs, mainly skeletal muscles, but also liver and adipocytes. This relative insulin deficiency is the consequence of β -cell dysfunction and/or β -cell death. The cause of this progressive β -cell failure remains elusive, but it has repeatedly been demonstrated *in vivo* that hyperglycemia is a prerequisite for β -cell dysfunction. It has been observed, in whole islets, as well as in different β -cell lines, such as INS-1E and MIN6, that insulin gene expression, insulin content and glucose stimulated insulin secretion, were drastically compromised over time upon exposure to high glucose concentrations. To date, the exact mechanisms and pathways involved in β -cell dysfunction by high glucose treatment have not been unraveled. The aim of the present study was to analyze protein changes in insulin-producing INS-1E cells exposed to high glucose.

Materials and methods: INS-1E cells were exposed to 25 mM glucose for 24 hrs (as compared to 11 mM for control cells) and alterations in protein profile were analysed by two-dimensional Difference gel electrophoresis (DIGE) (covering 2 different pH ranges, pH4-7 and pH6-9). Proteins altered in expression ($n=4$, $p<0,05$) were identified by MALDI-TOF/TOF. The proportion of apoptotic and necrotic cells was evaluated by microscopic counting after Hoechst/Propidium Iodide staining.

Results: Exposure of the cells to high glucose, increased the proportion of apoptotic cells ($14,40 \pm 1,71$ versus $2,87 \pm 0,19$ for control ($p < 0.001$)), as well as the necrotic rate ($6,94 \pm 2,2$ versus $1,15 \pm 0,15$ for control ($p < 0.05$)). 2D-DIGE analysis revealed within two different pH ranges a total of 2189 ± 16 (pH 4-7) and 1467 ± 97 (pH 6-9) spots. Of these, 124 protein spots were altered in expression ($n = 4$, $p < 0.05$), of which 102 spots (82.3 %) could unambiguously be identified by MALDI-TOF/TOF. The identified proteins were involved in different pathways of which the glycolysis/TCA cycle, endoplasmic reticulum (ER) stress response/protein folding, cellular transport, protein synthesis and degradation were most abundant. More specific, many chaperone proteins were downregulated by high glucose treatment. As these proteins have previously been associated with protective and anti-apoptotic functions, we conclude that downregulation of these proteins may hamper β -cell defenses, making them more vulnerable to apoptosis. In addition, also proteins involved in intracellular transport were downregulated by high glucose. These included proteins involved in nucleo-cytoplasmic transport, trafficking to the ER, transport between ER and Golgi apparatus and exocytosis-related proteins. We conclude that perturbations in this intracellular trafficking may hamper correct protein synthesis and formation of post-translational modifications, leading to β -cell dysfunction and death.

Conclusion: In this study we identified new molecular pathways that were not described before as being involved in high glucose-induced β -cell dysfunction and death. In addition, the present findings may provide new key target proteins for the prevention of β -cell dysfunction and death in type 2 diabetes.

Effects of deglycating enzyme Fructosamine-3-kinase gene knockout on pancreatic beta cell glucotoxicity

S.M.A. Pascal¹, M. Veiga-da-Cunha², E. Van Schaftingen², J.-C. Jonas¹

¹Unit of Endocrinology and Metabolism, Université catholique de Louvain,

²Laboratory of Physiological Chemistry, de Duve Institute and Université catholique de Louvain, Brussels, Belgium

Background and aims: Non-enzymatic protein glycation and the formation of Advanced Glycation End Products may play a role in the toxic effects of chronic hyperglycemia in various cell types. We have recently shown that the intracellular enzyme Fructosamine-3-kinase (FN3K), which initiates protein deglycation by phosphorylating fructosamines on the third carbon, is expressed in mouse pancreatic islets together with FN3K-related protein (FN3K-RP), a closely related enzyme that phosphorylates mainly ribulosamines and erythrusamines. To determine to what extent protein glycation contributes to beta-cell glucotoxicity, we tested the effect of *Fn3k* gene

ablation on the deleterious effects of high glucose and ribose on beta-cell function and survival.

Materials and methods: Islets isolated from *Fn3k* deficient mice (*Fn3k*^{-/-}) and their wild-type littermates (WT) were cultured for 1 week in serum-free RPMI medium containing 5g/l BSA and 10–30 mmol/l glucose (G10–G30) or G10 + 25 mmol/l ribose. After culture, glucose-induced changes in cytosolic $[Ca^{2+}]_i$ and insulin secretion (normalized for differences in islet DNA content) were measured in perfused islets. Islet caspase activation was measured with FAM-VAD-fluoromethylketone. The mRNA levels of *Fn3k*, *Fn3k-rp*, *c-Myc* and *Preproinsulin* were determined by real-time RT-PCR. Results are means \pm S.E. for at least 7 islets from 3 experiments.

Results: The *Fn3k* and *Fn3k-rp* to *Tbp* mRNA ratios were similar in islets from WT mice (1.24 ± 0.21 and 1.01 ± 0.18 , $n=4$). *Fn3k-rp* islet mRNA levels were not affected by *Fn3k* gene ablation. After 1wk culture in G10, stepwise glucose stimulation (from 0.5 to 7, 15 and 30 mmol/l) induced an initial decrease in $[Ca^{2+}]_i$ without changes in insulin secretion in G7, followed by concentration-dependent rises in $[Ca^{2+}]_i$ and insulin secretion in G15 and G30 that were fully abrogated by 250 μ mol/l diazoxide. In comparison, culture in G30 increased the glucose sensitivity for the rise in $[Ca^{2+}]_i$ and the stimulation of insulin secretion and reduced by ~40% the maximal rate of insulin secretion in G30 and by ~25% the islet insulin to DNA content ratio. These changes, which occurred without significant changes in *Preproinsulin* and *c-Myc* mRNA levels nor in caspase activity, were similar in *Fn3k*^{-/-} and WT islets. After culture in G10 + 25 mmol/l ribose, the glucose-induced changes in $[Ca^{2+}]_i$ were similar to those observed after culture in G10, but the amplitude of glucose-stimulated insulin secretion was significantly reduced by ~70%, in parallel with a ~20% decrease in the islet insulin to DNA content ratio. These changes were accompanied by a ~40% reduction in *Preproinsulin* mRNA levels and a ~3-fold increase in *c-Myc* mRNA levels without detectable changes in caspase activity. As observed after culture in high glucose, the effects of ribose were similar in *Fn3k*^{-/-} and WT islets.

Conclusion: A lack of FN3K deglycating enzyme does neither increase nor decrease the sensitivity of mouse islets to the deleterious effects of a 1 week culture in the presence of 30 mmol/l glucose or 25 mmol/l ribose, two conditions that increase protein glycation and oxidative stress in beta-cells. The possible role of other deglycating enzymes, such as FN3K-RP, in beta-cell glucotoxicity deserves further investigation.

527

Effect of RAGE ligands on pancreatic beta cell

S.-H. Ihm¹, B.-W. Lee¹, J.-G. Kang¹, M.-G. Choi¹, H.-J. Yoo¹, J. Ihm²

¹Internal Medicine, Hallym University, Anyang, ²Chemistry, Kyonggi University, Suwon, Republic of Korea

Background and aims: Type 2 diabetes is characterized by progressive beta-cell failure. AGEs formed under chronic hyperglycemia act via receptors such as RAGE and lead to cellular damage underlying the microvascular and macrovascular complications of diabetes. A recent study has shown that a RAGE ligand (S100b) in vitro directly upregulated the expression of inflammatory COX2 gene in human islets via RAGE activation. RAGE and a RAGE ligand (S100b) have been observed on islet cells with an inflammatory infiltrate in diabetic NOD mouse by immunohistochemistry (IHC). However, it is not clearly known to what extent AGE directly influence pancreatic beta cell function. Thus, the objective of this study was to investigate the direct effect of RAGE ligands (S100b & HMG-1) on islet cells in vitro and to see whether a RAGE ligand (S100b) and RAGE can be detected in islets of OLETF rats.

Materials and methods: RAGE expression in INS-1 cells and isolated islets was studied with RT-PCR and Western blot. S100b and RAGE expression in pancreatic section of OLETF rats was studied by IHC. INS-1 cell apoptosis was detected by FACS with Annexin-V and PI and ELISA of cytoplasmic fragmented DNA. Apoptosis of isolated islet cells was detected by APOPercentage assay. Intracellular (IC) ROS and MMP (mitochondrial membrane potential) were measured with specific fluorescent dyes.

Results: RAGE was detected in INS-1 cells, isolated rat islets and human islets at mRNA and protein levels. S100b and RAGE were observed on islet cells in 28 week-old OLETF rats by IHC. RAGE ligands (S100b, 3, 6 μ g/mL; HMG-1, 0.1, 1 μ g/mL; 4–48 hr) induced apoptotic cell death of INS-1 cells (Fig.), isolated rat and pig islet cells in a dose- and time-dependent manner. RAGE ligands-induced INS-1 cell apoptosis was inhibited by antioxidants (NAC 1 mM, α -lipoic acid 150 μ M) and accompanied by increased IC ROS and decreased MMP. This increase of IC ROS by RAGE ligands was inhibited by NADPH oxidase inhibitor, AEBSF (20 μ M).

Conclusion: Our results suggest that RAGE ligands and RAGE interaction which increases in diabetes may contribute not only to the development of chronic diabetic complications but also to the progressive pancreatic beta cell loss in type 2 diabetes by inducing IC oxidative stress.

Ca²⁺/calmodulin-dependent protein kinase II δ (CamK II) is necessary for the expression of beta cell phenotypic genes and may link to reversible glucotoxicity

M.A. Osterhoff^{1,2}, S. Bessenyei¹, A. Sharma¹, Ö. Gögebakan^{1,2}, M. Möhlig^{1,2}, A.F.H. Pfeiffer^{1,2}

¹Clinical Nutrition, German Institute of Human Nutrition, Nuthetal,

²Department for Endocrinology, Diabetes and Nutrition, Charité - University Medicine, Berlin, Germany

Background and aims: The expression of CamK II δ is necessary for insulin gene-expression in the rat insulinoma cell line INS-1. Prolonged activation of CamK II by chronically elevated $[Ca^{2+}]_i$, e.g. after chronic glucose-stimulation, leads to deactivation of CamK II and decreased expression of typical β -cell genes. In the present study we show that CamK II mediates the regulation of expression of PDX-1 controlled typical β -cell genes in INS-1 cells.

Materials and methods: INS-1 and, by an antisense RNA approach, CamK II δ suppressed INS δ -W12 cells were cultured in RPMI 1640 media. CamK II was re-expressed by transfecting a construct coding for the human hCamK II β_1 into INS δ -W12 cells by use of FuGene 6 (Roche). The gene-expression of β -cell genes was determined by quantitative real-time PCR (RotorGene, Corbett Research) using α -tubulin as a standard. For suppression of CamK II δ expression by an independent approach in unmodified INS-1 cells CamK II δ specific siRNA (Qiagen) was used and protein concentration detected in western-blots by use of a CamK II δ specific antibody.

Results: The reduction of the CamK II δ -expression in INS-1 cells by an antisense RNA approach (INS δ -W12) led to a markedly decreased expression of the β -cell genes insulin, IAPP, GLUT-2 and glucokinase while the expression of hexokinase I was increased. Metabolic assays showed a right-shift of the half-maximum glucose-induced metabolic activity from 5mmol/l (K_m of glucokinase) to 0.5mmol/l (K_m of hexokinase). The re-transfection of hCamK II β_1 into INS δ -W12 cells was able to restore - at least in part - the β -cell phenotype of INS-1 cells, represented by a doubling of the gene-expression of insulin, glucokinase and GLUT-2 while the expression of hexokinase I was reduced to 50%. Ongoing experiments demonstrated that CamK II δ expression can also be suppressed by transfection of CamKII δ specific siRNA into INS-1 cells.

Conclusion: The rescue of the β -cell phenotype of INS-1 cells after CamK II δ suppression by re-transfection of human CamK II β_1 not only proves the specificity of the retroviral antisense mRNA approach to selectively reduce the CamK II δ expression. It also shows clearly that CamK II is not deactivated in parallel to but controls the expression of β -cell genes. Possibly, CamK II is a mediator of reversible glucotoxicity since high intracellular Ca^{2+} -levels led to deactivation of CamK II and by this to a decreased expression of β -cell genes and finally to dedifferentiation of β -cells.

Lipotoxicity in insulin-producing cells is neither amplified by high glucose nor mediated by glucokinase

H. Schmitt, S. Lenzen, S. Baltrusch

Institute of Clinical Biochemistry, Hannover Medical School, Germany

Background and aims: In pancreatic beta cells, glucokinase (GK) acts as a glucose sensor and catalyzes the rate-limiting step for initiation of glucose-induced insulin secretion. Using the recently developed RheoSwitch[®] Mammalian Inducible Expression System, based on the synthetic inducer RSL1, it was shown that precise up-regulation of GK in the presence of high glucose did not cause cellular toxicity. In contrast, GK overexpression resulted in an increase in glucose-induced insulin secretion. However, high glucose as well as enhanced glucose metabolism has been considered to potentiate toxic effects of free fatty acids (FFA) in beta cells. The aim of this study was to elucidate whether high glucose or GK expression amplify lipotoxicity in insulin-producing cells.

Materials and methods: Previously generated RINm5F-R-EYFP-GK cells, in which GK can be adjustably expressed in response to the synthetic inducer RSL1 were incubated at different glucose concentrations with or without the FFA palmitic acid (PA). Cell viability was measured by MTT assay and GK enzyme activity by a photometric assay. The mitochondrial membrane potential was measured using the potentiometric dye JC-1 or TMRE in combination with MitoTracker Green[®]. The change of mitochondrial membrane potential induced by 10 mmol/l glucose was analyzed every minute over 60 min by fluorescence microscopy. The slope of the JC-1 ratio change and TMRE/ MitoTracker Green ratio change of the individual cells was calculated offline.

Results: RINm5F-R-EYFP-GK cells were cultured for 48h in the absence or presence of 0.5, 62.5, 125, 250 and 500 nmol/l of the inducer RSL1 in medium supplemented with 1, 10 or 20 mmol/l glucose with or without PA. The cell viability decreased consistently at all glucose concentrations and GK expression levels by 40% and 70% in the presence of 100 and 200 μ mol/l palmitic acid, respectively. The toxic effect of PA was comparable to that observed in RINm5F control cells. The glucokinase enzyme activity in RINm5F-R-EYFP-GK cells was only slightly affected by PA. An extended incubation time of 14 days at 30 mmol/l glucose in the presence of 0 or 500 nmol/l of the inducer RSL1 did not decrease cell viability of RINm5F-R-EYFP-GK cells. Furthermore, these cells pre-cultured at high glucose did not show a higher sensitivity in response to a 48h incubation at 200 μ mol/l PA. In addition, the mitochondrial membrane potential change was measured in RINm5F-R-EYFP-GK cells pre-cultured at 10 or 30 mmol/l glucose. After starvation for 90 min in the absence of glucose, RINm5F-R-EYFP-GK cells with GK expression showed in response to 10 mmol/l glucose a significantly faster increase in the mitochondrial membrane potential than RINm5F-R-EYFP-GK cells without GK expression.

Conclusion: Our studies show that culture at high glucose does not amplify lipotoxicity in insulin-producing cells. Furthermore, glucose metabolism in beta cells is apparently not involved in FFA induced toxicity. Increased expression of the glucose phosphorylating enzyme glucokinase accelerates metabolism and transmits the metabolic signal faster to the mitochondria.

Overexpression of anti-oxidative K_{ATP} channels protects pancreatic beta cell functions from glucose toxicityT. Lu¹, T. He², H.-C. Lee¹¹Internal Medicine, ²Anesthesiology, Mayo Clinic, Rochester, United States

Background and aims: ATP-sensitive K⁺ (K_{ATP}) channels, encoded by Kir6.2/SUR, are crucial for controlling pancreatic β -cell insulin secretion. Over produced reactive oxygen species (ROS) are known to be the key mechanism of β -cell glucose toxicity and impairs β -cell insulin secretion. However, whether ROS-mediated K_{ATP} channel modulation would affect β -cell function has not been determined.

Methods: Using patch clamp techniques and molecular biological approaches, we compared the K_{ATP} channel property and insulin secretion from HIT-T15 cell lines in 5 mM glucose (NG) and 22 mM glucose (HG) culture conditions. We found that the K_{ATP} current of HIT-T15 cells has a strong inward component and relative small outward component of currents in NG, appearing a weak inwardly rectifying property (Fig. A). In contrast, 2-week exposure to HG reduced the inward component of K_{ATP} currents from -21.9 ± 4.3 pA/pF in NG (n=6) to -5.9 ± 3.2 pA/pF in HG (n=6, $p < 0.05^*$) at -100 mV, and enhanced the outward component of currents from 1.2 ± 2.4 pA/pF in NG (n=6)

to 31.4 ± 2.3 pA/pF * in HG (n=6) at +100 mV (Fig. B). Thus, culture with HG converted the channel property from an inward rectifier into an outward rectifier (Fig. C). The HG effects on K_{ATP} channel property were mimicked by H₂O₂ applied to the cytoplasmic surface of cells, which were reversible by DDT, suggesting that the mechanism of cysteine oxidation was involved (Fig. D). Molecular determinant studies confirmed that the cysteine residue at 166 (C166) of Kir6.2 subunit were responsible for the HG and H₂O₂ effects. Replacement of C166 by alanine (C166A) on Kir6.2 eliminated 95% the H₂O₂ effects (Fig. E) and completely abolished the HG effects. 2 weeks culture with HG reduced the HIT-T15 cell insulin secretion in response to 22 mM glucose stimulation (from 1.08 ± 0.06 ng/ml of baseline to 1.82 ± 0.04 ng/ml at 60 min exposure to 22 mM glucose, n=3), compared to those cells cultured with NG (from 1.52 ± 0.05 ng/ml of baseline to 3.05 ± 0.11 ng/ml * at 60 min exposure to 22 mM glucose, n=3) (Fig. F). Importantly, over expression of Kir6.2C166A in HIT-T15 β -cells significantly increased insulin secretion by 50% in HG condition (Fig. F).

Conclusion: Our results indicated that redox modulation of K_{ATP} channels impaired pancreatic β -cell insulin secretion. The C166 residue of Kir6.2 is the molecular target of ROS. Prevention of K_{ATP} channel oxidation would enhance pancreatic β -cell functions in chronic hyperglycemia.

Development of a predictive model for pancreatic islet amyloidosis in the baboon based on fasting plasma glucose and age. Implication for the study of beta cell failure in human type 2 diabetes

F.B. Folli¹, A. Davalli², A.O. Chavez¹, A. Comuzzie³, E. Tejero⁴, P. Zuo¹, Z. Chang¹, E. Dick, Jr.⁴, G. Hubbard⁴, A. Cruz², C. Perez², G. Halff³, A. Gastaldelli², R.A. DeFronzo¹, R. Guardado Mendoza¹

¹Medicine/Diabetes, UTHSCSA, San Antonio, United States, ²Dept of Medicine, Istituto Scientifico San Raffaele, Milano, Italy, ³Southwest National Primate Center, Southwest Foundation for Biomedical Research, San Antonio, United States, ⁴Diabetes Research, Southwest Foundation for Biomedical Research, San Antonio, United States, ⁵Diabetes Research, Universidad de Colima, Mexico

Background and aims: Pancreatic islet amyloidosis (PIA) has been implicated in the pathogenesis of beta cell failure in human type 2 diabetes. The baboon genome shares 98% overlap with the human. Thus, the baboon represents an ideal model to understand the pathophysiology of PIA and beta cell-failure in humans. Thus, the aim of this work was to identify the predictors of PIA in baboon model of insulin resistance and T2DM.

Materials and methods: We studied 150 baboons in which glucose, insulin and glucagon concentrations were measured prior to necropsy. PIA, islet size, islets and amyloid volumes were quantified at necropsy using a stereological approach. Genetic characterization of the baboon islet amyloid polypeptide amylin (IAPP) showed that the sequence was 90% identical to that of humans at the cDNA level and 97% identical at the protein level.

Results: Severity of amyloid deposition was stratified into quintiles (Q1=5% to Q5= 51%). Progressive increases in age (from 16 to 22), FPG (from 75 to 187 mg/dl), HbA_{1c} (from 4.6 to 9.3%), FFA (from 0.53 to 1.15 mmol/l), glucagon (from 60 to 112 ng/l), islet size (from 9 to 13 mm²) and islets volume (from 2.6 to 5.4%) were observed from quintile I to quintile V. (all p<0.05). After adjusting for gender, age and weight, the differences in FPG and HbA_{1c} persisted (p<0.05). We used HOMA-B (log transformed due to the skewed distribution) as an index of beta cell function. Ln(HOMA-B) decreased progressively with increasing amyloid severity (r = -0.509, p < 0.0001) and increasing FPG (r = -0.589, p < 0.0001). In a multivariate analysis, age, gender, obesity, FFA, Ln(glucose), Ln(insulin) and Ln(glucagon) were the most important predictors of PIA (adjusted R² = 0.535, p < 0.0001). Using only glucose and age, the adjusted R² was 0.519, p < 0.0001. Thus, amyloid severity (%) was predict by the following equation = 1.118 x Age (years) + 37.57 x Ln(glucose mg/dl) - 164.

Conclusion: (1) FPG directly correlates with PIA severity in baboons, over the range of the metabolic abnormalities typically observed in human T2DM; (2) The main predictors of PIA in baboons are FPG and age. These data support the concept that the baboon is a novel and important non-human primate model for the study of pathophysiology, including beta cell failure, and novel therapies for preventing PIA in T2DM.

PS 033 Apoptotic mechanisms in beta cells

Impaired glucose tolerance in calbindin D28k-ablated mice *in vivo* is associated with impaired calcium response and insulin secretion in islets *in vitro*

S. Rohleder^{1,2}, U. Zeitze¹, R.G. Erben^{1,2}

¹Institute of Pathophysiology, Dept. of Biomedical Sciences, University of Veterinary Medicine Vienna, Austria, ²Institute of Animal Physiology, Ludwig Maximilians University, Munich, Germany

Background and aims: The calcium binding protein calbindin D28k (D28k) has been identified in various tissues including brain, kidney, bone, and pancreas. D28k is thought to enhance renal tubular calcium reabsorption, and may protect cells from apoptosis in the brain. Although it has been suggested the D28k may act as a calcium buffer in pancreatic alpha and beta cells, the role of D28k in islet cells *in vivo* is still unclear. It was the aim of the present study to explore further the functional role of D28k for insulin secretion and intracellular calcium handling in islets of Langerhans, using D28k knockout (D28k-KO) mice.

Materials and methods: All *in vivo* experiments were performed in 12-week-old male wild-type (WT) or homozygous D28k-KO mice. After an overnight fast, 1.5 mg glucose per g body weight was administered at time 0 by subcutaneous injection or gavage. Blood glucose levels were determined at 0, 10, 20, 30, 60 and 120 min in whole blood samples from the tail tip by a standard test system. At baseline and 10 minutes, additional blood samples were taken for measurement of serum insulin. Islet and beta cell area were quantified histomorphometrically in paraffin sections after anti-insulin immunostaining. For *in vitro* studies, islets were isolated from WT and D28k-KO mice by collagenase digestion. Static glucose stimulation tests were performed directly after isolation. Subsequently, the same islets were cultured in RPMI 1640 and 10% FCS; insulin secretion tests were repeated on day 2 of culture. For quantification of intracellular calcium peaks, freshly isolated islets were incubated with Fura2-AM and fastened in a quartz cuvette in modified KRBH buffer containing 5 mM glucose after adherence to APES/polylysine-treated glass cover slips. Changes in intracellular calcium in response to a 30 mM glucose stimulus were quantified using a Jasco FP 6300 spectrophotometer. Whole intracellular calcium was quantified after dissolution of 20 islets in a small volume quartz cuvette. All insulin samples were quantified by a mouse specific ELISA.

Results: In subcutaneous, but not oral, glucose tolerance tests we found slightly, but significantly impaired glucose tolerance (AUC increased by 8% from 28914±346 to 31403±1132, P<0.05) and a trend for lower insulin secretory capacity (reduction from 0.1649±0.02320 to 0.1101±0.013 ng/ml, P<0.051) in D28k-KO mice (data are means ± SEM). Freshly isolated islets of knockout mice displayed impaired insulin secretion, a 3-fold reduction in the intracellular calcium peak following glucose stimulation, and 80% lower islet calcium content compared with WT. However, insulin secretion returned to normal in islets of D28k-KO mice after 2 days of culture with 10% FCS. Histomorphometry revealed a 6% higher beta cell area per islet area in D28k-KO mice.

Conclusion: Our data show that D28k has a functional role in beta cells *in vivo*. The impaired insulin secretion in D28k-ablated mice may be caused by deteriorated calcium handling within beta cells. We hypothesize that this cellular defect is compensated for by an increase in beta cell mass *in vivo*, which might explain why it remains subclinical, and is only detectable after a glucose challenge. Further experimentation is required to dissect the intracellular function of D28k in the beta cell.

Subcellular distribution and function of Bcl-2 and Bcl-xL in the beta cell

D.S. Luciani, S. Widenmaier, J. Yeung, C. McIntosh, J.D. Johnson

Department of Cellular and Physiological Sciences, University of British Columbia, Vancouver, Canada

Background and aims: Bcl-2 family proteins are integral in the control of β -cell apoptosis and emerging evidence also suggests important roles in β -cell physiology. Both pro- and anti-apoptotic members of this family interact to regulate programmed cell death, and this control can be exerted at several

cellular organelles. Bcl-2 and Bcl-xL are both believed to be important for β -cell survival, but their relative abundance and localization within the β -cell are not well characterized. Moreover, much of the current knowledge regarding Bcl-2 family members stems from overexpression studies which do not necessarily recapitulate the state of the endogenous proteins. The aims of the present study were to determine the subcellular distribution of endogenous and overexpressed Bcl-2 and Bcl-xL in β -cells and to further clarify the organelle-specific functions of these important pro-survival proteins.

Materials and methods: Immunofluorescent staining of primary mouse β -cells, MIN6 cells and mouse pancreas sections was employed to visualize the localization of Bcl-2 and Bcl-xL relative to intracellular organelles. Association of Bcl-2 and Bcl-xL with organelles was further probed by subcellular fractionation and western blot. Liposome-based transfection was used to transiently overexpress fluorescent protein-tagged Bcl-2 and Bcl-xL. Small molecule inhibitors were used in combination with live cell microscopy and western blotting to study the impact of Bcl-2/Bcl-xL antagonism on mitochondrial function, glucose-stimulated insulin secretion and β -cell viability.

Results: In both cultured β -cells and pancreatic sections immunofluorescent staining with monoclonal and polyclonal antibodies to Bcl-2 revealed clear nuclear localization with no detectable signal in the cytosolic compartment. This differed significantly from the distribution of exogenous GFP-tagged Bcl-2 in transfected cells. Bcl-2:GFP was recognized by the antibodies, but localized exclusively to the cytoplasm with prominent mitochondrial co-localization. In contrast to endogenous Bcl-2, endogenous Bcl-xL was found by both immunostaining and cell fractionation to be primarily mitochondrial and non-nuclear. Indeed, a small molecule inhibitor of Bcl-xL/Bcl-2 caused immediate mitochondrial hyperpolarization and KATP-channel-dependent cytosolic Ca^{2+} signals. These events occurred hours before the onset of caspase-3-dependent apoptosis. We also observed an immediate effect on glucose-stimulated insulin secretion using Bcl-xL/Bcl-2 inhibitors. Together these data suggest links between Bcl family members and β -cell function.

Conclusion: Endogenous Bcl-2 and Bcl-xL differ markedly in their localization within the pancreatic β -cell. While Bcl-2 is found in the nucleus, Bcl-xL shows strong association with mitochondria. Prominent mitochondrial effects of Bcl-2/Bcl-xL inhibitors thus suggest that of the two proteins, Bcl-xL may be the primary regulator of β -cell mitochondrial apoptosis and physiology. Further studies on the roles of nuclear-targeted endogenous Bcl-2 are warranted. Moreover, differences in the intracellular partitioning of exogenous and endogenous Bcl-2 advocate caution when using overexpression to study Bcl-2 function in β -cells.

Insulin induces apoptosis at long-term in pancreatic beta cells

M. Benito, A. Bartolome, C. Guillen

Bioquímica y Biología molecular, Facultad De Farmacia, Universidad Complutense, Madrid, Spain

Background and aims: Type 2 diabetes results from a combination of insulin resistance and impaired insulin secretion. Insulin resistant states are associated with an increase in the beta cell mass and also high levels of circulating insulin. Ultimately the beta cells undergo a failure in the insulin secretion that leads to uncontrolled diabetes. At this stage, a question arises if those persistent high levels of circulating insulin may contribute to beta-cell damage. To address this important issue, we have submitted beta cells to a prolonged effect of increasing concentrations of insulin.

Materials and methods: We have previously established mouse beta cell lines lacking or not insulin receptors (IR) in culture from the LoxP/LoxP IR mice. Thus, immortalized loxP/LoxP IR beta cells were infected with adenoviruses bearing or not Cre and subsequently subcloned to assure cells lacking IR. These beta cells proliferate independently in response to insulin or glucose through the convergent signaling pathway mTOR/p70 S6 kinase.

Results: Insulin 10 nM induces at short term Akt and also p70 S6 kinase phosphorylation in beta cells in the absence of glucose (from 2 to 8 h). However, insulin effect on survival signaling attenuated at 15 h and was totally impaired at 24 h. In parallel, glucose-deprived beta cells enhanced caspase-3 in its active form (cleaved caspase-3). Under the same experimental conditions, insulin inhibited cleaved caspase-3 expression at short term, but increased its expression at long term. At 24 h, glucose-deprived beta cells increased caspase-3 activity and also the number of haploid cells but decreased the cell number. Under these conditions, there was a shift from inhibitory to stimulatory effects of insulin on caspase 3 activity and also haploid cells number in a dose-dependent manner. Opposite effects were observed regard-

ing beta cells number. The stimulatory effect at 24 h of high levels of insulin (from 10 to 100 nM) on cleaved caspase-3 expression, as confirmed by two-dimensional electrophoresis immunoblotting, was not observed in beta cells lacking IR or in beta cells bearing IR in the presence of glucose 5 mM. Finally, the long-term effect of insulin on the above parameters was cycloheximide-dependent, suggesting that an endogenous protein factor was required for the deleterious effect of insulin.

Conclusion: All these results seem to suggest that insulin, beside its survival short-term effect, was able to induce beta-cell death owing to apoptosis in a dose- and time-dependent manner. More importantly, this long-term effect of insulin was entirely dependent on endogenous protein synthesis. Thus persistent supra physiological levels of insulin observed in several insulin resistant states might contribute to beta-cell damage and subsequently to the progression to type 2 diabetes.

Serine/threonine protein phosphatase 5 mediates dexamethasone-induced beta cell death through its modulation of p38 MAPK phosphorylation

H. Orstäter, L. Fransson, N. Grankvist, R.E. Honkanen, Å. Sjöholm

Dept. of Clinical Science and Education, Karolinska Institutet, Stockholm, Sweden

Background and aims: Serine/threonine protein phosphatase 5 (PP5) is a single polypeptide chain containing a catalytic domain near its C-terminus and a regulatory domain at the N-terminus end. Through tetratricopeptide repeat domains the phosphatase interacts with heat-shock protein 90. By this interaction PP5 has been shown to coimmunoprecipitate with the glucocorticoid receptor (GR). A reduction in cellular levels of PP5 affects the pattern of genes that are activated after glucocorticoid treatment. Since glucocorticoids can evoke both insulin secretory dysfunction and pancreatic β -cell death when given to islets of Langerhans *in vitro*, and steroid diabetes in patients, we wanted to investigate whether PP5 influences dexamethasone-induced cell death in the insulin-producing cell line MIN6.

Materials and methods: Clonal pancreatic MIN6 cells were treated with a siRNA directed against PP5 to reduce the cellular levels of PP5. After siRNA treatment cells were exposed to 100 nM of dexamethasone with/out either 1 μM of the GR antagonist RU486 or 20 μM of the p38 MAPK inhibitor SB203580. After culture we assessed apoptosis induction by measuring the levels of cytoplasmic DNA-histone complexes. We also analyzed PP5 mRNA levels by quantitative PCR. Finally, we measured PP5 protein levels and the degree of p38 MAPK phosphorylation by Western blotting.

Results: In MIN6 cells, PP5 mRNA and protein levels were reduced by 50–60 % after 24–48 hours of siRNA treatment. Treating control MIN6 cells with dexamethasone for 30 hours caused a 4.5 ± 0.6 ($n=9$) fold induction of apoptosis compared to untreated cells. Such an effect was fully blocked by co-treating the cells with RU486. The ability of dexamethasone to induce apoptosis was attenuated by $25 \pm 4\%$ ($n=9$, $p<0.05$) in cells with reduced levels of PP5. We next investigated the ability of dexamethasone to activate p38 MAPK signaling. p38 MAPK phosphorylation was 5.1 ± 1.0 ($n=5$) fold increased after a 30-hour dexamethasone exposure. Again, such an effect was fully blocked by co-treating the cells with RU486. In cells with reduced levels of PP5, dexamethasone only managed to cause a 3.0 ± 0.7 fold ($n=5$) increase in p38 MAPK phosphorylation. Finally, we investigated whether inhibition of p38 MAPK signaling could protect MIN6 cells from dexamethasone-induced apoptosis. Co-culturing cells with dexamethasone and the p38 MAPK inhibitor SB203580 reduced apoptosis by 50% compared to cells treated with dexamethasone alone.

Conclusion: In the present study, we show that dexamethasone induces phosphorylation of p38 MAPK and cell death in insulin-producing MIN6 cells. Both of these effects seem to be mediated via the GR since RU486 inhibited them fully. It is also evident that they are connected because disruption of p38 MAPK signaling reduced dexamethasone-induced apoptosis. Furthermore, it is shown that PP5 is a key player in regulating glucocorticoid signaling in these cells. When cellular levels of PP5 were reduced by means of siRNA treatment, both induction of p38 MAPK phosphorylation and dexamethasone-induced apoptosis were attenuated. We hypothesize that reduced levels of PP5 change the GR transcriptional activity that subsequently reduces p38 MAPK phosphorylation and apoptosis. Inhibition of PP5 may prove valuable in efforts aimed at β -cell protection against apoptosis in steroid diabetes.

Transient oxidative stress in INS-1E cells and rat islets induces mitochondrial damages promoting prolonged beta cell dysfunction

N. Li, P. Maechler

Department of Cell Physiology and Metabolism, University of Geneva, Switzerland

Background and aims: Mitochondrial injuries caused by oxidative stress are putative mechanism of pancreatic beta-cell failure in the course of diabetes. We and others have previously shown that transient exposure of beta-cells to oxidant interrupts the transduction signals normally coupling glucose metabolism to insulin secretion. Here, we analysed beta-cell function after a 3-day recovery period following single exposure to oxidative stress.

Materials and methods: Using INS-1E beta-cell and isolated rat islets, we studied long-term impact of a single transient oxidative stress (200 μ M H₂O₂ for 10 min) applied 3 days before analyses. Then, key parameters for metabolism secretion coupling were measured: mitochondrial membrane potential (rhodamine-123 fluorescence), cytosolic ATP production (luciferase bioluminescence), oxygen consumption (on isolated mitochondria in an oxymeter), and glucose-stimulated insulin secretion (RIA). In order to detect putative mechanisms underlying prolonged dysfunction, mitochondrial ROS generation (Amplex Red), integrity of respiratory chain complex subunits (western blot), and mitochondrion associated gene expression (qRT-PCR) were analysed.

Results: Three days after the single transient oxidative stress INS-1E beta-cells exhibited markedly reduced mitochondrial function and secretory responses to glucose. Compared to non-stressed INS-1E cells, we observed impaired mitochondrial hyperpolarization (-55% upon glucose stimulation), reduced ATP production (-59%), decreased oxygen consumption (-43% and -60% upon NADH and succinate+ADP stimulations, respectively), and blunted glucose-stimulated insulin secretion (-51%, $P < 0.01$). Similar effects were observed in isolated rat islets. These parameters correlated with increased mitochondrial ROS formation (+60% and +40% upon NADH and succinate stimulations, respectively) accompanied by down-regulation of the respiratory chain subunits complex I (-24%), complex III (-21%) and complex IV (-29%). We also measured decreased expression of genes responsible for mitochondrial biogenesis, such as TFAM (-74%) and PGC-1 α (-84%). Three weeks after single oxidative stress, both mitochondrial respiration and secretory responses of INS-1E cells were totally recovered. Moreover, such recovered INS-1E cells exhibited resistance to a second transient oxidative stress.

Conclusion: INS-1E beta-cells and rat islets memorized one single transient oxidative stress as revealed by impairment of their mitochondrial respiratory chain and blunted glucose-stimulated insulin secretion 3 days after stress. This memory was induced by transient ROS exposure that in turn promoted molecular changes maintaining subsequent endogenous ROS generation. The cells could recover metabolism-secretion coupling after 3 weeks and even became more resistant to the secondary oxidative attack.

Serine/threonine protein phosphatase 5 regulates the phosphorylation status of JNK after hydrogen peroxide exposure in pancreatic beta cellsN. Grankvist, J. Pettersson, R. Honkanen, Å. Sjöholm, H. Orstäter
Department of Clinical Science and Education, Karolinska Institutet, Stockholm, Sweden

Background and aims: In type 2 diabetes, where pancreatic β -cells are exposed to elevated glucose concentrations, a reduced β -cell mass is seen. This could be the result from an increased production of reactive oxygen species (ROS) that cause cellular damage and initiate apoptosis. An important positive regulator of apoptosis is the mitogen-activated protein kinase (MAPK) signaling pathway. One mammalian MAPK is c-Jun N-terminal kinase (JNK) which can be activated by an apoptosis signal-regulating kinase (ASK1). Serine/threonine protein phosphatase 5 (PP5) is a single polypeptide chain that can be present both in the cytosol and the nucleus. It has been suggested that PP5 can act as a negative regulator of ASK1/JNK signaling. The aim of this study was to investigate the role of PP5 in the regulation of JNK signaling in MIN6 cells exposed to hydrogen peroxide (H₂O₂).

Materials and methods: Clonal pancreatic MIN6 cells were exposed to 0.5mM H₂O₂ to induce cell death, for 4, 8 and 16 hours. Cells were also co-treated with the H₂O₂ and ROS scavengers catalase and tempol. To analyze

if cells were able to recover from the H₂O₂ treatment, cells were exposed to H₂O₂ for 30 min and were then allowed to recover. Cell viability was then analyzed by lactate dehydrogenase activity assay. In order to reduce the PP5 expression level, MIN6 cells were treated with siRNA directed against PP5. The cells were then exposed to H₂O₂ for 0, 5, 15 and 30 min, together with control cells without reduced levels of PP5. In MIN6 cells with reduced levels of PP5 the scavengers catalase, MnSOD, CuZnSOD and thioredoxin peroxidase were measured. The PP5 and the different scavengers mRNA levels were analyzed by quantitative PCR. The protein levels and degree of JNK phosphorylation were measured by Western blotting.

Results: MIN6 cells treated with 0.5mM H₂O₂ for 4, 8 and 16 hours showed a 60–70% decrease in cell viability. This decrease was fully and partly prevented by the ROS scavengers catalase and tempol, respectively. A 30 min exposure to 0.5 mM H₂O₂ did not induce a decrease in cell viability. However, if the cells were left in the absence of H₂O₂ for an additional time period (3.5, 7.5 or 15.5 hours) reduced cell viability was as marked as in cells continuously exposed to H₂O₂. These results indicate that the cells were not able to recover from the H₂O₂ treatment. The degree of JNK phosphorylation was rapidly induced by H₂O₂ exposure. Phosphorylation of both JNK1 and 2 was enhanced 20-fold after 15 min of exposure. In cells treated with siRNA against PP5 mRNA levels of the phosphatase were reduced by 50% after 24 hours. The ability of H₂O₂ to increase the phosphorylation levels of JNK was doubled in cells with reduced PP5 levels. Down-regulation of PP5 as such did not affect catalase, MnSOD, CuZnSOD and thioredoxin peroxidase mRNA levels.

Conclusion: These data show that H₂O₂-induced β -cell damage is a rapid event that is hard for the cells to recover from. A cellular event that rapidly occurs after H₂O₂ exposure is phosphorylation of JNK1 and 2. The data presented here suggests that PP5 is a negative regulator of JNK signaling since MIN6 cells treated with siRNA against PP5 had much higher levels of phosphorylated JNK after exposure to H₂O₂ as compared to control cells. These findings suggest that enhancement of PP5 activity might be a way to reduce cellular damage induced by ROS and may prove valuable in efforts aimed at β -cell protection against apoptosis in diabetes.

Effects of exendin-4 and interferon-gamma antibody on beta cell apoptosis and proliferation in BB ratC. Segundo¹, G. Pérez-Arana¹, M. Blandino-Rosano¹, A. Cebada-Aleu¹, M. Aguilar-Diosdado²¹Investigation Unit, ²Endocrinology and Nutrition Service, Puerta del Mar Hospital, Cadiz, Spain

Background and aims: The autoimmune Diabetes Mellitus type 1 (DM1) is characterised by a loss of beta cell mass due to an autoimmune process (insulinitis). Proinflammatory cytokines and free radicals mediated apoptosis has been considered the main mechanism of beta cell destruction by altering the natural death/proliferation balance. Exendin-4, a GLP-1 analog, and interferon-gamma antibody (IFN- γ Ab) have been shown to make a benefit effect on beta cell mass. The aim of this work is to study “in vivo” changes in proliferation and apoptosis over the insulinitis period after exendin-4 and IFN- γ Ab administration.

Materials and methods: Biobreeding (BB) rat strain was used as DM1 model. Animals were killed at 5, 7, 9 and 11 weeks of age and beta cell apoptosis and proliferation were quantified in pancreatic tissue by TUNEL and BrdU staining, respectively. A daily treatment with intraperitoneal Exendin-4 (4186,6 ng/kg), alone or in combination with weekly IFN- γ Ab administration (100 mg/Kg) was initiated at 5 weeks of age. Normal saline treated rats were used as control and proliferation, apoptosis and lymphocytic infiltration score were compared in both groups.

Results: A decrease in proliferating beta cell percentage at 7, 9 and 11 weeks of age in BB rat was observed. The start point of the loss of proliferation was previous to the apoptosis enhancement which reached statistical significance at 9 weeks of age. Treatment of BB rat with Exendin-4 alone recovered beta cell proliferative capacity at 7 and 9 but not at 11 weeks of age, and decreased beta cell apoptosis at 11 weeks of age. Combination of Exendin-4 and IFN- γ Ab improved Exendin-4 effects alone by maintaining beta cell proliferation values higher than those in untreated rats all over the study. These effects were not related with the severity of insulinitis.

Conclusion: The BB murine DM1 model presents a diminished beta cell proliferation from early stages of insulinitis. Exendin-4+anti IFN- γ , and to a lesser extent Exendin-4 alone, partially restores proliferative capacity and inhibits apoptosis in beta cells during insulinitis without affecting islet infiltration. These results support a role of regulatory events of proliferation in DM1

pathogenesis and suggest that either beta cell apoptosis and proliferation control could be important in preventive strategies against DM1.

Oleate prevents apoptosis but not UPR activation in palmitate-treated INS-1E beta cells

E. Sargsyan, E.M. Sol, P. Bergsten

Medical Cell Biology, Uppsala University, Sweden

Background and aims: Saturated fatty acid palmitate (PA) and unsaturated fatty acid oleate (OA) are two of the most abundant fatty acids in the circulation. Whereas long-term incubation of β -cells with PA induces apoptosis, incubation with OA has no such effect. Interestingly, the negative effect of PA on β -cell apoptosis can be prevented by co-culturing the cells with PA and OA. Mechanisms for this protective effect of OA on β -cells exposed to PA are unclear, however. One of the potential mechanisms of how PA induces apoptosis is the unfolded protein response (UPR), which is not initiated in β -cells cultured in the presence of OA. Taking into consideration that OA reverses PA-induced apoptosis, we examined if the mechanism of such OA-induced reduction in apoptosis is via inhibiting development of the UPR.

Materials and methods: INS-1E cells were cultured for 24 hours in the presence of 0.5 mM PA, 0.5 mM OA complexed with 0.5% BSA or a combination of 0.5 mM PA and 0.5 mM OA complexed with 1% BSA. After culture, cells were lysed and cellular protein was isolated and used for measurements of phosphorylated (p)-PERK, p-eIF2 α , ATF4, CHOP, Bcl2 and caspase 3. Apoptosis was determined by measuring cytoplasmic oligonucleosomes and related to DNA content. Total protein concentration was also determined.

Results: INS-1E cells cultured in the presence of OA for 24 hours showed no induction of apoptosis. In contrast, when OA was replaced by PA seven-fold increase of apoptosis was observed. This rise in apoptosis was reverted when OA was also included in the culture medium. Protein content was reduced by 40% in cells treated with PA but remained unchanged in cells treated with combination of PA and OA, consistent with measurements of apoptosis. The PERK pathway plays a major role in the development of the UPR in PA-treated INS-1E cells. Therefore we measured targets of this pathway. We found that p-PERK, p-eIF2 α , ATF4 and CHOP were strongly up-regulated in cells cultured in the presence of PA but not induced when cells were cultured in the presence of OA. When both OA and PA were present in the culture medium, expression levels of the UPR targets were not lowered but remained at levels observed in cells cultured in the presence of PA alone. In support of other mechanisms than UPR activation responsible for PA-induced apoptosis, we found that neither pro-apoptotic protein Bcl-2, a downstream target of CHOP, nor caspase-3, which is essential for ER-stress induced apoptosis were affected in INS-1E cells exposed to palmitate.

Conclusion: The protective effect of OA on PA-treated β -cells is not mediated via attenuation of ER stress. Absence of PA effect on Bcl-2 and caspase-3 expression levels makes it unlikely that activation of UPR plays a major role in PA-induced apoptosis.

Communication between insulin-resistant skeletal muscle and the beta cell

K. Bouzakri¹, P. Ribaux¹, T. Berney², M. Donath³, P.A. Halban¹

¹Genetic and development, Centre Medical Universitaire, Geneva, ²Surgery, Cell Isolation and Transplantation Center, Division of Surgical Research, Geneva, ³Internal Medicine, Division of Endocrinology and Diabetes, Zurich, Switzerland

Background and aims: Obesity and type 2 diabetes mellitus are widespread metabolic disorders characterized by an overlapping phenotype of insulin resistance with a deficiency in insulin secretion underlying hyperglycemia. Systemic inflammation is also a feature of obesity and type 2 diabetes, raising the hypothesis that elevated cytokine levels may contribute to peripheral insulin resistance and decreased beta cell functional mass. In healthy humans, TNF- α infusion induces skeletal muscle insulin resistance. We now explore the potential communication between insulin-resistant skeletal muscle and the beta cell.

Materials and methods: Human skeletal muscle cells were cultured for up to 24h +/- 20 ng/ml TNF- α to induce insulin resistance. mRNA expression for cytokines was analysed after 8h by hybridising cDNA to low-density oligo-nucleotide arrays. Conditioned media were collected and the concentration of a small number of cytokines measured by Luminex multiplex assay. MIN6B1 cells (well-differentiated transformed mouse beta cell line) were used to explore the impact of exposure to these conditioned media for 24h on apoptosis (TUNEL assay), proliferation (BrdU incorporation) and short-term insulin secretion (1h 2.8 mM glucose followed by 1h 16.7 mM glucose). Data are mean \pm SE, for n=4 (muscle cells) and n=3 (MIN6B1 cells using conditioned media from 3 individual human muscle cells each time) independent experiments.

Results: Muscle cells treated for 8h show an increase of 19 chemokine genes on the oligo-nucleotide arrays. These results were confirmed and quantified by qRT-PCR for the following: CCL5; CX3CL1; CXCL10; CXCL2; IL-1b; IL6; IL8; C3; CCL11; CCL2; CCL7; CXCL11; CXCL6; CXCL3; CXCL9; IL15; CXCL1; TNF α ; IL-1Ra. The concentration of most candidate cytokines in the conditioned medium after 24 h of TNF- α treatment was too low for reliable measurement but IL-8 was clearly increased to >1.5 ng/ml. TNF- α conditioned medium increased MIN6B1 cell apoptosis by 13-fold compared to control cells (13.4 \pm 0.5 vs. 1.1 \pm 0.3 % TUNEL positive cells; p<0.001) and decreased proliferation compared to control cells at both low (2.8 mM) (9.8 \pm 0.3 vs. 5.9 \pm 0.3 % BrdU positive cells; p<0.01) and high (16.7 mM) glucose (26.7 \pm 0.7 vs. 8.7 \pm 1.3 % BrdU positive cells; p<0.01). There was also inhibition of glucose-stimulated insulin secretion after 24h culture of MIN6B1 cells in TNF- α conditioned medium compared to control cells (27.3 \pm 1.7 vs. 14.0 \pm 2.6 % total insulin content/h; p<0.01) and a small but significant increase in basal secretion (8.6 \pm 1.7 vs. 3.3 \pm 0.2 % total insulin content/h; p<0.01). These changes were not due to the direct effect of TNF- α itself on the beta cells but rather to the presence of as yet uncharacterised factors in the conditioned medium of muscle cells cultured with TNF- α . These results were confirmed using primary rat beta cells and in preliminary studies with human beta cells.

Conclusion: Taken together these results showed that induction of insulin-resistance skeletal muscle by TNF- α leads to secretion of myokines which impact negatively on beta cell function and survival. The identification of these myokines and their molecular targets on beta cells opens the possibility for new therapeutic strategies for preservation of functional beta cell mass in type 2 diabetes.

Islet cell mass and turnover in patients with chronic pancreatitis

B.A. Menge¹, H. Schrader¹, S. Schneider¹, A. Tannapfel², W. Uhl¹, W.E. Schmidt¹, J.J. Meier¹

¹Ruhr-University Bochum, St. Josef-Hospital, ²Ruhr-University Bochum, Institute for Pathology, Bochum, Germany

Background and aims: Chronic pancreatitis (CP) often leads to the subsequent development of diabetes, but the changes in islet cell mass and turnover in such patients have not yet been analysed in detail. We addressed the ques-

tions (1) Is beta-cell mass reduced in patients with CP? (2) Is beta-cell turnover increased in CP patients? (3) Are beta-cells less vulnerable to apoptosis than acinar cells in patients with CP?

Materials and methods: Pancreatic tissue from 29 patients with CP and 14 control subjects was stained for insulin, glucagon, Ki67, and TUNEL and morphometric analyses were performed. Pancreas volume was determined based on abdominal computed tomographies in 13 patients with CP and 11 control subjects. Islet cell mass was estimated from the product of the fractional islet cell areas and the mean pancreas volume in each group.

Results: The mean pancreatic volume was $64.9 \pm 4.3 \text{ cm}^3$ in CP patients and $82.3 \pm 6.7 \text{ cm}^3$ in control subjects ($p = 0.035$). Fractional beta-cell area was $0.64 \pm 0.09 \%$ in CP patients and $0.78 \pm 0.07 \%$ in controls ($p = 0.30$). Thus, beta-cell mass was estimated to be $0.42 \pm 0.06 \text{ g}$ in CP patients and $0.64 \pm 0.05 \text{ g}$ in controls ($\sim 34 \%$ reduction; $p = 0.016$). There was a significant reduction in islets number in CP patients ($p = 0.0017$), whereas islet size was even slightly increased ($p = 0.10$). Alpha-cell mass was not different between the groups ($p = 0.64$). There were no differences in the frequencies of replication in beta-cells, duct cells and acinar cells between the groups. The frequency of apoptosis was similar in beta-cells ($p = 0.48$), but ~ 10 fold increased in acinar cells in CP patients ($p < 0.0001$).

Conclusion: Beta-cell mass is reduced by only $\sim 35 \%$ in patients with CP, largely because of a reduction in the total number of islets. The similar frequencies of beta-cell replication in CP patients and controls despite an ~ 10 -fold increase in acinar cell apoptosis suggest that the self-destruction of the pancreas in patients with chronic pancreatitis is highly specific for the exocrine compartment and affects the endocrine islets to a much lesser extent. These findings serve to explain the late onset of overt diabetes in patients with CP.

Bone marrow-derived dendritic cells from NOD mice display elevated expression of CCR2 ligands

K. Takahashi¹, Y. Oka², J. Satoh¹

¹Department of Diabetes and Metabolism, Iwate Medical University, Morioka, ²Department of Molecular Metabolism and Diabetes, Tohoku University, Sendai, Japan

Background and aims: Dendritic cells (DC) are central to the initiation of immune response and maintenance of self-tolerance. In type 1 diabetes, DC display defective phenotype and function in type 1 diabetes, and possibly play crucial roles in the pathogenesis of this disease. To characterise molecular changes in CD11c+ bone marrow (BM)-derived DC from NOD mice, a model of type 1 diabetes, we compared transcript profiles of BMDC with those from the sister strain, NON mice. In the present study, we analysed our microarray data focusing on the chemokine (C-C motif) ligands (CCLs), which have roles in directing cell movements necessary for the initiation of T-cell immune response, and influence the direction of T-cell differentiation.

Materials and methods: BM cells from 4-week-old female NOD and NON mice were cultivated in the presence of GM-CSF and IL-4 over 5 days, and with LPS for following 2 days. The CD11c+ DC were then sorted by magnetic beads-conjugated anti-CD11c+ antibodies (MACSTM, Miltenyi Biotec Inc, Bergisch Gladbach, Germany). RNA extracted from the CD11c+ DC from 3 independent mice (10 µg/ mouse) was pooled, and used to prepare targets for hybridization to the GeneChip Mouse Genome 430A Arrays (Affymetrix, Santa Clara, CA).

Results: Among all known C-C motif ligands, mouse mature BMDC expressed CCL2-9, 12, 17 and 24, whereas CCL1, 11, 19-21, 25, 27 and 28 were absent. CCL2 (macrophage chemotactic protein 1; MCP1), CCL7/MCP3 and CCL12/MCP5 were noted to be more strongly expressed in the BMDC from NOD mice than those from NON mice (462%, 531% and 1417% vs NON, respectively). The other chemokines detected showed about equal intensity of expression between these strains.

Conclusion: Expression of CCL2, 7 and 12 was found in BMDC from 4-week-old female NOD mice, which are known to be CCR2 ligands. The early inflammatory changes associated with insulinitis are heralded by infiltration of macrophages and DC. CCR2 on macrophages and immature DC are involved in trafficking to lymph nodes and site of inflammation. Dysregulated expression of CCR2 ligands possibly lead to developing type 1 diabetes in NOD mice by affecting recruitment of antigen presenting cells into islets in a paracrine manner.

543

The role of oxidants and anti-oxidants in beta cell function and integrity

M. Michalska^{1,2}, P. Newsholme¹, G. Wolf², R. Walther²

¹School of Biomolecular and Biomedical Science, University College Dublin, Ireland, ²Department of Medical Biochemistry and Molecular Biology, Ernst-Moritz-Arndt-Universität, Greifswald, Germany

Background and aims: Type 1 diabetes mellitus is an autoimmune disease that results from selective destruction of pancreatic β -cells within the islets of Langerhans. Damage of the insulin-producing β -cells occurs via T-cell and macrophage infiltration of the islet. Immune cells can produce interleukin (IL)-1 β , tumor necrosis factor (TNF- α) and γ -interferon (IFN- γ). These cytokines induce the synthesis of reactive oxygen (ROS) and nitrogen (NO) species, in the beta cell which prompt dysfunction and apoptosis. The contribution of reactive oxygen species and NO production to glucolipotoxic β -cell dysfunction and death are unknown. Insulin-producing β -cells are very sensitive to oxidative stress due to their low antioxidant defense system e.g. superoxide dismutase (SOD) or catalase. For this reason, there is a significant interest in the regulation of expression of antioxidants such as peroxiredoxin III, superoxide dismutase or catalase in pancreatic islets. We have recently hypothesized that inhibition of ROS and/or NO generation at source would lead to better protection from insult. In addition to testing this hypothesis, we have investigated a possible novel role of Prx III the functionality of the insulin-secreting cells.

Materials and methods: Clonal BRIN BD 11 beta cells or mouse islets were treated with various stressors (cytokines: 0.3125U/ml IL-1 β , 31.25U/ml TNF- α , 15.625U/ml IFN- γ , or hydrogen peroxide 0.3%, or high glucose 25mM, or palmitic acid 0.1mM) in the presence or absence of antioxidants such as superoxide dismutase (20U/ml), catalase (100U/ml), NAC (0.2mM), the NADPH oxidase inhibitor Apocynin (0.2mM), or the iNOS inhibitor 1400W (0.2mM). Using Western blot analyses the expression of Prx III or p47phox was determined in BRIN BD 11 cells. To examine beta cell functionality after stress or protection (exposure to various antioxidants), insulin secretion was determined by ELISA.

Results: Treatment with either cytokines, hydrogen peroxide, or palmitic acid resulted in a 2- fold decrease in chronic (24hr) stimulated insulin secretion from the BRIN BD11 cell line, and a 3- fold decrease after exposure to cytokines or palmitic acid in mouse islets. Acute exposure to cytokines also resulted in decrease in insulin secretion, but to a lesser extent. Furthermore, antioxidants such as catalase, superoxide dismutase and N-acetylcysteine protected the secretory response against cytokines ($p < 0.01$), hydrogen peroxide ($p < 0.01$), or high glucose ($p < 0.01$) in the BRIN BD11 cell line, and against cytokines ($p < 0.01$), or palmitic acid ($p < 0.01$) in mouse islets. The expression of p47phox was upregulated at the protein level after treatment with cytokines or H₂O₂ in the cell line. The addition of Apocyanin and 1400W fully protected chronic (24hr) insulin secretion in mouse islets ($p < 0.01$).

Conclusion: The results demonstrate that various antioxidants protect pancreatic beta cells against immune, nutrient or hydrogen peroxide inducers of oxidative stress thus maintaining insulin secretion and preventing beta cell death.

The K_{ATP} channel subunit SUR1 influences cell viability of pancreatic beta cells exposed to oxidative stress

B. Gier¹, P. Krippeit-Drews¹, L. Aguilar-Bryan², J. Bryan², M. Düfer¹

¹Pharmazeutisches Institut, Universität Tübingen, Germany, ²Pacific Northwest Research Institute, University of Washington, Seattle, United States

Background and aims: In stimulated wildtype (WT) islets we observed that insulin secretion is impaired by low concentrations of H₂O₂, whereas hormone release from islets of SUR1 knockout (SUR1-KO) mice was not affected. To elucidate whether the protection of K_{ATP} channel-deficient pancreatic beta-cells against ROS-induced cell damage is coupled to cell viability, we determined apoptosis of WT and SUR1-KO beta-cells exposed to oxidative stress.

Materials and methods: Apoptotic beta-cells were identified by TUNEL and NucViewTM (determination of active caspase3) labeling, respectively.

Results: After one hour of incubation, 10 µM H₂O₂ increased the number of caspase3-positive WT beta-cells from $9.9 \pm 2.0\%$ to $28.2 \pm 4.1\%$ ($n=3$, $P < 0.01$). In SUR1-KO beta-cells basal apoptosis was increased compared to WT, but

cell viability was not affected by the addition of 10 μM H_2O_2 . Furthermore, 25 μM H_2O_2 augmented apoptosis of WT beta-cells from $9.9 \pm 2.0\%$ to $38.8 \pm 6.8\%$ ($n=3$, $P<0.01$) compared to an elevation from $17.52 \pm 0.5\%$ to only $24.9 \pm 1.0\%$ ($n=3$, $P<0.01$) in SUR1-KO beta-cells. Similar results were obtained after six hours of incubation with both concentrations of H_2O_2 . In order to elucidate if the effect is restricted to H_2O_2 , we analyzed the influence of the NO-donor SNOc (100 μM) on cell survival. The rate of apoptotic cells was increased from $9.9 \pm 2.0\%$ to $25.8 \pm 2.5\%$ ($n=3$, $P<0.001$) in WT beta-cells, whereas cell viability remained unchanged in SUR1-KO beta-cells. To investigate whether pharmacological closure of K_{ATP} channels induces similar protective effects against oxidative stress in WT beta-cells, they were preincubated with 25 μM tolbutamide for four hours. This maneuver prevented WT beta-cells from the destructive effect of 10 μM H_2O_2 and decreased the extent of apoptotic cells provoked by 25 μM H_2O_2 .

Conclusion: Modulation of K_{ATP} channel activity rendered pancreatic beta-cells less sensitive to oxidative stress. Cell function as well as cell viability were preserved in beta-cells from SUR1-KO mice during an oxidative insult with low concentrations of H_2O_2 . Influencing K_{ATP} channels in WT beta-cells significantly reduced ROS-induced apoptotic cell death. Thus, changing K_{ATP} channel activity may be an interesting approach to prevent beta-cell death mediated by oxidative stress during the development of diabetes mellitus as well as before islet transplantation.

Role of exogenous sphingosine-1-phosphate and over-expressed sphingosine kinase 1 in glucolipotoxicity-induced pancreatic beta cell death

J. Veret, J. Movassat, B. Portha, H. Le Stunff

Laboratoire de physiopathologie de la nutrition, UMR CNRS 7059, Paris, France

Background and aims: Chronic hyperglycaemia as seen in type 2 diabetes is often associated with excessive circulating lipid levels. Both abnormalities have been reported to exert adverse effects on beta cell function and survival, a phenomenon referred as glucolipotoxicity. The excessive delivering of lipids in islets of Langerhans influences diabetes progression through the accumulation of the bioactive sphingolipid ceramide, which has been involved in the induction of apoptosis in mammals. In contrast to ceramide, sphingosine-1-phosphate (S1P) another sphingolipid, stimulates vital biological processes such as cell proliferation and survival. Inside the cells, S1P is produced by the phosphorylation of sphingosine catalyzed by sphingosine kinases (SphKs). Sphingosine is also a precursor of ceramide synthesis. Because of the interconvertibility of ceramide and S1P and their opposing effects on cell fate, the dynamic balance between S1P and ceramide has been proposed to form a “sphingolipid biostat” that determines cell survival or death. Therefore, in the present study, we sought to determine the role of the SphK/S1P axis in glucolipotoxicity-induced beta cell death.

Materials and methods: INS-1 cells were transfected either by an empty plasmid (vector) or a SphK1 plasmid. INS-1 cells were cultured with 1% FCS, 0.4 mM palmitate, various concentrations of glucose in the absence or the presence of S1P for 48h. INS-1 cell viability was measured by MTT assay. INS-1 cell apoptosis was determined by chromatin condensation assessed by DAPI staining. SphK activity was measured in INS-1 cells using an in vitro kinase assay.

Results: Palmitate and glucose plus palmitate treatments induced a 3 fold-increase in chromatin condensation in INS-1 cells within 48 h, indicative of apoptosis. Millimolar concentrations of exogenous S1P were unable to prevent beta cell apoptosis induced by palmitate. In contrast, nanomolar concentrations of S1P completely inhibit the synergistic apoptotic action of 0.4 mM palmitate in the presence of 30 mM glucose. Both mammalian sphingosine kinase isoforms are expressed in INS-1 cells. In order to determine the role of SphK1 in glucolipotoxicity-induced beta cell death, we over-expressed SphK1 in INS-1 cells. Surprisingly, the over-expressed SphK1 was unable to reduce beta cell viability induced either by palmitate alone or combined with high glucose concentrations. Moreover, we found that glucolipotoxicity-induced beta cell death was associated with a reduction of SphK1 activity. Replacing D-glucose by the non-metabolizable L-glucose neither potentiated palmitate-induced beta cell death nor decreased SphK1 activity. Similarly, palmitate methyl ester, which is not metabolized, did not affect beta cell survival and SphK1 activity. In contrast, 2-bromopalmitate, an inhibitor of fatty acid mitochondria beta oxidation, reproduced the effect of palmitate on beta cell survival.

Conclusion: Collectively, our results suggest that S1P prevents glucolipotoxicity-induced apoptosis. However, exogenous S1P and SphK1, which produces intracellular S1P, have diverging role in glucolipotoxicity-induced beta cell death. These results also suggest that palmitate-induced SphK1 inhibition is associated with a glucose-dependent esterification of free fatty acid.

Autophagy: an age-related change in beta cells

S. Wang¹, X.J. Li², J. Li¹, L. Chao¹, B.R. Dong¹

¹Geriatrics, ²Endocrinology and Metabolism, West China Hospital, Chengdu, China

Background and aims: Autophagy is a highly regulated cellular mechanism for the bulk degradation of cytoplasmic contents. It has been implicated in a variety of physiological and pathological conditions such as cancer, neurodegeneration disease, as well as aging. However, whether autophagy involved in the age-related β -cell change and the high prevalence of glucose intolerance and type 2 diabetes in older population are not known. Thus, the present study was designed to observe the phenomena of autophagy, and its relation, if any, to apoptosis, which might be associated with the reduction of β -cell mass, and age-related ultrastructural changes in β -cell of different age rats.

Materials and methods: Natural aging SD rats with different age (6, 12, 20–24mon) was used in this experiment. After the BW were measured, rats were anesthetized with sodium pentobarbital (30mg/kg, ip), blood were drawn from heart for detecting fasting blood glucose, lipid profile and FFA as basal metabolic parameters. Pancreases were isolated quickly, fixed and embed. Islets were observed for: 1. Autophagolysosome and apoptotic bodies: observed by EM (H-600IV, HITACHI, Japan); 2. Apoptosis rate: tested by the method of Tunel immunohistochemical staining (Tunel-POD assay, Roche) and EM.

Results: 1. The significantly higher concentration of FFA was found in 12, 20–24 months groups (386.02 ± 88.08 ; 349.43 ± 93.47 vs. 263.93 ± 68.77 mmol/l, respectively, $p<0.05$), with no difference in WT, FBG, lipid profile among three groups; 2. Lysomic vacuoles were first found in the β -cell of 12mon. age rats (Fig. A); 3. Autophagic vacuoles (AV) appeared in β -cells of 20–24mon. age rats (Fig. B), with no any similar change in 6mon. rats (Fig. C). 4. There was no any evidence of apoptosis by both ways of EM and Tunel immunohistochemical staining in β -cells in different stages of aged rats. Furthermore, swelling and vacuolar degeneration were found in both mitochondrion and endoplasmic reticulum in β -cell of the oldest rats.

Conclusion: Our results showed for the first time that it is autophagy not apoptosis involved in age-related β -cell change, which firstly occurred in middle aged (12 month) rats. The mechanism within it is not yet understood. The relationship between activated autophagy and insulin secretion impairment in β -cell of aged rats needed to be further explored.

Fig: Autophagy in β -cells of different month SD rats. A: 12month, lysomic vacuoles (thick arrow); B: 20–24 month, autophagic vacuoles (thin arrow), atrophic mitochondria (triangle); C: 6 month.

Serum glucocorticoid inducible kinase 1 inhibits degradation of insulin receptor substrate-2 in insulin secreting cellsS.J. Ullrich¹, D. Avram¹, F. Ranta¹, J. Leveringhaus¹, A.M. Hennige¹, S. Hopp¹, F. Lang², H.-U. Häring¹¹Internal Medicine IV, University Hospital of Tuebingen, ²Institute of Physiology, University of Tuebingen, Germany

Background and aims: In insulin secreting cells, insulin receptor substrate-2 (IRS-2) transmits insulin and IGF-1 receptor signalling. Indeed, IRS-2 expression and stimulation has been found to guarantee survival and proper functioning of these cells. In addition to modifications of IRS-2 by stimulatory and inhibitory phosphorylations, IRS-2 has a fast turnover rate and thus signalling largely depends on protein degradation and synthesis. The serum-glucocorticoid-inducible kinase 1 (SGK1) regulates proteasomal degradation of membrane proteins. Previously, we observed that the synthetic glucocorticoid dexamethasone (dex) induces the expression of SGK1 in insulin secreting cells. While dex treatment inhibited tyrosine phosphorylation of IRS-2, the protein was increased 2-fold without changes in mRNA levels. This study was performed to analyze the role of SGK1 during glucocorticoid induced cell death and to examine whether SGK1 is responsible for increased expression of IRS-2 observed in insulin secreting cells under glucocorticoid excess.

Materials and methods: INS-1 cells were stably transfected with hSGK1. Apoptotic cell death was assessed using TUNEL staining of nuclear DNA. Mitochondrial potential was measured by fluorescence activated cell sorting (FACS) after staining of the cells with tetramethylrhodamine ethylester (TMRE). Expression and phosphorylation of proteins were analyzed using Western blot analysis. The rate of protein degradation was estimated in the presence of inhibition of protein synthesis by cycloheximide.

Results: In contrast to dex, stable transfection of INS-1 cells with hSGK1 did not affect cell growth, apoptotic cell death or glucose-induced insulin secretion. In accordance, cells in stimulatory high glucose developed a more negative mitochondrial potential than cells kept at 2.8 mM glucose. While in control cells incubated with cycloheximide, 60 % of IRS-2 protein was degraded after 8 h, in hSGK1 transfected cells no significant degradation was observed. The PI3K inhibitor LY294002 inhibited degradation of IRS-2 also in control cells. This inhibition of degradation was accompanied by an inhibition of an increase in apparent molecular weight of IRS-2. In contrast, SGK1 did not inhibit the shift in molecular weight of IRS-2.

Conclusion: These observations suggest that SGK1 does not contribute to dex-mediated apoptotic cell death but the kinase inhibits degradation of IRS-2 in insulin secreting cells.

JunB inhibits ER stress and apoptosis in pancreatic beta cells

E.N. Gurzov, F. Ortis, F. Moore, D.L. Eizirik

Laboratory of Experimental Medicine, Université Libre de Bruxelles, Belgium

Background and aims: Cytokines contribute for pancreatic beta cell apoptosis in type 1 diabetes but the mechanisms involved are not well understood. The transcription factor Activator Protein-1 (AP-1) is a key player in inflammation and apoptosis. Based on microarray analysis of cytokine-treated insulin-producing INS-1E and primary beta cells we have previously identified modifications in expression of the AP-1 components. We presently evaluated the role of the AP-1 subunit JunB for cytokine-induced beta cell dysfunction and death.

Materials and methods: INS-1E and primary FACS-purified beta cells were transfected with control or siRNAs targeting JunB and treated with cytokines (IL-1 β 10–50 U/ml+ IFN- γ 100–1000 U/ml). The siRNA-induced JunB knockdown (KD) phenotype was compared to fibroblasts constitutively lacking JunB expression. Upregulation of JunB was achieved by transfection with an adenoviral vector. Real time RT-PCR, Western Blot, and viability assays (Hoechst/PI) were performed to identify proteins involved in JunB-mediated responses.

Results: Cytokines induced an early increase in JunB expression in INS-1E cells (3-fold protein increase by 8 h, $n = 3$, $P < 0.05$). This protein upregulation was prevented by an NF- κ B repressor. JunB KD by RNA interference (>80% inhibition) in INS-1E cells augmented cytokine-induced iNOS (33-fold increase, $n = 3$, $P < 0.05$) and Chop expression (15-fold increase, $n = 3$, $P < 0.05$), leading to increased cell death (44% apoptosis in cytokine-treated JunB KD cells vs 19% apoptosis in cells treated with cytokines and control siRNA, $n = 5$, $P < 0.001$). Similar findings were observed in FACS-purified beta cells. Other ER stress markers (XBP-1s and ATF-4) were also upregulated following JunB KD and cytokine treatment. Chop expression and ER stress markers were similarly increased in JunB KD INS-1E cells after addition of cyclopiazonic acid, an endoplasmic reticulum stressor. In line with this, cytokines induced iNOS and apoptosis in mouse JunB knockout fibroblasts but not in wild-type cells. Conversely, adenovirus-mediated overexpression of JunB diminished cytokine-induced iNOS and Chop expression and protected INS-1E and primary beta cells against cytokines (10–14% apoptosis in JunB overexpressing and cytokine-treated INS-1E and primary beta cells respectively, vs >25% apoptosis in cytokine-treated control cells; $n = 3$ –5; $P < 0.05$).

Conclusion: Our findings indicate that JunB has a protective role against cytokine-induced ER stress and apoptosis in beta cells. This protein is probably part of the defense mechanisms triggered by beta cells during exposure to pro-inflammatory cytokines. Therefore, overexpression of JunB may be an interesting strategy for beta cell protection in early diabetes.

Involvement of endoplasmic reticulum stress in pancreatic beta cell death: a proteomic approachL. Overberger¹, W. D'Hertog¹, A. Cardozo², D. Eizirik², E. Waelkens³, C. Mathieu¹¹Catholic University of Leuven, Laboratory of Experimental Medicine and Endocrinology, Leuven, ²Université Libre de Bruxelles, Laboratory for Experimental Medicine, Brussels, ³Catholic University of Leuven, Laboratory of Protein Phosphorylation and Proteomics, Leuven, Belgium

Background and aims: Pancreatic β -cells are the crucial cells responsible for synthesizing, processing and secreting insulin. Because of this high demand on insulin processing, β -cells have a highly developed endoplasmic reticulum (ER) and are thus very sensitive to ER stress, in particular to agents that deplete the ER Ca²⁺, such as cyclopiazonic acid (CPA). In previous studies we have investigated, at the mRNA level, the global alterations induced by CPA, in rat insulin-producing INS-1E cells. The aim of this study was to investigate the changes induced by CPA at the protein level.

Materials and methods: INS-1E cells were treated with 25 μ M CPA dissolved in DMSO or with DMSO alone during 6 or 12 hours. Cell viability was as-

sessed by microscopic cell counting (Hoechst/Propidium Iodide staining). Differential protein expression was analysed by two-dimensional difference gel electrophoresis (2D-DIGE), covering 2 different pH ranges (pH4-7 and pH6-9). Proteins altered in expression ($n=4$, $p<0.05$) were identified after in-gel trypsin digestion and MALDI-TOF/TOF analysis. Altered expression of some of the identified proteins was confirmed by western blotting and analyzed at the mRNA level by real-time RT-PCR.

Results: Culturing of the INS-1E cells in the presence of 25 μ M CPA resulted in an increase in the proportion of apoptotic cells from 1.12% \pm 0.84% to 11.45% \pm 3.10% after 6 hours ($n=4$, $p<0.01$) and to 18.24% \pm 6.39% ($n=4$, $p<0.01$) after 12 hours of treatment. mRNA levels for the pro-apoptotic transcription factor CHOP increased 26-fold to 31-fold after 6 and 12 hours of CPA treatment, respectively ($p<0.01$). For the 2D-DIGE proteomic study, 1841 \pm 294 spots could be matched for the 6 and 12 hour time point in the pH 4-7 range. Of these, 48 and 90 spots were differentially expressed between control and CPA-treated cells for the 6 and 12 hour time point respectively ($p<0.05$). No differentially expressed spots (with $p<0.05$) were observed in the pH 6-9 range. Of these, 91 spots were unambiguously identified, resulting in 60 distinct proteins. We grouped these proteins according to their function in 9 groups. The results point to a marked decrease in multiple proteins involved in the ubiquitin-proteasome pathway. Also several chaperones were downregulated, a finding that was not observed at the mRNA level.

Conclusion: Discrepancies between mRNA and protein levels of several molecular chaperones point to the importance of post-transcriptional regulation in this pathway. Since chaperones are known to play a role in β -cell defenses, the observed downregulation may contribute to the high vulnerability of β -cells to ER stress.

Carboxypeptidase E deficiency causes beta cell dysfunction and apoptosis *in vitro* and *in vivo*

J.D. Johnson, K.D. Jeffrey, D.S. Luciani, E.U. Alejandro, T.B. Kalynyak
Cellular and Physiological Sciences, Diabetes Research Group, University of British Columbia, Vancouver, Canada

Background and aims: Diabetes is associated with high levels of circulating lipids. Many studies have shown that free fatty acids, such as palmitate, can cause beta-cell dysfunction and death. In an unbiased proteomics screen, we identified carboxypeptidase E as a major protein target of palmitate. In the present study, we investigated the islet phenotype of mice lacking carboxypeptidase E.

Materials and methods: Glucose homeostasis in CPE null mice was examined with intraperitoneal glucose tolerance tests. Pancreas sections were analyzed for beta-cell area, alpha-cell area, islet architecture, average islet size and islet density. Pancreatic beta-cell TUNEL and BrdU staining were employed to estimate apoptosis and proliferation *in vivo*. Islets were isolated via filtration. Apoptosis-related protein expression was examined by western blot using antibodies to cleaved caspase-3 and CHOP. The function of islets was assessed using islet perfusion. Proinsulin maturation was assessed using immunofluorescent staining. Fully processed insulin (i.e. CPE-cleaved) was identified using the mAB1 monoclonal antibody, whereas total insulin was identified using a polyclonal antibody. CPE levels were modulated in MIN6 cells using shRNA (combined with FACS sorting) or transient transfection.

Results: As noted by others, CPE null mice had impaired fasting glucose and significant glucose intolerance when compared to wildtype littermate controls. Pancreas sections from these mice had larger islets and >2 fold increased beta-cell mass, although the beta-cells had much weaker insulin staining. CPE null beta-cells exhibited a markedly higher rate of both apoptosis and proliferation *in vivo*. Similarly, islets isolated from CPE null mice had increased cleaved caspase-3 and CHOP protein levels. This was recapitulated in MIN6 cells with shRNA-mediated knockdown of CPE. CPE nulls islets were also displayed evidence of functional defects. For example, co-staining with antibodies to CPE-cleaved insulin and total insulin showed that fully mature insulin was virtually absent in pancreas sections from CPE null mice. Interestingly, this was also observed in islets from high fat fed mice and palmitate-treated MIN6 cells, corresponding to a reduction in CPE seen in both models. Perfusion experiments indicated that islets isolated from CPE null islets had elevated basal insulin secretion whereas the fold insulin responses to glucose and KCl were both impaired relative to control mice.

Conclusion: In the present study, we characterized key aspects of the islet phenotype of CPE null mice and of MIN6 cells with a 30% reduction in CPE. Together with our previous work demonstrating that palmitate and high fat feeding decrease beta-cell CPE levels, these new results suggest that some

aspects of type 2 diabetes pathology can be explained by lipid-induced suppression of CPE.

Diazoxide protects against hypoxia-induced beta cell damage

A. Björklund¹, Z. Ma¹, K. Brismar¹, V. Grill^{1,2}

¹Molecular Medicine and Surgery, Rolf Luft Center of Diabetes Research, Karolinska Institutet, Sweden, ²Norwegian University of Science and Technology, Dept of Cancer Research and Molecular Medicine, Trondheim, Norway

Background and aims: Islet transplantation is hampered by relative hypoxia after transplantation. Means to improve resilience toward hypoxia-induced beta cell damage could potentially improve the success of transplantation. To survey the impact of hypoxia and ways of promoting resilience we tested for effects of hypoxia *in vitro* on beta cell function and for a modulating effect of diazoxide, known from other tissues to protect against hypoxia-induced damage.

Materials and methods: Isolated rat islets were cultured in 11 mM glucose (G) over night (22h). The following day islets were exposed for 6h to hypoxia ($<1\%$ O_2). Glucose-(16.7 mM G)-induced release was tested 30 min later in 60 min batch incubations as well as after continued culture over night (22h) at normoxia (=re-oxygenation). Effects of diazoxide (325 μ M) were tested either by pre-exposure to the drug for 22 h preceding hypoxia or by addition of the drug during the 6 h of hypoxia.

Results: 6h of hypoxia attenuated insulin responses to 16.7 mM G when measured 30 min after hypoxia (8 ± 1.2 vs. 65 ± 15.7 μ U/islet/h ($p=0.012$, $n=7$). Hypoxia-inducible protein (HIF)-1 α was up-regulated immediately following hypoxia (Western blotting). Re-oxygenation improved insulin response to glucose in previously hypoxia-cultured islets (8 ± 1.2 vs. 22 ± 2.8 μ U/islet, $p<0.001$, $n=7$). However, the response was still much decreased vs. islets that had been continuously cultured in normoxia (22 ± 2.8 vs. 78 ± 17.2 , $p=0.01$, $n=7$). Hypoxia also decreased islet insulin content measured both directly after the 6h of hypoxia (from 954 ± 84 to 735 ± 95 μ U/islet, $p<0.001$, $n=7$) and after re-oxygenation (from 1044 ± 77 to 409 ± 44 μ U/islet, $p<0.001$, $n=7$). The pdx-1 protein was down-regulated after re-oxygenation vs. continuously normoxic controls. Previous diazoxide did not rescue the glucose-induced insulin response when tested immediately after 6h of hypoxia. However, previous diazoxide improved the response to 16.7 mM G in hypoxia-exposed islets when measured after re-oxygenation (47 ± 5 vs. 26 ± 3 μ U/islet/h, $p=0.027$, $n=4$). Furthermore, previous diazoxide increased islet insulin content when measured after re-oxygenation (926 ± 208 μ U/islet vs. 388 ± 58 μ U/islet, $p=0.01$, $n=4$). Diazoxide present during hypoxia failed to affect insulin secretion or content following re-oxygenation (results not shown). Thus diazoxide was beneficial only when present prior to hypoxia.

Conclusion: 1) hypoxia can induce permanent functional beta cell damage which affects both insulin secretion and biosynthesis 2) pre-exposure to diazoxide lessens these damaging effects. These findings may have implications for islet transplantation procedures.

Proteomically identified elevated serum levels of apolipoprotein CIII in individuals with type 2 diabetes mellitus may induce MAPK-mediated beta cell apoptosis

E.M. Sol, T. Sundsten, P. Bergsten

Department of Medical Cell Biology, Uppsala University, Sweden

Background and aims: Type 2 diabetes (T2DM) results from complex interplay between genetic predisposition and environmental factors that together promote impairment of the β -cell. To identify blood-borne proteins involved in the detrimental process, we have previously protein profiled serum from control individuals and T2DM individuals with impaired β -cell function. Among the differentially displayed proteins apolipoprotein CIII (apoCIII) was significantly up-regulated in T2DM individuals. ApoCIII plays an important role for plasma triglyceride levels and elevated levels of the lipoprotein have been connected with dyslipidemia in T2DM subjects. The present study was undertaken to investigate if the elevated levels of apoCIII could be caus-

ally linked to impaired β -cell function. In support of such a role increased β -cell cytoplasmic calcium concentration and apoptosis has been reported in the presence of the protein. We therefore hypothesized that the elevated intracellular levels of calcium might be related to induction of endoplasmic reticulum (ER) stress. In addition, activation of mitogen-activated protein kinases (MAPKs) was suggested to be a mechanism by which the lipoprotein could negatively affect the β -cell. The hypotheses were addressed by measuring the expression of ER stress markers and MAPKs in β -cells exposed or not to apoCIII.

Materials and methods: INS-1E cells were cultured in the absence or presence of apoCIII (10 μ g/ml) for 24 hours. In cells examined for expression of ERK and p38, ERK inhibitor PD98059 (100 μ M), p38 inhibitor SB203580 (10 μ M) or L-type calcium-channel inhibitor verapamil (100 μ M) were added or not to the culture medium prior to introducing apoCIII. After culture, apoptosis was determined by measuring the amount of cytoplasmic oligonucleosomes and related to DNA content. Protein expression of ER-stress markers phosphorylated (p)-eIF2 α and CHOP, and phosphorylated and unphosphorylated forms of the MAPKs ERK, p38 and JNK were determined with western blot analysis at different time points.

Results: INS-1E cells cultured for 24 hours in the presence of apoCIII had 2.5-fold increased apoptosis. ER-stress markers p-eIF2 α and CHOP were not changed at the end of the culture period. The expression of p-ERK was rapidly induced 3-fold 0.5 hour after introduction of apoCIII and declined to reach basal level after 12 hours culture. Inhibition of the L-type calcium channel with verapamil blocked the ERK induction. JNK was not altered by apoCIII. In contrast, p38 was induced by the lipoprotein after 18 hours and manifests as 2-fold rise after 24 hours. When inhibiting ERK and/or p38 activation, apoptosis in apoCIII-treated cells was modulated.

Conclusion: The observed elevated circulating apoCIII levels may induce β -cell apoptosis via activation of MAPKs ERK and/or p38.

Direct effects of palmitate on ER calcium, cytosolic calcium, and beta cell death, measured with real-time assays and fluorescent protein-based indicators

K.S. Gwiazda, T.-L.B. Yang, Y. Lin, D.S. Luciani, J.D. Johnson
Cellular and Physiological Sciences, University of British Columbia, Vancouver, Canada

Background and aims: There is a strong link between obesity, elevated free fatty acids, and type 2 diabetes. It has been shown that palmitate has pleiotropic effects on beta-cell function and survival. Acute administration of the fatty acid mildly augments glucose-stimulated insulin secretion, but chronically elevated levels inhibit insulin secretion and promote beta-cell apoptosis. Palmitate-induced signalling is thought to involve altered calcium homeostasis. Exposure to the fatty acid induces intracellular calcium signalling in INS-1 and HIT-T15 cells, as well as in primary mouse islets. However, more detailed studies regarding the role of these calcium signals are needed.

Materials and methods: We used both human beta-cells and the MIN6 beta-cell line. Calcium imaging in primary cells was performed using Fura-2-AM dye. Calcium dynamics in specific cellular locations were measured using the fluorescent protein-based genetically encoded calcium sensors D3cpv and D1ER for the cytosol and ER, respectively. Western blotting was used to assess the time-course of CHOP activation and propidium iodide incorporation was used to assay cell death in real-time. The in vivo effects of hyperlipidemia were assessed in C57B6/J mice fed a high fat diet.

Results: Acute palmitate treatment of MIN6 cells and human islet cells increased cytosolic calcium through intracellular calcium store release as well as extra-cellular calcium influx. The non-metabolizable analogue 2-bromopalmitate, which is not thought to activate ATP-dependent extra-cellular calcium influx, also increased cytosolic calcium, but to a much lesser extent. Both palmitate and 2-bromopalmitate induced cell death, although propidium iodide incorporation induced by 2-bromopalmitate was significantly slower. Palmitate also induced the expression of the pro-apoptotic transcription factor CHOP, indicating an increase in ER stress and suggesting a possible depletion of ER calcium. Indeed, acute palmitate treatment in MIN6 cells caused reversible calcium depletion from the ER lumen in a subpopulation of cells. We observed sustained oscillations of cytosolic calcium in cells treated with palmitate for two hours. However, we detected little palmitate-induced insulin secretion, suggesting these calcium signals are poorly coupled to exocytosis. We fed wild type mice a high fat diet to determine the

chronic effects of elevated lipid exposure. Islets from these mice exhibited basal hyperinsulinemia and a reduced relative glucose-stimulated insulin response, a phenotype similar to human type 2 diabetes.

Conclusion: We have characterized calcium-dependent mechanisms involved in altered beta-cell function and survival induced by the free fatty acid palmitate. We present the first direct evidence that palmitate depletes calcium from the beta-cell ER. Together, these data shed light on one of the many pathways that may be involved in the pathogenesis of lipotoxicity and type 2 diabetes.

Exposure to persistent organic pollutants, polychlorinated biphenyls, potentiates fatty acid-mediated beta cell death: role of ER-stress

L. Okafor¹, I. Chadbourn², A. Wale¹, E. Katsouliris², J. Cunningham², P. Chatterjee², J.G. Mabley²

¹Pharmacology, Brighton & Sussex Medical School, ²School of Pharmacy & Biomolecular Sciences, University of Brighton, United Kingdom

Background and aims: Exposure to polychlorinated biphenyls (PCB) -environmental contaminants - has been linked to increased incidence of Type II diabetes. Although exposure, particularly to PCB 126, has been shown to be a risk factor for development of Type II diabetes independent of obesity it has been proposed that environmental contaminant exposure coupled with a high fat diet synergistically increases the risk of developing Type II diabetes. The aim of this study was to determine the in vitro effect of PCB 126 alone and in combination with palmitic acid on β -cell viability and death.

Materials and methods: BRIN-BD11 cells were exposed to PCB 126 (1, 3, 10 or 20 μ M) for 24 or 48h. Cell viability was determined using the MTT assay and cell death assessed by propidium iodide/Hoechst staining. BRIN-BD11 cells were also exposed to PCB 126, 1 or 3 μ M, in combination with palmitic acid (10 or 30 μ M) for 24h before levels of cell viability and death were determined. Endoplasmic reticulum (ER) stress was measured in BRIN-BD11 cells exposed to palmitic acid alone or in combination with PCB 126 by Western blotting for the ER stress proteins GRP78 and CHOP.

Results: PCB 126 exposure for 24h decreased BRIN-BD11 cell viability only at 20 μ M (reduced to 77% \pm 4; $p < 0.05$ vs. untreated cells). However, 48h exposure to PCB 126 reduced BRIN-BD11 cell viability to 95% \pm 4, 81% \pm 6, 68% \pm 4 and 52% \pm 5 ($p < 0.05$ vs. untreated cells) for 1, 3, 10 and 20 μ M respectively. Exposure to PCB 126 for 24h increased BRIN-BD11 cell necrosis (from 2.6% to 7.4%, 8.5% and 15.5% for 1, 3 or 10 μ M PCB 126; $p < 0.05$ vs. untreated cells) but apoptosis levels were unaffected. Exposure to PCB 126 (1 or 3 μ M) or palmitic acid (10 or 30 μ M) alone for 24h had either no or minimal ($< 10\%$ decrease) effect on cell viability. However, simultaneous treatment of BRIN-BD11 cells with 10 μ M palmitic acid plus 1 or 3 μ M PCB 126 synergistically reduced cell viability to 92% \pm 3 and 82% \pm 3 ($p < 0.01$ vs. PCB 126 or palmitic acid alone) and 30 μ M palmitic acid combined with 1 or 3 μ M PCB 126 reduced cell viability to 71% \pm 4 and 58% \pm 5 respectively ($p < 0.01$ vs. PCB 126 or palmitic acid alone). Combination of PCB 126 (1 or 3 μ M) with 10 μ M palmitic acid increased BRIN-BD11 apoptosis levels but had no effect on cell necrosis. PCB 126 at 1 or 3 μ M had no effect on β -cell apoptosis levels whereas palmitic acid (10 μ M) increased it from 2.6 \pm 0.7 to 12% \pm 4 ($p < 0.01$ vs. untreated cells). Simultaneous treatment of BRIN-BD11 cells with 10 μ M palmitic acid and 1 or 3 μ M PCB 126 significantly increased apoptosis levels to 31% \pm 6 and 36% \pm 7 respectively. ER stress protein levels of GRP78 and CHOP were increased by 10 μ M palmitic acid but unaffected by PCB 126. Simultaneous treatment with both palmitic acid and PCB 126 synergistically increased β -cell expression of both GRP78 and CHOP above that observed in untreated, palmitic acid or PCB treated cells.

Conclusion: PCB 126-mediated loss of β -cell viability and increased cell death is observed only with high concentrations and long exposure times. However, exposure of β -cells to PCB 126 in combination with palmitic acid synergistically increased β -cell apoptosis possibly via potentiated ER stress. This data suggests that environmental contaminants may synergise with dietary fatty acids leading to increased β -cell loss and susceptibility to development of Type II diabetes.

Endoplasmic reticulum stress in INS-1 cells and human islets induced by glucose, TNF- α and IL-1 β

S. Erbel, C. Reers, G.L. Jansky, P.P. Nawroth, R.A. Ritzel

Department of Internal Medicine I and Clinical Chemistry, University of Heidelberg, Germany

Background and aims: Type 2 diabetes mellitus is characterized by insulin resistance, beta-cell dysfunction and beta-cell deficit due to apoptosis. One important mechanism is ongoing beta-cell stress, especially stress in the endoplasmic reticulum (ER). Chronic beta-cell stress is triggered by insulin resistance, hyperglycemia and as recently suggested by adipocytokines. Therefore we posed the following questions: 1) Which pathways of ER stress are activated in beta-cells by glucose and/or adipocytokines? 2) Does beta-cell stress impair beta-cell function and survival? 3) Does the incretin mimetic exenatide reduce beta-cell stress?

Materials and methods: INS-1 cells were incubated with 11 and 30mM glucose and TNF- α (100ng/ml) or IL-1 β (50U/ml) for 1 hour (n=3 experiments). The expression of ER stress markers were measured by immunoblotting (p-eIF2 α , p-JNK). Isolated human islets (n=3 donors) were incubated with glucose (5 and 30mM) and TNF- α (10ng/ml) or IL-1 β (50U/ml) for 48 hours. The function of human islets was determined by insulin secretion analysis in static incubation (2h at 5 and 20mM glucose). ER stress and apoptosis were measured by immunofluorescence (CHOP, TUNEL). In addition islets were incubated with exenatide (50nM) at identical conditions.

Results: In INS-1 cells different ER stress pathways were activated. The expression of p-eIF2 α was increased by 30mM glucose (+32 \pm 14%, p=0.07), TNF- α (+64 \pm 14%, p=0.02) and IL-1 β (+129 \pm 15%, p=0.007, each versus control). Similar results were obtained for p-JNK (glucose +27 \pm 12%, p=0.08; TNF- α +53 \pm 9%, p=0.01; IL-1 β +163 \pm 64%, p=0.06). In human islets CHOP expression (perinuclear and nuclear) was elevated 5 and 8-fold by 30 mM glucose und TNF- α , respectively (p<0.01 in all groups). IL-1 β increased the CHOP expression 6- and 15-fold (p<0.001). Islet function was impaired after 48h incubation with TNF- α (-55 \pm 3%, p<0.0001), while 30mM glucose or IL-1 β did not alter insulin secretion (p=n.s.). The number of apoptotic cells was increased with 30mM glucose or TNF- α (Control: 1.2 \pm 0.3% TUNEL-positive cells/islet; 30mM glucose: 2.9 \pm 0.4%, p=0.003; TNF- α : 2.6 \pm 0.4%, p=0.01), but not after incubation with IL-1 β (1.9 \pm 0.4%, p=0.15). ER stress in human islets (CHOP) was reduced by incubation with exenatide (p<0.05) in all groups, while after 48h incubation there was no change in apoptosis.

Conclusion: Glucose, TNF- α and IL-1 β activate different ER stress pathways in beta-cells. Exenatide reduced ER stress in human islets. Yet, ER stress, beta-cell function and beta-cell apoptosis are not synchronically regulated.

The murine pro-insulin II molecule contains strong-binding motifs for several H2-A and H2-E alleles that protect NOD mice from diabetesG.K. Papadopoulos¹, G. Bondinas¹, A.K. Moustakas²¹Floriculture and Landscape Architecture, Epirus Institute of Technology, Arta, ²Organic Farming, Technological Educational Institute of Ionian Islands, Argostoli, Greece

Background and aims: The incidence of type 1 diabetes in NOD mice can be markedly reduced by the transgenic expression of several mouse MHC II alleles, both of the H2-A and H2-E loci. We wished to investigate if this introduction in any way affects the antigenic presentation of the mouse proinsulin II molecule, especially the peptide B9-23, via tighter binding of overlapping epitopes.

Materials and methods: As a first step, we scanned the the entire mouse proinsulin II molecule for possible epitopes of H2-A^{b/d/k} and H2-E allele molecules. The presumed epitopes fulfilling established motifs were then modelled onto the respective structures of the MHC II alleles by energy minimisation, using the programme Discover of Accelrys. The various MHC II structures were obtained from the Protein Data Bank. Well-fitting epitopes were then compared for vicinity to known reactivities restricted to H2-A^{g7} of NOD mice.

Results: A number of epitopes (core nonamers, anchors in bold) were identified for each of the alleles in the following descending order of affinity: For H2-A^b, InsB1-9 (FVK**Q**HLCGS), InsB6-14 (LCG**S**HLVEA), InsC53-61 (LQTLALEVA), InsA2-10 (VDQ**C**CTSIC), InsC34-42 (VEDPQ**V**AQL), InsB12-20 (VEALYLVCG), and InsC58-A1 (LEVA**Q**QKRG). For H2-A^d, InsB6-14, InsC53-61, InsC34-42, InsB12-20, InsB58-66, InsB1-9, and InsA2-10. For H2-A^k, InsA4-12 (D**Q**CC**S**ICS), InsC52-60 (DLQTLALEV), and InsB4-12 (QHLCG**S**HLV). Remarkably, all H2-E alleles with known motifs can bind to the epitope B24-C32 (FFYTPMSRR). Furthermore, all epitopes identified are overlapping with known major NOD mouse epitopes, either for H2-A^{g7} (immunogenic epitope InsB9-23 with most probable core nonamer InsB12-20, regulatory epitope InsB24-C32), or for H2-K^d (InsB15-23 and InsB25-C34).

Conclusion: The results of modeling reveal that the above mouse MHC II alleles conferring protection to NOD mice from type 1 diabetes when transgenically expressed, probably do so by tightly binding to overlapping epitopes of known peptide fragments that are diabetogenic in NOD mouse, and do not bind so tightly to H2-A^{g7}. The possible biological results of such tight binding (epitope stealing, induction of Tregs, or other unknown mechanisms) must be investigated.

A pivotal role of proinflammatory cytokines in diabetes development and after recurrence of diabetes after pancreas transplantation in type 1 animal modelsA. Jörns¹, A. Meyer zu Vilsendorff², T. Taivankhuu¹, L. Overbergh³, C. Mathieu³, S. Lenzen¹¹Institute of Clinical Biochemistry, Hannover Medical School, Germany,²Visceral- and Transplantation Surgery, Hannover Medical School,³Department of Experimental Medicine, Laboratory of Experimental Medicine and Endocrinology, Katholieke Universiteit Leuven, Belgium

Background and aims: The IDDM (LEW.IAR1-*iddm*) rat and the NOD mouse are two animal models of human type 1 diabetes mellitus with either an early invasive islet infiltration without signs of peri-insulinitis or with a long pre-diabetic period with signs of peri-insulinitis resulting in an invasive infiltration. The aim of the study was to identify the pro-inflammatory cytokine pattern in the infiltrated islets and in parallel to identify changes in the cytokine profile in serum samples.

Materials and methods: For the purpose of identification of the different anti- and pro-inflammatory cytokines during spontaneous diabetes development as well as after isogeneic pancreas transplantation gene expression (*in situ* and *real time* RT-PCR) and protein expression (immunohistochemistry and bead-based Multiplex assay) of Th1- and Th2-cytokines were performed in pancreas organs at different stages during the development of insulinitis/diabetes manifestation and after recurrence of diabetes following pancreas transplantation.

Results: NOD mouse islets with signs of peri-insulitis showed no cytokine expression. Only after the invasive immune infiltration into the islet organ the pro-inflammatory cytokines IL-1 β and TNF- α as well as the anti-inflammatory cytokines IL-4 and IL-10 became evident in the immune cell infiltrate leading to diabetes manifestation over a period of two weeks. In the IDDM rat concomitant with the first appearance of immune cells pro- and anti-inflammatory cytokines became evident, initially IL-1 β followed by TNF- α leading to diabetes manifestation within 3–7 days. In both animal models the pro-inflammatory cytokine IFN- γ was detectable to a negligible extent only in the infiltrated islets as well as in the serum. After a whole pancreas transplantation in the IDDM rat half of the transplanted recipient rats remained normoglycaemic over 6 months after transplantation whereas the other half showed a recurrence of the disease with a very rapid onset. The immune cells in the grafted pancreas now revealed a massive IFN- γ expression both at the gene and protein level which was accompanied by an increase of IFN- γ in serum. This confirms similar observations after islet transplantation in the NOD mouse.

Conclusion: Primary diabetes manifestation in both type 1 diabetes animal models took place upon significant expression of the pro-inflammatory cytokines IL-1 β and TNF- α , but without a significant expression of IFN- γ in the islet infiltrate. Pancreas transplantation in an isograft manner permanently cured diabetes in half of the recipients whereas the other half showed a recurrence of diabetes in a fudroyant manner, characterized by a very significant involvement of IFN- γ .

Granulocyte macrophage-colony stimulating factor (GM-CSF) induces precursors of bone marrow-derived dendritic cells *in vivo* to acquire a tolerogenic phenotype in NOD mice

S. Gaudreau, C. Guindi, G. Besin, G. Dupuis, A. Amrani

Pediatrics, Immunology division, Université de Sherbrooke, Sherbrooke, Canada

Background and aims: The induction of tolerance is critical for the maintenance of immune homeostasis. In autoimmune diseases such as Insulin-dependent diabetes (IDDM), the immune system is defective in maintaining CD4 $^{+}$ and CD8 $^{+}$ T cell peripheral tolerance. IDDM is the result of a complex CD4 $^{+}$ and CD8 $^{+}$ T cell-dependent autoimmune process directed against pancreatic β cells. Professional antigen presenting cells, such as macrophages and dendritic cell (DCs) also play an important role in the pathogenesis of IDDM. In diabetes and particularly in NOD mice, it is well established that there is an accumulation of DCs and macrophages previous to the arrival of CD4 $^{+}$ and CD8 $^{+}$ T cells in the islet. These DCs capture islets antigens and then initiate the recruitment and activation of autoreactive CD4 $^{+}$ and CD8 $^{+}$ T cells in the islet. *In vivo* and *in vitro*, the development of DCs cells requires stimulation of bone marrow haematopoietic precursors with GM-CSF. We have recently reported that treatment with GM-CSF suppresses diabetes in NOD mice by inducing tolerogenic DC in the periphery. In present study, we investigated whether GM-CSF had a direct influence on BMDC stem cell precursor's commitment into a tolerogenic state *in vivo*.

Materials and methods: Three weeks old prediabetic female NOD mice were injected with rmGM-CSF or PBS twice a week beginning at 3 weeks of age until 40 weeks. Thereafter, DCs were generated from the bone marrow cells of GM-CSF-treated (GM-CSF.BMDC) and PBS-treated (PBS.BMDC) mice using a GM-CSF and IL-4 and assess their ability to induce tolerance of diabetogenic T cells *in vitro* and *in vivo*.

Results: We found that GM-CSF.BMDC produced more IL-10, less IL-12p70 and IFN γ as compared to PBS.BMDC when stimulated with pro-inflammatory agents such as liposaccharide (LPS). Furthermore, LPS-activated GM-CSF.BMDC expressed high levels of PD-L1, a cell surface molecule important to maintain T cell tolerance. GM-CSF.BMDC were also poor activators of diabetogenic T cells and induces an increased production of IL-10 by CD4 $^{+}$ CD25 $^{+}$ and CD4 $^{+}$ CD25 $^{-}$ T cells. In addition, only GM-CSF.BMDC can promote conversion of CD4 $^{+}$ CD25 $^{-}$ naive T cells in CD4 $^{+}$ CD25 $^{+}$ Foxp3 $^{+}$ regulatory T cells. Finally, a single injection of 2x10 6 LPS conditioned GM-CSF.BMDC into pre diabetic mice delayed significantly development of diabetes as compared to recipients injected with LPS conditioned PBS.BMDC.

Conclusion: Our results showed that GM-CSF injection into young pre-diabetic NOD mice induced BMDC precursors to differentiate into a tolerogenic DCs that promote tolerance of diabetogenic T cells. Therefore, these work may contribute to design novel therapeutic interventions that target BMDC to prevent development of diabetes in humans.

Priming monospecific, diabetes-inducing CD8 $^{+}$ T cell responses to insulin epitopes and mimotopes

A. Spyranitis¹, T. Rajasalu², H. Brosi¹, R. Schirmbeck¹, B.O. Boehm¹

¹Department of Internal Medicine I, University Medical Center of Ulm, Germany, ²Department of Internal Medicine and Immunology, University of Tartu, Estonia

Background and aims: The role of insulin as a major autoantigen for T cell-dependent autoimmunity in type 1 diabetes (T1D) has been well characterized. We have previously shown that genetic vaccination with insulin can induce diabetes in RIP-B7.1 (CD80) transgenic mice. Single epitope immunisations are also an efficient method to induce experimental autoimmune diabetes in RIP-B7.1 (CD80) mice. Here we have used single epitope immunisation to define both H-2K b and H-2K d restricted insulin A- and B-chain epitopes.

Materials and methods: RIP-B7.1 $^{+}$ C57/BL6 mice and RIP-B7.1 $^{+}$ BALB/c mice were immunised with A- and B-chain derived epitopes. The immunisation method involves the mixture of the epitope sequence extended by the cationic cell penetrating sequence derived from the HIV-tat_{49–57} motif RKKRRQRRR, complexed with short TLR-9-stimulating oligonucleotides (ODN1826), in a 6:1 molar ratio. Diabetes was defined by blood glucose >250 mg/dl. Epitope specific T cell activation and cytokine profiles were analyzed by multiparameter FACS.

Results: Hyperglycemia is observed in RIP-B7.1 C57/BL6 mice when immunised with insulin A-chain H-2K b -restricted A_{12–21}-tat/ODN and in RIP-B7.1 BALB/c mice when immunised with the extended H-2K d -restricted B_{9–23}-tat/ODN, both with a median onset of 7–8 weeks after immunization and a cumulative diabetes incidence of >95% at week 9–10. *In vitro* IFN γ^{+} CD8 $^{+}$ T cell frequencies were usually low ($\leq 0.05\%$ of total CD8 $^{+}$ T cell population). To check, if antigenicity of the peptide can be improved by changing its sequence, we replaced the C-terminal asparagine (N) at position A21 with alanine (A) of the A-chain cationic peptide (A_{12–21/N21A}-tat/ODN). This insulin mimotope accelerated diabetes onset (week 5–6 post-immunization; diabetes incidence >95% by week 7–8). *In vitro* IFN γ^{+} CD8 T cell frequencies for the modified peptide A_{12–21/N21A} were found to be largely increased (up to 5.5% of total CD8 $^{+}$ T cells).

Conclusion: The approach taken confirms the central role of insulin-specific CD8 $^{+}$ T cell reactivity in T1D and outlines the efficiency of a single epitope immunization to induce T1D. In addition, it provides a framework for pre-clinical assessment of novel peptide variants that may either augment T cell responses or may lead to T cell anergy or tolerance.

Intracellular inhibition of JNK kinase reduces lymphocyte homing into endocrine pancreas of non obese diabetic (NOD) mouse

C.P. Khoo^{1,2}, N. Hill¹, M.G. Valorani^{1,3}, A. Signore⁴, P. Pozzilli^{1,2}

¹Centre for Diabetes and Metabolic Medicine, Queen Mary University of London, United Kingdom, ²Area di Endocrinologia, Università Campus Bio-Medico, Rome, Italy, ³Stem Cell Research Department, Livio Patrizi Foundation, Research Group BIOS, Rome, Italy, ⁴Medicina Nucleare, University La Sapienza, Rome, Italy

Background and aims: Members of JNK family, JNK2 and JNK1 have often been implicated in type 2 and type 1 diabetes progression by causing β -cell apoptosis. XG-102 is a neuroprotectant acting by intracellular-inhibition of JNK kinase and is a protease resistant peptidic derivative of the human protein IB-1 selectively blocking the access of JNK to c-Jun and other substrates by a competitive mechanism. The role of JNK1 in type 1 diabetes however is not known. Since apoptosis of β -cells is one of the putative mechanisms involved in the cascade of events leading to type 1 diabetes, we intend to test XG-102 for β -cells protection and prevention of β -cells loss in the NOD mouse.

Materials and methods: Two groups of newly diabetic (0–3 days) mice (15–20 weeks of age) were used in this study: Group A- mice injected with XG-102 for once every week for 4 weeks and mice lasting past 7th week of follow-up re-administered with XG-102. Group B- control mice injected with PBS injected for once every week for 4 weeks. In order to investigate the influence of XG-102 on the homing of committed T-cells in the endocrine pancreas, insulinitis was rated using H&E stained sections. Insulinitis was quantified in all islets present in two H&E-stained sections from each animal, each section being

separated from the next by at least 200 µm. Blood glucose level of mice before culling was taken to compare the effect of XG-102 to delay β -cell death.

Results: Insulinitis of both treated and non-treated mice was evaluated in “blind”. After 4 weeks of injection with XG-102, insulinitis in group A mice was less prevalent compared to the control mice. The majority (45 %) of islets from Group A mice showed little infiltration and destruction of pancreatic β -cells (grade 0 insulinitis) whereas only 18 % of islets from Group B mice had no insulinitis (P-value : 0.002). Group A mice have twice the number of islets in treated mice (Group A, Average number of islets, Av = 20) compared to the control mice (Group B, Av = 13)(P-value: 0.047).

Conclusion: These preliminary data suggest that XG-102 may be acting by reducing lymphocyte homing into the islets as well as blocking apoptosis, which in turn may promote islet survival.

A diet rich in protein and poor in starch with reduced food intake prevents diabetes in the NOD mouse: the significance of Reg gene expression in the pancreas

C. Guglielmi¹, E. Astorri², R. Portuesi¹, M. Bombardieri², M. Valorani^{3,4}, P. Pozzilli¹

¹Endocrinology and Diabetes, Università Campus Bio-Medico, Roma, Italy, ²Centre for Experimental Medicine & Rheumatology, Barts and The London, London, United Kingdom, ³Diabetes & Metabolic Medicine, ICMS, Queen Mary University of London, United Kingdom, ⁴Stem Cell Research Department, Livio Patrizi Foundation, Research Group BIOS, Rome, Italy

Background and aims: The prevalence of diabetes is increasing rapidly in industrialized countries. Although most attention has focused on the increase in type 2 diabetes (T2D), there has been a parallel increase in type 1 diabetes (T1D). Hyperglycaemia might result from failure of the beta cells to secrete insulin, resistance of tissues to its action, or a combination of both. Increase of body weight can accelerate the loss of beta cells through apoptosis, i.e. constitution, insulin resistance and autoimmunity. The overall aim of this study was to evaluate the effects of a reduced amount of food (4 gr. per day) instead of the “ad libitum” diet on the development of diabetes in the NOD mouse model. The relationship between body weight and onset of diabetes has been examined in the context of weight at birth, weight changes since birth and weight at disease onset. Furthermore we tested the hypothesis that a diet with a lower protein and a greater starch amount could also impact disease development.

Materials and methods: 48 female NOD mice were randomly allocated in two different groups: group A) reduced food intake with 4 gr. per day using a high nutrient diet (RM3) and group B) reduced food intake with 4 gr. per day using a diet poor in protein and rich in starch (RM1). Mice were weighed regularly throughout their life span and tested weekly for urinary glucose (>56 mmol/l), as a sign of development of diabetes. At diabetes onset mice were removed from the experiment and their diabetic status confirmed by a blood-glucose reading of 11.5 mmol/l or greater. Culled mice at diabetes diagnosis were dissected and pancreas retained for studies aimed at expression of Reg genes (Reg1, Reg2, Reg 3 α , Reg3 β , Reg 3 γ , and Reg 3 δ) associated with beta cell regeneration. RNA from pancreas was extracted and then reverse-transcribed into cDNA using the Thermoscript RT-PCR System. The real-time PCRs were then run in duplicate and all Reg genes pancreatic expression was evaluated.

Results: No significant difference was observed between group A and group B in terms of weight at birth (10.3 ± 2 vs. 10.6 ± 1.9), weight changes since birth considering the pre-diabetes phase (24.9 ± 2.1 vs. 23.6 ± 2.1) and weight at disease onset (23.7 ± 2.1 vs. 21.5 ± 3.5). Incidence of diabetes was significantly reduced in group A (20.8 %) compared to group B (45.8 %, $p=0.001$). All Reg genes were expressed in pancreas but a different trend in their expression between the two groups was observed. Expression of all Reg genes increased until 30 weeks of age and then decreased in group A; on the contrary, in group B Reg gene expression decreased first and then peaked up again at 30 weeks of age suggesting active beta cell regeneration in animals that develop diabetes but which was not capable to reverse hyperglycaemia.

Conclusion: NOD mice exposed to a reduced food intake and consuming 33% vs. 44% of starch develop less diabetes. Both groups of mice showed different trends of Reg genes expression suggesting a relation between beta cell regeneration and disease onset, a finding which indicates that after onset of hyperglycaemia beta cell regeneration is an active, although unsuccessful, process.

562

Immunomodulation action of an agonistic anti CTLA-4 and a modulating anti CD4 antibody in the LEW.1AR1-*iddm* rat, a model for type 1 diabetes mellitus

H. Weiss¹, A. Siepert¹, R. Pagel¹, H. Nizze², M. Lehmann¹, M. Tiedge¹

¹University of Rostock, Institute of Medical Biochemistry and Molecular Biology, ²University of Rostock, Institute of Pathology, Rostock, Germany

Background and aims: The LEW.1AR1-*iddm* rat is an animal model of type 1 diabetes mellitus (T1DM) with a strong genetic component and an incidence of 60%. Modulation of the T-cell repertoire using monoclonal antibodies (mabs) may induce immune tolerance. It was the aim of this study to test whether (1) an agonistic anti CTLA-4 antibody (H4) and (2) a modulating anti CD4⁺ antibody (RIB5/2) may reverse autoimmune diabetes after onset of the disease.

Materials and methods: Diabetic LEW.1AR1-*iddm* rats (blood glucose > 7.8 mmol/l) were treated for 10 days with mabs (5 x 5 mg/kg b.w.) immediately after diabetes diagnosis. 20 days after diabetes manifestation the animals were killed and blood samples were analyzed for immune status via flow cytometry (FACS) for the T-cell surface markers T-cell receptor (R73), CD4 (Ox35), CD8 β -chain (341), CD25 (Ox39), CTLA-4/CD152 (WKH1203). Pancreas samples were examined for beta cell destruction and immune cell infiltration.

Results: From our cohort 15 out of 24 animals got diabetes (60%). Seven animals were treated with H4, eight animals were treated with RIB5/2. Six out of seven animals from the H4 cohort required insulin substitution starting 5 to 10 days after diabetes onset. Seven out of eight animals of the RIB5/2 cohort required insulin starting between day 4 and 16 after diabetes onset. One animal of the RIB5/2 cohort showed a complete remission of the diabetic state. FACS analysis of peripheral blood lymphocytes did not show significant differences in T-cell content between control, H4 and RIB5/2 treated animals. The content of CD4⁺ cells was significantly ($p<0.05$) different between all groups. The RIB5/2 cohort showed a low CD4⁺ cell content indicating a changed distribution in lymphoid compartments. In contrast a higher CD4⁺ cell content was observed in the H4 group compared to the control and the RIB5/2 group. The CD8⁺ T-cell content was significantly higher ($p<0.001$) in the RIB5/2 group compared to the control and to the H4 group ($p<0.001$). Animals of the RIB5/2 group additionally showed significantly decreased levels of CD25⁺ ($p<0.01$) and CD152⁺ ($p<0.01$) T-cells compared to the controls. Neither treatment with H4 nor RIB5/2 did reverse massive infiltration of islets by immune cells. Also beta cell mass was not different between the antibody-treated cohorts and control.

Conclusion: The therapeutic application of immunomodulating antibodies did significantly change the composition of the peripheral blood lymphocytes but did not lead to a regeneration of the beta cell mass or a slow down in disease progression. However, the reversion of the diabetic state after the administration of RIB5/2 shows that the modulation of CD4 on T-cells and the reallocation of CD4⁺ T-cells could have a positive influence on beta cell mass. In our model the inhibition of T-cell response by stimulation of the CTLA-4 signalling pathway could not stop the fulminant destruction of the beta cells. In future experiments we will characterize the prophylactic therapeutic efficiency of the antibodies when applied in the prediabetic state.

New approach for free rat C-peptide immunodetection

A.V. Kharitonov, A.G. Katrukha

R&D Department, HyTest Ltd, Turku, Finland

Background and aims: C-peptide - the product of enzymatic cleavage of proinsulin - is a peptide linking A and B chains of insulin in proinsulin molecule. While C-peptide is released into the blood stream in amounts equimolar to insulin and its half-life in blood is much longer than that of insulin (30 min vs. 4 min for insulin) C-peptide was accepted as a reliable marker for proinsulin metabolism disturbances during proinsulin processing. Measurement of C-peptide levels in the blood or urine is widely used for diagnosis of hypoglycemia and for investigation of pathogenesis of diabetes mellitus type I.

A rat is widely used animal model for the studying of pathophysiological mechanisms underlying diabetes mellitus. Unlike other animals, rats and mice have two isoforms of C-peptide - C-peptides I and II. A number of assays for rat C-peptide immunodetection are available. Most of commer-

cially available assays are radioimmunoassays or assays based on competition principle. However all of them have considerable disadvantages. The major problem of commercially available immunoassays is cross-reaction with intact and partially processed proinsulin (32,33 split; des32 split; des31,32 split; 65,66 split; des64 split and des64,65 split forms). Cross-reaction can be diminished by removal of cross-reactants by gel filtration chromatography but it is not suitable for routine diagnostics procedures.

The aim of our study was to develop monoclonal antibodies (MAbs) for sensitive and specific rat C-peptide immunoassay that would not cross-interact with proinsulin and all known forms of partially processed proinsulin.

Materials and methods: Special strategy of MAbs selection was applied.

Results: We have got a panel of unique monoclonal antibodies that recognize free rat C-peptide with high sensitivity and do not bind to rat proinsulin. MAbs CII-11, CII-29 (specific to N-terminal part of C-peptide molecule) and CC18, CC20, CC34 (specific to C-terminal part of C-peptide) detect both rat C-peptides I and II. Combination of N- and C-terminal specific MAbs can be used for the creation of highly specific C-peptide immunodetection systems of sandwich type. The assays utilizing pairs of MAbs described above have demonstrated high sensitivity (less than 30 pg/ml of free rat C-peptide in the sample). Moreover we have developed MAbs that could be also used for the differentiation between rat C-peptides I and II: MAbs CI-0 and 6H1 specifically recognize C-peptide I while MAbs CII-106 and CII-138 bind to C-peptide II and do not interact with C-peptide I.

Conclusion: We obtained a new generation of anti-rat C-peptide monoclonal antibodies that specifically recognize free rat C-peptides I and II with high sensitivity and having no cross-reactivity with rat proinsulin. These MAbs are recommended to be used in different immunoassays for quantitative determination of free rat C-peptides in biological samples.

Cellular therapy of type 1 diabetes: analysis of the immunomodulatory capacity of mesenchymal stem cells

M. Steinsdörfer, J. Seissler, C. Sattler

Diabetes Center, Medical Clinic Innenstadt, Munich, Germany

Background and aims: Until now the transplantation of the whole pancreas organ or isolated Langerhans-islets remains the only method to cure type 1 diabetes. Transplantation is largely limited by the lack of organ donors and the considerable side effects of the immunosuppressive therapy. The aim of this study was to develop a new strategy for tolerance induction after islet transplantation using the pleiotropic effects of mesenchymal stem cells (MSCs).

Materials and methods: From bone marrow of Balb/c mice MSCs were isolated and cultured for several passages. MSCs were characterised by FACS and by their capacity to differentiate into adipocytes, osteoblasts and chondrocytes using specific supplements. The immunosuppressive effect of unstimulated or IFN γ +/- TNF α pretreated MSCs was analysed by mixed lymphocyte reaction (MLR). T cell proliferation was determined by [3 H]-thymidine incorporation. To identify the mechanisms of MSC-mediated immunosuppression, we investigated the role of indoleamine-2,3-dioxygenase (IDO), hepatocyte growth factor (HGF) and cyclooxygenase-2 (Cox2) by semiquantitative RT-PCR, Western blot and the measurement of the tryptophane catabolite kynurenine, respectively.

Results: FACS analysis revealed the expression of characteristic MSC markers: CD105, CD73, CD140b, CD29, Sca1 and VCAM. Expression of CD90 and CD44 was weak. By using specific supplements the cells could be differentiated into adipocytes, osteoblasts and chondrocytes. MSCs stimulated with IFN γ reduced T cell proliferation significantly in the MLR experiments ($p < 0.01$). This effect was enhanced by prestimulation of MSCs with IFN γ and TNF α ($p < 0.01$). Unstimulated MSCs expressed IDO only at a low level. After stimulation with IFN γ or IFN γ +TNF α the expression of IDO mRNA significantly increased. However, no functional IDO protein was observed. HGF was found to be constitutively expressed in our MSCs. After stimulation with proinflammatory cytokines Cox2 expression was detected.

Conclusion: The murine MSCs described by our group show a typical expression of surface markers and distinct multipotency. Although no expression of active IDO protein after stimulation could be shown, the cells inhibited T cell proliferation by an IDO-independent mechanism. Our findings on the induction of Cox2 suggest that the immunomodulatory effect of MSCs may be associated with PGE2 production. In addition, HGF could be involved in the downregulation of T cell activity. Further experiments are being carried out to assess the molecular pathways of the immunosuppressive properties of MSCs. These data suggest that the cotransplantation of Langerhans-islets and MSCs could be a promising alternative to the standard therapy.

PS 037 Autoimmunity against GAD

565

GAD65 vaccination significantly reduces insulin dependence at five years follow-up in a dose escalating study in adult-onset autoimmune diabetes patients

C.-D. Agardh, K. Lynch, M. Palmér, K. Link, Å. Lernmark

Lund University, Malmö University Hospital, Sweden

Background and aims: Treatment of GAD65-autoantibody positive diabetes patients with alum-formulated recombinant GAD65 (DiamydTM) has previously been reported to be safe and not to compromise beta-cell function. The aim was to test the hypothesis that DiamydTM is still safe after five years follow-up and that the dose level affects the beta cell function.

Materials and methods: The study was a Phase II randomised, double blind, placebo-controlled, dose-escalation clinical trial including 47 GADA positive non-insulin dependent patients who at weeks one and four received subcutaneous injections of placebo, 4, 20, 100 or 500 μ g DiamydTM. Data on safety evaluations and insulin treatment during follow-up were obtained for all patients. Fasting C-peptide levels were measured at baseline and 5 years and used to confirm insulin dependency and change in beta cell function. Metabolic control was examined among patients who had not started insulin treatment.

Results: No significant study-related adverse events occurred during the five year follow-up. Six patients (three started insulin) dropped out in the first 13 months of the study, and another died (unrelated to the study) within the third year without starting insulin treatment. These patients were excluded from the rest of the analyses. Of the remaining 40 patients followed for five years, dose level was significantly associated with number of patients starting insulin treatment (placebo 7/11 (64%); 4 μ g group 5/7(71%); 20 μ g 1/7 (14%); 100 μ g 1/7(14%); 500 μ g 5/8 (63%); $p = 0.046$). Fasting C-peptide levels had declined significantly in the placebo (mean decline = 0.18; 95%CI = 0.02 - 0.34 nmol/L; $p = 0.03$) and 500 μ g group (mean decline = 0.33; 95%CI = 0.07 - 0.57 nmol/L; $p = 0.02$), but no change was observed in the 4, 20 and 100 μ g dose groups. Compared to placebo, fasting C-peptide had increased significantly only in the 20 μ g dose group (0.34; 0.09 - 0.60 nmol/L, $p = 0.01$). Of the patients who had not started insulin treatment, mean change in HbA1c was observed (although not statistically significantly) in the placebo ($n = 4$, 0.7 percentage), 4 μ g ($n = 2$, 1.8 percentage), 100 μ g ($n = 6$, 1.3 percentage) and 500 μ g ($n = 2$, 1.0 percentage) dose group but not in the 20 μ g dose group ($n = 6$, -0.0).

Conclusion: These findings suggest that a prime and boost injection with DiamydTM appears safe long term. The trial design allowed testing of doses to be potentially used in future efficacy studies. The 20 μ g dose continues to show preserved beta cell function and no adverse events. The rationale to test the 20 μ g dose for safety and efficacy in larger clinical trials is ongoing.

The clinical implications of GAD antibody positivity in older patients with established non-insulin requiring diabetes

G.A. Hitman¹, M.I. Hawa¹, R.D.G. Leslie¹, T. Ola¹, C.-C. Wun², D. DeMicco³, D.J. Betteridge³, P.N. Durrington⁴, J.H. Fuller⁵, H.A.W. Neil⁶, H.M. Colhoun⁷

¹Centre for Diabetes and Metabolic Medicine, Barts and The London School of Medicine and Dentistry, London, United Kingdom, ²Pfizer, New York, United States, ³Department of Diabetes, University College London, United Kingdom, ⁴Department of Medicine, University of Manchester, United Kingdom, ⁵Department of Epidemiology and Public Health, University College London, United Kingdom, ⁶Centre for Diabetes, Endocrinology and Metabolism, University of Oxford, United Kingdom, ⁷Public Health, University of Dundee, United Kingdom

Background and aims: Whilst the importance of screening using antibodies to glutamic acid decarboxylase (GADA) in younger patients with apparent type 2 diabetes (T2D) is established, its relevance in older patients in predicting the requirement for insulin treatment and susceptibility to microvascular complications is unknown.

Materials and methods: GADA were determined by a radio-immunoprecipitation method in 2425 patients participating in the Collaborative Atorvastatin Diabetes Study (CARDS); a randomised placebo controlled trial of 2838

patients with presumed T2D (defined by WHO criteria, median age 62yrs and duration of diabetes 8yrs) who received atorvastatin or placebo and were evaluated for diabetes outcomes over a median follow up of 4yrs.

Results: Of the diabetes patients, 7.1% (n=173) were GADA positive (GAD>40units). On multivariate analysis at baseline, GADA positive patients compared to GADA negative patients were younger (51.5 vs 55.0 yrs), leaner (BMI 27.3 vs 28.9 kg/m²), had higher HbA1c (8.5 vs 7.8%), less metabolic syndrome (64 vs 80%) and were more likely to be on insulin both initially (56% vs 17%; OR 5.8, 95%CI 4.1–8.2), and after 4yrs follow-up: cumulative incidence of insulin treatment in those not on insulin at baseline was 16 vs 5% (OR 3.1, 95% CI 2.0–4.9); all p<0.0001 apart from age of diagnosis (p=0.01). GADA positivity did not predict microvascular complications at baseline or follow-up.

Conclusion: Adult-onset autoimmune diabetes is not uncommon in these established patients with clinically defined type 2 diabetes. However, in such GADA positive patients, the rate of progression towards insulin treatment was slow (at 8 yrs post-diagnosis 44% were not on insulin) and was not associated with an increased risk of microvascular complications.

GAD₆₅ treatment induces high GADA levels in type 1 diabetic children - a relation to C-peptide response, but not to adverse events

M. Chéramy, J. Ludvigsson, R. Casas

Clinical and Experimental Medicine, Division of Pediatrics, Linköping, Sweden

Background and aims: In mice the protective effect of GAD₆₅ has been associated with the induction of high levels of GAD-specific IgG1 antibodies (GADA). In a previous study in LADA patients, GADA levels were not affected by GAD₆₅ injection except at a very high dose (500 µg). We investigated the effect of treatment with GAD₆₅ (Diamyd™) on the antibody response in type 1 diabetic children and its relation to C-peptide preservation and adverse events.

Materials and methods: 70 type 1 diabetic patients (10–18 years old) diagnosed within the previous 18 months, were included in a double-blind, randomised, placebo-controlled trial receiving a primary injection on day 1 of 20 µg recombinant human GAD₆₅ (n=35) or placebo (n=35) and a booster dose after 4 weeks. Blood samples were collected before the first injection and after 1, 3, 9, 15, 21 and 30 months. The serum levels of GADA, and antibodies to the islet cell antigen IA-2 (IA-2A), tetanus toxoid antibodies and total IgE were analysed, as well as C-peptide (AUC) after a Mixed Meal Tolerance Test. Adverse events were registered.

Results: Patients receiving GAD₆₅ or placebo had similar levels of the autoantibodies at baseline. GAD₆₅ treatment significantly increased GADA levels in the treated patients in comparison to the placebo group after 3 months (p=0.001). The levels remained higher in GAD₆₅ treated children still after 30 months (p<0.05). The 10% patients with best C-peptide preservation had higher levels of GADA pre treatment compared to intermediate responders (p<0.05) and to non-responders (loss > 65% of C-peptide) (p=0.07). No differences in the levels of IA-2A, tetanus antibody or IgE post treatment were observed indicating a treatment-specific effect. High GADA titers, seen in both groups, were not related to any signs of neurological or other adverse events.

Conclusion: The effect of GAD₆₅ treatment on the humoral response was antigen specific and induced a long lasting specific B cell memory, without adverse clinical events. The best C-peptide preservation was observed in patients with high GADA levels at baseline. Our data constitute novel information in the understanding of the effect of treatment with GAD₆₅ in children with type 1 diabetes.

GAD₆₅ specific monocyte activation in type 1 diabetic children treated with alum-formulated GAD₆₅

S. Axelsson, J. Ludvigsson, R. Casas

Clinical and Experimental Medicine, Division of Pediatrics, Linköping, Sweden

Background and aims: We have previously demonstrated that injection of alum-formulated GAD₆₅ (Diamyd™) to children with recent onset of type 1

diabetes (T1D) resulted in long lasting specific immune responses, which accompany a significant preservation of C-peptide. The immunomodulatory effect of GAD₆₅ was antigen specific and observed both in T and B cell immune response in treated individuals. However, memory specific immune responses of the adaptive immune system need to interact with the innate immune system for an effective activation, as the two systems complement each other and act in parallel. Among other components of the innate immune system, monocytes act to initiate and reinforce immune responses, permitting the establishment of the immunological memory. Thus, this study aimed to investigate the effect of GAD₆₅ treatment in the activation and maturation of monocytes.

Materials and methods: The phase II Diamyd™ study was designed as a randomised, double-blind, placebo-controlled, multi-centre trial including 70 T1D children, with a primary injection day one and a booster injection after 4 weeks. Peripheral blood mononuclear cells (PBMC) were collected 30 months after receiving 20 µg alum-formulated GAD₆₅ (n=21) or placebo (n=24), and stimulated with GAD₆₅ and IA-2 for 18 hrs, in parallel to cells cultured only in medium. Expression of CD14, CD80, CD86 and CD58 was analysed by flow cytometry. The chemokines IP-10, MCP-1, MIP-1α, MIP-1β and RANTES were measured in cell supernatants using multiplex fluorochrome technique (Luminex).

Results: After GAD₆₅ stimulation, the percentage of CD14+ cells expressing CD80/CD58 (p<0.05) and CD80/CD86 (p<0.05) was higher among the GAD₆₅ treated children. Additionally, stimulation with GAD₆₅ resulted in a reduction of the percentage of CD14 expressing cells (p<0.05) as well as the CD14 median intensity (p<0.05) in the same group. In contrast, no difference between the two groups was observed when cells were cultured in medium alone or in presence of IA-2. Further, after GAD₆₅ stimulation the levels of MCP-1, MIP-1α and MIP-1β increased in the cell supernatants from children who received GAD₆₅ (p<0.01).

Conclusion: Up-regulation of co-stimulatory molecules and decreased expression of CD14, in parallel with increased chemokine secretion after GAD₆₅ stimulation, suggests that recall responses in T1D children treated with GAD₆₅ involve activation of the innate immune system. This could in turn lead to a more efficient antigen presentation and antigen-specific T and B lymphocyte activation.

A low peptide concentration selectively promotes expansion of high avidity T cell clones: study of DRB1*0404-restricted human T cell clones specific to the GAD65 555-567 epitope

V. Öling¹, K. Geubtner², J. Ilonen¹, H. Reijonen²

¹Immunogenetics Laboratory, University of Turku, Finland, ²Benaroya Research Institute, Virginia Mason, Seattle, United States

Background and aims: T cells specific for islet proteins can be detected in the peripheral blood of T1D patients and at-risk individuals, suggesting failure of the central tolerance and the negative selection. Cells with low-avidity to self-antigens may escape the selection and later contribute to autoimmunity. We addressed a question how the antigen dose affects the diversity of autoreactive T cells. Our hypothesis was that low antigen dose will preferentially stimulate high avidity T cells. T cell clones specific for GAD65, a major autoantigen in T1D, were isolated and the T cell clones avidity and phenotype were investigated.

Materials and methods: CD4+ T cells isolated from a DR404-positive subject with a known response to GAD65 555-567 were stimulated with 10, 1 or 0.1 µg/ml of GAD65 557I peptide in the presence of adherent CD4 negative cells for 14 days. GAD65 557I is an agonist peptide previously described to induce a stronger proliferative response of GAD65 555-567 specific T cell clones. After 14 days the cells were stained with GAD65 and control tetramers. GAD65 tetramer binding CD4+ cells were single cell sorted and expanded. Peptide specificity of the T cell clones was confirmed by tetramer staining and antigen specific proliferation. Avidity was determined by proliferation in decreasing concentrations of the GAD65 557I peptide (0.001–10 µg/ml) and cytokine secretion was analysed in Cytometric Beads Array assay. T cell receptor usage was tested with Vβ chain specific monoclonal antibodies using FACS.

Results: Avidity of the T cell clones was determined by 50% of maximal proliferation response and the level of tetramer binding. An inverse correlation between the antigen dose used in the original cultures and the overall avidity of the isolated T cell clones was observed: T cell clones isolated from cultures originally stimulated by a low antigen dose (0.1 and 1 µg/ml GAD65 557I peptide), displayed a higher proliferative response in decreasing amounts

of the specific peptide in comparison to T cell clones originally cultured in presence of the highest antigen dose (10 µg/ml) (Mann-Whitney U test, tied $p=0.008$ and $p=0.023$, respectively). T cell clones derived from cells stimulated with the lowest peptide dose also displayed the highest tetramer binding affinity in comparison to the other T cell clones (tied $p=0.058$). We did not detect any significant differences in the release of IFN- γ , TNF- α , IL-10, IL-5, IL-4 and IL-2 between the T cell groups. Majority (75%) of the T cell clones induced by the low antigen dose (0.1 µg/ml GAD65 557I) expressed the V β 5.1 chain whereas only two (40%) of the T cell clones induced by the intermediate antigen dose (1 µg/ml) and only one (14%) T cell clone from the high antigen dose cultures (10 µg/ml) was V β 5.1 positive.

Conclusion: Our results suggest that antigen dose modulates diversity of the peripheral T cell repertoire observed subsequent to *in vitro* T cell expansion, both avidity and TCR usage of the T cell clones are dependent on the dose of peptide used for stimulation. Therefore, factors influencing the overall functional avidity should be taken into consideration when designing antigen specific assays to evaluate the diversity of autoreactive T cell populations and changes induced by immunomodulatory therapies in T1D.

Study of T cell response to Ii-key/MHC class II epitope hybrids in human type 1 diabetes

H. Beyan¹, E. Von Hofe², R.D. Leslie¹

¹Centre for Diabetes and Metabolic Medicine, Institute of Cell and Molecular Science, London, United Kingdom, ²Antigen Express, Biotech 3, Worcester, United States

Background and aims: Type 1 diabetes (T1DM) is a chronic, T cell-mediated autoimmune disease mediated by an adaptive immune response to antigen including glutamic acid decarboxylase65 (GAD65). A peptide of the Ii protein (Ii-Key) enhances *in vitro* presentation of antigenic peptides, thus creating a therapeutic opportunity to regulate the antigenic peptide binding to MHC Class II molecules. The aim of our study was to apply this technique to testing the use of Ii-Key/MHC class II GAD65 epitope hybrids in characterizing anti-GAD65 T cell responses in patients with T1DM.

Materials and methods: GAD65 peptides predicted to be recognized by DRB1*0301 and DRB1*0401 were identified with the Rammensee SYF-PEITH program. Peripheral blood mononuclear cells (PBMC) were tested from 21 established T1DM patients (age mean 43 years range 24 - 46 years, 11 male; mean disease duration 22 years) and 24 normal subjects (age mean 49 years range 25 - 58 years, 12 male). Patients and controls were selected for HLA-DR3 or 4 and tested for GAD65 autoantibodies. In an optimized assay PBMCs were cultured with positive and negative control peptides, whole GAD65 and GAD65 peptides, then analysed for interferon gamma (IFN γ) and interleukin-10 (IL-10) by U-Cytech ELISPOT.

Results: Patients with T1DM had significantly greater IFN γ responses to whole GAD65 compared to controls ($p<0.01$), but there was no difference in IL-10 responses between them. Patients with T1DM also showed increased IFN γ responses to any given GAD65 peptide compared with controls ($p<0.03$), again without differences in IL-10 responses. There was no dominant GAD65 peptides and the responses to GAD65 peptides were not influenced by the Ii-key.

Conclusion: We found out that patients with established T1DM have greater IFN gamma responses to both whole GAD65 and GAD65 peptides compared to controls. IL-10 responses, on the other hand, were similar between T1DM and controls. The results are consistent with a polarized pro-inflammatory response to GAD65 peptides in T1DM independent of the Ii-key protein. We conclude that even after many years of T1DM there is a detectable cellular and humoral immune response to GAD65.

GAD and IA-2 immunoreactivity in type 1 diabetic patient saliva

C. Tiberti¹, B. Shashaj², A. Verrienti¹, E.G. Vecchi¹, F. Lucantoni¹, M. Suma¹, D. Masotti¹, S. Morano¹, N. Sulli², F. Dotto³

¹Clinical Sciences, University of Rome "Sapienza", ²Pediatrics, University of Rome "Sapienza", ³Internal Medicine, Endocrine and Metabolic Sciences, University of Siena, Italy

Background and aims: Type 1 diabetes is characterized by the presence of autoantibodies directed against various islet autoantigens, including glutamic

acid decarboxylase (GAD) and tyrosine phosphatase 2 (IA-2) proteins. Some attempts have been made in assaying GAD autoantibodies (GADA) in human saliva, a body fluid which can be easily obtained by non-invasive techniques, bypassing blood sample collection. However, these salivary assays were not sensitive, specific and accurate enough in comparison to serum assays. The poor performances of GADA assays probably dissuaded the investigators to search for other diabetic-specific autoantibodies in human saliva, thus to our knowledge, no attempts were made to detect other diabetes specific autoantibodies in human saliva. Aim of this study was to evaluate the ability of a highly sensitive fluid-phase ³⁵S-radioimmunoassay method to detect salivary GAD and IA-2 immunoreactivity in newly diagnosed (ND) and long-standing (LS) type 1 diabetic patients.

Materials and methods: Human recombinant full-length GAD65 and IA-2(605-979) autoantibodies were detected in paired saliva and serum samples collected from: 39 ND (21m, 18f), 31 LS patients (15m, 16f), 24 GADA and IA-2A negative first degree relatives of patients with autoimmune disease (FDR) (13m, 11f), 76 healthy subjects (32m, 44f). To detect salivary autoantibodies were utilized the supernatants of unstimulated whole saliva samples previously spun at 10000 rpm.

Results: GADA were detected in the serum of 25/39(64.1%) ND, 20/31(64.5%) LS and in the saliva of 24/39(61.5%) ND and 19/31(61.3%) LS patients. IA-2A were detected in the serum of 19/39(48.7%) ND, 14/31(46.2%) LS and in the saliva of 18/39(46.2%) ND and 12/31(38.7%) LS patients. No presence of GADA and IA-2A was found in serum and saliva of GADA and IA-2A negative FDR subjects. A significant correlation was found between serum and saliva GADA titers ($r=0.739$, $p<0.0001$) and between serum and saliva IA-2A titers ($r=0.687$, $p<0.0001$). Altogether, salivary and serum GAD and IA-2 immune responses were concordant in 94.3% and 93.3% of subjects analyzed, respectively.

Conclusion: The present study demonstrates that immune changes typical of type 1 diabetes may be reflected in oral secretions. The use of saliva supernatant, the accurate choice of its dilution and the use of a fluid-phase radioimmunoassay method make possible the detection of salivary GAD and IA-2A with high sensibility and specificity. Human saliva, a specimen that can be easily collected, also repeatedly in the time by non-invasive procedures, may therefore represent a reliable, powerful tool for the study of humoral autoimmunity in type 1 diabetes.

572

Decreasing humoral activity in siblings of type 1 diabetes children over a ten year period with increasing incidence of the disease

J. Svensson¹, A. Nilsson², S. Eising³, H. Mortensen¹, Å. Lernmark², F. Pociot³, J. Johannesen¹

¹Paediatric Department, Glostrup University Hospital, Glostrup, Denmark,

²Department of Clinical Sciences, Lund University/CRC, Malmö, Sweden,

³Steno Diabetes Center, Gentofte, Denmark

Background and aims: Type 1 diabetes (T1D) is an immune-mediated disease, which develops on the basis of complex gene-environment interactions. Autoantibodies are important markers of the autoimmunity against the pancreatic islet beta cells. Despite the number of autoantibodies predict T1D, their possible pathogenic role remains unclear. High concentrations of GAD antibodies are associated with slower progression to clinical disease and Harrison et al. found in 1993 an inverse relation between humoral and cellular immunity to GAD in relatives of T1D patients. The objective of the present study was to test the hypothesis that levels of autoantibodies (GAD65 and IA2A) may decrease over a ten year period in high risk subjects (siblings of T1D patients) and at onset in T1D children as an explanation of a more accelerated disease process which would lead to an increasing trend in incidence rate.

Materials and methods: Data for the study are derived from a large population-based register of diabetic children with an attached bio bank. It is a random sample in newly diagnosed children ($n=481$) with blood sampling less than 3 months after onset collected 1997-2005. There were 479 siblings samples from the same time period. Blood samples are stored at minus 80 degrees until analysis. Autoantibodies (GAD65A, IA-2A) were measured using radioimmunoassay (RIA). The 97.5 percentile cut-off limits GAD65A and IA2A were 32 and 6 U/ml, respectively

Results: Six out of 479 siblings developed T1D 0.5-3.4 years after blood sampling. Among the siblings eight (1.7%) had both IA2A and GAD65A above the cut-off limit, three of those developed T1D. Two (2/479, 0.4 %) had IA-2A levels above 6 U/ml but GAD65A below cut-off, 19 (19/479, 4.0%) had GAD65A above 32 U/ml but IA2A below cut-off, one from each of these

groups developed diabetes. There was a significant negative correlation between year of measure and GAD65A and IA2A levels observed only in healthy siblings, not in the newly diagnosed T1D children. The IA2A level was 0 in 427 siblings, whereas GAD65A was only 0 in one sibling. GAD65A was positively correlated with age in patients, whereas IA2A showed no association with age. The GAD65A were significantly higher in female patients.

Conclusion: The levels of GAD65A and IA-2A was unchanged in newly diagnosed T1D children 1997–2005 while a decreasing level of GAD65A and IA2A were observed in their healthy siblings. The IA2A level was only above 0 in 52 cases, therefore the correlation with sample year and IA2A should be taken with this in mind. If lower levels of autoantibodies reflects less humoral activity, then siblings of T1D children seems over this ten year period to move towards a higher risk of developing diabetes in accordance with the increasing trend in incidence.

Latent autoimmune diabetes in adults vs recent-onset type 1 diabetes: differences in autoantibody levels, clinical course and residual insulin secretion capacity

L. Lukic, N.M. Lalic, A. Jotic, T. Milicic, M. Zamaklar, K. Lalic, N. Rajkovic
Institute for Endocrinology, Clinical Center of Serbia, Belgrade, Serbia

Background and aims: Previous studies have suggested that Latent Autoimmune Diabetes in Adults (LADA) exhibits similar immunological, metabolic and clinical characteristics compared to recent-onset Type 1 diabetes (T1D), but the similarities and differences between the two disorders have not yet been clarified. Therefore the aim of this study was to compare: (a) the incidence of glutamic acid decarboxylase (GAD) and thyrosin phosphatase (IA2) autoantibody positivity, (b) clinical course and (c) insulin secretory capacity during the first year of the disease in 30 patients with LADA (age >35 yrs) (group A) and in 30 patients with recent-onset T1D (age >26 yrs) (group B).

Materials and methods: All patients were analysed in insulin requiring state. The GADA and IA2 positivity was determined by RIA. The clinical course was evaluated using the following parameters: duration of symptoms before diagnosis, frequency of ketosis, weight loss and incidence of clinical remission (CR). The CR was defined as optimal metabolic control without insulin lasting >30 days. The insulin secretion capacity was evaluated by determining C-peptide levels (RIA) before and after 1 mg intravenous glucagon stimulation (0/6 min).

Results: We found that percentage both of GADA and IA2 positive patients was lower in group A compared to the group B (A:3.7% vs B:14.3%, $p<0.01$). However, when GADA positivity was analysed separately, the percentage was higher in group A in comparison to the group B (GADA A: 92.6% vs B: 65.3%, $p<0.01$). On the other hand, when IA2 positivity was separately analysed we did not find significant difference between groups (IA2 A: 2.5% vs B: 2.8%; $p=NS$). Simultaneously, the incidence of CR was significantly lower in group A than in the group B (A:13.8% vs B: 41.4%, $p<0.05$). Also, in group A compared to group B we detected significantly shorter duration of symptoms (A: 2.83 ± 1.97 vs B 7.57 ± 0.87 months, $p<0.01$), lower frequency of ketosis (A:19.2% vs B: 50%, $p<0.01$), and smaller weight loss (A: 4.03 ± 2.18 vs B: 6.73 ± 3.64 kg, $p<0.05$). In addition, we found that basal and stimulated C peptide levels were significantly higher in group A than in group B (C-pep. 0 min. A: 0.37 vs B: 0.20 nmol/l ; C-pep. 6 min. A: 0.53 vs B: 0.35 nmol/l, $p<0.01$, respectively).

Conclusion: Our data have shown that patients with LADA exhibited lower autoantibody response, together with milder clinical course and better preserved insulin secretion capacity. In contrast, our results have demonstrated that the LADA patients exhibited lower incidence of CR in comparison to the adult recent-onset T1D.

Interim results of a phase I/II clinical trial of a DNA plasmid (BHT-3021) for type 1 diabetes

P. Gottlieb¹, G.S. Eisenbarth¹, M. Kipnes², R. Ratner³, J. Rockell¹, R. Wagner¹, F. Valone⁴, H. Garren⁴

¹Barbara Davis Center, University of Colorado Health Sciences Center, Aurora, ²Diabetes and Glandular Disease Clinic, San Antonio, ³Diabetes, Medstar Research Institute, Washington, ⁴Bayhill Therapeutics, Palo Alto, United States

Background and aims: Current therapies approved and in development for autoimmune diseases are only partially effective and largely non-antigen specific. Recently, DNA plasmids have proven to be a very effective antigen-specific method of autoimmune disease treatment in various animal models and in a clinical trial in multiple sclerosis. We have previously demonstrated that a proinsulin encoding DNA vaccine is effective in treating the NOD animal model of T1D, and that it causes antigen-specific immune tolerance. We have initiated a phase I/II clinical trial of BHT-3021, a DNA plasmid that encodes full-length human proinsulin, in type 1 diabetes (T1D) patients.

Materials and methods: This is a randomized, blinded, placebo-controlled trial in T1D patients. Key eligibility criteria are an age of 18 to 40 years at the time of diagnosis of T1D diabetes and the presence of antibodies to at least one diabetes-related antigen (insulin, GAD-65, or IA-2). Both C-peptide + and - patients are enrolled in two separate groups. Within each group, subjects are randomized to BHT-3021 or saline placebo in a 2:1 ratio. BHT-3021 or placebo is injected intramuscularly weekly for 12 weeks after which subjects are followed in a blinded manner for 40 weeks. Four dose levels of BHT-3021 are being tested (0.3 mg, 1 mg, 3 mg and 6 mg). The primary outcome measures are safety and changes in antigen-specific immune response. Immune response measures include antibody and T cell reactivity to insulin, GAD-65 and IA-2 and T cell frequency assessed by tetramer assays.

Results: To date, 14 patients (9 C peptide positive; 5 C peptide negative) have been randomized to the initial 1.0 mg dose level. Safety data on these patients demonstrate that BHT-3021 is safe with no increase in adverse events relative to placebo. No subjects have discontinued therapy and no serious adverse events have been reported. Adverse events (AEs) occurred with equal frequency in the placebo and BHT-3021 treatment arms. All AEs were mild or moderate in severity. There were no clinically significant laboratory abnormalities. There was also no evidence of accelerated loss of beta cell function as measured by C-peptide levels. In fact, in the three BHT-3021 treated patients where we have data to week 15, the mean change in peak stimulated C-peptide is an increase by 19% compared to baseline.

Preliminary data on the first several patients treated with BHT-3021 demonstrate that in both patients treated with 1 mg BHT-3021, there was an approximately 50% reduction in titers of anti-insulin antibodies rapidly after the initiation of dosing that was sustained throughout the dosing period. In contrast, in the one placebo treated patient from whom we have data, the anti-insulin antibody titers were unchanged with placebo dosing. Autoimmune T cell data from these patients are pending at this time.

Conclusion: The preliminary data from this phase I/II trial indicate that BHT-3021 is safe and may suppress immune responses in an antigen-specific manner. Additional patient data are expected by the middle of 2008.

High prevalence of autoimmunity in adult onset diabetes subjects with high GADA titre

M. Capizzi¹, A. Petrone¹, C. Tiberti¹, M. Spoleitini¹, S. Di Pietro², M. Locatelli³, F. Dotta⁴, A. Falorni⁵, E. Bosi⁶, R. Buzzetti¹

¹Clinical Sciences, "Sapienza" University, Rome, ²Diabetes Unit, Istituto Nazionale Riposo e Cura Anziani (INRCA), Rome, ³Endocrinology, Bambino Gesù Hospital, Rome, ⁴Internal Medicine, Siena University, ⁵Internal Medicine, University of Perugia, ⁶General Medicine, Diabetes & Endocrinology, San Raffaele Scientific Institute and Vita Salute University, Milan, Italy

Background and aims: Previous studies showed that LADA is not one clear-cut disease entity, but a heterogeneous population of diabetes subjects wherein subgroups can be identified based on their autoimmune status: the titre of

autoantibodies to GAD. Compared to low GADA, subjects with high GADA titre have more prominent traits of insulin deficiency and a higher prevalence of the genotypes known to increase the risk of type 1 diabetes. The aim of the present study was to correlate GADA titre, in LADA subjects, with the presence of other organ and non organ specific autoantibodies.

Materials and methods: Adult onset GADA positive autoimmune diabetes subjects (n=191) and a twofold number of age and sex matched GADA negative type 2 diabetes subjects (n=382) were selected from the Non Insulin Requiring Autoimmune Diabetes (NIRAD) study cohort of 4,250 type 2 diabetes subjects. The analysis of GADA titre showed a bimodal distribution which identified two subgroups of patients with high (>32 GADA U) and low GADA titre (≤32 GADA U). All subjects were further characterized for other autoantibodies as protein tyrosine phosphatase IA-2 (IA-2A), thyroid peroxidase antibodies (TPO), steroid-21-hydroxylase (21OHAb), anti-parietal cell antibodies (APCA), tissue transglutaminase antibody IgA (tTGA). IA-2As were measured using a radiobinding assay with in vitro-translated IA-2_{IC} (amino acids 605-979). Thyroid peroxidase (TPO) antibodies were measured by a radioimmunoassay using a commercial kit. 21-hydroxylase were measured using a radiobinding assay. IgG anti-tyrosine phosphatase 2 (IA-2A_{IC}) and IgA anti-transglutaminase autoantibodies (tTGA) were detected by a radioimmunoprecipitation assay using the ³⁵S-methionine labeled human antigen. Anti-parietal cell antibodies (APCA) were detected by using a commercial ELISA method.

Results: Compared with those with low GADA titer, LADA subjects with high GADA titer showed a profile of more severe autoimmunity resulting in higher prevalence of several types of autoantibodies. Patients with high GADA compared to low GADA titer showed a significantly higher prevalence of IA-2A_{IC} (25.5% vs 8.2%; p<0.002), TPOAb (37.2% vs 16.5%; p=0.002) reported elsewhere, and APCA (23.3% vs 9.3%; p<0.01). 21OHAb showed a prevalence of 3.2% (3/94) in high GADA titer and were not present in low GADA titer (0/97) (p=ns) and in type 2 diabetes subjects (0/382; high GADA titer vs type 2 diabetes p=0.03). tTGA showed a prevalence of 4% (3/94) in high GADA, 1.2% (1/97) in low GADA and 0.4% in type 2 diabetes (p for trend =0.007, high GADA vs type 2 diabetes p=0.03).

Conclusion: High GADA titre, in LADA subjects, is associated with a profile of more severe autoimmunity consisting in higher prevalence of organ and non organ specific autoantibodies. Previous longitudinal studies indicate that the prevalence of multiple autoantibodies is a better index of disease progression than prevalence of antibodies directed at individual antigens. This may indicate intermolecular epitope spreading and, hence, amplifying the autoimmune response.

Innate immunity and human insulinitis during beta cell coxsackie B4 infection

F. Dotta^{1,2}, V. Bonato^{1,2}, R. Gallo^{1,2}, F.A. Grieco^{1,2}, G. Sebastiani^{1,2}, P. Marchetti³, G. Gambelunghe⁴, A. Falorni⁴

¹Department of Internal Medicine and Endocrine and Metabolic sciences, University of Siena, ²Fondazione Umberto Di Mario, Toscana Life Sciences, Siena, ³Department of Endocrinology and Metabolism, University of Pisa, ⁴Department of Internal Medicine, Section of Internal Medicine and Endocrine and Metabolic Sciences, University of Perugia, Italy

Background and aims: Type 1 diabetes mellitus (T1DM) is a multifactorial disease in which multiple genes interplay with environmental factors leading to autoimmunity against self-antigens in T-cells. Viral infections are associated epidemiologically with T1DM. Recently we reported that in a subset of T1DM patients signs of enteroviral infection were detected. Infecting virus was identified as a novel Coxsackie B4 (CVB4) strain, named "Tuscany Strain". Viral infection, was beta-cell specific and caused beta-cell dysfunction as shown by impaired glucose-stimulated insulin secretion. Several studies demonstrated that during stress, such as viral infections, cells synthesize factors, such as FAS, IFN- α , MICA, which interact with innate immunity. In particular MICA (MHC class I chain-related) molecules are stress induced, and recognized by NKG2D receptors on natural killer (NK) and CD8-positive T-cells. In addition studies on animal models demonstrated the pathogenic role of CXCR3+ autoreactive lymphocytes, recruited in the pancreatic islet by CXCL10 and CXCL9. We aimed at characterizing the occurrence of innate immunity-related phenomena and chemokine expression in human insulinitis during CVB4 infection.

Materials and methods: Pancreas and collagenase purified islets were obtained from organ donors (2 recently diagnosed T1DM found positive at islet

levels for CVB4 strain, and 5 controls). Pancreatic specimens were formalin-fixed and paraffin-embedded for immunohistochemical studies, while pancreatic islets were employed for mRNA expression studies.

Results: In pancreas of CVB4 positive T1DM patients, insulinitis was present and was characterized mainly by NK cells (CD94+) and by a small amount of CD3 expressing T-cells. Strong positivity for IFN- α and FAS was detected in the majority of pancreatic islets as shown by immunohistochemistry. In addition insulinitic lesions were characterized by presence of elevated levels of the chemokine CXCL10 and infiltration of lymphocytes expressing the corresponding chemokine receptor CXCR3. This result was paralleled by real time PCR analyses on isolated T1DM islets. Both in islet and endothelial cells we observed an over-expression of class I MHC molecules. Interestingly, MICA-positive cells were detected in most of the islets and in scattered exocrine cells. MICA expression co-localized with insulin producing beta-cells in the islets as shown by confocal microscopy experiments.

Conclusion: We have demonstrated that: during beta-cell viral infection, innate immunity is indeed involved in human T1DM, thus suggesting that strategies aimed at modulating NK cell function may interfere with the natural history of beta-cell destruction. In addition, our study suggested a relevance of the CXCL10-CXCR3 pathway in facilitating human leucocyte migration to inflamed pancreatic islets, which may lay the basis for the development of a novel therapeutic target.

Polyclonal anti-T-lymphocyte globulin preserves C-peptide production in type 1 diabetes of recent onset

F. Saudek¹, T. Havrdova¹, P. Boucek¹, H.H. Hirsch², K. Zacharovova¹, V. Lanska¹

¹Diabetes Center, Institute for Clinical and Experimental Medicine, Praha 4, Czech Republic, ²Institute for Medical Microbiology, University of Basel, Switzerland

Background and aims: The destruction of pancreatic B-cells typical for type 1 diabetes (T1DM) is mediated by autoreactive T-lymphocytes. Their identifications and specific targeting has been so far not successful. Recently, studies with 2 different monoclonal antibodies directed against the CD3 molecule showed encouraging results in delaying the loss of C-peptide production and improving metabolic control in T1DM of recent onset. We report on the results of an immune-intervention study in new onset T1DM (within 6 weeks of diagnosis) using polyclonal anti-T-lymphocyte globulin which in contrast to anti-CD3 antibodies displays multiple anti-T-cell specificities and might stop the autoimmune process by deletion of different activated T-cells clones and restore self-tolerance.

Materials and methods: Twenty four adult subjects fulfilling the ADA criteria of T1DM 18-35 years of age with C-peptide level following glucagon stimulation ≥ 0.3 nmol/l and positivity of 1 or more islet autoantibody tests were randomized for treatment with 4 doses of ATG-Fresenius (9 mg/kg with subsequent 3 doses of 3 mg/kg) in addition to intensive insulin treatment (ATG-group, n=13) or for intensive insulin therapy only (I-Group, n=11). The insulin doses, glucagon-stimulated C-peptide levels and metabolic control were compared at 6, 12 and 24 months after the study start.

Results: While the basal and stimulated C-peptide levels did not differ between the groups, the area under the C-peptide curves were different (basal C-peptide 0-12 months p=0.016, 0-24 months p=0.021, stimulated C-peptide 0-12 months p=0.016, 0-24 months p=0.036; Mann-Whitney test). ANOVA with repeated measures and grouping factor showed different trends in C-peptide levels and insulin doses between the groups (all p<0.05). Mean fasting C-peptide levels in the ATG and Placebo groups at 12 months were 0.52 ± 0.40 and 0.23 ± 0.19 pmol/ml, respectively; p=0.03) and stimulated levels were 0.90 ± 0.66 and 0.36 ± 0.32 pmol/ml, respectively; p=0.026 (Mann-Whitney test) and the differences remained significant for 24 months. Complete clinical remission occurred in 2 subjects in the ATG group and in none in the I Group. The ATG treatment resulted in long-lasting inversion of the CD4/CD8 T-cell ratio suggesting immunoregulatory effect of the therapeutic intervention. Adverse events were observed only in the 1st month of therapy and included cytokine release syndrome and transient symptoms of serum sickness both in 7 subjects in the ATG-group. For comparison, symptoms of the serum-sickness were retrospectively not found in any of the last 110 consecutive pancreas and kidney recipients and 7 islet recipients treated with similar doses of ATG in combination with other immunosuppressive drugs. Specific virological examination did not show any activation of the herpes virus type 1 and 2, cytomegalovirus or EB-virus in any of the ATG treated subjects during a 1-year follow-up.

Conclusion: Short-term ATG therapy in T1DM of recent onset results in lower insulin need due to preserved C-peptide production. Safety of this therapeutic approach could be possibly improved by prevention of the febrile serum-sickness-like disease. Combination therapy with other drugs modulating the immune system or stimulating beta-cell regeneration could further improve the efficacy of this approach.

Prospective study of latent pernicious anaemia markers in patients with type 1 diabetes mellitus

E. Colomé¹, N. Alonso¹, M. Granada², J. Juncà³, E. Martínez-Cáceres⁴, B. Soldevila¹, I. Salinas¹, A. Sanmartí¹

¹Endocrinology and Nutrition Service, ²Biochemistry Service,

³Hematology Service, ⁴Immunology Service (LIRAD-BST), Hospital Universitari Germans Trias i Pujol, Badalona, Spain

Background and aims: Patients with type 1 diabetes mellitus (DM1) present a high prevalence of autoimmune associated diseases such as pernicious anaemia that has a long pre-clinical or latent phase. Recently, we described a prevalence of latent pernicious anaemia (LPA) of 12.4% in DM1. A five year follow-up study of a cohort of DM1 patients in order to evaluate the evolution of biochemical markers of LPA, defined as a serum pepsinogen I (PI) concentration below normal limits, as well as several hematological parameters.

Materials and methods: Prospective study of 186 DM1 patients (93 men, aged 30±9.4 yrs). All patients underwent in 2001 and 2006 a measurement of: serum PI (2001: RIA; 2006: ELISA), gastrin (RIA), HbA1c, cobalamin and parietal cell antibodies (PCA) (indirect immunofluorescence, positive title ≤ 1/40).

Results: In 2001, 23 out of 186 DM1 patients presented LPA. Of these, 17 (77.3%) persisted with low PI in 2006 and in 5 PI concentrations were normalized. One patient was lost at follow-up. 100% of patients with positive PCA and low PI in 2001 continued with low PI in 2006. Nevertheless, only 33.3% (3/9) of patients with low PI and negative PCA in 2001 persisted with low PI in 2006. All those patients whose PI normalized in 2006 had normal gastrin concentrations and negative PCA in 2001. In 2006, PI was low in 6 new patients who presented normal PI in 2001. Of these, 50% presented positive PCA and another 33% high gastrin concentrations in 2001. However, only 8.8% (3/34) of patients with positive PCA and normal PI in 2001 evolved to LPA in 2006. The cobalamin concentration in 2001 was similar in patients with or without LPA, but in 2006 it was significantly lower in the group with LPA diagnosed in 2001 ($p=0.007$).

Conclusion: The best markers of LPA in DM1 patients were the presence of low concentrations of PI together with positive PCA. The prevalence of LPA in DM1 patients increases with the temporal evolution of diabetes. This combination would allow to identify and treat those patients with low cobalamin concentrations and therefore avoid the possible clinical complications derived from its deficit.

Prevalence of atopy in children with type 1 diabetes, hepatitis B virus carriers and healthy children: role of Th1 type immune response

G. Karagüzel¹, F. Orhan², M. Cakır³, A. Ökten¹

¹Pediatric Endocrinology, Karadeniz Technical University, School of Medicine, Trabzon, ²Pediatric Allergy, Karadeniz Technical University, School of Medicine, Trabzon, Turkey, ³Pediatrics, Karadeniz Technical University, School of Medicine, Trabzon, Turkey

Background and aims: Type 1 diabetes (DM1) and a chronic viral infection, hepatitis B virus (HBV) carriers - are associated with a Th1-dominant and Th1-insufficient cytokine profile, respectively. Our aim was to analyze the frequency of allergic disease in patients with DM1 and in HBV carriers in order to evaluate the role of Th1 type immune response in atopy and allergic disease.

Materials and methods: The study included the patients with DM1 (group I, n: 52), HBV carriers (group II, n: 47); and healthy control group (group III, n: 209). Participants were screened for allergic disease and atopic sensitization.

Results: There was no significant difference between the groups in terms of age and gender. The duration of disease was 4.3 ± 1.2 and 3.1 ± 2.1 years in patients with DM1 and HBV carriers, respectively. The prevalence of atopy in HBV carriers (36.1%) was significantly higher than in both patients with DM

(13.4%) and the children in the control group (18%) ($p<0.05$). Comparison of the frequency of the allergic symptoms and allergic diseases showed that the prevalence of history of ever wheezing, current wheezing, and doctor-diagnosed asthma or eczema were significantly higher in chronic HBV carriers than in patients with DM1 ($p<0.05$ for all parameters). The IgE levels were 193.7 ± 201.2 , 208 ± 347.4 and 166.1 ± 231.8 IU/mL in DM, chronic HBV carriers and the control group, respectively and there were no statistically significant differences between the groups. No significant difference was found between the groups in terms of family history of atopic diseases.

Conclusion: Our study supports the Th1/Th2 model. The prevalence of allergic disease and atopy is decreased in Th1-mediated autoimmune disease, DM1 and conversely is increased in insufficient Th1 response, chronic HBV carriers.

Organ specific autoantibodies in patients with type 1 diabetes, LADA and type 2 diabetes

N.C. Schloot¹, M.I. Hawa², W.A. Scherbaum³, P. Pozzilli⁴, R. Leslie², J. Seissler⁵ for the Action LADA consortium

¹German Diabetes Center, Heinrich-Heine University, Düsseldorf, Germany, ²Queen Mary's College, Institute of Cell and Molecular Science, London, United Kingdom, ³University Hospital Dueseldorf, Heinrich-Heine University, Dept of Endocrinology, Diabetes and Rheumatology, Germany, ⁴University Campus Bio-Medico, University Campus Bio-Medico, Rome, Italy, ⁵Medical Clinic, Diabetes Center, Muenchen, Germany

Background and aims: LADA (latent autoimmune diabetes of the adult) presents clinically similar to type 2 diabetes but is characterized by type 1 diabetes associated autoantibodies. Objective of the study was the investigation of patients with diabetes for organ-specific autoantibodies including type 1 associated autoantibodies.

Materials and methods: We investigated 998 patients (mean age 52.8 years, 30–69 years) with diabetes duration less than five years. Patients were recruited from the Action LADA study. Serum samples of patients from Germany, Austria, Belfast, Rome and London were investigated in a blinded fashion for antibodies: glutamic acid decarboxylase (GAD)65, tyrosine phosphates like antigen (IA2A), islet cells (ICA), thyroid peroxidase (TPO), parietal gastric cells (PCA) and tissue transglutaminase (tTG) antibodies.

Results: Adult patients with diabetes showed positive antibodies in 10.7% for GADA, 2.6% for IA2A, 4.0% for ICA, 14.9% for TPO, 10.8% for PCA and 0.9% for tTGAb. Further analysis showed, that 6.5% of all patients with diabetes were positive for only GADA, 0.3% positive for only ICA, 0.2% positive for only IA2A. 3.5% of diabetes patients were positive for GADA and ICA, 2.6% were positive for GADA and IA2A, 1.6% were positive for GADA, IA2A and ICA. 11.29% of the patients were positive for GADA or ICA or IA2A. In GADA positive patients we found: 23.8% positive for IA2A, 32% positive for ICA, 14.8% positive for IA2A and ICA, 19.7% positive for TPO, 17.2% positive for PCA and 1.6% positive for tTGA.

Conclusion: Measurement of GADA identifies 94% of patients positive for type 1 diabetes associated autoantibodies. The prevalence of organ-specific autoantibodies is increased in patients with GADA compared to patients negative for GADA.

Antibodies against intestinal CD163⁺ macrophages in a patient with type 1 diabetes and celiac disease

B. Sonier, G.-S. Wang, A. Strom, F.W. Scott

Chronic Disease Program, Ottawa Health Research Institute, Ottawa, Canada

Background and aims: Recent studies have described histological and immunological abnormalities in the gastrointestinal tract of animal models and humans with type 1 diabetes (T1D). Oral exposure to dietary antigens normally leads to the induction of tolerance in the mucosal immune system, a process that is facilitated by resident antigen presenting cells. Our group has described the case of a highly wheat sensitive index patient with both T1D and celiac disease (CD) who displayed antibody and T cell reactivity to wheat proteins, including a homologue of wheat storage globulin-1 (Glb1). Antibody and T cell reactivity to Glb1 was also observed in a subset of patients

with T1D. In the present study, we purified Glb1 antibodies from this index patient to identify possible autoimmune targets in the gastrointestinal tract. **Materials and methods:** Recombinant His-tagged Glb1 (His-rGlb1) was produced using the Bac-to-Bac Baculovirus Expression System in SF21 insect cells. His-rGlb1 was then used to enrich Glb1-specific antibodies from plasma of the index patient by batch affinity chromatography. The presence of antibodies in the enriched sample was confirmed by ELISA. This antibody mixture was used to probe Bouin's fixed intestinal sections from 11, 30, 45, 70 and 100 day old Wistar Furth rats. The antibody preparation was also used to probe fixed human monocytes which were enriched from peripheral blood mononuclear cells (PBMC).

Results: Probing rat intestinal sections with the enriched Glb1 antibody preparation revealed binding to a subset of cells in the lamina propria. This labeling was only present on sections from animals that were past the age of weaning. Binding was not blocked by rGlb1 and was therefore attributable to non-Glb1 antibodies that were co-purified during the enrichment process. Additional experiments indicated that this labeling predominantly co-localized with cells that express CD163, a marker of alternatively activated, mature tissue-resident macrophages. A subset of PBMC-derived human monocytes was also labeled, suggesting that these anti-macrophage antibodies could represent novel T1D- and/or CD-related autoantibodies. Additional preliminary data suggested that macrophage autoreactivity was also present in other autoimmune patients with T1D, CD or both T1D/CD.

Conclusion: These results suggest that intestinal macrophages are an autoimmune target in this index patient. Although this immune reactivity was not Glb1 antibody specific, putative anti-macrophage autoantibodies were co-purified during the batch affinity chromatography. Resident intestinal macrophages are thought to be important for maintaining immune tolerance in the gut. Immune reactivity was only detected on rat gut sections of animals \geq 30 d of age, past the age of weaning. This is consistent with an immune response that targets a population of CD163⁺ mature intestinal macrophages that are only present in animals that have been exposed to complex dietary antigens. This study raises the novel possibility that an autoimmune response against mucosal immune cells is present in some patients with T1D and/or CD.

Association between anti-ZnT8 autoantibodies and *SLC30A8* Arg325Trp variant

E. Kawasaki¹, M. Uga¹, G. Kuriya¹, T. Satoh², K. Fujishima², A. Moriuchi¹, K. Fukushima¹, M. Ozaki³, N. Abiru², H. Yamasaki³, K. Eguchi¹

¹Department of Metabolism/Diabetes and Clinical Nutrition, Nagasaki University Hospital of Medicine and Dentistry, ²Department of Endocrinology and Metabolism, Graduate School of Biomedical Science, Nagasaki University, ³Health Center, Nagasaki University, Nagasaki, Japan

Background and aims: Recently, the zinc transporter protein member 8 (ZnT8) has been reported as a new autoantigen in type 1 diabetes. Furthermore, a recent genome-wide association study identified the *SLC30A8* rs13266634 polymorphism encoding an Arg325Trp polymorphism in the ZnT8 to be associated with type 2 diabetes. The facts that major epitope(s) for ZnT8 antibodies lies within the cytoplasmic domain of the molecule (aa268–369) and the variant residue at aa325 is located at the most distal loop between β -strand and α -helix prompt us to analyze the association between humoral autoreactivity to ZnT8 and *SLC30A8* polymorphism.

Materials and methods: Sera from total 286 patients with type 1 diabetes were screened for ZnT8 antibodies using radioligand binding assay and a hybrid ZnT8 cytoplasmic cDNA construct generated by ligation of the cDNA with 325Arg (CR) and 325Trp (CW). Autoreactivity to CR or CW construct was also determined separately using each cDNA.

Results: Of 286 patients with type 1 diabetes 75 (26%) were ranked as positive for ZnT8(CRCW) antibodies. Among them 44 patients whose genomic DNA were available were used for further analysis. Of these 15 (34%) patients were homozygotes of the 325Trp (WW) in *SLC30A8*, 19 (43%) were RR homozygotes, and 10 (23%) were RW heterozygotes, respectively. The autoreactivity to ZnT8 was closely associated with *SLC30A8* genotype, and the level of ZnT8(CR) antibodies in patients with R allele (RR+RW) was significantly higher than that in WW homozygotes (0.139 ± 0.158 vs. 0.002 ± 0.014 , $P < 0.0001$). Furthermore, the level of ZnT8(CW) antibodies in patients with W allele (WW+RW) was significantly higher than that in RR homozygotes (0.093 ± 0.103 vs. 0.029 ± 0.053 , $P < 0.005$). Among 19 patients with RR genotype CW-specific antibodies were found in only 1 patient (5%), CR-specific antibodies in 7 patients (37%), and CR/CW cross-reactive antibodies in 7 patients (37%), respectively. In contrast, 11 (73%) of 15 patients with WW genotype had CW-specific antibodies and no one had CR-specific antibodies. Nine (90%) of 10 patients with RW genotype reacted with either CR or CW constructs.

Conclusion: These results indicate that variant residue at aa325 is a key determinant of humoral autoreactivity to ZnT8 and *SLC30A8* genotype is an important determinant of autoantibody specificity.

The common non-synonymous SNP in the *Slc30A8* gene at aa325 determines ZnT8 autoantibody specificity in type 1 diabetes

J.M. Wenzlau, O. Moua, Y. Liu, L. Yu, L.M. Frisch, K.T. Fowler, S. Rangasamy, G.S. Eisenbarth, H.W. Davidson, J.C. Hutton

Barbara Davis Center for Childhood Diabetes, University of Colorado Denver, Aurora, United States

Background and aims: Zinc transporter 8 (*Slc30A8*) is a major target of autoimmunity in human type 1A diabetes (T1D). Genome wide SNP association studies have shown that it is also associated with type 2 diabetes susceptibility, which may suggest that there are common mechanisms in the pathogenesis of T1D and T2D. The common non-synonymous polymorphism at aa325 is located in a region where more than 60% of new onset T1D patients exhibit antibodies. The aim of this study was to examine the relationship between subject genotype and autoreactivity in this region and its association with the prevalence of autoantibodies, their levels and the age of onset of clinical disease.

Materials and methods: T1D new onset individuals ($n=348$; median age at onset 8.6yr; range 1–38yr) were assayed for ZnT8 autoantibodies (ZnT8A) by radioimmunoprecipitation assays using C-terminal 102aa constructs bearing

the common polymorphic aa325 variants encoding Arg and Trp as well as the rare Gln variant. Assay specificity was confirmed by preabsorption with recombinant versions of the corresponding variant constructs. Genotypes were determined by PCR-based SNP analysis using quantitative RTPCR (ABI assay on demand) and direct nucleotide sequencing.

Results: ZnT8 autoantibodies were found in 63% of subjects. Individually, 56% were reactive to Arg325 constructs, 44% to Trp325, and 36% with Gln325. Of the total, 15–20% were Arg325-restricted (Arg but neither Trp nor Gln reactive), 6–10% Trp325-restricted (Trp but neither Arg nor Gln reactive), and 0.3% Gln-restricted. Restriction to Arg325 and Trp325 corresponded to the inheritance of the corresponding C or T allele. A strong gene dosage effect was also evident such that the frequency of Arg or Trp-restricted ZnT8A levels were much lower in heterozygous than in homozygous individuals. Gln variant reactivity in the majority of cases was equivalent to Arg and Trp construct reactivity and not affected by genotype. The SLC30A8 SNP allele frequency in our group (75%C; 25%T) was typical of non-diabetic Caucasian populations, and the SLC30A8 genotype neither affected the levels and prevalence of insulin, GAD65 and IA-2 autoantibodies, nor correlated with age of T1D onset. The median age of onset of type 1 diabetes did not vary as a function of genotype or allele frequency however in the 0–4yr age group the CC genotype was more frequent (65 vs 50% in the 10–15 age group) accompanied by a lower prevalence of Trp-restricted autoreactivity.

Conclusion: Humoral autoreactivity to ZnT8 shows a remarkable restriction depending on variation of a single amino acid in the molecule. Although the autoantibody response is polyclonal, it is primarily focused on a limited number of epitopes, two of which are sensitive to residue 325 (Arg or Trp), and at least one other that is independent of the residue at this position. The strict linkage between genotype and Arg- or Trp-restricted antibodies indicates that autoimmunity to ZnT8 is indeed reactivity to self rather than arising from immunity to a foreign antigen through a process of molecular mimicry. Moreover, the existence of “isoeptopes” in autoantigens has both implications for diagnostic strategies and for antigen-based therapeutic interventions. In particular, it raises the question as to whether immunoregulation should be tailored to self or non-self molecular variants in homozygous individuals.

Zinc transporter 8 antibodies complement GAD and IA-2 antibodies in the identification of adult-onset autoimmune diabetes

V. Lampasona¹, R. Buzzetti², E. Bazzigaluppi¹, A. Petrone², M. Capizzi², C. Tiberti², M. Songini³, F. Giorgino⁴, E. Bonifacio⁵, E. Bosi¹

¹Internal Medicine, San Raffaele Scientific Institute, Milan, Italy, ²Clinical Sciences, La Sapienza University, Rome, Italy, ³Diabetes, San Michele Hospital, Cagliari, Italy, ⁴Endocrinology & Metabolism, Bari University, Italy, ⁵Center for Regenerative Therapies, Dresden University of Technology, Germany

Background and aims: Zinc Transporter 8 (ZnT8) is an islet beta-cell secretory granule membrane protein that has recently been reported as autoantigen in type 1 diabetes. ZnT8 antibodies (ZnT8A) are directed against epitopes expressed in the cytosolic domains in the COOH-terminal and, less frequently, within the NH₂-terminal of the protein. The aim of this study was to determine the prevalence of ZnT8A in adult-onset diabetes.

Materials and methods: Overall, 541 patients with initial non insulin-requiring diabetes participating in the NIRAD study were studied: of these, 193 (age 50.3 ± 12.8yr) had autoimmune diabetes defined as having antibodies to either GAD(A) or IA-2(A) (4.5% overall prevalence) and 348 were age and sex matched patients with antibody-negative type 2 diabetes (age 51.1±10.8yr). ZnT8A were measured by a radiobinding and immunoprecipitation assay using in vitro translated and transcribed ³⁵S-labelled COOH-terminal (aa 268–369) and NH₂-terminal (aa 1–74) ZnT8 cloned constructs. Sensitivity of the assay in juvenile type 1 diabetes was 64% for ZnT8A-COOH and 11% for ZnT8A-NH₂, with 99% specificity.

Results: ZnT8A-COOH were detected in 36/193 (18.6%) autoimmune (all 36 with GADA, 2 with both GADA and IA-2A) and 6/348 (1.7%) patients with type 2 diabetes (p<0.0001); within the GADA positive patients, GADA titre was higher in the ZnT8A-COOH positive group (median 100 vs 19.4 units, respectively; p=0.001 Mann-Whitney test). ZnT8A-NH₂ were rare and found in 4/193 (2.1%) autoimmune (3 having also ZnT8A-COOH) and 1/348 (0.3%) patients with type 2 diabetes.

Conclusion: ZnT8A-COOH appear to be a valuable additional marker of adult-onset autoimmune diabetes since they confirm autoimmunity in a sub-

group of single GADA positive patients, and identify additional patients who had none of the previous markers of autoimmune diabetes. It remains to be established whether the single ZnT8A-COOH positive patients have clinical features associated with autoimmune diabetes.

Engineering single chain multi-component autoantigens for enhanced detection of autoantibodies in type 1 diabetes

J.C. Hutton, Y. Liu, C. Patel, L. Yu, G.S. Eisenbarth, J.M. Wenzlau, H.W. Davidson
Barbara Davis Center for Childhood Diabetes, University of Colorado
Denver, Aurora, United States

Background and aims: Autoantibodies provide highly sensitive and specific measures of autoimmunity prior to clinical diabetes in genetically-at-risk populations. However, the currently available assays fall short of the required level of >99.5% specificity required to make neonatal screening in the general population a realistic possibility. To reach this level it is estimated that up to 10 single target assays might have to be run concurrently. We therefore investigated the potential of multimerizing epitopes and combining epitopes from different autoantigens into single vectors for improving specificity and increasing throughput of autoantibody assays.

Materials and methods: Model systems were developed using ZnT8, an autoantigen that has 2 major polymorphic variants with differential reactivity, and IA2 and phogrin that represent related autoantigens encoded by different genes. Molecular modeling of ZnT8 using the bacterial Ziip gene product as template was used to construct free energy minimized homo- and heterodimers of ZnT8. The actual crystal structure of IA2 and deduced structure of phogrin (IA2β) were similarly used to design dimeric structures of these proteins. Multidomain ZnT8 and IA2/IA2β fusion proteins were fused into a single chain analyte using a Fc hinge to connect to the 2 molecule flanked by Gly triplets. All constructs were tested against a panel of 145 sera derived from new onset T1D patients and a blinded panel of 50 diabetic and 100 control sera provided by the Diabetes Autoantigen Standardization Program (DASP).

Results: Antibodies to the ZnT8 Arg325 variant was detected in 53% of new onset sera compared to 48% that bound the ZnT8 Trp variant. However, the same sera analyzed with a heterodimer of ZnT8 Trp variant fused to ZnT8 Arg variant showed 78% sensitivity without loss in specificity (>99%). The improved sensitivity was both the result of combining the 2 major epitopes in one molecule (nominally 63%) and the higher avidity resulting from duplication of other epitopes within the monomers. The latter was evidenced by the increase sensitivity of assays to homodimers versus monomers that was achieved without any loss in the detection rate or change in the background signal in the assay (<1%). An additional 2.5% increase in detection was attributable to neoepitopes present in the dimeric but not the monomeric construct. Comparison of responses to homodimeric and heterodimeric constructs of IA2 and phogrin showed increased sensitivity of the assays both as a result of the duplication of the epitopes and the incorporation of multiple epitopes within the same molecule. A heterodimer of IA2 with ZnT8 could be used to detect both antigenic specificities in a single molecule without changes in the background.

Conclusion: Our data indicate that there is a substantial advantage in assaying multimeric autoantigen constructs, both in terms of increasing the number of epitopes within the one molecule and increasing the sensitivity of the assays as a result of higher avidity. It should be noted that the increased sensitivity and specificity is accompanied by the loss of specific information regarding the molecular form of the autoantigen and isoeptopes involved, although this is unlikely to be a concern for general screening. Our strategies could presumably be extended to trimeric and higher order constructs, provided that the background signal in such assays are not compromised.

Long term vs. short-term clinical remission in type 1 diabetes: an analysis of CD4+CD25+ and CD4+CD161+ T cell subsetsA. Jotic¹, N.M. Lalic¹, T. Milicic¹, I. Markovic², B. Djuricic², M. Zamaklar¹, K. Lalic¹, L. Lukic¹, N. Rajkovic¹, M. Macesic¹¹Institute for Endocrinology, Diabetes and Metabolic Diseases, Clinical Centre of Serbia, ²Institute for Biochemistry, School of Medicine, Belgrade, Serbia

Background and aims: It has been previously suggested that changes in CD4⁺ T lymphocyte subsets might correlate with the clinical course of the disease in patients with recent-onset Type 1 diabetes (T1D). However, the relevance of the changes in CD25⁺ and CD161⁺ subsets of the regulatory T cells, potentially exerting suppressive effect on the ongoing autoreactive response, on the duration of clinical remission (CR) has not been clarified. Therefore, the aim of this study was to compare the changes in CD4⁺ T cell subsets in peripheral blood between two groups of recent-onset T1D patients exhibiting difference in duration of CR. We included 64 recent-onset T1D patients grouped as follows: group A (N=34) long-term remission (> 180 days) (392±/–62 days), group B (N=30), short-term remission (< 180 days) (135±/–37 days). In each patient, the analysis of the percentage of regulatory CD25⁺ and CD161⁺ subsets of CD4⁺ T lymphocytes was done sequentially: (a) in insulin-requiring state (IRS) and (b) at day 30 of CR.

Materials and methods: The CR was defined as optimal metabolic control without insulin lasting >30 days. The percentages of CD3⁺, total CD4⁺, CD4+CD25⁺ and CD4+CD161⁺ T cell subsets were analyzed in peripheral blood by using two-color immunofluorescence staining and flowcytometry.

Results: The percentages of CD3⁺, and total CD4⁺ T cells did not differ significantly neither between IRS and CR in the group A, nor between the groups A and B. However, when the percentage of CD4+CD25⁺ T lymphocytes was analyzed at onset of T1D, in IRS, it was found to be higher in group A vs group B (A/IRS: 2.78±0.51 vs B: 2.01±0.65%, p<0.05). Moreover, in the state of CR, in both groups the percentage of CD4+CD25⁺ T cells increased but remain higher in group A than in group B (A/CR: 5.52±0.17 B: 3.41±0.55%, p<0.05), while the increase was significantly higher in group A vs group B (p<0.05). Simultaneously, the percentage of CD4+CD161⁺ T cells was found to be higher at IRS in group A vs group B (A/IRS: 4.28±0.63 vs B/IRS: 3.18±1.01, p<0.05), while in the state of CR the percentage of CD4+CD161⁺ T increased and remained higher compared to the group B (A/CR: 6.23±0.86, vs B/CR 4.28±0.98, p<0.05) and the increase was also higher in group A vs group B (p<0.05).

Conclusion: Our results have demonstrated that in recent-onset T1D patients, the duration of CR was strongly associated with an increase in both CD25⁺ and CD161⁺ regulatory CD4⁺ T cell subsets. The results imply that the clinical course of T1D might be strongly influenced on the level of the activity of these suppressor subsets of the regulatory CD4⁺ T lymphocytes.

Distinctive differences in the phenotypic characteristics of Tregs of newly-diagnosed type 1 diabetics, long-standing patients, relatives and controlsS.A. Paschou¹, G. Vartholomatos², L. Dova², N. Kolaitis³, E. Giotaki⁴, A. Tsatsoulis¹, G.K. Papadopoulos⁵¹Endocrinology Clinic, University of Ioannina Regional Hospital, Ioannina, ²Haematology Laboratory, Molecular Biology Unit, University of Ioannina Regional Hospital, Ioannina, ³Haematology Laboratory, University of Ioannina Regional Hospital, Ioannina, ⁴Department of Nursing, Epirus Institute of Technology, Ioannina, ⁵Laboratory of Biochemistry and Biophysics, Faculty of Agricultural Technology, Epirus Institute of Technology, Arta, Greece

Background and aims: In order to gain better understanding of the mechanisms leading to the autoimmune destruction of beta-cells and consequent type 1 diabetes (t1d), we have documented by flow cytometry the proportion of T regulatory lymphocytes (Tregs, CD4⁺CD25^{high}) as well as the phenotypic characteristics of Tregs from newly-diagnosed and long-standing t1d patients as well as first and second-degree relatives and controls.

Materials and methods: Peripheral blood from 9 newly-diagnosed patients (ages 14.9 ±/– 10.3, 6M/3F), 17 t1d patients with long-term disease (ages 29.2 ±/– 9.2, mean disease duration 13.8 years, 8M/9F), 29 controls with no first or second degree relatives suffering from any autoimmune disease (ages 25.3 ±/– 11.5, 11M/18F), and 13 first and second degree relatives of t1d patients

(ages 26.2 ±/– 5.8, 5M/8F), was analysed by triple colour flow cytometry for various phenotypic markers (CD27, CD28, CD45RO, CD95, CD122 (IL-2Rβ), CD127, CD152 (CTLA-4, membrane and intracellular), CD220 (InsR), TGFβ, TGFβRII, and the FoxP3 transcription factor, characteristic of Tregs. The Tregs were distinguished from the Tefector population in CD4-CD25 dot and contour plots, as well as by the distinct expression of FoxP3 (high in Tregs) and CD127 (low in Tregs).

Results: There is a highly statistically significant difference in the Tregs of newly-diagnosed, long standing t1d patients and relatives of t1d patients, all compared to controls, expressed as percent of CD4⁺ T cells (1.046 ±/– 0.240 (p<0.001), 1.330 ±/– 0.229 (p<0.001), 1.842 ±/– 0.243 (p=0.001), 2.297 ±/– 0.527, respectively). This difference is also significant between newly-diagnosed and long term patients (p=0.007), and between each these two groups and relatives (p<0.001, and p<0.001). Besides the previously reported lower frequency of TGFβ⁺ and CD220⁺ Tregs but at higher intensity per cell in newly-diagnosed t1d patients, we note a remarkable difference in the level per cell of mCD152 in the Tregs of long standing diabetics versus controls (368 ±/– 272 versus 199 ±/– 86, p=0.027), and a similar but not statistically significant difference in the Tregs of newly-diagnosed t1d patients. Yet, newly-diagnosed and long standing t1d patients have a lower percent of membrane CD152⁺ Tregs compared to controls. The vast majority of Tregs from newly-diagnosed t1d patients express iCD152 at significantly higher proportion compared to long-term patients (p=0.039), relatives (p<0.001) and controls (p=0.01) (values at 85.96 ±/– 13.9 %, 59.1 ±/– 39.2, 38.9 ±/– 23.4, and 61.9 ±/– 36.2 respectively).

Conclusion: The significantly lower proportion of Tregs in t1d extends to long-term patients and relatives, in addition to newly-diagnosed patients. There are several defects in m/iCD152 expression in patients and relatives which point to a possible role of this molecule, an already known genetic factor for the disease, in t1d pathogenesis.

Recent-onset type 1 diabetes: clinical remission is associated with increases of CD 25+ and CD 45RA+ regulatory subsets of CD 4+ T lymphocytes and improvements in insulin sensitivity levelT. Milicic¹, N.M. Lalic¹, A. Jotic¹, I. Markovic², B. Djuricic², M. Zamaklar¹, K. Lalic¹, L. Lukic¹, N. Rajkovic¹, M. Macesic¹¹Institute for Endocrinology, Diabetes and Metabolic Diseases, Clinical Centre of Serbia, ²Institute for Biochemistry, School of Medicine, Belgrade, Serbia

Background and aims: Previous studies have reported an important role of the changes in CD4⁺ T cell subsets in the initial phase of Type 1 diabetes (T1D). However, the relevance of the changes in CD4+CD25⁺ and CD4+CD45RA⁺ T subset of the regulatory suppressive T cells and insulin sensitivity level, during the initial phase of T1D has not been clarified. Therefore, the aim of this study was to analyze (a) the percentage of regulatory suppressor CD4+CD25⁺ and CD4+CD45RA⁺ T cell subsets; (b) insulin sensitivity level during the first year of the clinical course of the disease comprising (1) insulin-requiring state (IRS) at the onset and (2) the state of clinical remission (CR) in 37 recent-onset T1D patients (group A) as well as in 20 healthy, age-matched control subjects (group B).

Materials and methods: The CR was defined as optimal metabolic control without insulin lasting >30 days. The percentage of CD4+CD25⁺ and CD4+CD45RA⁺ T cell subsets was analysed by using two-color immunofluorescence staining and flowcytometry. Euglycemic hyperinsulinemic clamp was performed and insulin was infused at the rate of 1 mU/kgbw/min during 180 min and glucose infusion was adjusted manually, at 5 minutes intervals, to maintain target glycemia at 90 mg/dl. Total glucose uptake was calculated on the basis of the amount of glucose infused during steady state period (20-180 minutes).

Results: When the percentage of CD4+CD25⁺ T lymphocytes was analyzed, we found that at onset of T1D, in IRS, it was lower in group A vs group B (A: 2.33±0.30 vs B: 5.17±0.74%, p<0.01). However, in the state of CR, in group A the percentage of CD4+CD25⁺ T cells increased and it became higher than at onset (A: 4.17±0.11 vs B: 5.19±0.72%, p=NS), reaching the values similar to those in group B. Moreover, the percentage of CD4+CD45RA⁺ T cells was found to be lower at IRS in group A vs group B (A/IRS: 23.0±1.1 vs B:28.4±2.4, p<0.05), while in the state of CR it also increased and became similar to those in the group B (A/CR: 26.9±1.1, p=NS). In addition, total glucose uptake was significantly lower in group A at onset of T1D in comparison to group B (A: 3.83±0.12 vs B: 6.78±0.25 mg/min/kg, p<0.01). However,

in the state of CR, total glucose uptake significantly increased in group A, reaching the levels detected in healthy controls (A: 5.95 ± 0.10 vs B: 6.78 ± 0.25 mg/min/kg, $p = \text{NS}$).

Conclusion: Our results have demonstrated that in recent-onset T1D patients, the state of CR was associated with an increase in regulatory CD4+CD25+ and CD4+ CD45RA+ T cell subsets and in insulin sensitivity levels. The results imply that the appearance of the CR might be influenced by both immunological and metabolic phenomena, i.e. by the increase in the number of the suppressor subsets of the CD4+ T lymphocytes as well as by the improvements in insulin sensitivity.

Higher serum dipeptidyl peptidase-4 activity in type 1 diabetes mellitus than in type 2: a direct comparison

T. Varga, A. Somogyi, G. Nagy, Z. Tulassay, L. Selmei, G. Firneisz
2nd Department of Internal Medicine, Semmelweis University, Budapest, Hungary

Background and aims: Serum dipeptidyl peptidase-4 (DPP-4, CD26) has an important role in the carbohydrate metabolism with the degradation of the entero-hormones (gastric inhibitory polypeptide /GIP/, glucagon-like peptide-1 /GLP-1/). Certain studies implicate that type 2 diabetic (T2DM) patients have impaired incretin effect. The function of the entero-insular axis might be influenced by the enzymatic activity of the DPP-4 through the degradation of both incretin hormones. Soluble CD26 has been identified as an activation marker in immune cells which can modulate *in vitro* T-cell proliferation. Serum DPP-4 levels are altered in different autoimmune diseases. The present study was designed to assess serum both the fasting and postprandial DPP-4 activity in patients with type 1-(T1DM), type 2(T2DM) diabetes and healthy controls.

Materials and methods: A cross sectional study of 87(F/M=47/40) patients with T2DM, 41(F/M=17/24) with T1DM and for comparison sex- age- and BMI-matched 25(F/M=15/10) healthy volunteers was performed. Fasting serum DPP-4 activity was assessed in all the 153 subjects. Postprandial serum DPP-4 enzyme activities were also determined at 60 min and 180 min periods after test meal (50g carbohydrate+24g protein+12g fat = 410 kcal) in 50 patients(15 type 1- 17 type 2 diabetic and and 18 healthy individuals) out of 153 subjects. Serum DPP-4 activity was measured by microplate-based (Multiskan-Plus-MKII, LabSystem at 405 nm, 25°C for 30 min) kinetic assay. Gly-Pro-pNA (Bachem, Bubendorf, Switzerland) was used as substrate. Results are expressed in nmol/ml/min (U/L) pNA hydrolysis.

Results: There was no increase after test meal in serum DPP-4 activities in any of the groups studied (type 1-, type 2 diabetes, healthy control(CNTRL)). However we experienced significant increase(T1DM vs CNTRL $p < 0.0075$; T1DM vs T2DM $p < 0.0001$) in the fasting serum DPP-4 enzyme activity in **type 1 diabetes (29.065 (95%CI:27.30-30.826))** compared not only to **healthy individuals (25.64 (95%CI:24.348-27.430))** but also in comparison with **type 2 diabetes(24.10 (95%CI:22.75-25.46))**. There was neither difference in the fasting plasma glucose (T1DM: mean= $9.2 \text{ mmol/L} \pm 3.91$, T2DM: mean= $8.1 \text{ mmol/L} \pm 3.037$) nor in the HbA1c mean values (T1DM: mean= $7.80\% \pm 1.574$); (T2DM: mean= 7.47 ± 1.569) between the two diabetic groups.

Conclusion: We concluded that not the hyperglycaemia, rather the type of diabetes determines the the serum DPP-4 enzymatic activity. The increased serum DPP-4 enzyme activity in type 1 diabetes, may be the cosequence of the autoimmune process itself, hormonal feed back mechanism or the endothelial damage. Serum DPP-4 as an activation marker of the immune cells (T- lymphocytes) may be an indicator of the autoimmune inflammation in the pancreas. Furthermore the increase in the serum DPP-4 activity may even be a result of a concomitant autoimmune disorder such as the Basedow-Graves disease. The diagnostic accuracy of the serum DPP-4 activity determination is limited by its highly aspecific alterations, therefore in T1DM the enzyme activity alone maybe insufficient for the discrimination from the T2DM. However the increase in fasting serum DPP-4 enzyme activity presented here in patients with T1DM may call for further studies on the potential extension of the indications of the DPP-4 inhibitor treatment, especially because these drugs demonstrated beta-cell protective properties in certain experimental animal studies in diabetes.

Supplemental islet infusions restore insulin independence after graft dysfunction in islet transplant recipients

A. Koh, S. Imes, J. Shapiro, P. Senior
Clinical Islet Transplant Program, University of Alberta, Edmonton, Canada

Background: Previous reports suggest that the success of supplemental islet infusions (SII) to restore insulin independence in islet transplant recipients with graft dysfunction was due to the use of exenatide. However, recent use of more potent induction therapies and intensive peri-transplant anticoagulation and metabolic control has led to improved islet transplant outcomes. We sought to determine whether SII alone using current protocols is effective to restore insulin independence in islet transplant recipients with graft dysfunction.

Methods: Ten previously insulin-independent subjects who had resumed insulin therapy because of graft dysfunction (fasting glucose > 7 mmol/L and/or post-prandial glucose > 10 mmol/L; and/or C-peptide : glucose < 0.06 nmol/mmol) received a single SII. One subject received a second SII. Induction therapy was with thymoglobulin plus etanercept ($n=7$) or daclizumab (Edmonton protocol, $n=3$) . All subjects received intensive peri-transplant management with intravenous heparin and insulin infusions for 48 hours. Maintenance immunosuppression consisted of tacrolimus plus either sirolimus or cellcept.

Results: SII was performed 49.3 (34.5 - 57.8) months (median with inter-quartile range) after the preceding islet transplant. Subject characteristics are summarized in Table 1.

Table 1: Subject Characteristics

Gender (M/F)	7/3
Duration of insulin independence prior to SII (months)	15.9 (14.0 – 23.3)
Pre-SII Fasting glucose (mmol/L)	8.1 (7.6 – 9.8)
Pre-SII 90-min glucose after mixed meal (mmol/L)	15.2 (11.7 – 19.8)
Pre-SII Fasting C-Peptide/Glucose (nmol/mmol)	0.04 (0 – 0.09)
Pre-SII Mixed meal Stimulated C-Peptide/Glucose (nmol/mmol)	0.05 (0.03 – 0.09)
Pre-SII Insulin use (units/kg/day)	0.38 (0.27 – 0.48)
Pre-SII HbA1c(%)	7.0 (5.9 – 7.6)

Subjects received an islet mass of 5493 (4951 - 6134) IEQ/kg for the SII vs. 8787 (6661 - 12427) IEQ/kg with their initial transplant(s) ($p = 0.059$). Nine of the 10 subjects became insulin independent 2.7 (1.5 - 4.3) months after SII. After a follow-up period of 17.3 (10.1 - 20.8) months, insulin independence has been maintained in 8 of the 9 subjects. Only 1 subject has returned to insulin use to date, after 14.7 months of insulin independence. The duration of insulin independence following SII has already exceeded that of the initial transplant(s) in 2 subjects. All subjects have maintained good glycemic control after SII as indicated by current fasting glucose 6.1 (5.7 - 6.6) mmol/L, and 90-min glucose after mixed meal 7.4 (6.1 - 8.3) mmol/L. The peak mix meal stimulated C-peptide:glucose ratio after SII was 0.31 (0.25 - 0.37) nmol/mmol, indicating excellent islet graft function.

Conclusion: Using current potent induction and intensive peri-transplant therapies, SII alone with a relatively small islet mass is effective to achieve impressive insulin independence rates. Longer follow-up will be required to confirm the durability of insulin independence achieved in this study.

Perfluorocarbons, a new tool for the preservation of pancreatic islets *in vitro*

E. Maillard¹, M. Sanchez Dominguez², C. Kleiss¹, M.-C. Sencier¹, A. Langlois¹, W. Beitiger¹, C. Vodouhe¹, M.-P. Krafft², M. Pinget¹, A. Belcourt¹, S. Sigris¹

¹Laboratoire de recherche, Centre Européen d'Etude du Diabète, ²CNRS UPR22, Institut Charles Sadron, Strasbourg, France

Background and aims: Pancreatic islets transplanted to treat type 1 diabetes often fail to function likely because of islets hypoxia. Perfluorocarbons

(PFCs) have a high oxygen solubility coefficient and maintain high oxygen partial pressures for extended time. They serve also as oxygen “reservoirs” for harvested organs in pancreas organ transplantation. The use of oxygen carriers as perfluorocarbons could reduce islets loss. The aim of this study was to test whether the use of PFCs could be beneficial for the secretory activity and overall viability of cultured purified islets before transplantation.

Materials and methods: Purified rat islets were cultured in static conditions for 1, 3 or 5 days with or without emulsion of PFCs 10% (v/v) saturated or not with oxygen. Cell death and apoptosis were assessed by Fluorescein Diacetate/Propidium Iodide and Hoechst staining and by the measure of Bax, Bcl-2 mRNA expression using RT-PCR. Insulin secretion was measured by ELISA and expressed as stimulation index. Hypoxia was evaluated by the study of VEGF, Matrix Metalloproteinase-2 and Matrix Metalloproteinase-9 expression using RT-PCR, western blotting, immunohistochemistry and ELISA.

Results: Study of islet viability demonstrated no toxicity of the treatment during the experiment, whereas there was a significant increase of Bcl-2 mRNA expression in islets incubated in PFCs emulsions (1.28 ± 0.3 vs 0.36 ± 0.1 ; $p < 0.001$; $n = 3$) and a significant decrease of Bax mRNA expression (0.5 ± 0.2 vs 0.9 ± 0.07 ; $p < 0.05$; $n = 3$) after 24 hours of culture. Moreover, there was a preservation of islets functionality in the presence of PFCs during the experiment, while a decrease of this functionality was observed in culture medium alone (2.78 ± 0.54 ; 1.46 ± 0.07 and 1.15 ± 0.56 ($p < 0.01$) after 1, 3 and 5 days respectively). The study of hypoxia showed a decrease of VEGF mRNA expression with oxygenated PFCs (0.49 ± 0.15) as compared to control (0.75 ± 0.19 ; $p < 0.05$; $n = 5$). The analysis of protein expression showed a decrease of VEGF secretion with oxygenated PFCs after 2 and 3 days of culture ($0.05 \pm 0.03 \mu\text{g}$ of VEGF/mg of protein vs $0.44 \pm 0.12 \mu\text{g}$ of VEGF/mg of protein for control; $p < 0.001$; $n = 3$). In agreement with these results, MMP-2 secretion of PFCs incubated islets was decreased in comparison to control (0.05 ± 0.03 versus $0.13 \pm 0.06 \text{ pg}$ of MMP-2/mL) after 1 and 3 days of incubation. Finally immunohistochemistry studies showed that this decrease of hypoxia was linked to a preservation of islet structure in the presence of PFC. In contrast, without PFCs, a disruption of islets and fibrosis was observed.

Conclusion: Our results suggested that PFCs are very useful to fight against hypoxia. Thus, the use of PFC emulsions in the culture may provide advantage over conventional protocols to preserve islets before transplantation.

Metabolic effect of sirolimus versus mycophenolate mofetil on pancreatic graft function - a prospective randomised study

T. Havrdova¹, F. Saudek¹, P. Boucek¹, K. Lipar², R. Koznarova¹, T. Jedinakova¹, J. Skibova³

¹Diabetes Center, ²Transplant Center, ³Statistical Department, Inst Clin Exp Medicine, Prague, Czech Republic

Background and aims: Metabolic effects of immunosuppressive agents are of great importance in pancreas or islet transplantation. The aim of our study was to compare glucose metabolism in Type 1 diabetic recipients of kidney and pancreatic grafts on tacrolimus-based immunosuppression in conjunction with sirolimus (RAPA) or mycophenolate mofetil (MMF) in a prospective randomised study.

Materials and methods: The investigation was performed in 32 insulin-independent rejection-free patients after simultaneous pancreas and kidney transplantation (with systemic venous drainage of pancreatic graft) at 2 occasions: at 0.6 ± 0.2 [mean \pm SD] month post-transplant (with steroid dose 11.6 ± 3.91 mg/day) and subsequently at 22.1 ± 10.67 months (steroid-free). All recipients had a good function of the kidney graft. Fasting glycemia, insulin and C-peptide levels, HbA_{1c}, IVGTT with K_G-calculation were assessed in both groups. Insulin sensitivity was evaluated by HOMA-IR. Areas under the insulin/C-peptide curves during the IVGTT (AUC-IRI, AUC-CP) were used as the parameters of insulin/C-peptide secretion.

Results: The RAPA and MMF groups did not differ in age, BMI, post-transplant period and steroid daily dose. Trough levels of tacrolimus had no significant impact on any of examined parameters. K_G and HOMA-IR of whole study group significantly improved between the exams (1.03 ± 0.4 vs. 1.35 ± 0.54 , $p < 0.01$ and 3.57 ± 2.32 vs. 2.42 ± 1.7 , $p < 0.05$, respectively). We found the significant differences between the groups in AUC-CP and K_G values after steroid withdrawal.

Conclusion: Glucose tolerance measured with the use of IVGTT significantly improved due to better insulin sensitivity after steroid withdrawal in whole study group. Stimulated insulin production did not changed during our study. Parameters of glucose metabolism in steroid-free period (K_G and AUC-CP) were more favourable in patients treated with MMF than in recipients treated with RAPA.

Successful combined pancreas kidney transplantation in type 1 diabetic patients: normal intrahepatocellular and -myocellular lipid content despite systemic venous drainage

M. Anderwald-Stadler^{1,2}, C. Anderwald³, S. Zbyn⁴, G. Pacini⁵, M. Promintzer³, M. Mandl³, M. Bischof³, S. Gruber⁴, P. Nowotny³, A. Luger³, R. Prager^{1,2}, M. Krebs³

¹3rd Medical Department of Metabolic Diseases and Nephrology, Hietzing Hospital Vienna, Austria, ²Metabolic Diseases and Nephrology, Karl Landsteiner Institut, Vienna, Austria, ³Department of Internal Medicine III, Division of Endocrinology and Metabolism, Medical University Vienna, Austria, ⁴NMR Center of Excellence, Medical University Vienna, Austria, ⁵Metabolic Unit, ISIB-CNR, Padova, Italy

Background and aims: Insulin replacement in Type 1 diabetes mellitus (T1DM) is usually performed via a systemic (subcutaneous) instead of the physiologic portal route. So far it is unclear whether this systemic route of insulin delivery might contribute to metabolic defects in these patients. This hypothesis is supported by the finding that T1DM is associated with decreased intrahepatocellular and increased intramyocellular lipid content. Successful pancreas kidney transplantation (PKT) with systemic venous drainage is an ideal model of optimized systemic insulin therapy resulting in systemic hyperinsulinemia and relative portal hypoinsulinemia. Therefore, the aim of the present study was to investigate the effects of PKT on intracellular lipid distribution and insulin sensitivity.

Materials and methods: A 3-hour 75g-oGTT was performed in 9 T1DM patients after successful PKT ($26 \pm 1 \text{ kg/m}^2$, 50 ± 3 yrs, 4 f/5 m) with systemic venous drainage, thus reversed to nondiabetic state (basal glucose $99 \pm 3 \text{ mg/dl}$,

Stimulated AUC-CP (pmol/mL/60min.)	50.2 ± 25.3	43.7 ± 20	70.6 ± 31.4	59.5 ± 20.0 ($p < 0.05$ vs. b)
HOMA-IR	2.8 ± 1.8	2.2 ± 1.2	4.2 ± 2.5	2.7 ± 2.0

HbA1c $5.4 \pm 0.1\%$) and in 9 matching nondiabetic controls (CON) (26 ± 1 kg/ m^2 , 53 ± 3 yrs, $3f/6m$, 92 ± 3 mg/dl, $5.6 \pm 0.1\%$) to assess plasma concentrations of glucose, free fatty acids (FFA), insulin and C-peptide. Whole body insulin sensitivity was calculated from oGTT using the clamp-like insulin sensitivity index (CLIX). Fasting endogenous glucose production (EGP) was measured using DD-glucose tracer dilution. Intracellular lipid content of the liver (IHCL) and the soleus muscle (IMCL) was non-invasively measured using 1H -nuclear-magnetic-resonance spectroscopy.

Results: Fasting concentrations of insulin and C-peptide were markedly higher in PKT vs. CON (insulin: 17 ± 3 vs. 9 ± 2 μ U/ml; C-peptide: 3.0 ± 0.4 vs. 2.2 ± 0.3 nmol/l; both $p < 0.02$), while fasting glucose and FFA and areas under concentration curves of insulin, C-peptide, glucose and FFA were similar. IHCL (PKT: 2.9 ± 1.0 ; CON: $4.4 \pm 2.5\%$) and IMCL (PKT: 1.0 ± 0.2 ; CON: $1.0 \pm 0.2\%$), CLIX and EGP were comparable between in PKT and CON.

Conclusion: Despite systemic hyperinsulinemia, T1DM after successful PKT exhibit unchanged intracellular lipid content of liver and skeletal muscle, whole body insulin sensitivity and EGP in comparison with age- and BMI-matched non-diabetic controls. Thus, this study (which for the first time evaluated IHCL and IMCL in PKT) indicates that systemic insulin substitution does not cause alterations or intracellular lipid distribution or of insulin sensitivity.

Neuropathy assessment in type 1 diabetic patients after islet transplantation

M.-C. Vantyghem^{1,2}, J.-F. Hurtevent³, F. Faivre-Defrance⁴, V. Raverdy¹, T. Hubert¹, M. Hazzan⁵, J. Kerr-Conte¹, C. Noel⁵, F. Pattou¹

¹INSERM U859, ²Endocrinology and Metabolism Department, ³Neurophysiology Department, Endocrinology and Metabolism Department, ⁴Lille University Hospital, Nephrology Department, Lille, France

Background and aims: The benefits of islet transplantation in type 1 diabetic patients should be weighed against the potential side effects of immunosuppressive drugs. The aim of this study was to assess whether islet transplantation (Tx) was able to stabilize neuropathy (NP) in type 1 diabetic patients with or without kidney graft.

Patients and methods: From 2003 to 2007, 24 type 1 diabetic patients aged 44 ± 7 years, weighing 72 ± 9 kg received 2 to 3 islet infusions during a period of 3 (n=20) to 6 months (n=4). The 24 patients were divided in 2 groups: 14 having received islet transplantation alone (ITA) and 10 islet-after-kidney transplantation (IAK) with a mean time between kidney and islet graft of 22 ± 9 months. The immunosuppressive regimen included daclizumab, tacrolimus, and sirolimus. An electromyogram with study of sensory and motor potentials of the 4 limbs was performed before islet transplantation (and after kidney graft for IAK), and then yearly in the 23/24 patients having a distance of at least 1 year from first islet transplantation (14 ITA + 9 IAK), whatever blood C-peptide level. At the last assessment, 20/23 patients had a detectable blood C-peptide level, 10/23 received insulin, and 16/23 patients had HbA1c level below 6.5 %.

Results: Before transplantation, 6/14 ITA and 8/9 IAK patients showed a NP and 8/14 ITA and 1/9 IAK no neuropathy. One to 4 years after transplantation, an improvement of NP was observed in 3/6 ITA and 4/8 IAK patients suffering from NP before transplantation. A steadiness was noticed in the 7 other patients suffering from NP (3 ITA and 4 IAK) before transplantation. No deterioration was noted in the 8 ITA and in the unique IAK patient without NP before transplantation. A significant improvement of the mean sensitive nerve conduction velocity of the upper (pre Tx 46.7 ± 9.8 vs post Tx: 51.2 ± 7.9 m/s; $p < 0.02$) and lower (pre Tx: 41.6 ± 5.4 vs post Tx: 46.3 ± 7.8 m/s; $p < 0.01$) limbs was observed. Nevertheless it did not significantly correlate with one-year blood C-peptide, anti-GAD auto-antibodies, tacrolimus, sirolimus, and HbA1c levels despite a trend toward a positive correlation between HbA1c and sensitive nerve conduction velocity. Discussion: DCCT study has demonstrated that optimized insulin therapy could prevent occurrence of NP (1995) and improve subclinical forms (2007). An improvement of electrophysiologic scores in IAK patients has also been shown (Del Carro, Diabetes Care 2007).

Conclusion: Our results suggest that islet transplantation allows not only to prevent, but also to improve established NP. Indeed 1) An improvement of the NP shown by electromyogram was demonstrated in 7/14 patients (50%) initially suffering from NP one to 4 years after islet transplantation; 2) The

same efficiency was observed in ITA and IAK patients; 3) Despite the potential neurotoxicity of immunosuppressive drugs, no deterioration was noticed in patients with no neuropathy before transplantation.

Does pancreas transplantation in type 1 diabetes reduce the progression of foot pathology leading to amputation?

J. Aron-Wisniewsky¹, M.-L. Tanguy², B. Barrou³, A. Harteman-Heurtier¹

¹Diabetology, ²Biostatistic, ³Transplant Surgery, Pitie-Salpetriere hospital, Paris, France

Background and aims: Simultaneous pancreas-kidney transplantation (SPKT) has become the therapy of choice in patients with type 1 diabetes mellitus with end stage renal disease as it improves patient survival and quality of life. Moreover stabilization or even reversion of diabetic microvascular complications is known to be achieved after SPKT. But little is known about its effect on foot complications. The aim of our study was to evaluate the outcome of successful SPKT on foot pathology.

Materials and methods: A retrospective single center review was made of all the simultaneous pancreas kidney transplants performed in type 1 diabetes patients between January 1989 and April 2006 with a follow up of at least one year. Mono and multivariate statistical analysis were conducted to identify foot complication's risk factors. Differences between the group of patients with a functioning graft and those who rejected it were tested with a chi-squared test.

Results: 69 patients, mean age at transplantation 37 ± 7 years, mean duration of diabetes 24 ± 7 years, mean HbA1c $9.2 \pm 2.4\%$, mean duration of dialysis prior to the transplant of 18 ± 14 months, were followed for a mean period of 9.3 ± 4.1 years. At inclusion, 100% of our cohort suffered from peripheral neuropathy complication and 20% had peripheral vascular disease. At the end of the follow up period, 30 patients developed at least one foot lesion (annual incidence of 5%) and 16 patients suffered from either a lower limb or toe amputation (amputation rate 23%). Peripheral disease prior to transplantation was the only significant risk factor of foot lesions after SPKT ($p < 0.04$) and pretransplant history of foot lesions was the only significant risk factor of amputation after SPKT ($p = 0.008$).

Conclusion: From our results, transplanted patients have the same risks than diabetic patients with peripheral neuropathy (grade 1) with regards to foot problems. We conclude that simultaneous pancreas kidney transplantation fails to halt or reduce the progression of foot complications. We suggest that even after successful pancreas transplantation, patients should continue to benefit from close lower limb medical supervision.

Islet and pancreas transplantation alone: one center short-term results

P. Gorman¹, M. Mindlova¹, Z. Berkova¹, T. Koblas¹, K. Zacharovova¹, L. Pektorova¹, E. Dovolilova¹, E. Vavrova¹, R. Koznarova¹, V. Bobek¹, M. Adamec², K. Lipar², F. Saudek²

¹Diabetes Center, ²Transplantation Surgery, IKEM, Prague, Czech Republic

Background and aims: Pancreas transplantation alone (PTA) is an established approach in the treatment of selected non-uremic Type-1 diabetic patients with hypoglycemia unawareness syndrome. Recently, transplantation of pancreatic islet (ITx) was introduced in our center as an alternative method for the same indication. The aim of the study was to compare the short-term safety and efficacy of both procedures in terms of patient and graft survival rates metabolic control and the rate of complications.

Materials and methods: From 1998 to 2007 27 PTA (and 4 re-transplantations) and 14 ITx were performed in 31 and 8 type-1 diabetic recipients with hypoglycemia unawareness syndrome, respectively. Pancreas was placed extraperitoneally with systemic venous anastomosis and either with enteral or bladder pancreatic duct drainage. Islets were isolated from pancreases distended by Liberase and purified in COBE 2991. Patient survival, graft function, complications and metabolic control were compared at 6 month after transplantation and after the last infusion of islets.

Results: Survival of patients was 100% at 6m in both groups. At the time of follow-up 70% (19/27) patients with PTA and 13% (1/8) after ITx were insulin-free. 29% (8/27) patients after PTA lost their grafts early after transplantation due to thrombosis (5) rejection (2) and bleeding (1). In ITx group 1 patient had primary non-function, in the others insulin daily dose (\pm SD)

decreased significantly from 31 ± 5 to 13 ± 6 IU/day. In comparison with the ITx group (21%), the PTA group had a high rate of serious complications (62%). The mean values (\pm SD) of HbA1c were 3.3 ± 0.7 and $5.4 \pm 0.6\%$ in PTA and ITx recipients, respectively (normal value $<4.2\%$).

Conclusion: PTA immediately restored normal glucose metabolism in the majority of diabetic recipients. More than a half of the recipients experienced surgical or other serious adverse event. ITx itself did not lead to insulin independence in most of patients. However, it stabilized glucose control close to the normal range and eliminated the episodes of severe hypoglycemia. Here we present our first clinical results with islet transplantation which, of course, need further improvement.

The direct effects of immunosuppressive drugs on isolated human islets

M. Bugliani, M. Masini, R. Lupi, S. Del Guerra, M. Galli, V. D'Aleo, F. Filippini, S. Del Prato, U. Boggi, F. Mosca, P. Marchetti
Dept. Endocrinology and Metabolism, Metabolic Unit, University of Pisa, Italy

Background and aims: The use of immunosuppressive drugs is associated with the development of diabetes, possibly due to beta-cell toxicity. To better understand the mechanisms responsible for these effects, we investigated the actions of prolonged exposure of isolated human islets to therapeutical levels of tacrolimus (Tac) or cyclosporin A (CsA).

Materials and methods: Islets were isolated from the pancreas of 16 multiorgan donors (age: 63 ± 14 yrs; gender: 10M/6F; BMI: 25.1 ± 3.7 kg/m²) by enzymatic digestion and density gradient centrifugation. Functional, survival and molecular studies were then performed after 96hr incubation with 10 ng/ml Tac or 150 ng/ml CsA.

Results: Glucose-induced insulin secretion was significantly decreased in Tac ($p < 0.05$), but not in CsA exposed islets, (stimulation index, i.e. the ratio of insulin release at 16.7 vs 3.3 mM glucose: control islets, Ctrl, 2.3 ± 0.5 ; Tac 1.6 ± 0.2 ; CsA, 2.0 ± 0.4). Electron microscopy (EM) showed a significant ($p < 0.05$) decrease of insulin granules in Tac exposed beta-cells (volume density, ml%: 0.63 ± 0.39), but not in the CsA group (1.55 ± 0.01), as compared to Ctrl (1.54 ± 0.09). The percentage of apoptotic beta-cells was higher in Tac (11.7 ± 4.7) than Ctrl (2.7 ± 1.2) (the respective value in CsA was 6.31 ± 2). Microarray analysis (Affymetrix) showed that of the 22,215 probe sets present on the HG U133A chip, 94 and 60 were significantly ($p < 0.05$) altered in Tac and CsA, respectively. In the Tac group, 23 genes were upregulated and 71 downregulated: among them, 5 were associated with apoptosis, 4 with cell proliferation, and 6 with transcription pathways. In the CsA group, 23 genes were upregulated and 37 were downregulated, with 2 regarding apoptosis and 7 transcription phenomena. Compared to Tac, microarray of CsA treated islets showed 78 upregulated and 51 downregulated genes, of which 6 regarded apoptosis, 8 cell proliferation and 12 transcription pathways. FKBP 12.6, a key gene involved in calcineurin inhibition, was significantly less expressed with CsA than Tac, as shown by quantitative RT-PCR.

Conclusion: In conclusion, CsA had less deleterious effects on isolated human islets, possibly due to a lower influence on gene expression.

Effectiveness of exenatide as a potent anti-rejection therapy for islet cell allo-transplantation in the non-human primate

J.L. Buss¹, A. Rajab¹, E. Diakoff², K. Osei²

¹Surgery, The Ohio State University, Columbus, ²Endocrinology, Diabetes and Metabolism, The Ohio State University, Columbus, United States

Background and aims: The use of islet cell transplantation in the treatment of type 1 diabetes has shown promising results. However, numerous limiting factors such as islet availability, early death of islets post-transplant and ineffective immunosuppressive regimens have continued to prevent islet cell transplantation from becoming more widely used clinically. Exenatide is an incretin mimetic and has demonstrated a wide range of beneficial effects on islet beta cells. Among these are protection from apoptosis, improved insulin production in response to glucose and promotion of beta cell regeneration. We propose that the beneficial effects of Exenatide will make it an effective *in vivo* treatment for islet cell allo-transplantation and that Exenatide alone may even be sufficient to protect islet allografts from rejection.

Materials and methods: Diabetes was induced in the non-human primate, *Macaca fascicularis* by total pancreatectomy. Islets were isolated following the procedure for human islet isolation and transplanted into the portal vein ($11,096 \pm 6996$ IEq/kg). Group 1 (N=3) received islet allografts and were treated with Exenatide alone (5µg bid) days -2 - 90. Group 2 (N=5) received islet allografts and were treated with rabbit anti-thymocyte globulin (1.5mg/kg) and prednisone on days 0-3 and cyclosporine (25mg) and mycophenolate mofetil (250mg) days 0-90. Group 3 (N=5) received islet allografts and were treated with the same regimen as Group 2 plus Exenatide (5µg bid) on days -2 - 90. Finally, Group 4 (N=2) received islet allografts with no immunosuppressive treatment. Blood glucose was monitored daily for the first month post-transplant and weekly thereafter. Intravenous glucose tolerance tests were performed on days 0, 28 and 90, and glucose disappearance rate constants (k_g) at 10-30 min were determined.

Results: Blood glucose monitoring indicated that all animals in Groups 1-3 (islet allografts with Exenatide and/or immunosuppression treatment) remained normoglycemic for at least 90 days post-transplant with an average blood glucose of 51.2 ± 26.0 mg/dl. Blood glucose for animals receiving islet allografts and Exenatide treatment alone (Group 1) at 90 days post-transplant was 47.7 ± 7.23 mg/dl, indicating functional islet grafts despite a lack of conventional immunosuppression in these animals. One animal in Group 4 (allograft + no treatment) showed immediate rejection of the islet graft with blood glucose levels rising to >200 mg/dl by day 2 post-transplant.

ivGTTs post-transplant showed normal responses in animals from Groups 1-3 in both blood glucose and serum insulin levels. In fact, serum insulin levels were notably higher in Group 1 than in any other group (Figure 1). Additionally, there was not a significant difference in the k_g (%/min) for allograft recipients plus Exenatide alone before and after transplant (6.73 ± 3.49 vs. 4.48 ± 3.68 , $p=0.34$).

Conclusion: We conclude that Exenatide appears to be an effective *in vivo* anti-rejection treatment in islet allo-grafts in the non-human primate. Despite a lack of conventional immunosuppressive treatment in animals treated with Exenatide alone, islet allografts showed no signs of rejection and, in fact, demonstrated increased insulin production compared to animals not receiving Exenatide. The mechanisms of the anti-rejection properties of Exenatide remain to be elucidated.

Effects of IL-1 on the revascularization of islet grafts

O. Castaner, N. Tellez, E. Estil·les, G. Joanny, J. Escoriza, E. Montanya
Lab. Diabetes and Experimental Endocrinology, University of Barcelona, Endocrine Unit, Hospital Universitari de Bellvitge; IDIBELL; CIBERDEM, L'Hospitalet de Llobregat, Spain

Background and aims: In the initial days after islet transplantation, a non-specific inflammatory process takes place at the grafted site, and contributes to the initial damage of transplanted islets and to early graft failure. The inflammation involves the expression of pro-inflammatory cytokines, among

them IL-1 β . We have recently shown that the blockade of IL-1 action by IL-1 receptor antagonist protein (IL1RN) improved the metabolic outcome of the recipients, that achieved consistent normoglycaemia despite the transplantation of a borderline beta cell mass (800 islets). These results supported the deleterious role of IL-1 expression on islet grafts and the potential therapeutic value of IL1RN. In experimental tumor models, IL-1 β has increased endothelial migration and proliferation, and modulated angiogenesis, and IL-1 receptor antagonism has shown anti-angiogenic effects. IL-1 could therefore play a role on the revascularization of islet grafts. We aimed to determine whether the over expression of IL1RN in transplanted islets, modifies the revascularization of islet grafts.

Materials and methods: Islets from Lewis rats were infected *ex vivo* with an adenovirus encoding for IL-1 receptor antagonist (Ad-*Il1rn*). Streptozotocin-diabetic Lewis rats were syngeneically transplanted with 500 or 1200 Ad-*Il1rn* infected (Ad-*Il1rn* group) or uninfected islets (control group) under the kidney capsule. 500 islets are a clearly insufficient mass to restore normoglycaemia, and we expected that all animals would remain hyperglycaemic, after transplantation. In contrast, 1200 islets are a sufficient mass to restore normoglycaemia. The islet grafts, harvested on days 10 and 28 after transplantation, were double stained with the lectin Griffonia simplicifolia, which binds to α -galactosyl and N-acetylgalactosaminyl terminations, expressed on the surface of the rat's endothelial cells, and with an insulin antibody. Vascular density was determined by point counting morphometry.

Results: As expected, rats transplanted with 500 islets remained hyperglycaemic throughout the study (Ad-*Il1rn* group: 20.1 ± 1.83 ; control group: 21.03 ± 1.19 mmol/L). All animals showed similar hyperglycemia ensuring comparable metabolic conditions among groups. Normoglycaemia was achieved in the recipients of 1200 islets (day 30: Ad-*Il1rn* group: 5.47 ± 0.11 ; control group: 5.81 ± 0.18 mmol/L). On day 10 after transplantation, the vascular density was lower in the 500-islet Ad-*Il1rn* group than in the control group (5.96 ± 0.7 vs $11.8 \pm 3.0\%$, $p < 0.05$). On day 28 after transplantation, vascular density in the Ad-*Il1rn* group was higher than on day 10 ($13.3 \pm 0.9\%$ $p < 0.01$), and similar to the control group ($13.2 \pm 2.6\%$). In normoglycaemic 1200-islet grafts, the vascular density was determined on day 30 after transplantation, and was also similar in Ad-*Il1rn* and control groups (15.4 ± 0.9 vs $12.5 \pm 2.4\%$).

Conclusion: The over expression of IL-1 receptor antagonist protein in transplanted islet grafts inhibited the initial revascularization of the graft. The inhibition of angiogenesis was observed as a delay, as vascular density increased subsequently and reached similar values to those of control islet grafts, both in normoglycaemic and in hyperglycaemic recipients. Our results suggest that, the initial expression of IL-1 may enhance the revascularization of the graft in islet transplantation.

Muscle-targeted gene therapy for the treatment of diabetes mellitus: investigating the role of the immune system when employing mutant (pro)insulin plasmids

S.J.M. Niessen^{1,2}, A. Mahmoud², A. Aldibbiat², C. Huggins³, D.B. Church¹, J.A.M. Shaw²

¹Department of Veterinary Clinical Sciences, Royal Veterinary College, University of London, Hatfield, ²Diabetes Research Group, Newcastle University, ³Comparative Biology Centre, Newcastle University, United Kingdom

Background and aims: The tight glycaemic control required to prevent microvascular complications without limiting hypoglycaemia in Type 1 and 2 diabetes is difficult to attain using conventional subcutaneous insulin therapy. Alternative approaches have therefore been pursued. Muscle-targeted gene therapy (MTGT) employing (pro)insulin constructs is promising and provides possible cost-effective off-the-shelf treatment for diabetes. However, uncertainty still remains over the influence of the immune system on this type of treatment, especially in view of currently encountered 10-fold decreased levels of efficiency with mutant proinsulin constructs designed to yield fully processed insulin, compared to wild-type constructs. This study aimed to assess the influence of immune system on efficacy of MTGT with wild-type (hppI1) and mutant furin-cleavable (hppI4) human proinsulin constructs or β -galactosidase reporter gene (β -gal) (all subcloned in pVR1012 plasmid).

Materials and methods: After injection of 10U hyaluronidase, tibialis anterior muscles in 9 male CD-1 mice and 9 male SCID (immunodeficient) mice were injected with 50 μ g pVR1012-hppI1 (n=3 each group), -hppI4 (n=3), - β -gal (n=2) or 50 μ l saline (n=1), followed by electroporation (8 pulses, 200V/

cm, 20ms, 2Hz). Blood samples for glucose, human (pro)insulin and C-peptide estimation were obtained at set time points, as were muscles for histology (with insulin and C-peptide immunostaining), human (pro)insulin, C-peptide and β -gal estimation. The same plasmid preparations were used for *in vitro* transfections in the C2C12 murine muscle cell line to ensure adequate functioning of these plasmids, with subsequent RT-PCR to prove preproinsulin expression.

Results: Blood glucose and body weight was not affected in any animal. Serum human proinsulin was 35.1 ± 10.2 and 35.3 ± 21.2 pmol/l (mean \pm SD) at 2 and 7 days post gene-transfer in hppI1-injected CD-1 mice and 29.8 ± 15 and 37 ± 7.4 pmol/l in hppI1-treated SCID mice. Human insulin was undetectable in either group. Although expression was confirmed by insulin and C-peptide immunostaining of muscle sections, no significant serum human proinsulin, insulin or C-peptide concentrations were detected following hppI4 gene transfer in CD-1 or SCID mice. β -gal activities in muscle homogenates of β -gal transfected mice were 3.3 ± 0.3 (CD-1) and 0.34 ± 0.05 (SCID) U/ μ l.

In vitro transfection studies revealed adequate functioning of the employed plasmids with significant proinsulin in hppI1 (medium: 328 ± 52 , lysate: 18.2 ± 6.9 pmol/l), insulin in hppI4 (medium: 16.4 ± 4.4 , lysate: 8.7 ± 6.8 pmol/l) and β -gal activity (52.8 ± 2.0 U/ μ l) in β -gal transfected cells. RT-PCR confirmed preproinsulin expression in hppI1 and hppI4 transfected cells.

Conclusion: Immune responses do not appear to play a significant role in the low insulin levels encountered when employing mutant furin-cleavable proinsulin plasmids for MTGT. Absence of significant C-peptide demonstrates that increased metabolism of mature insulin is also not the sole cause. Successful clinical translation will require plasmid refinement and enhancement of gene transfer efficiency.

601

Optimal liraglutide therapy improves engraftment and function of a marginal mass islet transplant in mice

S. Merani¹, W. Truong¹, J.A. Emamaullee¹, C. Toso¹, L.B. Knudsen², A.M.J. Shapiro¹

¹Surgical Medical Research Institute, University of Alberta, Edmonton, Canada, ²Diabetes Research Unit, Novo Nordisk, Måløv, Denmark

Background and aims: The scarcity of high quality deceased pancreas donors prevents widespread application of islet transplantation for treatment of labile type 1 diabetes mellitus. Opportunities for the improvement of current techniques includes optimization of islet isolation and purification, use of culture with pharmacologic insulintropic agents, strategies to reduce graft rejection and inflammation, and the search for alternative insulin producing tissue. Here we report the efficacy of the once-daily human glucagon-like peptide 1 analog, liraglutide, in a mouse model of marginal mass islet transplantation.

Materials and methods: Liraglutide was administered (200 μ g/kg sc) either once or twice daily because it is metabolized more rapidly in mice than in humans. The model used was a marginal mass (250 syngeneic islets/mouse) syngeneic islet transplant in streptozotocin-induced diabetic BALB/c mice.

Results: Time-to-normoglycemia, defined as the first day of sustained post-transplantation normoglycemia was significantly shorter in twice daily liraglutide treated animals versus control (median 1 day vs. 7 days, $p = 0.0003$), even if animals were concurrently administered a daily dose of sirolimus (median 1 day vs. 72.5 days, $p < 0.0001$). However, animals given only a single dose of liraglutide daily, or given a once daily liraglutide plus pantoprazole (to increase serum gastrin levels, administered 50 mg/kg/day ip) did not show improved islet engraftment. Twice daily liraglutide treated animals also demonstrated improved glucose tolerance during intraperitoneal glucose tolerance test (IPGTT).

To investigate the mechanism of action of twice daily liraglutide treatment on islet engraftment, animals were discontinued of liraglutide on post-transplant day 90, which resulted in diminished glucose tolerance during IPGTT. Late start liraglutide therapy at 90 days post-transplant resulted in no improvement in engraftment. These findings suggest that liraglutide therapy mediates both early and late insulintropic effects. Insulin/TUNEL fluorescence microscopy showed reduced transplanted beta-cell apoptosis in liraglutide treated recipients 48 hours post-transplant.

Conclusion: Overall, our data shows that liraglutide has beneficial impact on the engraftment and function of syngeneic islet transplants in mice, when administered continuously starting on the day of transplant.

602

Improved glucose metabolism by islet transplant at periportal site than intraportal site

K. Toyoda¹, T. Okitsu², T. Uonaga¹, X. Liu¹, S. Yamane¹, Y. Seino³, N. Inagaki¹

¹Diabetes and Clinical Nutrition, Kyoto University, ²Transplantation Unit, Kyoto University Hospital, ³Diabetes and Clinical Nutrition, Kansai-Denryoku Hospital, Osaka, Japan

Background and aims: Intraportal site is common in clinical islet transplantation. However, its superiority is not elucidated yet. In terms of glucose metabolism, it should have a drawback because islets are located at the peripheral end of portal vein and insulin acts only on the restricted area of the liver. We, therefore, consider periportal site as another site for islet transplantation, which allows whole liver to be exposed to secreted insulin. Then, we tested the efficacy of periportal site by comparing with intraportal site using mouse islet transplantation model.

Materials and methods: Syngeneic mouse islet transplantation was performed using male C57BL/6 mice. Recipient animals were rendered diabetic by streptozotocin (STZ) and received four hundred islets. Body weight and blood glucose were monitored in the mice of the following four groups; STZ induced diabetic mice receiving islets at periportal site (PP group), those at intraportal site (IP group), those without any islet transplant (STZ group) and sham-operated wild mice (Control group). Oral glucose tolerance test (OGTT) was performed 30 days and 60 days after transplantation and HOMA-IR was calculated.

Results: In both PP and IP group, random non-fasting glucose levels were significantly lower than STZ group after 400 islets transplantation, but it took significantly longer time to get normoglycemia in PP group than IP group (PP 11.2 ± 1.5 , IP 3.5 ± 1.2 (days), $p < 0.01$) (Figure.1). OGTT in PP group showed higher levels of post-load blood glucose than IP and Control group on Day30 and showed similar normal glucose tolerance as IP and Control group on Day60. HOMA-IR on Day60 in IP group was also significantly higher than PP and Control group (both, $p < 0.05$) (Control 1.53 ± 0.15 , PP 1.35 ± 0.10 , IP 2.46 ± 0.35) (Figure.2).

Conclusion: These results indicated that islet transplantation at periportal site was superior in terms of glucose metabolism to intraportal site, although this superiority is limited only after islet transplant became engrafted. The periportal islet transplantation site might enable islet grafts to survive for longer term due to its less stressful condition than intraportal site, and might serve as a possible strategy to increase feasibility of clinical islet transplantation.

IBMIR reaction and macrophage migration: role of the exocrine tissue

S. Sigrist¹, N. Ebel¹, W. Bietiger¹, C. Vodouhe¹, A. Langlois¹, A. Belcourt¹, L. Kessler¹, J. Oberholzer², M. Pinget¹

¹Research laboratory, CeeD, Strasbourg France, ²Division of Transplantation, University of Chicago, United States

Background and aims: After infusion into the portal vein, a substantial percentage of islets are lost in the immediate post-transplant period through an inflammatory response termed the instant blood-mediated inflammatory reaction (IBMIR). Coagulation, platelet aggregation, complement activation, and neutrophil and monocyte infiltration play roles in this reaction. There is also evidence that exocrine contamination may impair the implantation of islet tissue. Our objective was to identify the role of exocrine tissue in the IBMIR reaction and to prevent these reactions using several anti-inflammatory strategies.

Materials and methods: The culture mediums conditioned for 48 hours by rat pancreatic islets were incubated with peritoneal murine macrophages to study their migration. Chemotaxis was evaluated using the Boyden chamber and expressed as the chemotactic index. To validate that the Boyden chamber mimics the IBMIR, we developed 3 models: syngenic model was realized with Lewis rat, allogenic with Lewis rat and xenogenic with human pancreatic islet and Lewis rat macrophages. To understand the role of exocrine tissue on IBMIR, we have exposed macrophages to several purities of islet supernatant from 90% to 1%. Finally, to modulate inflammation, macrophages were pre-incubated with PSC-RANTES (1, 10, 100 nmol/L), a potent antagonist of CCR5 or added heparin or pentosan (1 μmol/L).

Results: Study on macrophages migration using the syngenic, allogenic et xenogenic models showed that the Boyden chamber mimics the IBMIR reaction because macrophage migration was comparable in all the conditions tested. Moreover, this migration was increased in the presence of exocrine tissue from 1.41 ± 0.12 with 90% of purity to 1.92 ± 0.19 with 50% ($n=6$; $p < 0.001$) indicating that exocrine tissue play a crucial role in IBMIR. Finally, PSC-RANTES significantly reduced, in a dose-dependent manner, macrophage chemotaxis by islets supernatant from 1.92 ± 0.19 to 0.67 ± 0.18 ($n=6$; $p < 0.01$). The trapping of chemokines by heparin or pentosan also reduced the chemotactic activity of islets supernatant with heparin or pentosan from 1.92 ± 0.19 to 1.1 ± 0.12 and 0.95 ± 0.19 respectively.

Conclusion: The quality of human islets is one of the factors decisive for the success of human islet transplantation. Exocrine tissue may be more immunogenic than islet tissue, and complete purification may have advantages for the prevention of IBMIR. Furthermore, modulation of macrophages migration using PSC-RANTES or heparinoids could be a strategy to limit IBMIR reaction and merits further evaluation *in vivo*.

Magnetic iron nanoparticles in rat pancreatic islets: post-transplantation tracking

K. Zacharovova¹, Z. Berkova¹, V. Herynek², P. Girman¹, T. Koblas¹, L. Pektorova¹, E. Dovolilova¹, M. Vancova³, J. Nebesarova³, F. Saudek¹
¹Laboratory of Langerhans Islets, IKEM, Prague, ²Department of Magnetic Resonance, IKEM, ³Institute of Parasitology, Biology Centre, Ceske Budejovice, Czech Republic

Background and aims: The pancreatic islets *in vitro* cultivated with iron paramagnetic ferucarbotran nanoparticles - Resovist® - incorporate the particles into the cells including endocrine cells. The integrated iron particles allow the islets detection for several months by magnetic resonance after transplantation. We used transmission electron microscopy and immunohistochemical methods for post-transplantation tracking of the iron localization and the way of particles storage and retention.

Materials and methods: Isolated rat islets were incubated with ferucarbotran for 48 hours. Iron labeled islets were transplanted into the portal vein and/or under the kidney capsule of syngeneic animals. The livers and kidneys were removed 7, 30 days and 3 months after transplantation. For transmission electron microscopy samples were fixed with mixture of 4 % formaldehyde and 2 % glutaraldehyde, postfixed in 1 % OsO₄, dehydrated and embedded in Epon resin. For immunohistochemistry the tissue was fixed in Bouin's solution, embedded in resin Tissue Tek and frozen. Immunodetection of endocrine cells and macrophages was combined with Fe³⁺ iron detection.

Results: After the islet transplantation, the iron particles changed the localization. After 1 week post-transplantation, ferucarbotran was rarely found in the endocrine cells however it was detected in huge amounts inside the macrophages and fibroblasts surrounding the islets. The particles were found surprisingly also inside the endothelium of newly formed vessels. 1 month after transplantation, the iron wasn't detectable in the endocrine cells however it was even more accumulated in islet surrounding cells. After 3 month post-transplantation period, the localization of iron particles was the same as after the 1-month period, only the extracellular matrix fibers surrounding the islets were multiplied. The immunodetection combined with iron detection excluded the localization of iron in endocrine cells after the transplantation. The ultrastructure of the islets and surrounding tissue arrangement was very similar in liver and under kidney capsule.

Conclusion: After the islet transplantation, the ferucarbotran particles translocated from the endocrine cells and iron was concentrated inside the macrophages and other islet surrounding cells. The iron particles were stored in these cells without changes for months. The process of posttransplant particle transfer needs to be further investigated.

Labelling of insulin-secreting INS-1E cells and rodent islets of Langerhans with ferucarbotran for non-invasive MR imaging

V.J. Auer^{1,2}, E. Schremmer-Danninger^{1,2}, J.N. Bucher^{1,2}, N. Schantz^{1,2}, M.C. Raggi², M. Reiser³, M.J. Stangl², F. Berger³

¹IMETUM, Technical University Munich, Garching, ²Transplant Surgery, Technical University Munich, ³Clinical Radiology, Ludwig-Maximilians-University Munich, Germany

Background and aims: Transplantation of purified pancreatic islets is a promising method of restoring insulin secretion in selected patients with type 1 diabetes mellitus. To monitor the fate of transplanted islets, transplantation efficiency and graft survival, a method to evaluate the location, distribution and long term viability in a noninvasive manner *in vivo* is needed over a period of time. MRI of islets labeled with magnetically visible contrast agents after transplantation has the potential to fulfill this goal as MRI provides high spatial and high contrast resolution images. The aim of the study is to set up viability assays and to establish protocols for labeling and visualizing. INS-1E cells, a stable differentiated, insulin secreting cell line, and rodent islets *in vitro* were used as our models for the potential human clinical setting using FDA-approved SPIOs and clinical scanners.

Materials and methods: For labeling INS-1E cells *in vitro*, concentrations of ferucarbotran range from 12,5µg/ml to 1000µg/ml in the culture medium. The INS-1E cells were incubated for 3 days. Labeling efficiency was measured by separating magnetically labeled cells from unlabeled by incubation in a special magnetic tool. Rat islets were labeled with 5,4mg/ml ferucarbotran in the culture medium. For assessment of magnetic resonance contrast in a

clinical 3T scanner, we placed both a layer of labeled INS-1E cells and 5-10 SPIO-labeled, handpicked rodent islets between two layers of 4% gelatine. Viability assay was performed by double staining the cells with ethidium bromide as an exclusion dye and calcein AM as an inclusion dye for living cells, and by WST-1 test. Cell function was evaluated by static incubation assay to assess insulin secretion. Using the calcium-indicator Fluo-3AM, intracellular calcium concentration was studied in response to glucose. Fluorescence was measured in a multiwell spectrophotometer.

Results: Iron labeled insulin secreting INS-1E cells did not show altered viability or reduced glucose stimulated insulin secretion *in vitro*. Double staining of INS-1E cells showed no difference between labeled and non labeled INS-1E cells. This result was confirmed by WST-1 test. We visualized SPIO-labeled INS-1E cells and rat islets *in vitro* using a clinical 3T scanner. Diabetic rats transplanted with 500-1000 SPIO-labeled islets became normoglycemic. T2*-weighted MRI protocols for visualizing transplanted islets in rats, are under way.

Conclusion: Labeling the insulin secreting INS-1E cell line and rat islets with SPIOs does not alter their viability, while enabling MR imaging contrast.

Optimization of pancreatic islets revascularization after transplantation: pharmacological approach or gene therapy?

A. Langlois, W. Bietiger, E. Seyfritz, K. Mandes, E. Maillard, A. Belcourt, M. Pinget, L. Kessler, S. Sigris
 Laboratoire de recherche, Centre européen d'étude du Diabète, Strasbourg, France

Background and aims: The formation of new microvasculature by capillary sprouting at the site of islet transplantation is crucial for the long-term survival and function of the graft. Vascular endothelial growth factor (VEGF), an endothelial cell-specific mitogen with potent angiogenic and vascular permeability-inducing properties, may be a key factor in modulating the revascularization of islets after transplantation. Delivery of human vascular endothelial growth factor (hVEGF) gene to the islets is likely to promote islet revascularization and survival. Some of the gene therapy enhancement presents significant ethical/societal questions. Then development of pharmacological approach to enhance VEGF expression could be an alternative to gene therapy. The aim of this work was to study the effect of adenoviral infection or Deferoxamine (DFO), an iron chelator, on islets revascularization and metabolic control of diabetic rat after transplantation.

Materials and methods: *In vivo* streptozotocin-treated diabetic Lewis rats received 1000 Lewis islets beneath the liver *via* the portal vein. Transplanted islets were not treated or infected *in vivo* using an adenovirus encoding human VEGF gene (4.10⁸pfu/pancreas) or incubated with DFO (10µmol/L) during 1 and 3 days. Islets revascularization was studied by immunohistochemistry using lectine, VEGF and insulin staining. Metabolic control of diabetic rat was evaluated by the measures of body weight gain, Fasting blood glucose and the secretion of C-peptide during two months.

Results: Immunostaining study of vascularisation surrounding the islets showed a stimulation of islet revascularization using DFO which was maintained during the experiment. Moreover, this revascularization was associated to a preservation of islets viability. These results suggested that overexpression of VEGF promoted islet survival by the inhibition of necrosis and apoptosis. The metabolic study has shown a gain of body weight using DFO and infection 2 months after transplantation (DFO: 28.5±34.45 g; Infection: 30.67±57.33 g vs -12.70±17.03 g; n=3), a syngeneic recipients were euglycemic for all conditions during the fast and a better secretion of C-peptide after fasting and refeeding using DFO (1 month after fasting: DFO: 533.38±44.61 pmol/L; Infection: 256.88±126.40 pmol/L vs 270.33±44.61 pmol/L; n=3).

Conclusion: These results demonstrate that VEGF production in islets stimulates graft angiogenesis and enhances islet revascularization. This mechanism might be explored as a novel strategy to accelerate islet revascularization and improve long-term survival of functional islet mass posttransplantation. In conclusion, the pharmacological approach of VEGF overexpression using DFO seemed more promising to improve islets vascularization after transplantation than adenoviral infection with human VEGF 165 gene.

Intestinal gluconeogenesis is a key factor in the early improvement of insulin sensitivity after gastric by-pass in mice fed on a high fat-diet

G. Mithieux¹, S. Troy², M. Soty¹, L. Ribeiro², S. Migrenne³, X. Fioramonti³, V. Fauveau⁴, R. Aubert², B. Viollet⁵, M. Foretz⁵, J. Leclerc⁵, C. Zitoun¹, B. Thorens⁶, C. Magnan³, F. Andreelli²

¹Unité 855, Inserm, Lyon, France, ²Unité 695, Inserm, Paris, France, ³Unité 7059, CNRS, Paris, France, ⁴Institut Cochin, IFR Alfred Jost, Plateforme de microchirurgie, Paris, France, ⁵Institut Cochin, Université Paris Descartes, France, ⁶Department of Physiology and Center for Integrative Genomics, University of Lausanne, Switzerland

Background and aims: Gastric by-pass (GBP) surgery promotes a rapid improvement of insulin sensitivity and insulin secretion in obese diabetic patients, before a significant weight loss has occurred. On the contrary, the improvements observed in the patients after gastric lap-band (GLB) surgery take place later, after weight loss. It is generally thought that GLP-1 could be a possible effector of this improvement. The aim of this work was to document the role of GLP-1 and of other possible mechanisms involved in the amelioration of glucose homeostasis after GLB in mouse models

Materials and methods: we studied food intake, weight gain, insulin sensitivity (glucose and insulin tolerance tests, hyperinsulinic euglycemic clamp), the role of GLP-1 (effect of the exendin [9–39] amide antagonist), the expression of intestinal genes of gluconeogenesis (glucose-6 phosphatase and phosphoenolpyruvate carboxykinase), intestinal glucose fluxes (arterio-venous glucose balance and ³[H] glucose tracer dilution determinations), in mice fed on a high-fat diet, after GBP or GLB surgery, compared to sham pair-fed mice.

Results: GBP mice exhibited a strong and lasting decrease of food intake. In addition, a marked restoration of insulin sensitivity, of glucose tolerance, and of insulin secretion, was observed by 10 days only after surgery. Hyperinsulinic euglycemic clamp revealed that the improvement took place at the level of hepatic glucose production. In contrast, no restoration of these parameters was observed in pair-fed sham- and GLB mice. In GBP mice treated with the GLP-1 antagonist, the increase of insulin secretion was cancelled, whereas the decreased food intake and the restored insulin sensitivity and glucose tolerance were still present. Glucose-6 phosphatase and phosphoenolpyruvate carboxykinase enzymes were markedly increased along the whole small intestine of GBP mice, but not in sham- and GLB mice. The intestinal glucose release, measured in postabsorptive GBP mice, was sufficient to counterbalance the intestinal glucose uptake, so that the portal glucose concentration was equivalent to the arterial glucose concentration. No portal glucose release took place in pair-fed sham- mice. The beneficial effects of GBP were not observable in mice with inactivation of the glucose transporter Glut-2, or in mice with inactivation of portal nervous afferences.

Conclusion: Portal glucose appearance per se has been shown to decrease food intake, suppress hepatic glucose production, and increase peripheral glucose uptake. These effects do not take place in Glut-2 invalidated mice or after inactivation of portal nervous afferences. Our data thus strongly suggest that: 1) GLP-1 might play a key role in the restoration of insulin secretion in GBP mice; 2) a “portal glucose signal”, resulting from intestinal gluconeogenesis, is a crucial factor for the decreased food intake and the rapid improvement of insulin sensitivity occurring after gastric by pass in mice.

608

Impact of weight loss on the incretin effect in obese non-diabetic subjects

E. Muscelli¹, S. Camastra¹, M. Anselmino², F. Santini³, A. Mari⁴, J.J. Holst⁵, E. Ferrannini¹

¹Department of Internal Medicine, University of Pisa, Italy, ²IV Surgery Unit-Bariatric Surgery Division, Santa Chiara Hospital, Pisa, Italy,

³Department of Endocrinology, University of Pisa, Italy, ⁴Institute of Biomedical Engineering, Consiglio Nazionale delle Ricerche, Padua, Italy, ⁵Department of Medical Physiology, Panum Institute, Copenhagen, Denmark

Background and aims: The incretin effect is commonly defined as the potentiation of insulin release after oral glucose (OS) vs intravenous glucose (IV) administration at matched plasma glucose levels. Both diabetes and obesity

are associated with an impaired incretin effect independently of one another, but whether weight loss (WL) restores the incretin effect is not known.

Materials and methods: Oral (75 g glucose, 3 hours) and isoglycaemic intravenous IV glucose administrations were performed on separate days in 15 obese non-diabetic subjects (42±3 years; BMI=40.3±2.2 kg.m⁻²) before and after weight loss (induced by caloric restriction in 6 patients, laparoscopic gastric banding in 7 patients and gastric bypass in 2 patients). C-peptide deconvolution was used to calculate insulin secretion rates, and a mathematical model was used to measure β-cell glucose sensitivity (βGS), defined as the slope of the dose-response curve of insulin secretion rate and plasma glucose concentration. Incretin effect was taken to be the ratio of OS to IV responses. Insulin sensitivity was also estimated by the oral glucose sensitivity index, OGIS.

Results: Over a period of 1 year, subjects lost 21±2% of their initial weight and 63±6% of their weight excess. Plasma glucose responses were similar with oral and isoglycemic IV glucose both before and after WL, and were somewhat lower on the OGTT after WL (%; p=0.06). The total amount of insulin secreted with oral glucose (TIS) was higher than with IV glucose both before (75±6 vs 61±6 nmol.m⁻², p=0.004) and after WL (63±5 vs 43±4 nmol.m⁻², p=0.0007). The incretin effect on TIS was significantly improved by weight loss (OS/IV=1.3±0.1 before WL vs 1.5±0.1 after WL, p=0.03). βGS was higher during oral than IV glucose both before (113±11 vs 84±13 pmol.min⁻¹.m⁻².mM⁻¹, p<0.0001) and after WL (107±10 vs 66±9 pmol.min⁻¹.m⁻².mM⁻¹, p=0.002). The incretin effect on βGS was only marginally improved (1.6±0.2 vs 1.9±0.2, p=ns). Both, insulin sensitivity (325±20 vs 410±21 ml.min⁻¹.m⁻², p=0.002) and insulin clearance (1.76±0.18 vs 2.28±0.24 l.m⁻², p=0.01) increased after WL. The WL-induced change in the incretin effect on IS was directly related to corresponding change in BMI (r=0.61 p<0.02). In contrast, neither the GLP-1 nor the GIP response to oral glucose changed significantly after WL (GLP-1=2.97±0.40 vs 3.74±1.12 nmol.l⁻¹.3h, p=ns; GIP=5.85±1.32 vs 4.56±0.58 nmol.l⁻¹.3h, p=ns).

Conclusion: In obese non-diabetic subjects, substantial weight loss proportionally improves the incretin effect on insulin secretion - but not the incretin effect on β-cell glucose sensitivity - largely independently of changes in GLP-1 or GIP responses.

Resistin-like molecule beta regulates intestinal glucose absorption

J.-C. Marie, P. Lettéron, C. Nazaret, R. Belharbi Krime
U773, CRB3, INSERM, Paris, France

Background and aims: Gastrointestinal peptides can modulate intestinal absorption of alimentary glucose, while the primary regulator is glucose itself. We investigated the effect of gut derived resistin-like molecule β (RELMβ) on intestinal sugar absorption.

Materials and methods: Oral (OGTT) and intraperitoneal (IGTT) glucose tolerance tests (1g/Kg) were performed in wild type Wistar rats and C57BL/6 mice. Studies of rat Jejunal transmural transport and uptake of D-(¹⁴C)-glucose were performed as well as Western blotting.

Results: After a bolus of glucose without (control) or with 1nM RELMβ, blood glucose level of mice or rats was significantly (p<0.05) higher with RELMβ versus control. Mice receiving an intraperitoneal injection (IP) of 55μg/Kg RELMβ or not (control) had similar glucose level during OGTT or IGTT. The addition of 1nM RELMβ increased 30mM glucose transmural transfer by approximately 2-fold as compared to control. Such a potentiating effect of RELMβ on sugar transfer was significantly inhibited by 50 to 60% in the presence of either an intracellular traffic inhibitor, cytochalasin B (20μM) or an AMPK inhibitor, compound C (10μM) or a PKC inhibitor; chelerythrine chloride (1μM). In agreement with these results, stimulation of rat intestinal glucose uptake by luminal RELMβ was respectively associated with recruitment of GLUT-2 to the brush-border membrane and phosphorylation of PKC-βII, AMPK.

Conclusion: The gut hormone RELMβ can directly affect intestinal sugar transport at the luminal site with a likely involvement of GLUT-2, and AMPK, PKC activation.

Regulation of intestinal sugar absorption by GLUT2 in healthy and insulin resistant miceE. Brot-Laroche¹, M. LeGall¹, V. Tobin¹, X. Fioramonti¹, E. Stolarczyk¹, A.G. Blazquez², P. Serradas¹, C. Magnan³, A. Leturque¹¹Centre de Recherche des Cordeliers, INSERM UMRs 872, Paris, France,²CIBERehd, University Salamanca, Spain, ³Université Paris 7, UMR 7059 CNRS, France

Background and aims: Dietary manipulations in mice revealed regulations of intestinal sugar absorption at the level of transporter gene expression. Intestinal sugar transport is mediated by SGLT1 and by GLUT5 in the brush border membrane (BBM) of enterocytes and by basolateral GLUT2. A transient translocation of GLUT2 into the BBM in response to sugar ingestion occurs to complement SGLT1 and GLUT5 transport. Sugar absorption then promotes insulin secretion. The aim of the study was to investigate the role of insulin on GLUT2 trafficking in enterocytes. Insulin effects were analysed in healthy and insulin resistant mice.

Materials and methods: Mice fed a standard chow diet were compared to mice fed high fructose (65%) or high fat (72%), both diets known to induce insulin resistance. Insulin sensitivities were measured in hyperinsulinemic-euglycaemic (HI-EG) clamp conditions (glucose infusion rates: control = 67 ± 4 ; high-fructose = 36 ± 6 ; high-fat = 7 ± 4 mg.kg⁻¹.min⁻¹). Compared to control, GLUT2 protein was increased by high-fructose but not by low-sugar high-fat diet. Enterocyte membranes were sorted on density gradients (iodixanol; 10–30%) and analysed by western blotting for GLUT2 content and appropriate BBM, basolateral and intracellular membrane markers.

Results: Insulin decreased fructose uptake in jejunal rings of control mice. This was associated with a decrease in BBM GLUT2 and a mirror increase in internal membranes. Interestingly, the injection of insulin to control mice prior an oral fructose or glucose load prevented GLUT2 from inserting into the BMM as expected in response to dietary sugars. Consequently sugar absorption was reduced. Total GLUT2 was unaltered by insulin perfusion. In both type of insulin resistant mice, BBM GLUT2 was abnormally high in the basal state and could not be removed by HI-EG clamp. In addition, GLUT2 levels in basolateral membranes were reduced in high-fat fed mice in both basal and clamp conditions. This could explain why initial rates of glucose absorption in mice fed a high-fat diet were lower than that measured in fructose-fed mice despite increased apical GLUT2 location in both groups.

Conclusion: Insulin resistance in mice was characterized by a permanently high amount of GLUT2 in the BBM of enterocytes, then basolateral GLUT2 levels will determine the efficiency of dietary sugar absorption. Taken together, our results indicate that the rapid acceleration of sugar absorption by the transient translocation of GLUT2 into the BBM in response to dietary sugar is physiologically controlled down by insulin. The intestinal action of insulin by delayed sugar absorption might thus constitute a mechanism to limit the magnitude of glucose excursions in blood after a meal.

Diurnal variation in the incretin response to a meal challenge in humansO. Lindgren¹, M. Söhrhede Winzell¹, C. Deacon², B. Åhrén¹¹Department of clinical sciences, Lunds University, Sweden, ²Biomedical Sciences, Copenhagen University, Denmark

Background and aims: Glucose tolerance is better in the morning than in the evening. As the incretin effect is responsible for a substantial portion of insulin secretion after a meal, we investigated whether the diurnal variation in glucose tolerance may be explained by a similar diurnal variation in the release of incretins. To accomplish this we compared the incretin response to a standardized meal consumed in the morning (8 am) and in the late afternoon (5 pm) in young healthy males.

Materials and methods: The study was undertaken in healthy lean males (n=12; BMI 20–25 kg/m²). After an overnight fast the subjects consumed a standard breakfast at 8.00 am and 5.00 pm respectively. The subjects were fasted between the test meals. Blood samples were collected before and up to 5 hours after the meal for measurement of glucose, insulin and total and intact glucagon-like peptide-1 (GLP-1) and glucose-dependent insulinotropic polypeptide (GIP).

Results: Baseline glucose was slightly lower in the afternoon compared to in the morning (4.3 ± 0.1 vs. 4.6 ± 0.1 mM, $P=0.0008$). Plasma glucose increased similarly after meal ingestion during the first 30 min with no difference between morning and afternoon. However, following the first 30 min, glucose levels declined after the morning meal, whereas glucose continued to rise throughout a 60 min period in the afternoon meal. Thus, the mean glucose peak was reached earlier in the morning (26 ± 3 min) than in the afternoon (56 ± 2 , $P<0.0001$) and the peak level was higher in the afternoon than in the morning (7.4 ± 0.3 vs. 6.1 ± 0.2 mM, $P=0.0015$). Baseline insulin did not differ between morning and afternoon. There was however, a marked delay in the insulin response in the afternoon and insulin levels peaked later compared to the morning meal (61 ± 5 vs. 30 ± 2 minutes, $P=0.0005$). The early (0–30 min) insulin response was higher in the morning as evident by a higher insulinogenic index (530 ± 201 vs. 128 ± 31 pmol insulin/mmol glucose at 5pm, $P=0.017$), whereas the total response was higher in the afternoon than in the morning (AUCins: 34.4 ± 4.1 vs. 24.8 ± 3.3 nM*min, $P=0.011$), which was due to a prolonged increase throughout a 60 min period. Baseline iGLP-1 was significantly higher at 8 am compared to 5pm (6.7 ± 2.8 vs. 5.5 ± 2.2 pM, $P=0.0322$), while there was no difference in tGLP-1. There was an increase in GLP-1 levels after meal ingestion both in the morning and in the afternoon. The peak of tGLP-1 after meal was higher in the morning (35 ± 4 vs. 28 ± 2 pmol/l; $P=0.03$) and the peak was reached faster (24 ± 3 vs. 46 ± 3 min; $P=0.0005$). There was however no statistical difference for iGLP-1, although at 20 minutes iGLP-1 was significantly higher in the morning (12.2 ± 2.7 vs. 9.2 ± 2.1 pM, $P=0.0342$). There was no difference in baseline values for neither tGIP nor iGIP between the morning and the afternoon meal. tGIP peaked later in the afternoon (51 ± 4 vs. 34 ± 2 min at 8am, $P=0.0020$) but with no difference in peak height. iGIP also peaked later in the afternoon (43 ± 4 vs. 23 ± 2 min at 8am, $P=0.0039$).

Conclusion: Glucose tolerance after a standardized meal is better in the morning than in the afternoon. This is associated with an increased early insulin response and increased GLP-1 secretion in the morning than in the afternoon. The results suggest that the diurnal variation in glucose tolerance can, at least partly, be explained by a similar diurnal variation in incretin release with a more abundant GLP-1 secretion in the morning than in the afternoon as the predominant mechanism.

PS 043 Insulin action: liver and skeletal muscle

612

Regulation of glucose metabolism in rat skeletal muscle cells by the nuclear orphan receptor Nur77

T. Kanzleiter, D. Wilks, E. Preston, N. Turner, G.J. Cooney
Diabetes and Obesity Research Program, Garvan Institute of Medical Research, Darlinghurst, Sydney, Australia

Background and aims: Skeletal muscle accounts for ~50% of energy expenditure and is a major tissue for nutrient oxidation. Muscle plays a key role in insulin-stimulated postprandial glucose disposal, a process known to be impaired in Type 2 Diabetes. Therefore a detailed knowledge of the molecular mechanisms regulating substrate metabolism in skeletal muscle is of the utmost importance for the understanding of this disease. Recently it was suggested that the nuclear orphan receptor Nur77 is involved in the transcriptional regulation of several genes important for glucose and lipid metabolism in skeletal muscle. The aim of our study was therefore to investigate the functional consequences of Nur77 regulated changes in gene expression to glucose and lipid metabolism in skeletal muscle cells.

Materials and methods: L6 myotubes were used 7 days post differentiation. The myotubes were transfected with a Nur77 coding adenovirus or a GFP control virus. Two days post transfection the cells were incubated in the presence of ^{14}C -glucose or ^{14}C -oleate for 1 hour at 37°C to determine oxidation of these substrates. Medium was transferred to a sealed container and acidified to release $^{14}\text{CO}_2$. For ^{14}C -glucose treated cells glycogen was precipitated and ^{14}C -glucose incorporation into glycogen and total glycogen content were also measured. Statistical significance of differences between treatments was assessed by unpaired Student's t-test.

Results: Nur77mRNA expression was increased 77-fold two days after adenoviral transfection compared to control cells. There was no significant difference in fatty acid oxidation between Nur77 over-expressing cells (L6-Nur77) and control cells (L6-Con) (3.0 ± 0.2 vs. 3.4 ± 0.2 nmoles oleate/well/hour, respectively). However, basal glucose oxidation was significantly increased in L6-Nur77 cells (2.0 ± 0.1 vs. 1.5 ± 0.2 nmoles glucose/well/hour, $p=0.014$). An increase of a similar magnitude was also observed when the cells were insulin-stimulated (2.3 ± 0.1 vs. 1.7 ± 0.1 nmoles glucose/well/hour, $p=0.005$). The incorporation of ^{14}C -glucose into glycogen was also increased in L6-Nur77 cells in the presence and absence of insulin as compared to control cells (+Ins: 1.5 ± 0.1 vs. 1.1 ± 0.03 , $p=0.003$ and -Ins: 1.0 ± 0.1 vs. 0.8 ± 0.06 pmoles glucose/well/hour, $p=0.003$, respectively). The total glycogen content was not significantly different between L6-Nur77 and control cells (+Ins: 2.4 ± 0.03 vs. 2.3 ± 0.04 and -Ins: 2.3 ± 0.05 vs. 2.5 ± 0.04 μmoles glucose).

Conclusion: Our data provide compelling evidence that the nuclear orphan receptor Nur77 is a regulator of skeletal muscle glucose metabolism. Nur77 overexpression augments two functional endpoints of glucose metabolism (glucose oxidation and glycogen synthesis) but has no effect on lipid oxidation. Interestingly, the observed increases in glucose metabolism were independent of the stimulatory effects of insulin, indicating that Nur77 may regulate pathways of glucose metabolism directly rather than insulin signalling mechanisms.

Regulatory mechanisms of AMP-activated protein kinase gene expression and protein level in young and old twins

B. Mortensen¹, P. Poulsen¹, R. Ribel-Madsen¹, M. Friedrichsen¹, J.B. Birk², A. Vaag¹, J. Wojtaszewski²

¹Steno Diabetes centre, Gentofte, Denmark, ²Department of Exercise and Sport Sciences, University of Copenhagen, Molecular physiology group, Denmark

Background and aims: Some of the beneficial effects of exercise on insulin action and prevention of type 2 diabetes are currently suggested to be mediated by activation of AMP-activated protein kinase (AMPK). Recent studies suggest that antidiabetic drugs such as metformin acts through AMPK. These findings indicate that AMPK might be involved in development of insulin resistance, and might be a target candidate for treatment of type 2 diabetes.

We aimed to identify mechanisms involved in regulation of AMPK gene and protein expression and to identify the impact of AMPK protein levels on glucose metabolism.

Materials and methods: This cross-sectional study included young ($n=100$) and old ($n=82$), non-diabetic twins. AMPK $\alpha 1$, $\alpha 2$ and $\gamma 3$ mRNA and protein levels were analyzed in skeletal muscle biopsies excised during the basal and insulin-stimulated state of a physiological hyperinsulinemic euglycemic clamp ($40\text{mU}/\text{m}^2/\text{min}$). Gene expression levels were investigated using real time PCR with Cyclophilin-A as endogenous control. Protein levels were measured by Western blot technique.

Results: Males had higher expression of AMPK $\alpha 2$ mRNA (1.43 ± 0.07 vs. 1.01 ± 0.06 ; $p<0.0001$), and AMPK $\gamma 3$ mRNA (1.58 ± 0.09 vs. 0.81 ± 0.06 ; $p<0.0001$) and protein (1374 ± 44 vs. 928 ± 40 ; $p<0.0001$) compared to females. No influence of sex was demonstrated on AMPK $\alpha 1$ mRNA or protein levels. AMPK $\alpha 1$ or $\alpha 2$ mRNA/protein levels were similar in young and old subjects, whereas AMPK $\gamma 3$ expression was higher in young compared to elderly subjects, both on mRNA (1.38 ± 0.08 vs. 0.92 ± 0.05 ; $p<0.0001$) and protein level (1182 ± 47 vs. 1113 ± 49 ; $p=0.0451$). Comparison of intra-pair correlations on AMPK measures from monozygotic and dizygotic twins demonstrated that AMPK mRNA and protein levels were not under genetic influence. Multivariate regression analysis demonstrated that whole-body $\text{VO}_{2\text{max}}$ was negatively related to AMPK $\gamma 3$ mRNA ($p=0.004$) and protein expression ($p=0.001$), and total body fat was negatively related to AMPK $\alpha 2$ mRNA ($p=0.03$) and AMPK $\gamma 3$ protein expression ($p=0.04$). AMPK $\gamma 3$ protein level was negatively associated to insulin-stimulated glucose uptake ($p=0.048$) through the non-oxidative glucose metabolic pathway ($p=0.0034$), the latter association being independent of aerobic capacity and obesity.

Conclusion: Skeletal muscle AMPK mRNA and protein levels are regulated by sex, age, obesity and aerobic capacity. AMPK $\gamma 3$ is associated with glucose metabolism through the non-oxidative glucose metabolic pathway. This association may mechanistically be linked through the ability of AMPK to down regulate glycogen synthase activity.

Background and aims: Resveratrol (RSV), a naturally occurring polyphenol found in grape and red wine, is known as an activator of silent information regulator 2 (Sir2) which is a NAD^+ -dependent histone deacetylase. Recently, it has reported that expression of hepatic gluconeogenic genes, such as phosphoenolpyruvate carboxykinase (PEPCK) and glucose-6-phosphatase (G6Pase), are inhibited by insulin and the inhibition was relieved by RSV treatment. However the molecular mechanism of RSV action on the insulin-inhibition of gene expression is not well established yet. The forkhead transcription factor (FOXO1) is known as a transcriptional activator of genes involved in the gluconeogenesis. In the presence of insulin, FOXO1 is phosphorylated and exported from nucleus to cytosol, losing the ability to activate gene transcription. In this study, we demonstrate that RSV up-regulates the expression of gluconeogenic genes through deacetylation of FOXO1 by activating SIRT1.

Materials and methods: The mRNA level of gluconeogenic genes was measured in primary cultured hepatocytes of rat and mouse by real-time PCR. In the presence of insulin, the effect of activator or inhibitor of SIRT1 was studied using Western-blot analysis using primary cultured hepatocytes of rat. Also its effect was identified by observing the localization of FOXO1 and SIRT1 in Alexander cell lines by using immunofluorescence microscopy. The binding of FoxO1 to the promoter regions of gluconeogenic genes are tested by chromatin immunoprecipitation (CHIP) assay using primary cultured rat hepatocytes.

Results: Down-regulation of gluconeogenic gene by insulin was reversed by RSV in a dose-dependent manner and its effect was counteracted by Sirtinol. Insulin signaling pathway was affected by activator or inhibitor of SIRT1. RSV induced the localization of FOXO1 to nucleus, presumably by increasing its deacetylated form. As a result, FOXO1 may be able to bind to the promoter regions of gluconeogenic gene. Indeed, CHIP assay showed that nuclear FOXO1 directly binds to the promoter and increases the mRNA level of gluconeogenic gene in the presence of insulin.

Conclusion: SIRT1 is known to deacetylate the FOXO1 through direct interaction. In this study, we showed that SIRT1 activator, RSV, may increase the deacetylated form of FOXO1, a form which may be less phosphorylated by insulin and thereby localized to nucleus. As a result, the deacetylated FOXO1 binds to the promoter regions of gluconeogenic genes. This observation may help explain how RSV increases gluconeogenic gene expression which is suppressed by insulin.

Tfe3 activates hepatic glucokinase gene expression at transcriptional level

M.-Y. Kim^{1,2}, S.-S. Im³, T.-H. Kim^{2,4}, J.-S. Bae^{1,2}, J.-M. Park^{2,4}, Y.-S. Park^{2,4}, Y.-H. Ahn^{2,4}

Background and aims: TFE3 (transcription factor E3) is a bHLH protein that is first identified and characterized in enhancer element in the immunoglobulin heavy-chain and T cell receptor gene. E-boxes, the *cis*-elements for bHLH protein binding, are located in the promoters of numerous genes involved in metabolism. Most bHLH proteins have been shown to be responsible for the gene expression involved in the metabolism. Previously it was reported that TFE3 activates hepatic IRS-2, an important component of insulin signaling. In this study, we demonstrate that glucokinase (Gck) gene, which is a key regulator of glycolysis in liver and pancreas is upregulated by TFE3 at the transcriptional level.

Materials and methods: Transcriptional activity of hGck promoter by TFE3 was measured by luciferase assay in HepG2 cells. In vitro translated TFE3 protein was used in EMSA to show the binding of TFE3 in hGck gene promoter. Chromatin immunoprecipitation (ChIP) was performed to show the binding of TFE3 to hGck promoter *in vivo*. mRNA level of Gck was measured by real time PCR in the primary cultured rat hepatocyte which is infected with TFE3 adenovirus.

Results: *In silico* search suggested that there are several E-boxes in the human Gck (hGck) promoter. Luciferase assay showed that TFE3 activates the hGck promoter activity by 20 fold. Introduction of mutation at the E-boxes resulted in the decrease the transcriptional activity. EMSA and ChIP assay showed that TFE3 binds directly to hGck promoter. Infection of TFE3-adenovirus to primary cultured hepatocytes increased endogenous hGck mRNA level. The transcriptional activation of hGck by TFE3 was greater in hepatocyte maintained at low glucose media than in high glucose media.

Conclusion: We demonstrated that TFE3 activates the gene expression of Gck by direct binding on Gck promoter.

PET measurements of glucose uptake in the skeletal muscle and myocardium of Wistar and diabetic ZDF rats

C. Schölch, C. Hecker, P. Thomanek, C. Hertenberger, H.G. Niessen, D. Stiller
Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach an der Riss, German

Background and aims: Type 2 diabetes is a metabolic disorder characterized by hyperglycaemia, relative insulin deficiency and insulin resistance with abnormal glucose uptake and utilization. Here, the skeletal muscle is the major locus for insulin resistance, playing a key role in whole-body glucose homeostasis. Additionally, it has been demonstrated in rodents that the diabetic heart exhibits increased fatty acid oxidation that preceded reductions in carbohydrate oxidation. Rosiglitazone (RSG), a peroxisome proliferator-activated-receptor- γ (PPAR- γ) agonist, improves glucose tolerance and the sensitivity of peripheral tissues to insulin in various insulin-resistant states.

The aim of the study was to determine whether small-animal PET can be used to non-invasively measure substrate metabolism in skeletal muscle and myocardium and to quantify changes after RSG treatment.

Materials and methods: In our study, we used non-invasive small animal PET as a method to quantify insulin-stimulated 2- ^{18}F fluoro-2-deoxy-D-glucose (FDG) uptake in forearm skeletal muscle and myocardium of fed rats under Pentobarbital anaesthesia. Immediately after iv. injection of FDG into the tail vein, male Wistar and male diabetic ZDF rats had been treated iv. with different doses of insulin (Wistar rats: 0.01 and 0.05 IE/kg BW; ZDF rats: 0.05, 1, and 2 IE/kg BW) to stimulate muscle glucose uptake. In a subchronic experiment male obese ZDF rats have been treated for 14 days with RSG (15 mg/kg/day). FDG uptake had been measured after stimulation with 1 IE/kg BW insulin using small animal PET on day 15. In all studies the glucose utilization was determined by Patlak analyses of PET data.

Results: In Wistar and ZDF rats an insulin-dose dependent increase in FDG uptake in the skeletal muscle tissue was observed. In ZDF rats higher insulin doses had to be used, reflecting their severe insulin resistance. However, despite using higher insulin concentrations, insulin stimulated myocardial FDG uptake was much higher in Wistar rats compared to ZDF rats. Treatment with RSG significantly decreased fasting blood glucose (-52%) and HbA1c (-0.7%) by the end of the treatment period in ZDF rats. This improvement of the diabetic state was accompanied by a significant increase in insulin stimulated FDG uptake in the skeletal muscle and also in the myocardium compared to untreated ZDF rats.

Conclusion: We show that non-invasive PET measurements of skeletal muscle substrate metabolism in ZDF rats are consistent with expected metabolic abnormalities that occur in this well characterized model of type 2 diabetes compared to normal Wistar rats. Furthermore, the results of our study are consistent with the well established early onset of cardiac substrate metabolic derangement in the ZDF rat. Treatment with RSG improved the diabetic situation, with an increased FDG uptake in skeletal muscle and interestingly also increased myocardial FDG uptake, therefore reflecting an overall improvement of the diabetic situation in the RSG treated rats. In summary, small animal PET is a suitable method to measure basal or treatment-induced changes in muscle and myocardium glucose utilisation with the advantage of repeated non-invasive measurements in one individual rat.

Regulation of insulin signalling by insulin degrading enzyme in HepG2 cell line

O. Pivovarov^{1,2}, N.N. Rudovich^{1,2}, A.F.H. Pfeiffer^{1,2}

¹Department of Clinical Nutrition, German Institute of Human Nutrition Potsdam-Rehbruecke, Nuthetal, ²Department of Endocrinology, Diabetes and Nutrition, Charité University Medical School Berlin, Germany

Background and aims: Insulin-degrading enzyme (IDE) is thought to be the major enzyme responsible for insulin degradation. Evidence for a role of IDE in the pathogenesis of type 2 diabetes mellitus (T2DM) was obtained in animal models and in associative studies in some human populations, but the mechanism of this influence is poorly understood. The aim of present study was to investigate the role of IDE in insulin signaling in HepG2 human hepatoma cells.

Materials and methods: Inhibition of IDE (by bacitracin and specific siRNA) and IDE overexpression was used to study its function in insulin signaling. HepG2 cells were exposed to short-term (30, 60 min, 100 nM) or long-term (24h, 10 nM) insulin treatment. For IDE inhibition experiments, bacitracin (1 mg/ml) was added to the cell medium 1h before insulin treatment. For IDE silencing, HepG2 cells were transfected with two specific human IDE siRNAs (80nM). For IDE overexpression, cells were transfected with pCMV-hIDE vector. Insulin signaling activation after insulin treatment was assessed by western blotting (phospho-Akt, FOXO1), expression of insulin target genes - by real-time PCR (G6PC, PEPCK, FAS, ACC).

Results: In comparison to control cells, IDE protein level was decreased by up to 30% in IDE knockout cells and increased 1.5-2 fold by IDE overexpression. Inhibition of IDE, both with bacitracin and IDE siRNA, increased Akt phosphorylation by 15-25% and decreased FOXO1 levels by 20-35% after insulin treatment. Inhibition of IDE also elevated basal activity of Akt by 25% in cells without insulin stimulation. Moreover, in insulin-untreated IDE knockout cells, gluconeogenic gene expression (G6PC, PEPCK) was decreased by 35%, whereas expression of lipogenic genes FAS and ACC was not significantly affected. IDE overexpression led to opposite effects that confirmed received data. The effects of IDE suppression or overexpression in insulin-untreated

cells may be associated with recently described regulation of proteasome activity by IDE or other, as yet unknown, mechanism.

Conclusion: Alterations of IDE levels influence insulin signaling and gluconeogenic gene expression in HepG2 hepatoma cells. IDE appears to inhibit insulin signaling not only through the mechanism of insulin degradation, but also through some other mechanism, possibly through the regulation of proteasome activity. Thus, disturbances in the regulation of IDE expression and activity in liver may contribute in T2DM pathogenesis.

Sex differences in human skeletal muscle metabolism

A. Rune, F. Salehzadeh, L. Al-Khalili

Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden

Background and aims: Men and women appear to metabolize lipids differently. While men store fat in the abdominal area, women preferably store fat subcutaneously and around the hip area. Increased abdominal obesity is positively correlated with an increased incidence of type 2 diabetes. Resting fat oxidation is lower and intramuscular triglyceride storage is higher in women compared to men. During exercise women metabolize lipids to a higher degree than men. The aim of this study was to determine whether intrinsic sex differences influence glucose and lipid metabolism in human skeletal muscle.

Materials and methods: Human skeletal muscle cell cultures were established from *vastus lateralis* muscle biopsies obtained from 9 male and 9 female donors. The women were post-menopausal (60 ± 1 year) and age-matched to the men (61 ± 2 year). Subjects reported no known metabolic disorders. Cultures were grown in steroid-free serum, and differentiated to form myotubes. Glucose and lipid metabolism and mRNA expression of candidate genes was determined.

Results: Basal and insulin-stimulated glucose incorporation to glycogen was similar between cultures established from women and men. Basal glycogen synthesis was 8.0 ± 1.4 vs. 7.4 ± 0.8 nmol/mg protein/h, for men vs. women, respectively. Insulin-stimulated glycogen synthesis was 18.7 ± 3.1 vs. 16.0 ± 3.8 nmol/mg protein/h for men vs. women, respectively. Interestingly, cultures established from men had a higher basal rate of lipid oxidation, as compared to cultures established from women (675 ± 175 vs. 361 ± 70 CPM/mg protein/120 min, for men vs. women, respectively; $p < 0.05$). Moreover, the magnitude of the insulin-induced suppression of lipid oxidation was greater in men compared to women. mRNA of expression of uncoupling protein (UCP) 2, UCP3, fatty acid binding protein 3, sterol regulatory element binding protein, carnitine palmitoyltransferase 1, peroxisome proliferator-activated receptor (PPAR) γ was similar between the sexes. Paradoxically, mRNA expression of PPAR δ , a gene implicated in regulation of lipid oxidation, was 1.6-fold higher in muscle cultures established from women vs. men (1.90 ± 0.3 vs. 1.18 ± 0.1 AU for women vs men, respectively; $p = 0.04$).

Conclusion: Glucose metabolism in primary human skeletal muscle cultures does not appear to be influenced by intrinsic sex differences. In contrast, basal lipid oxidation was higher in muscle cultures derived from male donors compared to female donors indicating lipid oxidation is influenced by sex differences between men and women. Intrinsic sex differences in skeletal muscle metabolism may account for alterations in whole body lipid metabolism between men and women

Absence of CuZn superoxide dismutase (SOD 1) leads to glucose intolerance

G. Muscogiuri¹, B. Balas¹, S. Reyna¹, A. Giaccari², H. Van Remmen¹, R. DeFronzo¹, N. Musi¹

¹Diabetes, University of Texas Health Science Center, San Antonio, United States, ²Endocrinology, Catholic University, Rome, Italy

Background and aims: Oxidative stress is thought to be involved in the pathogenesis of insulin resistance and type 2 diabetes mellitus (T2DM). CuZn superoxide dismutase (SOD 1) plays a critical role in scavenging superoxide anion production in the cytosol. We studied mice with whole body deletion of SOD 1 to test the hypothesis that increased oxidative stress (due to SOD 1 ablation) would impair insulin action.
